WELCOME ADDRESS BY THE VICE-CHANCELLOR,
FEDERAL UNIVERSITY OF LAFIA.

PROF. ABDUL RAHMAN SHEHU, *FNAAE, FORTSON, FASI, FASN, Hon. FNSPS*

Protocols/Salutations

It is my honour and privilege to welcome you all to the 57th Annual Conference and General Business Meeting of the Agricultural Society of Nigeria (ASN). An event that takes place annually and hosted by worthy ambassadors of the Society. It gladdens my heart to stand here to welcome you to Federal University of Lafia as a worthy member of the Society and as a Fellow of this noble profession. Agricultural Society of Nigeria, as we all know is an umbrella that shields all other professional societies that has to do with the profession of our fore fathers, i.e. Agriculture. No nation, talk less of individuals that can survive without food albeit agriculture.

The Society was founded on the premise of improving the study and science of agriculture. As the theme of this year conference suggests: "*Strengthening Agriculture for Food and Nutrition Security, Market Development and Export in a Climate Change Environment". You will agree with me that the theme of this year conference is apt in view of the changes that are happening in the world and the need to secure food and nutrition for everybody. I believe we the scientists in the fore front of improving food and nutrition will proffer solutions to the challenges the world is facing at this conference. I want to thank everyone that has joined the battle in improving food and nutrition security in a changing economy and global warming.*

I therefore, welcome you all to Lafia the capital City of Home of Minerals and in fact Home of Peace as the name suggests, Lafia is Peace.

You are all welcome.

Thank you.

PRESIDENT'S ADDRESS

ADDRESS BY PROF. JUDE A. MBANASOR *FASN, FASN, FNAAE, FSM*

THE NATIONAL PRESIDENT OF AGRICULTURAL SOCIETY OF NIGERIA AT ITS 57TH ANNUAL CONFERENCE HOLDING AT

FEDERAL UNIVERSITY OF LAFIA, NASARAWA STATE FROM OCTOBER 23RD - OCTOBER 27TH, 2023.

PROTOCOL

On behalf of the National Executive Council, I am most delighted to welcome you to this 57th Annual Conference of Agricultural Society of Nigeria holding at this serene city of Lafia. I am most grateful to His Excellency, the Governor of Nasarawa State, Alhaji Abdulahi Sule, the government and people of this peace loving state for availing us of the opportunity to host this conference here. Let me also acknowledge in a special way, the assistance of our Chief Host, the Vice-Chancellor of the Federal University of Lafia, Prof. Shehu Abdu Rahman towards making the conference a reality. I am grateful to Prof. Garba Hamidu Shanubutu, the Executive Secretary, Agricultural Research Council of Nigeria for accepting to be the Keynote Speaker. To other lead speakers. I say welcome. I also commend the Local Organizing Committee for assiduously working hard for the realization of this conference. I am most grateful to God for the travelling mercies He granted each and every one of us to be at this conference.

Your Excellency, distinguished guests and my esteemed colleagues, let me refresh our minds, especially for the benefit of those who do not know, that our Society was founded sixty one years ago, making us one of the oldest professional bodies in Nigeria. Many Nigerians may not be aware of this due to the fact that we make our contributions to nation building quietly.

However, it is worthy of note that Agricultural Society of Nigeria was set up as an umbrella body for all practitioners to assist in fostering cohesion in the quest for excellence in the execution of our professional mandate. We also collaborate with national and international authorities to enhance exchange and dissemination of knowledge in all areas of agriculture. Through conferences such as this, we harvest ideas and transmit same to policy makers in a bid to assist government make progress in food production.

Our theme for this year's conference which is "*STRENGTHENING AGRICULTURE FOR FOOD AND NUTRITION SECURITY, MARKET DEVELOPMENT AND EXPORT IN A CLIMATE CHANGE ENVIRONMENT*" is more than apt in combating challenges posed by a weak economy, dwindling foreign exchange, climate change and inconsistent government's policies.

The germane question is… how do we strengthen agriculture to achieve the results that we desire? From research carried out by our members, the results showed that Nigeria has one of the most arable lands in the world. It was also shockingly discovered that farming activities are taking place only in about one quarter of this huge available land. Similarly, 90 percent of the activities are being undertaken by subsistence farmers. In this scenario, the food and nutrition security we seek may remain elusive except something drastic is done.

The society was happy when His Excellency, President Bola Ahmed Tinubu announced that the Federal Government was declaring a state of emergency on food security. We not only welcomed the idea but announced our availability to collaborate with the government for the realization of that bold policy initiative. For now, we are still awaiting the government's response, especially now that ministers have assumed office.

Most, if not all, of our members are employees of government, either as teachers or researchers. Over the years, we have worked very hard in policy formulation aimed at strengthening agriculture in Nigeria. But it is most unfortunate that some of us are really frustrated because of the scant attention paid to our works. I will not exactly say that the results of our research works are gathering dust in government's offices, but I believe that if policy implementors hasten to apply our suggestions, solutions would be found quickly to the lingering challenges before us in the agricultural sector. Be that as it may, it is not yet late for the government to work closely with our members in the development of policy initiatives that would be productively applied for the overall acceleration of food security in Nigeria.

Another area of interest is funding for researchers. Most times, due mainly to paucity of funds and bureaucratic bottlenecks, research grants are not readily made available to our members. The little that TETFUND releases to universities and other institutions of higher learning is hardly enough to go round. In this respect, I call on well to do corporate organizations to support the government in the funding of researchers in Nigeria. That is the way to go if we are to achieve the much anticipated food and nutrition security we crave. On our part, we shall not relent in encouraging our members to improve upon their capacity and knowledge in tackling new frontiers in agricultural research.

Indeed, I believe that from the quality of papers lined up for presentation and the attendant technical sessions, the 57th conference of our professional body will come out, once again, with far reaching proposals and recommendations that will see our nation march forward in its quest for self-sufficiency in food production. Because we are also not omniscient, we shall gladly welcome ideas on how to make our jobs better.

Once again, I welcome all of us to the 57th Annual Conference of Agricultural Society of Nigeria holding in Lafia. I also thank His Excellency for being a gracious host.

Thank you so much and may God continue to bless all of us

Prof. Jude Mbanasor *fasn, fnaae, fsm*
National President

KEYNOTE ADDRESS:

TRIPLE HELIX AND INTEGRATED RESEARCH: A CATALYST FOR STRENGTHENING AGRICULTURE FOR FOOD SECURITY, MARKET DEVELOPMENT AND EXPORT IN A CLIMATE CHANGE ENVIRONMENT

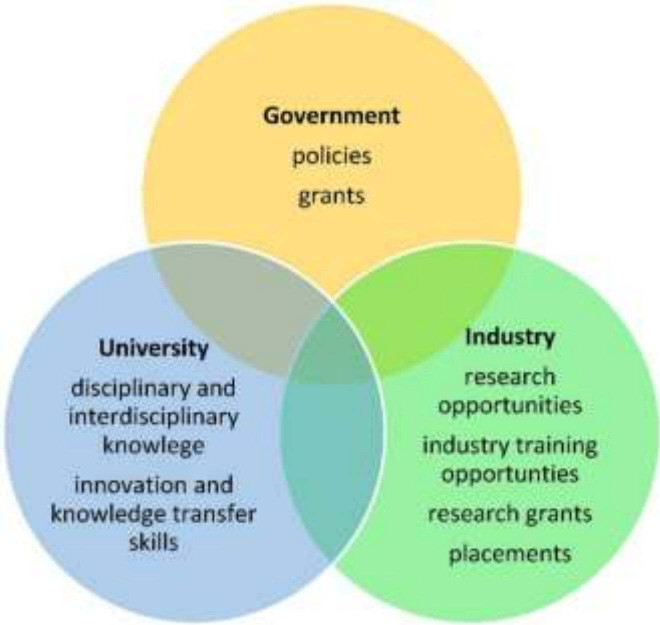
Professor Garba Hamidu Sharubutu
Executive Secretary, Agricultural Research Council of Nigeria (ARCN),

1.0 INTRODUCTION

1.1 Triple Helix: The triple helix is a model of innovation that refers to a set of interactions between academia, industry and government to foster economic and social development. It is also a model of collaboration between university, government and business. This model has attracted considerable attention in both developed and developing economies as an integral policy making tool to enhance innovation and promote economic development (Etzkowitz and Dzisah, 2008).

Studies of the factors driving economic growth has received considerable attention, especially now when sustainability is the main focus of the scientific discourse. It is evident that alternative sources of economic growth are required (Etzkowitz *et al*., 2007), since technology transfer has not lived up to expectations and failed to lead to sustainable economic growth (Saad *et al*., 2008). Researchers have discovered that entrepreneurial activity and innovation are key drivers of economic growth. Consequently, industrial societies have gradually transitioned to knowledge-based, thus creating a new social order the "Triple Helix" (Etzkowitz, 2002; Caceres-Carrasco and Guzman-Cuevas 2010; Galindo-Martin *et al*., 2010; Cai and Etzkowitz, 2020).

A keynote Address by the Executive Secretary, Agricultural Research Council of Nigeria (ARCN), at the 57th Annual Conference of the Agricultural Society of Nigeria on 24th October 2023 at Federal University Lafia, Nasarawa State.



The triple helix theory provides a general paradigm, analytical framework, and method for studying the relationship between innovation actors at the system level (Strand *et al*., 2017). Specifically, it advocates the strengthening of the collaborative relationships between academia, industry and government to improve innovation. A good, working relationship between the three partners of the triple helix can lead to a productive research environment, and enhance innovation and economic development in a country or region. The triple helix plays a crucial role in integrating the universities, firms, and governments whose close interaction and optimal collaboration enable nations to anticipate how they could create wealth and build a knowledge-based society (Sarpong *et al.*, 2017). Although, sustainable development and technological advancement can hardly be isolated from each other, a significant challenge in attaining a harmonious and mutually reinforcing dynamic between them, while minimising the adverse social and economic effects such as resource depletion, environmental degradation, escalating inequality and population explosion is of enormous importance to humanity (Zhou and Etzkowitz, 2021).

1.2 Integrated Research:

The sustainability challenges confronting humanity are incredibly complex and are thought to necessitate integrated transdisciplinary approaches (Morales, 2017) and (Luthe, 2017). Consequently, scientists are increasingly being asked by funding bodies to develop large, integrated research programmes (Hoffmann *et al.*, 2017). These integrated programmes are expected to encompass multiple projects involving various disciplines and stakeholders, and working towards a common goal (e.g., [Laursen and O'Rourke (2019) and Niesten *et al.*, (2021). Combining different projects into one integrated programme is expected to have several benefits such as avoiding duplication of efforts, creating synergies among projects, achieving better collaboration among researchers, realising efficiency gains and obtaining higher returns on invested funds (Lattanzio *et al.*, 2020). Moreover, large-scale integrated programmes can become expensive (e.g., by incurring high overhead costs), while they often fail to deliver the desired outcomes for stakeholders (Grigorovich et. al., 2018) and Wognum *et al.*, 2019). Communication, politics, power imbalances and hidden agendas often form major obstacles.

Integrated research from the perspective of agricultural development is synonymous with Integrated Agricultural Research for Development (IAR4D) promoted by Forum for Agricultural Research in Africa (FARA). The concept is based on the realization that researches are designed and implemented by teams drawn from different disciplines, institutions and stakeholder groups rich in knowledge to solve complex problems and meet multiple objectives. Besides, this is likely to come up with the full range of technological, policy and institutional options needed if a broader set of users is to support and benefit from change. (ICRA 1999). The defining principles of IAR4D include the following: -

i. IAR4D integrates the perspectives, knowledge and actions of different stakeholders around a common theme.
ii. It integrates the learning that stakeholders achieve through working together.
iii. Integrate analysis, action and change across the different (environmental, social, economic) 'dimensions' of development.
iv. It integrates analysis, action and change at different levels of spatial, economic and social organization.

Agricultural Research for Development is characterized by the following factors:

- Action research that is demand driven or problem solving.
- Participatory processes that include collective action at multiple levels (that is at community, organizational, policy, institutional, and agro-industrial levels);
- Stakeholders participation in identifying needs, strategies, and solutions to problems and in collective innovation systems involving joint learning and the generation of knowledge and research outputs;

- Systemic approaches integrating disciplinary and stakeholder perspectives and analysis and action at different levels (such as the farm, community, enterprise, district, and national levels);
- Teamwork and partnerships as mechanisms for solving complex problems by addressing issues that cut across sectors.
- Contributions to broader development goals as opposed to mere increases in productivity.
- Recognition that technological innovation is insufficient, and that research must lead to social, economic, and political reform if it is to bring lasting benefits.

2.0. STRENGTHENING AGRICULTURE FOR FOOD SECURITY IN A CLIMATE CHANGE ENVIRONMENT

The economy of any nation lies in its ability to develop key sectors that can drive sustainable production and create jobs. It was on this light that the United Nations in 2016 agreed on a common framework to address 17 Sustainable Development Goals (SDGs) to be achieved by 2030. Agriculture being the major pillar for every country to achieve food and security occupied the topmost SDGs 1 and 2 which addresses the ending of poverty and zero hunger, while climate change action against emission of greenhouse gas and clean energy security which is the backbone of industries are SDGs 13 and 7 respectively. In Nigeria, agriculture including forestry and land use are the highest contributor to GHG emission while energy sector is the second most contributor to emission of GHG. Curbing greenhouse gas emissions to mitigate climate change has proven to be a difficult objective, in large part because international coordination of the required mitigation efforts is very difficult. As a result, in a recent special report, the Intergovernmental Panel on Climate Change (IPCC) pointed out that limiting global warming to no more than 1.5°C (2.7°F) would require large reductions in emissions and important societal changes, although it remains within the realm of the possible (IPCC 2018). Given the difficulty of achieving these changes and the fact that past emissions alone are likely to cause some warming over the coming decades, adaptation to climate change will be necessary. As noted by Anderson et al. (2018) an upside of adaptation is that it does not rely on international coordination; individual countries, and even economic agents, can undertake adaptation, incentivized by environmental and price changes.

Nigeria's agriculture and food production systems are based on exploitation of natural resources, with extensive crop and livestock production systems, rain-fed agriculture, hunting, and fishing from natural water bodies. Climate change, in addition to non-climate drivers such as soil degradation, land tenure systems, and poor technology are expected to have significant impacts on these systems, and consequently on food security. In particular, climate change is expected to intensify existing problems and create risks in the environment.

Agricultural potential in Nigeria is still far from being developed to guarantee food security owing to many daunting challenges including low level of agricultural investment, huge post-harvest losses, lack of adequate infrastructure, rudimentary technologies, limited irrigation systems, weak agricultural advisory services, poor access to market, lack of finance and poorly developed National Agricultural Research System (NARS) and currently the vagaries of climate change. The most expedient way to achieving food security amidst climate change is by embracing and investing in climate smart agricultural research and technology dissemination/adoption processes. Climate related Innovative/cutting edge technologies have to be exploited and adopted in order to enable self-sufficiency in food availability and surplus production for commercialization in the future.

2.1. Role of Government on strengthening food security amid climate change environment.

i. **Policy development:** It is the responsivity of Government to develop climate change related policies to safeguard food security of the country. The following are some of policies existed in Nigeria.
   - National Agricultural Technology and Innovation Policy (NATIP) 2022 – 2027. The current policy of Federal Ministry of Agriculture and Food security. Promoting climate smart agriculture and nutrition are among the cross-cutting issues guiding the implementation of the ten (10) strategies earmarked to drive the Nigerian agriculture to achieve food security.
   - National Policy on the Environment (Revised 2016). The goal of the National Policy on the Environment is to ensure environmental protection and the conservation of natural resources for sustainable development. Its strategic objective is to coordinate environmental protection and natural resources conservation for sustainable development.
   - Climate Change Act, 2021: The Act provides a framework for mainstreaming of Climate Change actions, provide for a system of carbon budgeting and the establishment of the National Council on Climate Change. The Act also provides a framework for achieving low greenhouse gas emission Objectives. Funding and grants
   - Tertiary Education Trust Fund (TETFUND): Established by Education Tax Act Cap. E4, Laws of the Federation of Nigeria, 2004 and Education Tax Fund Act No. 17, 2003 charged with the responsibility for imposing, managing and disbursing the tax to public tertiary institutions for education and research.in Nigeria.
   - National Agricultural Development Fund: Established by Act of the national assembly in 2023 to provide for agricultural development in Nigeria.

ii. Regulation:
   - Agricultural Research Council of Nigeria (ARCN): Has the mandate for coordination, supervision and regulation of agricultural research, training and extension services in Nigeria. This include research on climate change impact, mitigation and adaptations methods.
   - National University Commission (NUC): The main functions of the Commission among others include granting approval for all academic programmes run in Nigerian, ensure quality assurance of all academic programmes offered in Nigerian universities and channel for all external support to the Nigerian universities.
   - National Biosafety Management Agency (NBMA): Regulating food safety including genetically modified products.
   - National Biotechnology Development Agency (NABDA): Regulate biotechnology application and uses in Nigeria.

iii. Establishing innovation incubation centres
   - National Office for Technology Acquisition and Promotion (NOTAP). The mandate is evaluation /registration of technology transfer agreement, patent and promotion of intellectual property, technology advisory and support services, commercialization of R&D results and research industry linkage.

iv. Other activities of government include provision of Infrastructural support, advisory services, engagement of university research, research fellowship support and patent licensing.

2.2. Role of Academia/Agricultural Research Institutes on strengthening food security amid climate change environment.

i. Research and development:
   - *Research into development of biofortified products such as pro-vitamin A cassava, quality protein maize, pro-vitamin A maize, industrial sorghum and orange fleshed sweet potatoes.*
   - Development of climate resilient crops and livestock breeds. Eg. Drought, heat, flood and pest tolerant varieties,
   - Improvement of nutritious indigenous crops and livestock breeds.
   - Research into early planting and early maturing crops
   - Research into land use on crop suitability

ii. Education: Transmission of knowledge, skills, and character traits to populace including knowledge on food, nutritional products and climate change impact.

iii. Spin offs/Consultancy services.

iv. Incubation: The process to create, perfect and commercialize technologies from technological ideas or scientific research and technological development results or from unfinished technologies through assistance activities in terms of necessary technical infrastructure, resources and services.

v. Other roles of universities include joint projects, Joint patent, spin offs, Contract research, Training and development and New product idea/innovation.

2.3. Role of Industry on strengthening food security amid climate change environment.

i. Offtakers of research technology: Industries commits to partially or wholly purchase output from a research technology.

ii. Product and service development: Involves strategic assessment of concepts and how it delivers value to the customers.

iii. Entrepreneurship venturing: The ability and readiness to develop, organize and run a business enterprise, along with any of its uncertainties in order to make a profit.

iv. Research grant: Offer *Research Grants* to supports education, research and technology generation.

v. Others include establishing industrial parks, creating research opportunities and industrial training opportunities

3.0. STRENGTHENING AGRICULTURAL MARKET DEVELOPMENT AND EXPORT IN A CLIMATE CHANGE ENVIRONMENT

Market and businesses in the agricultural, forestry and fishing sectors are most at risk of catastrophic climate change impacts because their operations rely on the natural environment. Climate change impacts business vary depending on industry, location and vulnerability such as what your business facilities are made from, and the services it depends on. Impacts of climate change on markets/business can be direct such as physical damage from floods or bushfires, or forced closures or indirect such as supply chain interruption by extreme weather conditions.

Given our collective failure to mitigate greenhouse gas emissions, the world will have to adapt to a certain level of climate change. This may mean that as climate change affects crops' yield potential, new patterns of comparative advantage, and hence new trade flows, will emerge.

3.1. Role of Government:

- Policies that create enabling environment for market development and export
- Establishment of institutions that promote market development e.g. Nigeria Export Promotion Council, Nigeria Export Processing Zones and free trade zones.
- Establishment of commodity boards e.g. Cocoa board.

- Creating access to finance. E.g. Establishment of Nigeria Import export bank.
- Regulation of cooperative associations.

3.2. Role of Universities/Research Institutes

- Technology development in adaptive role of changing varieties or planting times to escape climate change impact
- Research into reallocation of land to crops or other uses more consistent with the yield under the new climate.
- Research into intensification of crop production, agricultural product substitution in food demand.
- Research into crop substitution in livestock-feed demand e.g. converting previously crop cultivated land to pasture land to mitigate climate change impact.

3.3. Role of Industry

- Investment in climate adaptive technological development and research on industrial processes.
- Plan for carbon storage in the design of industries.
- Efficient use of resources and energy to reduce GHG emission.
- Immediate and active actions to environmental problems (mitigation).
- Promoting use of renewable energy.
- Developing market solutions example green packaging.

3.4 Effects of triple Helix in a climate change Environment

- Adaptation of Suitable crops and measures to climate change environment.
- Policy Enhancement on information generation for climate change.
- Early maturing crops for food Security in a climate change environment.
- Research development on sustainable agriculture and resolution of challenges faced by industries with a backup of government policy to adapt crops and animals to changing climate environment.

CONCLUSION

The advent of knowledge-based economies with a particular focus to the roles of Government, academia and industries played to drive sustainable economic growth has garnered attention in recent times. While the Government role is largely in the area of policies and regulations that provide conducive/sustainable environment for academia to generate improve research technologies to withstand the present and future shocks such climate change and for the industries is off take of such innovations to adapt to such shocks such as disruption of supply chain due climate change and transition to the use of renewable energies to mitigate climate change impact.

STRENGTHENING AGRICULTURE FOR FOOD AND NUTRITION SECURITY, MARKET DEVELOPMENT AND EXPORT IN A CLIMATE CHANGE ENVIRONMENT

A LEAD PAPER PRESENTATION AT THE 57TH ASN ANNUAL CONFERENCE HELD AT THE FEDERAL UNIVERSITY OF LAFIA, NASARAWA STATE

MONDAY 23RD OCTOBER 2023

BINDIR – ASN, FED UNI LAFIA 2023

22

Nigeria
Good People Great Nation

SCIENCE, TECHNOLOGY AND INNOVATION: IMPLICATIONS ON STRENGTHENING AGRICULTURE FOR FOOD AND NUTRITION SECURITY, MARKET DEVELOPMENT AND EXPORT IN A CLIMATE CHANGE ENVIRONMENT IN NIGERIA

BINDIR – ASN, FED UNI LAFIA 2023

23

KEY PHRASES:

- **STRENGTHENING AGRICULTURE**
- **FOOD & NUTRITION SECURITY**
- **MARKET DEVELOPMENT**
- **EXPORT**
- **CLIMATE CHANGE ENVIRONMENT**
- **IN NIGERIA**

BINDIR – ASN, FED UNI LAFIA 2023

24

IN REAL TERMS…

THE EFFECTIVE APPLICATION OF STI

BINDIR – ASN, FED UNI LAFIA 2023

25

KEY (IMPLICATIONS):

- STRENGTHENING AGRICULTURE (ALL ASPECTS)
- FOOD & NUTRITION SECURITY (PEOPLE/SUPPLY CHAIN)
- MARKET DEVELOPMENT (JOBS, WEALTH, ECONOMY)
- EXPORT (TECHNOLOGY, STANDARDS, LOGISTICS)
- CLIMATE CHANGE ENVIRONMENT (NEW PARADYM)
- IN NIGERIA (MEANINGFUL)

BINDIR – ASN, FED UNI LAFIA 2023

26

IS MAINLY MEASURED ON THREE THINGS

BINDIR – ASN, FED UNI LAFIA 2023

27

1. **Absolute poverty** is **totally eradicated**
    - **BASIC EDUCATION**
    - **BASIC HEALTHCARE**
    - **POTABLE WATER**
    - **DECENT SHELTER**
    - **DECENT CLOTHING**
    - **ETC**

BINDIR – ASN, FED UNI LAFIA 2023

28

1. <u>Absolute</u> **poverty** is **totally eradicated**
2. Every man, woman, and child in the Country should **have access**, **not just to basic minimum needs, but to all the opportunities** to lead a happy, safe and fulfilling life
   - **SKILLS & COMPETENCES**
   - **PRODUCTIVITY & JOBS**
   - **SAFETY & SECURITY**
   - **ETHICS (DISCIPLINE & RESPECT)**
   - **PLAY & ENJOYMENT**
   - **etc**

BINDIR – ASN, FED UNI LAFIA 2023

29

1. <u>Absolute</u> **poverty** is **totally eradicated**
2. Every man, woman, and child in the Country should **have access**, **not just to basic minimum needs, but to all the opportunities** to lead a happy, safe and fulfilling life
3. Develop institutions to ensure that the country **emerges** as a **knowledge and a learning society** built on core values of development (***hard work, honesty, discipline, productivity, sincerity, and a collective sense of purpose***
   - ***WORLD CLASS INSTITUTIONS, GLOBAL COMPANIES, PRODUCTS & KNOWHOW, INNOVATIONS & COMPETITIVENESS***

BINDIR – ASN, FED UNI LAFIA 2023

30

THE EVIDENCE:

THOSE THAT HAVE EFFECTIVELY DONE THESE 3 THINGS…

BINDIR – ASN, FED UNI LAFIA 2023

31

- **DEVELOPED & RICH** 1ST

BINDIR – ASN, FED UNI LAFIA 2023

32

WHAT THEY DID RIGHT INCLUDE…

- **National Policies (evidence based, practical and implementable) on moving ALL SECTORS)**
- **Vibrant Science, Technology and Innovation (STI) system**
- **Institutional Systems of Innovation (NSI)**
- **Sustained Research and Development (R&D) Investment**
- **If Raw Materials Endowed, adopt a value addition culture**
- **Prioritised Technology Acquisition Focus and Core Mentor**
- **Strong Intellectual Property (IP) culture/system**
- **Innovative, Deliberate and Intense Deployment of ICE-T**
- **Viable Research - Industry Linkage models**
  - **Hi-Tech companies, Efficient Technology Incubation, Science and Technology Parks, Research Parks, Innopolis, Technopolis etc**
- **etc**

KEY PERFORMANCE INDICATORS

- **GLOBAL TECHNOLOGY VISIBILITY**
- **GLOBAL OPS/COMPANIES**
- **GLOBAL KNOW-HOW, SKILLS**
- **GLOBAL INDUSTRIAL PRODUCT RANGE**
- **CAPABILITIES & SERVICES**
- **DYNAMIC CREATIVITY & INNOVATION**
- **etc…**

IN THOSE EARLY DAYS, ONLY, EUROPEANS & AMERICANS...

BUT THEN:
FOLLOWERS, LEARNERS, ADAPTERS...

WHAT THEY FOLLOWED, LEARNT & DID…

- National Policies (evidence based, practical and implementable) on moving ALL SECTORS)
- Vibrant Science, Technology and Innovation (STI) system
- Institutional Systems of Innovation (NSI)
- Sustained Research and Development (R&D) Investment
- If Raw Materials Endowed, adopt a value addition culture
- Prioritised Technology Acquisition Focus and Core Mentor
- Strong Intellectual Property (IP) culture/system
- Innovative, Deliberate and Intense Deployment of ICE-T
- Viable Research - Industry Linkage models
  - Hi-Tech companies, Efficient Technology Incubation, Science and Technology Parks, Research Parks, Innopolis, Technopolis etc
- etc

BINDIR – ASN, FED UNI LAFIA 2023

37

- DEVELOPED & RICH
- EMERGING RICH

1ST, 2ND

BINDIR – ASN, FED UNI LAFIA 2023

38

THEIR KPIs ALSO…

- GLOBAL TECHNOLOGY VISIBILITY
- GLOBAL PRODUCT RANGE
- GLOBAL COMPANIES
- GLOBAL KNOW-HOW, SKILLS
- CAPABILITIES & SERVICES
- DYNAMIC CREATIVITY & INNOVATION
- etc…

BINDIR – ASN, FED UNI LAFIA 2023

39

BUT MANY ARE YET TO REALISE TO FOLLOW, LEARN & ADAPT...

BINDIR – ASN, FED UNI LAFIA 2023

40

WHAT THEY DID NOT DO WELL…

- National Policies (evidence based, practical and implementable) on moving ALL SECTORS)
- Vibrant Science, Technology and Innovation (STI) system
- Institutional Systems of Innovation (NSI)
- Sustained Research and Development (R&D) Investment
- If Raw Materials Endowed, adopt a value addition culture
- Prioritised Technology Acquisition Focus and Core Mentor
- Strong Intellectual Property (IP) culture/system
- Innovative, Deliberate and Intense Deployment of ICE-T
- Viable Research - Industry Linkage models
  - Hi-Tech companies, Efficient Technology Incubation, Science and Technology Parks, Research Parks, Innopolis, Technopolis etc
- etc

BINDIR – ASN, FED UNI LAFIA 2023

41

- DEVELOPED & RICH
- EMERGING RICH
- *DEVELOPING/POOR*
- *LEAST DEVELOPED*
- *UNDERDEVELOPING*
- *UNDERDEVELOPED*

1ST, 2ND

3RD

BINDIR – ASN, FED UNI LAFIA 2023

42

THEIR KPIs….

- NO REAL TECHNOLOGY VISIBILITY
- LOW PRODUCTIVITY
- FEW/NO GLOBAL ORGANISATIONS
- FEW/NO GLOBAL CAPACITY, SKILLS
- WEAK CAPABILITIES & SERVICES
- etc…

BINDIR – ASN, FED UNI LAFIA 2023

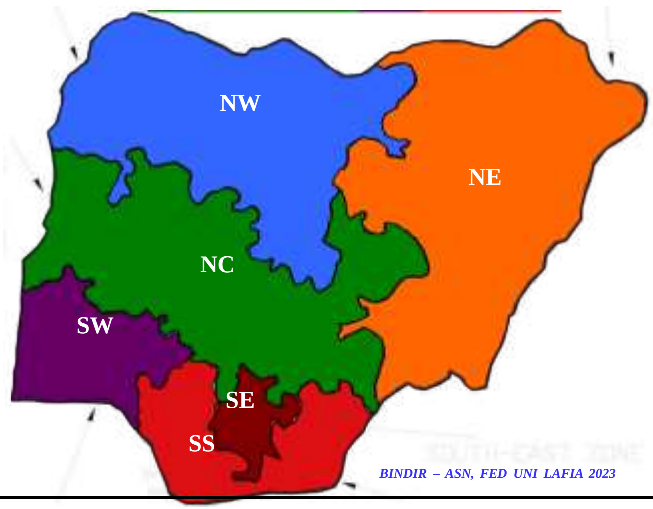
43

SO….. HOW ARE ALL THESE RELEVANT TO NIGERIA??

BINDIR – ASN, FED UNI LAFIA 2023

44

NIGERIA IN BRIEF



BINDIR – ASN, FED UNI LAFIA 2023

45

FACTS & REALITIES

- POPULATION (Over 200 Million)
  - Young, English Speaking, Traditionally Entrepreneurial, etc etc
- RESOURCE BASE (Agro/Minerals/Water, Oil/Gas etc)
- WEAK INFRASTRUCTURE
  - Physical, Socio-economic
  - **Suffocating Education System**
- WEAK “LOCAL” **INDUSTRIES**
- **INSECURITY**/**CORRUPTION** CHALLENGES
- HIGH ABSOLUTE POVERTY (60/70%) – **> 110 MILLION**
  - **Dominance of weak Rural Life**
- EMERGING CHALLENGES OF **ENVIRONMENT**
- “MATURING” DEMOCRACIES, etc etc

BINDIR – ASN, FED UNI LAFIA 2023

46

FACTS & REALITIES…

- **FEW OR NO GLOBAL PRODUCTS**
- **FEW OR NO GLOBAL COMPANIES**
- **FEW OR NO GLOBAL KNOW-HOW, SKILLS AND CAPABILITY SERVICES**
- **FEW “GLOBAL” TECHNOLOGIES**
- **Etc etc etc**

BINDIR – ASN, FED UNI LAFIA 2023

47

SOBER REFLECTIONS & AGENDA!

BINDIR – ASN, FED UNI LAFIA 2023

[57] **ABSTRACT**

A phytochemical composition for treating sickle cell disease is provided. The composition is a cold water extraction product of a mixture containing *Piper guineenses* seeds, *Pterocarpus osun* stem, *Eugenia caryophyllum* fruit, *Sorghum bicolor* leaves and potash. Also described are mixtures of phytomaterials used for preparing the extraction product, methods for making the extraction product, and methods for using the extraction product.

LEAD PAPER 2

Dr. Ibitoye Oyewale *FCA, ACIT*

Necessity For Resilience & Nutrient-Dense Improved Quality Crop Varieties: *Strength For Market Development, Export, Reduction of Farmers Vulnerability and Food Security.*

By

Dr. Ibitoye Oyewale
MD/CEO Premier Seed Nigeria Limited

A paper presented at the 57th Annual Conference of the Agricultural Society of Nigeria held at Federal University of Lafia, Nasarawa Sate.
24th October, 2023

ABOUT PREMIER SEEDS

Premier Seeds is a leading agricultural seed company in Nigeria with focus on production and marketing of certified seeds of improved crop varieties to farmers in Nigeria and across the West African sub-region

Seeding Nigeria to feed the Nation

In business since 1994 in Nigeria

Scaled to Ghana and Benin Republic in 2022

28 Zonal offices across the Nation and large agro-dealer networks well as last mile seed delivery system

- Agriculture is the most vulnerable sector to climate change, owing to its huge size and sensitivity to weather parameters, thereby causing huge economic impacts. The changes in climatic events such as temperature and rainfall significantly affect the yield of crops.
- Several mitigation measures such as regenerative agricultural practices need to be considered in order to reduce the effects of climate change on farmers productivity.

6 Core Principles of
REGENERATIVE AGRICULTURE

Effects of climate change on farmers productivity

- The effects of climate change such as temperature increases, irregular and variable rainfall patterns, flooding of riverbanks, drought and desertification, more frequent extreme weather events, and loss of biodiversity affects the productivity of smallholder farms.

- As far back as 2012, the country was already suffering from variability in the climate and high-intensity rainfall events in the central and southern regions, which led to perennial flood disaster with total losses and damages of about USD 16.9 billion.

- Unless urgent measures are taken to address these challenges, Nigeria's food security and by extension the economy is at great risk.

Micronutrient Deficiency

- More than 2 billion people worldwide do not get enough essential micronutrients in their diets to properly sustain health.

- Micronutrient deficiencies lead to negative nutritional and health outcomes, including increased susceptibility to infectious diseases, poor physical growth, and diminished cognitive development.

- They also result in significant losses due to decreased productivity and economic potential later in life.

- Several development partners lead the development and delivery of biofortified crops to improve micronutrient intake and the health status of millions of people living in low-income smallholder farm households globally.

- **Vitamins:** 29% of children under five years old in Nigeria are deficient in vitamins A which impairs growth, causes eye damage leading to blindness, and increases the risk of infection such as diarrrhea diseases.

- **Zinc:** 47% of pregnant women and 20% of children under five are deficient in zinc, which contributes to stuntiingand a loss of appetite, llowers immunity and increases the risk of diarrhea diseases and respiratoet infection

- **Iron:** Report show that 76.1% of pre-school age children and 66.7% of pregnant women suffer from anemia, oftencaused by iron deficiency, which affects mental development and learning capacityincreasesweakness and fatigueand may increase the risk of women dying in childbirth.

- One major breakthrough over the years was the support to develop, register, release and commercialize improved seeds of various nutrient dense crop varieties.

Climate-smart solutions

- Climate-smart agriculture is an approach to guide actions to transform and reorient agricultural systems to effectively and sustainably support development and food security under a changing climate (FAO).

- The climate smart agriculture (CSA) concept reflects an ambition to improve the integration of agriculture development and climate responsiveness. It aims to achieve food security and broader development goals under a changing climate and increasing food demand.

- PSNL supports smallholder farmers to increase crop productivity and farm output through several affordable options made available to farmers across the nation depending on their specific needs.

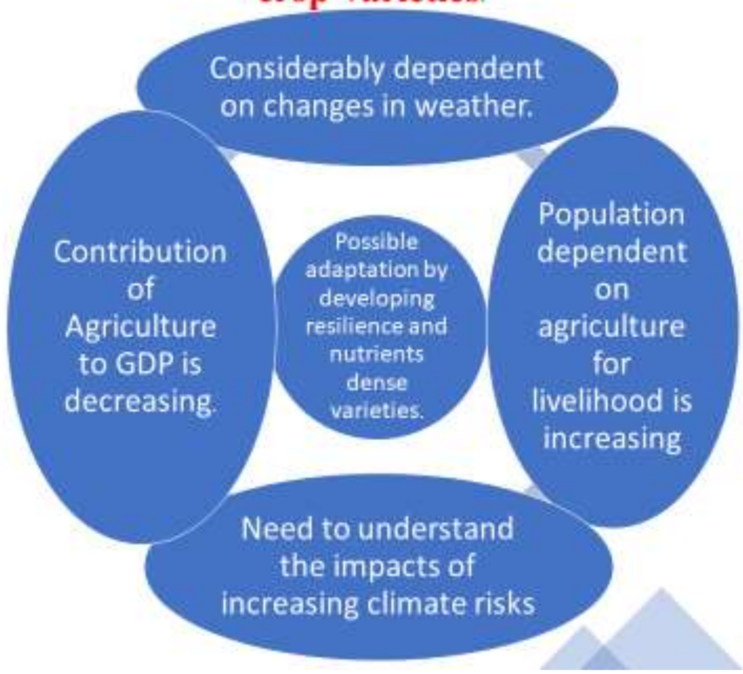
Concept of resilience of improved crop varieties

- These refers to crops that have been bred or developed to be more resistant to environmental stressors, such as drought, pests, or disease.

- These crops may also have improved nutritional value or other qualities that make them more attractive to consumers.

- It is a relatively new approach to developing the variety that will promote technical, political and financial condition for the achievement of sustainable developments goal.

Nigeria agriculture and necessity for resilience and nutrient dense crop varieties.



Roles of the public and private sector in promoting resilient and nutrient dense crop varieties.

Roles of Private sectors.

- Development of new nutrient dense varieties that better adapted to climate change.
- Commercialization
- Protection of the intellectual property while making their product available to the public.

Roles of Public sector

- Breeding and development of nutrient dense varieties that better adapted to climate change.
- Collaboration with private partners for commercialization.
- Protection of the intellectual property while collaboration with private partners for commercialization

Supplier of innovative goods and services:

✓The private sector has an enormous role in providing solutions to climate change.

✓There is a clear need to meet the adaptation priorities with expertise to technology and service delivery.

Adaptation through innovative, technology and design of resilient infrastructure:

✓The private sector has competencies which can make a unique contribution to adaptation through innovative technology, design of resilient infrastructure, development and implementation of improved information system and the management of major project.

Scaling up or leveraging public sector capital:

✓Private sector should be seen battle against climate change not as a burden but rather the major economic opportunity of our generation.

✓The greater involvement of private sector is critical, if any region is to prepare itself for both the challenges and opportunity rather than rely on public sector.

Potential benefits for seed companies involving in development and commercialization of resilient and nutrient dense varieties

Competitive advantage → If a company is know for developing high quality, resilient crops and nutrient dense crop varieties, it could gain a competitive advantage.

Creation of tied products → A company could develop a crop variety that work best with a particular fertilizers or herbicides that is also sell.

Development of crops to a specific need of the society → A company could develop a crop variety that is especially well suited for a particular climate and society.

Resilience and Nutrition Dense Improved Seed Varieties are crucial for several reasons, Including the following

- Enhancement of food security.
- Boosting export Potential
- Reduction of farmers' vulnerability.
- Market development.
- Export growth

Significance of Resilience and Nutrition Dense Improved Seed Varieties

Enhancement of food security.

These varieties are bred to possess specific traits such as disease resistance, high yield potential, and adapitality to varying environmental condition, by cultivating these improved seeds, farmers can ensure a more reliable and abundant food supply, thereby strengthening food security at both local and global level

Reduction of farmers' vulnerability

.

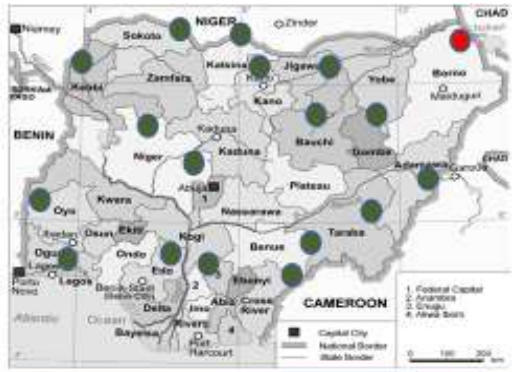
The traditional seeds often lack resilence against pests, diseases , and climate change adaptitlity. By Using improved seeds that posses resistance traits, farmers can minimize crop losses, thereby reducing the financial burden caused bycrop failure, Furthermore, these varieties often have higher yields, enabling farmers to generate more incomes and improved their livelihoods.

Market development and Export growth

They can be developed to meet market demand for specific quality attribute and traits, such as colour, taste, or shelf life , maturity period . By producing and exporting crops from improved seeds , country can capitalize on their unique agricultural strengths, increase their competitiveness in the global market and boosting economy.

Challenges to adoption of resilient and nutrient dense crop varieties

- ✓ Lack of awareness about resilient crop varieties
- ✓ Lack of access due to infrastructure or resources
- ✓ Farmers may be skeptical of new varieties
- ✓ Some of the crops might not be affordable in term of price



Ways to address these challenges

- ✓ Creation of awareness through campaigns and training programs,
- ✓ Framer to farmer exchange can help to overcome the lack of awareness
- ✓ Availability of seed in the open market
- ✓ Subsidies the price of seeds by Government.

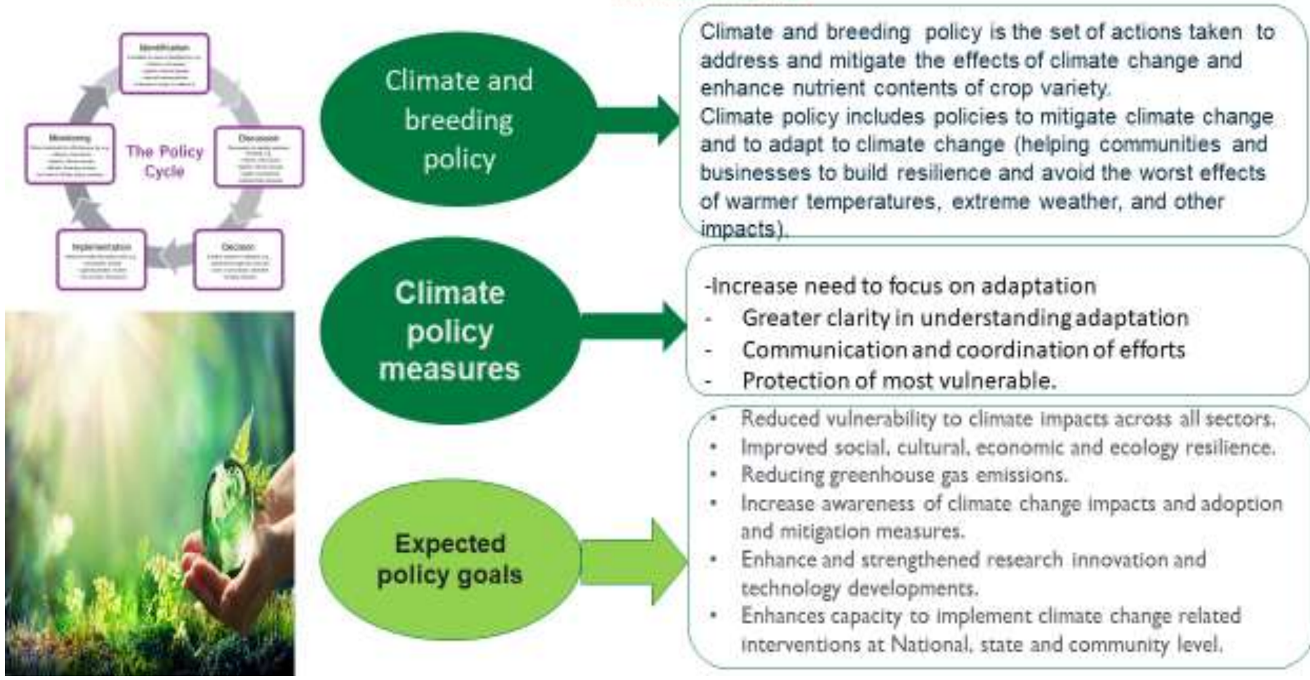
Investment models to enhance resilience and nutrition dense crop varieties

Climate resilience investment model → Climate resilience investment models aims to create a more resilient global financial industry in which key incentive structures foster an accurate pricing of physical climate risks in investment decision-making, resulting in more resilient economies and communities across the world

Pillars of resilient/ nutrient dense investment model → This models consists of five pillars: threshold capacity, coping capacity, recovery capacity, adaptive capacity, and transformative capacity

strategies for resilient & nutrient dense investment model → Strategies for Climate resilience investment is the ability to anticipate, prepare for, and respond to hazardous events, trends, or disturbances related to climate. Improving climate resilience involves how climate change will create new, or alter current, climate-related risks, and taking steps to better cope with these risks in the investment.

Policy frameworks and regulatory measures to incentivize climate resilience investments



Economics & policy innovation for resilient and nutrition dense crop varieties

- Identifying synergies and align food security, adaptation, market development and mitigation that may arise in transforming.
- Identifies the local institutions needed to support the breeding and development of resilient and nutrition dense varieties.
- Provide assistance for strategic planning that integrates resilient and nutrition dense varieties, agricultural development, food security, market development, policy and objectives.
- Builds mechanisms and investment plans to combine resilient and nutrition dense crop varieties finance with agricultural investments finance to support the innovation.
- Make agriculture productive, sustainable, remunerative and climate resilient.

How can Policy Enable Scaling Integrated Solution

Some key questions to get us started:

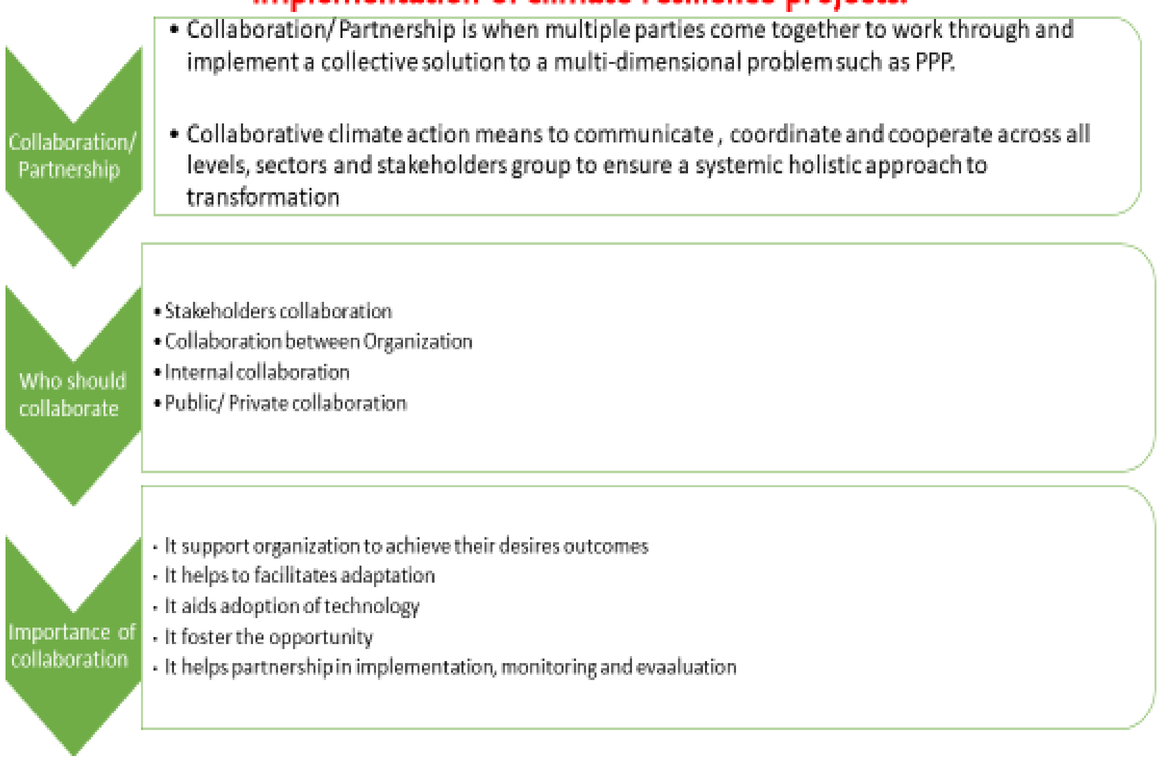
National Agriculture Technology and Innovation Policy (NATIP) – 2022 – 2027 - has laid strong foundations for enabling reforms in both climate and nutrition smart agriculture. How can the key relevant elements of NATIP be catalyzed and implemented?

Reduced emissions and promoting carbon sinks not always easy because markets default to choices that often work for short term goals rather than long term sustainable development. How can environment policy play a role in supporting sustainable and nutritious agriculture and natural resource use behaviours through the National Climate Change Strategy?

What are the key institutional supports – e.g in R&D for National Agriculture Research Systems, for rapid varietal release and standards, early generation seed access, that can bring innovations in CSA and NSA to markets quickly and cost effectively?

Finally what policy and planning coordination mechanisms and roadmaps at both the federal and state level can help realize policy goals.

Fostering partnership and collaboration among stakeholders for effective implementation of climate resilience projects.



Conclusion

- The importance of resilient and nutrition-dense quality crop varieties cannot be overstated. Their multifaceted impact on market development, export competitiveness, reduction of farmers' vulnerability, and food security underscores their indispensable role in global agriculture.
- Governments, agricultural organizations, Research institute, seed companies and communities must collaborate to promote the cultivation and consumption of these crops. By investing in research, technology, and education, Nigeria can create a resilient agricultural sector capable of addressing the challenges of the 21st century, ultimately leading to a healthier, more secure, and prosperous world.
- The necessity of improved seed varieties lies in their ability to strengthen food security by ensuring a more reliable food supply, boosting export potential by meeting market demands, and reducing farmers' vulnerability to risks. By embracing and promoting the use of these varieties, countries can create a more sustainable and prosperous agricultural sector.

LEAD PAPER 3

BIO-ECONOMY AND BIO-ENTREPRENEURSHIP: THE NEW PARADIGM IN AGRICULTURAL EDUCATION SYSTEM IN NIGERIA

Prof. Olumuyiwa James Jayeoba ***FSSSN, FHORTSON, RSS***

President, Association of Deans of Faculty of Agriculture in Nigerian Universities (ADAN)

Introduction

In Nigeria, the agricultural sector has long been the backbone of the economy, providing livelihoods for millions and contributing significantly to the nation's GDP. However, as global dynamics and the challenges of the 21st century continue to evolve, the need for innovation, sustainability, and entrepreneurship in agriculture has never been more pressing. This shift has given rise to a new paradigm in the agricultural education system, one centered on the bio-economy and bio-entrepreneurship.

The bio-economy represents a fundamental rethinking of our approach to agriculture, highlighting the sustainable utilization of biological resources, from crops and livestock to forestry and fisheries. In this context, bio-entrepreneurship emerges as a powerful force, igniting innovation and creativity in the agricultural sector, and equipping the next generation with the tools to transform challenges into opportunities. The Bio-Economy is a comprehensive framework that transcends traditional farming practices, encompassing the sustainable utilization of biological resources, innovative agricultural technologies, and the cultivation of bio-entrepreneurship. It seeks not only to enhance food security but also to create a resilient and diversified economy deeply rooted in agriculture. The confluence of traditional farming wisdom with cutting-edge biotechnology, renewable energy solutions, and value-added product development has given rise to an era where the boundaries of agriculture have expanded far beyond the fields.

This lecture delves into the transformation underway within the Nigerian agricultural education system. It will analyze the adoption of the Bio-Economy and Bio-Entrepreneurship as the driving forces propelling this sector towards innovation, sustainability, and economic prosperity. Through this lens, I will examine the evolving curricula, government initiatives, research endeavors, and the collaborative spirit of institutions both local and international. By understanding this new agricultural paradigm, we seek to shed light on the challenges, opportunities, and the promise it holds for Nigeria as it strives to meet the demands of a rapidly changing world and build a future that combines sustainable agricultural practices with entrepreneurial spirit.

Definition of Bio-Economy and Bio-Entrepreneurship

Bio-Economy:

The bio-economy is an economic system and framework that centers on the sustainable utilization of biological resources and processes to produce goods, services, and energy. It encompasses a wide range of sectors, including agriculture, forestry, fisheries, biotechnology, and healthcare. The key characteristic of the bio-economy is its reliance on renewable biological resources and the efficient utilization of waste streams, aiming to promote environmental sustainability while fostering economic growth and societal well-being. In the context of Nigeria, the bio-economy holds the potential to revolutionize traditional agricultural practices and create value-added products and services, contributing to the nation's economic development.

Bio-Entrepreneurship:

Bio-entrepreneurship is a dynamic and innovative approach to business within the bio-economy. It involves the identification, development, and commercialization of entrepreneurial opportunities related to biological resources and processes. Bio-entrepreneurs use their creativity, scientific knowledge, and business acumen to create sustainable ventures that address societal challenges, enhance resource efficiency, and generate economic value. In the agricultural context, bio-entrepreneurs may focus on areas such as agribusiness, biotechnology, sustainable farming practices, and the development of bio-based products. Bio-entrepreneurship plays a pivotal role in transforming traditional agricultural systems into more productive, environmentally friendly, and economically viable models, contributing to food security and rural development in Nigeria.

Significance of Agricultural Education in Nigeria

Agricultural education has a rich historical significance in Nigeria. It has been an integral part of the nation's educational landscape for decades, reflecting the country's strong agrarian tradition. Historically, many communities in Nigeria have relied on agriculture for sustenance and livelihoods, making it a fundamental aspect of the nation's heritage. Agricultural education is crucial in Nigeria due to the sector's economic significance. Agriculture has been a major contributor to the country's Gross Domestic Product (GDP) and provides employment to a significant portion of the population, especially in rural areas. Therefore, educating and training individuals in modern agricultural practices is vital for sustaining and enhancing the sector's contributions to the national economy.

Nigeria faces food security challenges, including insufficient food production, post-harvest losses, and inadequate access to nutritious food. Agricultural education plays a pivotal role in addressing these issues by equipping farmers and agricultural professionals with the knowledge and skills needed to improve food production, reduce losses, and enhance nutritional outcomes for the population.

Agriculture is a key driver of poverty reduction in Nigeria. By educating individuals in agricultural practices, entrepreneurship, and value chain development, agricultural education empowers people to engage in productive agricultural activities, increase their income, and escape the cycle of poverty. This aligns with Nigeria's broader development goals of poverty alleviation and economic empowerment.

The agricultural sector is evolving rapidly with advancements in technology and innovation. Agricultural education serves as a vehicle for introducing farmers and agribusiness professionals to modern, sustainable farming practices, cutting-edge technologies, and efficient resource management techniques. This helps increase agricultural productivity and competitiveness. Sustainable agriculture is critical for preserving Nigeria's natural resources, such as soil and water. Agricultural education promotes environmentally friendly farming practices, conservation methods, and the responsible use of resources. It helps mitigate the negative environmental impacts of agriculture while ensuring long-term sustainability.

Agriculture is the backbone of many rural communities in Nigeria. Agricultural education contributes to rural development by creating opportunities for rural youth, promoting entrepreneurship, and enhancing the overall well-being of rural populations. It encourages the development of agribusinesses and value chains, thereby reducing rural-urban migration.

The New Paradigm in Nigerian Agricultural Education

The evolving landscape of agriculture, characterized by the integration of bio-economy and bio-entrepreneurship, necessitates a new paradigm in agricultural education. To equip students and professionals with the skills and knowledge needed for success in this dynamic field, educational institutions must adapt and innovate. This new paradigm in agricultural education equips individuals with the skills, knowledge, and entrepreneurial mindset needed to thrive in the evolving bio-economy and bio-entrepreneurship landscape. It empowers the next generation of agricultural leaders to drive innovation, sustainability, and positive change in agriculture and related sectors.

The key components of this new paradigm in agricultural education are as follows:

a) ***Interdisciplinary Approach:***
Recognize the interconnectedness of agriculture with various sectors, including biotechnology, environmental science, business, and economics. Encourage interdisciplinary learning and collaboration to address complex agricultural challenges comprehensively.

b) ***Bio-Economy Integration:***
Incorporate bio-economy principles into the curriculum. Teach students about the sustainable utilization of biological resources, circular economy concepts, and the economic opportunities presented by the bio-economy.

c) ***Bio-Entrepreneurship Education:***
Offer courses and programs focused on bio-entrepreneurship. Equip students with the skills needed to identify opportunities, develop bio-based innovations, and navigate the challenges of starting and managing bio-entrepreneurial ventures.

d) ***Technology and Biotechnology Training:***
Emphasize training in cutting-edge technologies, including biotechnology, genomics, precision agriculture, and digital farming. Equip students with the ability to leverage these tools for sustainable agriculture and bio-based innovations.

e) ***Sustainability and Environmental Stewardship:***
Integrate sustainability principles into agricultural education. Teach students about sustainable farming practices, resource management, and environmental conservation, emphasizing responsible agriculture within the bio-economy.

f) ***Ethical Considerations:***
Include discussions on ethical considerations in biotechnology and bio-entrepreneurship. Foster an understanding of the ethical implications of genetic engineering, intellectual property rights, and responsible use of biological resources.

g) ***Experiential Learning:***
Promote experiential learning opportunities, such as internships, fieldwork, and research projects, to provide students with hands-on experience in agricultural settings and bio-entrepreneurial endeavors.

h) ***Innovation and Research Focus:***
Encourage a culture of innovation and research within educational institutions. Support faculty and students in conducting research projects that address real-world agricultural challenges and opportunities.

i) ***Global Perspective:***
Foster a global perspective by exposing students to international agricultural practices and global challenges. Encourage study abroad programs, partnerships with international institutions, and global research collaborations.

j) ***Entrepreneurship Incubators and Centers:***
Establish entrepreneurship incubators and centers within educational institutions to support students and alumni in launching bio-entrepreneurial ventures. Provide mentorship, access to funding, and resources for business development.

k) ***Continuous Learning and Adaptation:***

Emphasize the importance of continuous learning and adaptation within the rapidly evolving bio-economy. Encourage students and professionals to stay updated with emerging trends and technologies.

l) Partnerships with Industry:

Collaborate with industry partners to ensure that educational programs align with industry needs. Industry partnerships can provide students with real-world insights and opportunities for internships and employment.

m) Community Engagement:

Promote community engagement and outreach initiatives. Encourage students to work with local farmers and communities to address agricultural challenges and contribute to sustainable development.

n) Digital Learning and Online Resources:

Leverage digital learning platforms and online resources to make agricultural education more accessible and flexible for learners, including working professionals and remote students.

Role of Association of Deans of Faculty of Agriculture in Nigerian Universities (ADAN) in Developing Entrepreneurial Skills in Agricultural Students in Nigeria

Over the years, Association of Deans of the Faculty of Agriculture in Nigerian Universities (ADAN) played a crucial role in developing entrepreneurial skills in agricultural students in Nigeria. As a collective body representing academic leadership in agricultural education, ADAN can influence policies, curricula, and initiatives that promote entrepreneurship within the agricultural education system. Some key activities of ADAN in support of the development of entrepreneurial skills among agricultural students are as follows:

1. Establishment of Agribusiness Incubation Centers (AICs)

The Federal government of Nigeria through the Federal Ministry of Agriculture and Rural Development (FMARD) acting on the Memorandum of Understanding (MOU) between the Association of Deans of Agriculture in Nigerian Universities (ADAN) and Youth Initiative for Sustainable Agriculture (YISA) established Agribusiness Incubation Centers (AICs) in ten (11) Universities in Nigeria. The centers are designed to create successive generation of young agricultural entrepreneurs from the Faculties/Colleges of Agriculture in Nigeria Universities. The AICs will serve as the capacity-building component of the Agripreneurship Incubation & Mentorship (AIM) Programme. The AIM programme is anchor on five core pillars as listed

Pillar 1: Agribusiness Mindset Clinic (AMC)
Pillar 2: Incubation Model Farms (Imof)
Pillar 3: Agribusiness Incubation Lab (AIL)
Pillar 4: Young Agripreneurs Innovation Fund (YAI-Fund)
Pillar 5: Agribusiness Mentorship Platform (AMP)

The overall objective of the centers is to establish standard hands-on practical agribusiness training where the capacity of Agriculture students and community youths will be built on agricultural entrepreneurship skills to reduce practical agro-knowledge gap among Agriculture students and other youths so as to establish and run successful agro enterprises for job creation and food/social security.

The specific objectives is to create successive team of young Agribusiness Entrepreneurs to drive successful agricultural enterprises for national food and social security while creating jobs for other unemployed youths.

1. Training and capacity development of youths in agricultural entrepreneurship.
2. Providing trainings for innovative agribusiness start-ups and cooperatives.
3. Development of managerial skills and knowledge of the Nigerian agribusiness sector.

4. Creation and development of sustainable, globally competitive Agri-based SMEs that contribute towards the accelerated growth of the economy.
5. Creation and transfer of need-driven agricultural innovation.
6. Assist to create value added jobs and services by making individuals relevant in different areas of the agriculture value chain.
7. Create Awareness about Technology Incubation and Commercialization of Research and Development products and processes.
8. Foster an entrepreneurial culture, by providing the students, alumni, and faculty, opportunities to transform their business ideas to reality.

2. Strategic partnerships of ADAN and AFAN

Strategic partnerships between the Association of Deans of the Faculty of Agriculture in Nigerian Universities (ADAN) and the All Farmers Association of Nigeria (AFAN) have significant implications for students' bio-entrepreneurship in agriculture. These partnerships can create a supportive ecosystem that equips students with the skills, knowledge, resources, and real-world experience needed to become successful bio-entrepreneurs. Here are the implications for students:

i. ***Practical Exposure***: Students can gain practical exposure to the agricultural industry through internships, on-farm training, and industry visits facilitated by AFAN. This exposure helps them understand the challenges and opportunities in agriculture, a crucial foundation for bio-entrepreneurship.

ii. ***Mentorship and Guidance***: AFAN can provide experienced farmers and agribusiness owners as mentors to agricultural students. These mentors can offer guidance, share insights, and provide real-world perspectives on starting and managing agricultural businesses, including those based on bio-entrepreneurship.

iii. ***Access to Resources***: Students can access resources such as land, equipment, and financial support through AFAN's network. This is particularly valuable for students looking to launch bio-entrepreneurial ventures that may require physical resources.

iv. ***Networking Opportunities***: Joint events and networking opportunities between ADAN and AFAN bring students into contact with industry professionals, potential partners, and mentors. These connections are invaluable for students looking to launch or advance their bio-entrepreneurial endeavors.

v. ***Market Access***: AFAN's market knowledge and connections can help students navigate the complexities of selling agricultural products, including bio-based products. This support can be instrumental in the commercialization of student-led ventures.

vi. ***Collaborative Research***: Students can participate in collaborative research projects that address real-world agricultural challenges and opportunities. This practical research can form the basis for innovative bio-entrepreneurial ventures.

vii. ***Business Incubation***: Strategic partnerships can support the establishment of agricultural incubation centers where students can receive mentorship and practical support for launching and scaling their bio-entrepreneurial initiatives.

viii. ***Training and Capacity Building***: Students can benefit from joint training programs and workshops that equip them with essential skills in areas such as business planning, financial management, and sustainable agriculture practices, all of which are integral to bio-entrepreneurship.

ix. ***Access to Funding***: Collaboration with AFAN can provide students with information on funding opportunities, grants, and loans for starting and growing their bio-entrepreneurial projects. AFAN's expertise in this area can help students secure financial support.

x. ***Advocacy for Student Interests:*** ADAN and AFAN can work together to advocate for policies and initiatives that support the interests of student bio-entrepreneurs, including favorable regulatory frameworks, financial incentives, and educational programs.

xi. ***Youth Engagement***: Joint programs can focus on attracting and engaging young people in bio-entrepreneurship. This includes educational initiatives that foster entrepreneurial thinking and opportunities for students to participate in the agricultural value chain.

xii. ***Technology Transfer***: Students can gain access to advanced agricultural technologies, including biotechnology applications, through ADAN's collaboration with AFAN. This access allows them to explore innovative approaches to bio-entrepreneurship.

The strategic partnerships between ADAN and AFAN can empower agricultural students to become bio-entrepreneurs by providing them with practical experiences, mentorship, resources, market access, training, and networking opportunities. These collaborations can help students bridge the gap between academic knowledge and real-world application, fostering a new generation of bio-entrepreneurs who drive innovation and sustainability in the Nigerian agricultural sector.

3. Other activities of ADAN now or in the future for the development of entrepreneurial skills among agricultural students are as follows:

i. ***Curriculum Development***: ADAN works with faculties of Agriculture in Nigerian universities to enhance the curriculum of agricultural programs. This includes the incorporation of entrepreneurship courses, business management, and agribusiness training. The association advocates for a well-rounded education that not only emphasizes technical knowledge but also business acumen.

ii. ***Faculty Development***: ADAN organizes training and workshops for faculty members to equip them with the necessary skills and knowledge to teach entrepreneurship effectively. This includes best practices for engaging students in entrepreneurial activities and fostering innovation.

iii. ***Promotion of Entrepreneurial Culture***: ADAN actively promotes an entrepreneurial culture within agricultural faculties. This involves encouraging students to think creatively, take risks, and identify entrepreneurial opportunities in the agricultural sector. The association can also support entrepreneurial clubs and student organizations.

iv. ***Mentorship Programs***: ADAN can establish mentorship programs that connect agricultural students with experienced entrepreneurs and professionals in the industry. These mentors can provide guidance, share insights, and offer real-world perspectives on agribusiness.

v. ***Access to Funding and Resources***: The association can work to connect students with funding opportunities, grants, and resources for starting and scaling agricultural ventures. This may involve partnerships with financial institutions, government agencies, and private sector organizations.

vi. ***Internships and Practical Training***: ADAN can collaborate with industry partners to facilitate internships and practical training for students. This hands-on experience is invaluable in developing entrepreneurial skills and understanding the realities of agribusiness.

vii. ***Research and Innovation Support***: Encouraging research in areas of agribusiness and innovation is essential. ADAN can promote and fund research projects that focus on developing new agricultural products, technologies, and business models.

viii. ***Entrepreneurial Competitions***: Organizing entrepreneurial competitions and challenges within universities can foster a competitive spirit and encourage students to develop and pitch their agribusiness ideas.

ix. ***Advocacy and Policy Influence***: ADAN can advocate for policies that support entrepreneurship in agriculture at the institutional and government levels. This includes lobbying for favorable regulatory frameworks and incentives for young agribusiness entrepreneurs.

x. ***Networking and Collaborations***: The association can facilitate networking opportunities, both nationally and internationally, for students to connect with potential partners, investors, and customers.

xi. ***Information Dissemination***: ADAN can provide students with up-to-date information on market trends, technological advancements, and investment opportunities in the agricultural sector.

xii. ***Assessment and Evaluation***: Implementing mechanisms to assess and evaluate the impact of entrepreneurial programs and initiatives to ensure they are effective and beneficial to students.

ADAN, as an influential body within the Nigerian agricultural education system, has the potential to significantly impact the development of entrepreneurial skills among agricultural students. By promoting entrepreneurship and innovation, the association can help create a new generation of agribusiness leaders who contribute to the growth and sustainability of Nigeria's agricultural sector.

Conclusion

In conclusion, the emergence of the bio-economy and bio-entrepreneurship as a new paradigm in the agricultural education system in Nigeria marks a transformative era in the nation's pursuit of sustainable agriculture, economic prosperity, and global competitiveness. This paradigm shift represents a promising future where traditional farming practices harmoniously coexist with modern biotechnological innovations and entrepreneurial spirit. The implications of this new approach are vast and profound:

- ✓ Sustainability: Bio-economy emphasizes sustainable practices, leading to resource-efficient agriculture and the conservation of natural ecosystems. This commitment to sustainability ensures the long-term health of Nigeria's agricultural sector and the environment.
- ✓ Innovation: The integration of cutting-edge biotechnology, renewable energy solutions, and value-added product development fosters innovation in agriculture. This innovation is essential for addressing the challenges of food security, resource constraints, and climate change.
- ✓ Economic Growth: Bio-entrepreneurship, as a core component of this paradigm, provides opportunities for job creation, economic growth, and diversification. It encourages the development of small and medium-sized enterprises (SMEs) within the agricultural sector.
- ✓ Youth Engagement: The new paradigm attracts and engages young people in agriculture by presenting agribusiness as an attractive and profitable career option. It equips students with entrepreneurial skills, positioning them as future leaders in the agricultural industry.

- ✓ Global Competitiveness: Nigeria's participation in the global bio-economy market allows it to leverage its agricultural resources and expertise to compete on the international stage. The nation can emerge as a prominent player in the bio-economy, contributing to global food security and economic growth.
- ✓ Collaboration and Partnerships: The paradigm encourages collaboration between educational institutions, government bodies, international organizations, and industry stakeholders. This collaborative approach leverages diverse expertise and resources to propel Nigeria forward.
- ✓ Policy Reform: Bio-entrepreneurship and the bio-economy are reshaping policy landscapes in agriculture. Nigeria is working to create regulatory frameworks and incentives that support sustainable, innovative, and entrepreneurial practices in the sector.
- ✓ Value Addition: Bio-entrepreneurship encourages the development of value-added products from agricultural resources. This not only increases income for farmers and entrepreneurs but also adds value to Nigeria's agricultural exports.

As Nigeria navigates the dynamic landscape of the 21st century, the embrace of the bio-economy and bio-entrepreneurship represents a bold step towards realizing its agricultural potential. This paradigm transcends conventional farming, ushering in a future where agriculture is a beacon of sustainability, innovation, and economic empowerment. By nurturing a generation of bio-entrepreneurs, the agricultural education system becomes the bedrock of change, equipping students with the knowledge and skills needed to navigate the complexities of the modern agricultural sector.

In this journey, challenges remain, such as the need for increased investment, environmental concerns, and the fostering of a culture that values entrepreneurship. However, the promise and potential of the bio-economy are undeniable. It is an era of transformation where Nigeria's agricultural past converges with its future, forging a path that marries tradition with innovation, ethics with entrepreneurship, and sustainability with prosperity. The new paradigm is a testament to the resilience, adaptability, and forward-thinking spirit of Nigeria's agricultural sector and its commitment to a brighter, sustainable future.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The deficiency in authentic and ordered data concerning livelihoods makes it impossible to effectively support decision making for reducing poverty, enhancing food insecurity and sustaining living standard. This study seeks to assess the Anchor Borrower`s Program on livelihood of smallholder rice farmers in Kebbi State, Nigeria. Multistage and random sampling methods were used to select 397 each for beneficiary and non-beneficiary rice farmers giving a sample size of 794. Data collected was analyzed using Principal Component Analysis (PCA). The results reveal that the Asset Score Index of the poorest smallholder farmers is -0.0173 and the richest farmer is 0.526 with a total net asset score index of 0.061 for beneficiary rice farmers and -0.022 for non-beneficiary rice farmers. This suggests an improved livelihood of ABP beneficiary over the non-beneficiary thus, it is recommended that the program be sustained and be extended to more smallholder farmers in the State and country at large.
Keywords: *Anchor Borrowers' Program, Livelihood, Smallholder farmers, Beneficiaries, Non-beneficiaries.*

INTRODUCTION
Agriculture generates an average of 23.1million tons of food per day, offers livelihoods for about 2.5 billion individuals and the major source of income and jobs for poor, rural households (Convention on Biological Diversity, 2018). In spite of decades of attention given to; agricultural development, food security and rural poverty, poverty and food insecurity remain, especially amongst rural dwellers in Asia, Africa and Central America (Thornton *et al*., 2019)**.** Report has shown that in 2017, 3.4 billion inhabitants lived in rural areas, having most 15% and 79% of low and middle income countries for which many sourcing their income from small-scale agriculture (Lowder *et al*., 2019) and there are about 570 million farms out of which approximately 500 million are less than 2 ha thus, accounting for about 12% of the world's agricultural land.
Nigeria has a land area of 924, 000km^2, 3/4 of the land is good for farming, nevertheless, less than half of it has not been exploited to produce crops, because majority of the smallholder farmers are deficient in access to capital to purchase inputs such as improved seeds, fertilizers, agrochemicals and to buy or rent mechanized equipment and other services that may enhance their productivity and increase their incomes enough to be out of poverty (Aderemi, 2017). Thus, Anchor Borrowers Programmes (ABP) was introduced to create a linkage between large scale processors involved in both primary and secondary processing and the smallholder farmers (SHFs). The main driving force of the ABP is the provision of farm inputs in kind (i.e. farm equipment, fertilizer, seeds, agrochemicals etc.) and in cash for farm labor and extension services to smallholder farmers to stimulate agricultural production, stabilize inputs supply to agro processors and address the country's negative balance of payments on food crops (Inara Foundation, 2023). Therefore, gathering the needed, relevant and efficient information on livelihoods is very germane for facilitating evidence-based policy decisions. The lack of authentic and ordered data concerning different aspect of livelihoods makes it impossible to effectively and efficiently support decision making for reducing poverty, enhancing food insecurity and sustaining living standard. It is based on this idea that this study aims to assess the anchor borrower`s intervention program (ABP) on livelihood of smallholder rice farmers in Kebbi State Nigeria. Furthermore, little or nothing is known about the livelihood of beneficiaries' of ABP rice farmers in Kebbi State, hence there exists a clear knowledge gap that this current research attempts to bridge.

METHODOLOGY
Study Area
The study was conducted in Kebbi State which has a total projected population of approximately 4,738,267 people (National Population Commission, 2019). A GPS coordinate of between latitude $10^0\ 05^1$ N and $13^0\ 27^1$ N and longitude $3^0\ 35^1$ E and $6^0\ 03^1$. The State is bordered by Sokoto State, Niger State, Zamfara State, Republic of Niger and Benin Republic. It has a total area of 36,800 km² characterized by Sudan and Sahel-Savannah. The southern part is generally rocky with the Niger

River traversing the State from Benin Republic to Ngaski LGA. The northern part of the State is sandy with the Rima River passing through Argungu to Bagudo LGA where it empties into the Niger. State is tropically characterized by two season's i.e. rainy and dry seasons. The rainy season starts from April and ends in October with its peak period between July and August, while the dry season starts from November and last to February (harmatan period) with low temperature in the nights. The weather between March and June is hot with an average temperature between 38^0 and 43^0 c. Agriculture is the main occupation of the people especially in rural areas, crops produced are mainly grains in addition to animal rearing and fishing.

Sampling Procedure and Sample Size

A multistage sampling technique was used in the selection of sample size for the study. At stage I, Kebbi State was divided into four Agricultural zones (i.e. Argungu, Bunza, Yauri and Zuru zones), At stage II, two local governments areas were purposively selected based on the prevalence of ABP beneficiaries, given a total of eight (8) local government areas for the study. At stage III, a proportionate sampling of 0.08% (i.e. Argungu 58, Dandi 26, Shnga 37, Yauri 74, Birnin Kebbi 87, Bagudo 88, Sakaba 11 and Zuru 16) was employed to establish the sample size given a total sample size of 397 respondents from ABP beneficiaries and a corresponding number of non-beneficiaries.

Analytical Technique

Principal Component Analysis (PCA) was used to determine and Compare the level of improvement in livelihood of ABP beneficiary and Non beneficiary Rice Farmers using farmer's asset as proxy to income. The result of the asset index model derived from PCA for each household asset is specified by the following formula:

$$Y = \frac{x_1 - \bar{x}_1}{a_1(s_1)} + \frac{x_2 - \bar{x}_2}{a_2(s_2)} + \cdots + \frac{x_k - \bar{x}_k}{a_k(s_k)}$$

Where:

$\bar{x}_k$ and s_k are the mean and standard deviation of asset x_k and α represents the weight for each variable x_k for the first principal component. The first principal component variable across households has a mean of zero and a variance of λ, which corresponds to the largest eigenvalue of the correlation matrix of x. The first principal component Y yields a wealth index that assigns a larger weight to assets that vary the most across households so that an asset found in all households is given a weight of zero (McKenzie, 2003). The first principal component or wealth index can take positive or negative coefficient. PCA coefficients have a fairly intuitive interpretation. The coefficient on any one variable is a function of how much information it provides about the other variables. If ownership of one type of asset is highly indicative of ownership of other assets, then it receives a positive coefficient. If ownership of an asset contains almost no information about what other assets the household owns (its correlation coefficient is near zero), then it receives a coefficient near zero. And if ownership of an asset indicates that a household is not likely to own few other assets, then it receives a negative coefficient. Higher and lower coefficients mean that ownership of that asset conveys more or less information about the other assets (Booyson *et al*., 2005). The higher the sum total of net coefficient or the closer the sum total of net coefficient is to one, the better the standard of living of the respondents.

RESULTS AND DISCUSSION

The result in Table 1 shows that majority (75%) of Non Beneficiary farmers owned a radio, TV, Mobile Phones, goats and sheep's while a very few (25%) of Non beneficiary farmers owned a car, truck, power tillers. The source of water supply, and type of roofing materials used by the non-beneficiary homes, vary across households with majority (75%) using shallow well water and grass materials for roofing. In ABP beneficiary's homes, majority (75%) of households owned all/most of the assets listed, and had a tap water in their abodes with variation in type of sanitation facility. The walls of their building are made of cement block unlike the non-beneficiary farmers whose majority (75%) of their buildings is made of clay blocks. In non-beneficiaries homes, few households have assets/sanitation facility. The major sanitation facilities in non-beneficiaries' homes are dug hole and latrines. Table 1 shows the mean, standard deviation and percentile distribution of the assets consider in this study.

Assets Scores Model

The responses of both ABP Beneficiary and Non beneficiary farmers regarding their ownership of assets captured in Table 1. Both the parties were asked if they had the assets in their homes. A simple "Yes" or "No" response was expected. Yes responses were assigned a value of 1, while No responses were assigned 0 values. The results from the PCA presented in Table 2 show the factor scores (weights of each of the asset). Asset with positive factor scores are associated with higher social economic status, and asset with negative factor score are associated with lower social economic status. However, in some studies, ownership of durable assets such as a bicycle have been attributed a negative weight from PCA (Gwatkin *et al*., 2000; McKenzie 2003). This implies, all things being equal, that a household with a bicycle will be ranked lower in terms of social economic status than a household that does not own a bicycle. The reason for such a result may be due to ownership of a bicycle being more strongly correlated with variables that are expected to be associated with lower social economic status, for instance, lower quality housing and sanitation conditions. In estimating the value of an asset, the researchers estimate the value of not owning the asset as well as the value of owning it. Table 2 present values of owning an asset and values of not owing the asset. The difference between the components values of owing an asset and not owing the asset is the net value of the asset. The table further shows the individual item scores for each asset as well as the net asset scores for both beneficiary and non-beneficiary farmers. Table 3 shows the net asset score for non-beneficiary farmers is a negative value of - 0.022 indicating that most of the non-beneficiary farmers belong to the lowest quintile of the wealth distribution while that of ABP beneficiary farmers is a positive value of 0.061 indicating that majority of the beneficiary farmers belong to the highest wealth quintile and have improved their livelihood more than non-beneficiary farmers.

CONCLUSION

Result from the study revealed that the net asset score for the ABP Non beneficiaries was a negative value of - 0.022 indicating that majority of the non-beneficiary farmers were power and score low on asset score index, while those farmers that benefited from the program had a positive value of 0.061 indicating an improvement in their livelihood as a result of the program intervention.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A Field Trial of Advanced Sweetpotato Lines for Agronomic Quantitative and Marketable Qualitative Traits Preferred in Export Markets was carried out at National Root Crops Research Institute Umudike Umuahia, Abia State in the rain fed agro-ecology of southeastern Nigeria with the following objectives: to select genotypes producing heavy commercial roots weight with high harvest index, to select genotypes possessing smooth storage root skins, good storage root shape and no cracks for export markets, to select genotypes with non-oxidizing and unique storage flesh root colour of marketable attributes that appeals to the eye. The experiment was laid out in a randomized complete block design with three replications, each plot measured 3 x 3 m. Sixteen sweetpotato clones were used for the trial. Data collection were on: total number of storage roots per plot, number of large roots per plot, total weight of storage roots in t/ha, weight of large roots in t/ha, and weight of foliage in t/ha. Marketable storage root attribute include: Storage root shape, Storage root flesh browning (oxidation), Storage flesh colour uniqueness, storage root surface defects such as cracks: The yield data were analyzed using Analysis of variance. Results indicated that the genotypes selected were based on the agronomic attributes such as high commercial fresh root weight, Marketable attributes include: non-oxidizing unique flesh colour, smooth surface skin without cracks and good shape index. Genotypes that merited these export standard with high harvest index (HI) were selected for further evaluation.

Keywords: *Sweetpotato, commercial roots, Export markets, attributes and harvest index.*

INTRODUCTION
Sweetpotato is an important food, feed and vegetable crop in many countries. The storage roots of sweetpotato are rich in carbohydrate and its leaves are rich in proteins. Orange fleshed sweetpotato varieties are rich in Beta-carotene, a precursor of vitamin A, while purple-fleshed sweetpotato varieties contain anthocyanin, which is a powerful anti-oxidant (Lebot, 2009). Globally, sweetpotato productivity in 2020 was only 89,487,835 tons on an area of 7,400,472 hectares (FAOSTAT, 2022) as compared to 543,567, 326 ton on an area of 5,334,605 hectares in 2003. In West Africa, Nigeria is the largest sweetpotato producer (3,867,871 tons) (FAOSTAT, 2022). Despite the increase, these current yields are still low by comparison with other crops like yam and cassava because of the limited yield potential of sweetpotato landraces in farmers' fields, and which are also vulnerable to an array of stresses. Yield limiting factors are lack of seed vigour and slow growth after planting, low harvest index, low or no response to inputs like fertilizer and exposure to various biotic and abiotic stresses. Major abiotic limiting factors to sweetpotato storage root and vine production are low moisture availability and non-adaptability to various types of soils though localized do cause substantial yield loss as a result export opportunities for the crop becomes limited. The average yield of sweetpotato in Nigeria is 6t/ha and is 83% lower than the world average of 35t/ha (FAO, 2007). The reason for low yield are occurrence of various biotic and edaphic factors at different growth stages. Being a tropical crop, sweetpotato is grown during and post rainy season. As a result, soil water deficit during sweetpotato establishment and mainly during root bulking emerges as the major yield constraints along with the rising temperature. Deficiencies in soil nutrients are also observed locally as other militating factors. For example, organic matter deficiency has been identified as a limiting factor in some part of the country.

Additional constraints to sweetpotato storage root and vine production include agronomic problems such as inability of some developed varieties to compete with weeds. Adequate variability for many of the crops genetic constraints exists within the sweetpotato gene pool and all these constraints affect sweetpotato marketability in both quantitative and qualitative traits and all these hindered the crop potential as article of international trade. There is a need of high harvest index (HI), and breeders consider a HI of 45 to 55% closer to optimal (Grüneberg *et al*., 2015). Storage Root Yield and HI had the same correlation profiles with their trait stability (Andrade *et al*., 2016), suggests the possibility on indirect selection for storage root yield and its stability through selecting simultaneously for a high harvest index. Therefore the objectives of this trial were: to select genotypes producing heavy commercial roots weight with high harvest index, to select genotypes possessing smooth storage root skins, good storage root shape and no cracks for export markets, to select genotypes with non-oxidizing and unique storage flesh root colour of marketable attributes that appeals to the eye.

MATERIALS AND METHODS

The trial that was conducted at the Western experimental field of NRCRI, Umudike was for assessing the advanced sweetpotato breeding lines for agronomic quantitative and marketable qualitative traits of storage roots for export potential. The trial comprised of 16 clones (14 genotypes and 2 checks). The site for the experiment was cleared, ploughed, harrowed and ridges constructed and spaced 1m apart. The experiment was laid out in a randomized complete block design with three replications. There were 16 plots replicated 3 times which gave a total of 48 plots, each plot measured 3 x 3 m which was a plot size of 9m^2 that comprised of 3 ridges with length of 3m long. Sixteen sweetpotato clones were used for the trial. The sweetpotato vines were cut 25 cm long, with at least 4 nodes. The seeds were inserted two nodes on the crest of the ridges in a slanting position and placed 1m between ridges and 0.3m apart along the row on the ridge. Weeding was manually done three times, using the West African hoe and subsequent hand pulling of tall weeds until harvested. Cross bars were constructed to control erosion and conserve soil moisture.

Data collection and analysis: At harvest, agronomic plant attributes collected were: total number of storage roots per plot, number of large roots per plot, total weight of storage roots in t/ha, weight of large roots in t/ha, and weight of foliage in t/ha.

Marketable storage root attribute include:

Storage root shape: This was visually observed. Score 1= long or round elliptic and 2 = long irregular or curved (Huamán and Zhang, 1997).

Storage root flesh browning (oxidation). This was tested by cutting the freshly harvested storage root and cut in cross section, expose the surface to the atmospheric air for 5 to 10 seconds and observe the cut surface for browning (oxidation), Score using 1 to 5. (Rate as 1= no browning, 2 = little browning, 4 = more browning, 5= abundant browning) (Huamán and Zhang, 1997).

The Storage flesh colour uniqueness: The freshly harvested storage root was washed and dried, the storage root was cut at the middle in longitudinal section. The flesh colour was compared for uniqueness/secondary flesh colour that appeals to the eye. Score 1 = appeals to the eye. 2 = no appeal to the eye (Huamán and Zhang, 1997).

The storage root surface defects such as cracks: The surface storage root was observed for cracks and rated using the scale 1 to 9. Where 1 = very low, 2 = low, 3 = intermediate, 4 = high, and 5 = very high (Huamán and Zhang, 1997).

Data Analysis: The data collected on agronomic yield were analyzed using Analysis of variance (ANOVA) and means between test genotypes were compared using standard error of difference. Procedures for performing these comparisons in ANOVA.

RESULTS AND DISCUSSION

Yield performance: The stand count at harvest, total number of storage roots, number of storage roots, total weight of fresh roots, weight of fresh roots, weight of above ground biomass and the harvest index are presented in Table 1.

Table 1: Stand count at harvest, number and weight of storage roots, dry matter content and harvest index of the advanced sweetpotato genotypes evaluated

ANOVA	240.2**	334.7**	5032.1**	45.7**	132.5*	=

The ANOVA results indicated significant ($p<0.01$) variation observed among the investigated genotypes in storage root yield attributes in terms of mean total number of storage roots and mean number of commercial roots. Also significant ($p<0.01$) mean total storage root weight and mean weight of commercial roots was observed. However, the harvest index (HI) for estimating the genotypes yield performance per unit areas was not significant ($p>0.05$) for the genotypes. The results are presented in Table 1.

Number of storage root per plot: Mean total number of storage roots indicated the number of large storage/commercial root yield and number of small root performance of the genotypes evaluated during the trial. The mean minimum number of total storage roots was 0.0t/ha (NRSP.UYT/420) while the maximum mean number of total roots was 56.0 per plot of 9m^2 (NRSP/UYT/580). Mean total number of storage roots showed the yield potential of a genotypes which comprised both the large/commercial roots and small /non-commercial roots of a genotype. The mean minimum number of large/commercial roots produced by the genotypes was 0.0t/ha (NRSP/UYT/420), while the maximum number of commercial roots was 36.0 (87/OP/195 and PGA14398-4) per plot of 9m^2 respectively. This was followed by NRSP/UYT/490 (Smiles) with 32.0 number of storage roots per plot of 9m^2. High number of commercial roots are for marketability. However, genotypes are bred to ensure that they have quantitative traits that are acceptable to domestic and international markets. These genotypes produced high number storage roots per plot of 9m^2 more than the two check varieties (UMUSPO/3 with 14.0 and TIS87/0087 with 26.0 per plot of 9m$^{2)}$. High number of storage roots is a good agronomic trait that should be given consideration for sustaining fresh of storage roots for export markets.

Weight of fresh roots: The mean minimum total fresh root weight produced by the genotypes under investigation was 0.0t/ha (NRSP/UYT/420) while the maximum mean total fresh root weight was 19.5t/ha (NRSP/UYT/580) followed by 16.6t/ha (NRSP/UYT/490 (Smiles) with range of 19.5t/ha. The total storage root weight included the weight of small roots which were not for export. The genotypes that gave minimum weight of commercial fresh roots for domestic and international trade was NRSP/UYT/420 that gave 0.0t/ha while the genotypes that yielded the mean maximum weight of commercial root was NRSP/UYT/580 with 15.0t/ha followed by NRSP/UYT/490 (Smiles) with 14.2t/ha. These genotypes produced heavy fresh root weight higher than the two check varieties UMUSPO/3 and TIS87/0087 that yielded 6.1t/ha and 5.2t/ha respectively. In this study, consideration was given to genotypes that had high storage root weight since in domestic and export trade, sales of storage roots are measured in kilogram. Genotypes with agronomic traits such as heavy weight of commercial roots were given consideration to be acceptable to international markets. According to FAO (2007), these genotypes also yielded more than the average yield of sweetpotato in Nigeria which is 6t/ha. Genotypes yielding heavy weight of storage roots also have high Harvest index. This indicated that their yield per unit area is very high and should be selected for cultivation for sustaining domestic and export market for fresh root yield (Table 1). The genotype NRSP/UYT/420 produced no storage root. However, the genotype could be maintained and cultivated for livestock fodder. Animals such as cattle and pigs cherish the consumption of sweetpotato leaves. Potential storage roots is different from commercial storage roots which are potential for marketing.

Marketable qualitative storage root traits of the genotypes: Many of the traits needed for domestic markets are the same as those needed for export markets. The Marketable qualitative traits of the sweetpotato genotypes evaluated for export potential are presented in Table 2.

Table 2: Marketable qualitative traits of the sweetpotato genotypes evaluated for export potential

Genotypes	Flesh root browning (oxidation< 5mins)	Storage root shape	Skin colour	Storage root flesh colour	Storage root surface defect/cracks	Flesh colour eye appeal

TIS87/0087	1	1	LP	C	1.0	1.0
Mean	1	1	=	=	1.0	1.0

Note: SKIN COLOUR: O = Orange, LP= Light pink, P = Pink, C = Cream; FLESH COLOUR: Orange, DO = Deep orange, W = white, C = Cream, Y = Yellow, LY = Light yellow, M = Milky. **Oxidation:** 1= no browning, 2 = little browning, 4 = more browning, 5= abundant browning). **Storage root shape**: Score 1= long or round elliptic, 2 = long irregular or curved. **Flesh colour appeals to eye**: Score 1 = appeals to the eye. 2 = no appeal to the eye.

Some qualitative traits evaluated included the following

Storage root shape: All the genotypes have storage root shape score of 1.0 which means that all the storage roots produced by the sweetpotato genotypes were elliptic and oval elliptic. Therefore no long irregular shaped storage roots.

Storage root flesh colour: The flesh colour of the sweetpotato genotypes ranged from cream, white, and yellow to deep orange. The uniqueness of the fleshed colour of the storage roots of the sweetpotato genotypes indicated the varied utilization the storage roots could be put into in the export markets. The white/cream fleshed storage roots could be used for processing flour for other confectioneries. The yellow and orange fleshed storage roots could be used in both domestic and export market for processing baby food as well as using all the colours for food and feed or humans and animal population and to improve health. Breeding for different flesh colours has become increasing important market traits as marketers and consumers have more choice and become more sophisticated in their preferences (Issa et al, 2022). Quality traits such as protein and amino acids concentration are lesser concern and not physical attributes. The average score of 1.0 for the eye appeal of the storage root flesh indicated that the flesh colour of the storage roots were all pleasant to the eye and could command high market value.

Non-browning/oxidation of storage root flesh colour: The oxidation rate of the score of 1.0 showed that the sweetpotato storage root flesh colour did not brown after cutting. This was a good marketable attributes. The non-oxidizing white, yellow or orange fleshed sweetpotato appealed to the eye. All the sweetpotato genotypes evaluated were non- oxidizing storage root fleshed.

Storage root surface defects/cracks: All the sweetpotato roots harvested has score rating of 1.0 which indicated absence of cracks and constriction. Surface root defects such as cracks and constrictions lower the marketability attributes of the sweetpotato fresh root in the international market (Huamán and Zhang, 1997). The genotypes evaluated yielded storage roots that were crack and constriction free and other surface root skin defects such as alligator skin. Surface skin restrictions hamper sweetpotato root skin peelings during processing of the storage roots for food. Physiological cracks on the sweetpotato roots reduced the shelf life of the sweetpotato fresh root by predisposing the fresh storage roots to rot.

CONCLUSION

Genotypes were selected based on their agronomic marketable attributes such as high commercial fresh root weight and other marketable attributes such as non-oxidizing, unique flesh colour, smooth surface skin without cracks and good shape index. Genotypes that merited these export standard had high harvest index (HI) and were; White/Cream fleshed genotypes: Cemsa 74-228 10.0t/ha with HI of 0.5, Buttermilk 10.2t/ha with HI of 0.7, PGA14008-9 10t/ha with HI of 0.7, NRSP/UYT/601 12.2t/ha with HI of 0.8, Orange Fleshed Genotypes: NAN 11.3t/ha with HI of 0.7, PGA16021-39 = 7.5t/ha with HI of 0.6, NRSP/2019/490 (Smiles) = 14.2t/ha with HI of 0.8, and PGA14442-1 = 8.4t/ha with HI of 0.6, These genotypes yielded more than the two reference varieties UMUSPO/3 6.1t/ha and TIS87/0087 5.2t/ha. NRSP/2019/580 =15t/ha with HI of 0.8 and 87/OP/195 = 10.8 with HI of 0.7. However, the performance of a genotype is influenced by its genotype and the environment in which it is grown. It is therefore recommend to test these genotypes across the country for possible release for export trade.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The paper examined the determinants of extent of market participation on food security among rural households in Zamfara state, Nigeria. ***.*** *Multi-stage sampling procedure was employed to select a sample size of one hundred and sixty (160) respondents for the study. Primary data were sourced from structured questionnaire designed in line with the study objectives. Both descriptive and inferential statistics were used for data analysis. The results of the study showed that 37.5% of the respondents were within the age range of 40-49 years of age with a mean age of 43years. Male formed the majority of market participants in the study area with 71.9% respondents while female constituted 28.1%. The coefficient of household size was positive and significant at 10% level of significance indicating that as the number of household members' increases, the quantity of produce sold in the market also increases. Farm income was significant at 5% significant level indicating that as income of household increase, market access also increases. Primary occupation and market participation were both negative and significant at 1%. The marginal effect shows that farmers who are fully into farming and participated in the markets had fewer chances of being food secured than their counterparts. It is concluded that market access will not only lower transportation costs but will also increase the accessibility of low-cost food items at the neighbourhood level. It is recommended that government and non-governmental organizations should form policies which will improve rural farm household income. Also, farmers should be encouraged to develop entrepreneurship skills in order to increase farm household off-farm income.*

Keywords: *Determinant, Market Participation, Food Security, Rural Households*

INTRODUCTION

Nigeria is the most populous country in Africa, with majority of the households being food insecure, especially the rural farming households. Several evidences have suggested that majority of the world's food insecure live and work in the rural areas (IFAD, 2019). This indicates that reducing rural food insecurity is very important to reducing overall food insecurity. Given the role of agriculture in the Nigerian economy, food insecurity and poverty could be attributed to the poor performance of the agricultural sector, which in turn, creates food availability and accessibility problems at the household and national levels (Agboola, 2014). In other words, the poor performance of the sector directly creates supply shortages and indirectly creates demand shortages by denying the rural farming households access to sufficient income. The Nigerian economy, in terms of revenue and foreign exchange, is undoubtedly dominated by the oil sector but agriculture holds the key to sustainable development of the country with respect to provision of employment opportunities, the provision of raw materials for agro-industries, as a source of income for rural families, and perhaps most importantly, provision of food for the population. The right to an adequate standard of living including food security is recognized in the universal declaration of human right. It is a widely accepted fact that food is a basic necessity of life. As such, adequate intake of quality food is a key requirement for a healthy and productive life (IFPRI, 2018). Food security is defined as a situation that exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life (IFAD, 2019). Food security entails ensuring sustainable access, availability and affordability of adequate quantity and quality food to all citizens to meet up with their physiological requirements (Babatunde *et al.*, 2021). The main goal of food security is for individuals to be able to obtain adequate food needed at all times, and to be able to utilize the food to meet the body's needs. Food security is multifaceted. Arene and Anyaeji (2020) identified three pillars underpinning food security; these are food availability, food accessibility, and food utilization. This infers from the concept that food security is not just a production issue.

Food security refers to a situation whereby individuals have access at all times to quality and sufficient food resources to maintain a healthy and active life. On the other hand, food insecurity exists when there is constrained physical and economic access to secure sufficient quantities of nutritionally adequate food to allow individuals sustain an active and healthy living (Agboola, 2014). Food insecurity comes with unpleasant conditions with consequences detrimental to human health, well-being and productivity (Babatunde *et al*., 2021). It is against this backdrop that this study aims at examining the determinants of the extent of market participation among farmers in Zamfara state, Nigeria. The specific objectives are to; i. describe the socio-economic characteristics of the farmers, ii. Examine the determinants of extent of market participation of the farmers.

METHODOLOGY

The Study Area

This study was conducted in Zamfara State, North-western Nigeria. The capital of Zamfara State is Gusau. The State comprises of fourteen (14) Local Government Areas, with an area landmass of 38,418 sq. km. The state stretches between Latitude 10 21/ to 13 15/N and Longitude 60 20/E. Zamfara Sate is bordered in the North by Niger Republic, in the South by Kaduna State, in the East by Katsina State and in the West by Sokoto, Kebbi and Niger States respectively, the state lies in the Sudan Savannah Agro Ecological Zone of Nigeria and has a population of 4,515,400 according to (NPC, 2017) projection of 2.47%.

Sampling procedure and Sample Size

Multi-stage sampling technique was employed to select a sample size of one hundred and sixty (160) respondents for the study. The respondents were selected in stages. In stage one, a random selection of two Local Government Areas (LGAs) in the zone were made. In stage two, two (2) villages were randomly selected from each of the two LGAs. In stage three, 2 households from each of the selected villages were chosen at random thereby giving a total number of Eight (8) households to be used as sample size for the study. In stage four (4) 20 respondents were drawn from each of the selected villages thereby giving a sample size of (160) respondents used as the sample size for the study.

Method of data collection and Analysis

Both primary and secondary data were used for the study. Primary data were sourced from structured questionnaire designed in line with the study objectives. The questionnaire were administered to one hundred and sixty (160) respondents. Descriptive statistics such as mean, frequency and percentage was used to analyse objective i. While objective ii was achieved using Tobit regression model which is called censor regression model.

Tobit model

A Tobit model is any of a class of regression models in which the observed range of the dependent variable is censored in some way.

Tobit regression

$Y_i = X_i\beta$, if $i^* = X_i\beta + U_i > T$

$= 0$; if $i^* = X_i\beta + U_i \leq T$

$i = 1, 2$……….

Where, Y_i = the dependent variable measuring the extent of market access

Yi{ 1 if $i^* > T$, if the farmer have access to the market { 0 if $i^* \leq T$, if the farmer does not have access to the market

X_i= a vector of explanatory variables, which consists of the socio-economic characteristics of the respondents in this study.

β = vector of parameters to be determined

U_i = an independently, normally distributed error term with zero means and constant variance, The explanatory variables (X_i) specified as socio-economic determinants of the extent of market access and used in the analysis are shown below:

X_1 = Age of the respondent in years, X_2 = Gender of the respondent (Dummy =1, if male; 0 if female), X_3 = Household size of respondent (number), X_4 = Educational level of the respondent (Dummy =1, if illiterate, 0 if otherwise), X_5 = Primary occupation of the respondent, X_6 = farm income of the respondent, X_7 = Remittance, X_8 = Market participation.

Table 1: Socio-economic characteristics of the respondents (n = 160)

The result in Table 1 showed that majority of the respondents were male accounting to (71.88%) while female was (28.13%). This suggests that there were more male household heads in the study area. Farming is a labour intensive enterprise, hence male dominance is paramount. The result further agrees with the findings of (Ishaku, 2017) who reported that farming is male dominant while female are more involved in processing of agricultural products. The implication of male dominance in market participation is to ensure that their households are food secured because they are vested with the responsibility of meeting their household nutritional needs. The result of the study shows that 13.75% of the respondents fell within the age range of 20 - 29, 6.25% were above 59 years of age. Most of the respondents were less than 59 years old. The result of the study shows that 77.50% of the respondents were married, 15% were single, 5.63% of the respondents were widows and 1.88% of the respondents were divorced. Opeyemi *et al.*, (2020) opined that the significance of marital status on agricultural production can be explained in terms of the supply of agricultural family labour. It is therefore expected that family labour would be more available where the household heads are married. The results in table 1 further revealed that higher percentage of the farmers in the study area have a household size ranging 1 - 5, and 49.38% have a household size of above 5. The mean household size in the study area is approximately 6 persons. As indicated in the table 1, only (3.75%) of the respondents did not have any form of education, 52.50% had secondary education and 31.25% had tertiary education. Further results indicated that 56.25% of the respondents generated an income of ₦100, 000 - 200,000 annually, and more than ₦ 500,000 annual farm income were generated by 7.5% of the farmers in the study area. The regression result shows that as the household size, primary occupation, education and income of the household improves, the probability of household's participation in marketing increases.

CONCLUSION AND RECOMMENDATIONS

The study determined extent of market participation on food security among rural households in Zamfara state, Nigeria. A multistage sampling technique was used to select 160 respondents. The households were interviewed with the use of questionnaire which were administered in line with the objectives of the study. The households were selected from two Local Government and two communities from each of the Local Governments. The Tobit Model results also reveal that an increase in household's size and household's income increases their likelihood. Based on the findings of this study, it is recommended that interventions should be provided and should focus on improving smallholder farmers' market participation, such as selling their produce collectively so that they will be able to supply large retail stores. Government and non-governmental organizations should form policies which will improve rural farm household income. Also, marketers should be encouraged to develop entrepreneurship skills in order to increase farm household off-farm income.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study analyzed costs and returns of plantain production in Tai Local Government Area of Rivers State, Nigeria. Objectively, the study described the socio-economic characteristics of plantain producers, estimated the costs and returns of plantain production, and identified the constraints associated with plantain production in the study area. Using survey research design, copies of structured questionnaire were administered to 90 farmers by simple random sampling technique and the emanating data were analyzed with the use of descriptive statistics, mean score, and gross margin. On socioeconomic characteristics, the result showed that 55.6% of the plantain farmers were male against 44.4% whom were female. Also 54% of them were between the ages of 31-35 years and 17.8% were between the ages of 44-56 years. On education status, 40% of the farmers had secondary education, 34% of them had primary education, and 25.6% of the farmers had tertiary education. Gross margin analysis showed that, the annual variable cost of plantain production was ₦2,133,056 which accounted for a gross margin of ₦309,167.00. In addition, the estimated average annual profit of the plantain farmers stood at ₦2,075,577, an indication of the profitability of plantain production. Result on the constraints associated with plantain production showed that lack of storage facility and theft were the major constraints identified having a respective mean score of 3.61 and 3.17. The study recommended that Government and civil society should work to enhance security in rural areas to curb the incidence of theft of agricultural produce.
Keywords: *Plantain production, Plantain farmers, Costs and returns*

INTRODUCTION
Nigeria is one of the largest plantain producing countries in the world and despite its prominence, Nigeria does not feature among plantain exporting nations because it produces more for local consumption than for export (FAO, 2011). Plantain is a versatile food in the kitchen as well as a raw material for many popular delicacies and snacks. This reason and the growing population of Nigeria gave way to the enormous increase in demand for the crop in the consumers market (Aina *et al.*, 2012). Among plantain products are plantain flower, chips, beer and ethanol. The ripe ones are sliced and fried in oil as "dodo". Over-ripe ones are both compacted and fried in oil as "dodo Ikire" or mixed with plantain flour to make "ekuru", a delicious local dish (Aina *et al*., 2012).
The growing of plantain is left in the hands of subsistence farmers who account for about 80% of Nigeria`s agricultural output. The crop is grown in the backyard or home stead and recently in plantations for the commercial market (Aina et al., 2012). Perhaps, this drawback explains why the demand for plantain surpasses the supply such that, plantain is becoming more and more expensive in Rivers State (Alagoa, 1999). To harness the economic potentials of plantain, the current level of its production must be improved. This implies that the limited resources available to plantain have to be used efficiently. The poor plantain output problem in Nigeria therefore centers on the efficiency with which farmers use resources on their plantain farms. It also borders on how the various factors that affect plantain production can be examined so as to increase plantain production in the Nigeria.

Objective of the Study
The specific objectives of this study were to:
i. describe the socio-economic characteristics of plantain producers in the study areas;
ii. estimate the costs and returns of plantain production in the study area; and

iii. identify the constraints associated with plantain production in the study area.

MATERIALS AND METHODS

The study was conducted in Tai Local Government Area (LGA), Rivers State Nigeria. Tai has an area of 159km2 and a population of 117,797 and a projected population of 173,000 in 2022 (NPC, 2022). The LGA lies between latitudes 4° 43' and 7° 18'N of the equator and longitudes 4.72°and 7.30°E of the Greenwich Meridian. The LGA is within the tropical climate and experiences two distinct seasons, the rainy season and the dry season. Tai LGA has two broad sections: the Tua Tua Kingdom and the Barasi Nonwa Kingdom, both under the overall Tai Kingdom. The primary occupations are farming, and fishing to a lesser degree.

Survey research design was employed by the study and copies of structured questionnaire were used in obtaining the data. In respect to the study population, the Rivers State Ministry of Agriculture (2018) gave an estimate of 105 registered plantain farmers in the LGA. Therefore, 105 plantain farmers served as the population of this study. Thus with a level of significance of 5%, the Taro Yamane (1967) formula yielded a sample size of 83 plantain farmers and for the purpose of equal allocation among the communities selected in the study area, the study increased the sample size to 90 plantain farmers.

Multi-stage sampling procedure was used in selecting the sample size of the study. The first stage involved the purposive selection of ten (10) communities out of the seventeen (17) communities in Tai LGA was employed. This was owing to the fact that there were more plantain farmers' concentration in the selected communities. The second stage involved the simple random selection of nine (9) farmers in Botem, Kpite, Korokor, ueken, Bunu Nonwa, Sime, Kira, Borobara and Gbene-ue, thus making a total of 90 respondents.

Objective (i) was achieved using frequency count and percentages. Objective (ii) was achieved using gross margin analysis objective. Objective (iii) was analyzed using mean score.

Gross Margin

Gross margin mode was used to determine the costs and returns from gross margin obtained; further analysis was conducted to obtain profit associated with the trade in the study area. The model is specified as:

$GM = TR\text{-}TVC$ equ.1

Where: GM = Gross margin; TR = Total revenue; TVC = Total variable cost; TFC = Total fixed cost; and π (profit) = GM-TFC

Likert Scale Rating Technique

The 4-point Likert scale rating technique was used particularly in identifying problems associated with plantain production. This was done on a four-point basis. According to Umoinyang (2014) the 4-point scale rating technique does not give room for the respondents to be indifferent. The rating is presented in the following order:

Strongly agreed (SA) = 4; Agreed (A) = 3; Disagree (D) = 2; and Strongly disagree (SD) = 1.

The mean scores of the respondents based on the 4-point scale was 4 + 3 + 2 + 1 = 10, 10/4 = 2.5.

Benchmark: The benchmark using the four-point Likert Scale to analyze the constraints militating against plantain production was 2.5. The 2.5 benchmark indicates that mean values from 2.5 and above shows that the parameter is a constraint.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Respondents

The socio-economic characteristics of plantain producers in the study area are presented Table 1. Table 1 shows that 55.6% of the respondents were males, while 44.4% of them were females. This may imply that because, plantain bunch is bulky and the sucker grows to it may require more of masculine energy to cultivate. Furthermore, 54.4% of the farmers were within the age of 31-43 years, 17.8% were within the age of 44-56 years, 16.7% were of ages 18-30 years and 11.1% were greater than 50 years. This indicates majority of the respondents were young and in their active ages. According to Ibekwe *et al.,* (2010) young individuals have the ability to withstand stress and risk. On marital status, 73.3% of the farmers were single, 17.8% of them were married, and 8.9% were separated. This implies that majority of the respondents were single. Since majority were single, it would mean that they would invest more time and resources in their plantain farms since there would be little or no distraction from family obligations and commitments. The result on household size shows that 54.4% of the respondents had household size of 2-4 persons and was followed by 25.6% of the farmers who had household size of 5-7persons. Entries on farming experience shows that 38.9% of the respondents had greater than 9 years of experience in plantain production while 26.7% of them had 1-3years experience. Years of experience in agricultural production is handy in lowering risk suffered by farmers. It can be applied in areas of farm financing, product storage and marketing and can also be of use in sourcing for farm inputs which may eventually translate into increase in farm profit or reduction in farm cost. Result on educational attainment shows that 40% of the farmers received secondary school education, 34.4% of them received primary school education, and 25.6% of them had tertiary educational attainment. This indicates that majority of the respondents had secondary school educational attainment. This also implies that all the respondents were educated as they had one form of formal education or the other. Higher educational level or literacy level can lead to better adoption of farm technology in agriculture. This result is in agreement with the observation of Kainga and Seiyabo (2012) which stated that majority of their respondents were educated. Table 1 further shows the majority (45.6%) of the plantain farmers earned ₦41,000 - ₦80,000 monthly. The Table also shows that majority (55.6%) of the farmers had farm size of 1-3 plots.

Costs and Returns of Plantain Production

Table 2 presents the costs and returns analysis of plantain production. Result shows that the total variable cost of production per annum was ₦2,133,056 and the total revenue was given as ₦2,442,222. The average annual gross margin for plantain production stood at ₦309,167.00 followed by an annual profit of ₦2,075,577. The rate of return on investment of ₦6.67 was obtained by (TR/TC), implying that for every ₦1 invested ₦6.67. Overall, this result shows that plantain production is profitable and is supported by the findings of Agbagwa *et al.* (2021).

Table 2: Average Annual Costs and Returns on Plantain Farming

Items	Amount (₦)
Total Revenue (TR)	**2,442,222**
Cost of plantain seedling	266,386.7
Fertilizer	16097.56
Herbicide	24280
Labour	28,702
Total Variable Cost (TVC)	309,167
Gross Margin (GM)	**2,133,056**
Depreciation	3,392
Rent on Land	54086.67
Total Fixed Cost (TFC)	57,478
Total Cost (TC)	**366,645**
Profit (TR – TC)	**2,075,577**
Net return on Investment (TR/TC)	6.67

Source: Field Survey, 2022

Constraints Associated with Plantain Production

The problems associated with plantain production as identified by the respondents are presented in Table 3. The result shows that the most dominant constraint was the lack of storage facility with mean score of 3.61. The economic implication of this finding is that, since plantain is a perishable commodity, its producers will likely suffer loss when it is not quickly disposed in the market place. Incidence of theft had mean score of 3.17. Theft of plantain will adversely affect the profit of the farmer and could weaken his/her ability to continue production. Conversely, the plantain farmers, did not identify high cost of land and poor demand of plantain as constraints because their respective mean scores of 1.58 and 2.12 fell below the benchmark of 2.50. Availability of demand for agricultural products can serve as an incentive in fostering agricultural production.

Table 3: Constraints to Plantain Farming

Constrains	**SA (4)**	**A (3)**	**SD (2)**	**D (1)**	**Total Score**	**Freq.**	**Mean ($\bar{X}$)**
Fragmented land	8	53	30	0	251	90	2.79
High cost of land	0	7	38	45	142	90	1.58
Theft	30	45	15	0	285	90	3.17
Poor demand	9	16	42	23	191	90	2.12
Lack of storage facility	55	35	0	0	325	90	3.61
Poor roads	13	37	6	34	209	90	2.32

$\bar{X}$ >= 2.50 = important; $\bar{X}$ < 2.50 = un important

Where: SA = Strongly Agree A = Agree, D = Disagree, SD =Strongly Disagree

Source: Field Survey, 2022

CONCLUSION

From the findings gathered, the study concludes that plantain production in Tai Local Government Area is profitable. The study affirms that lack of storage facility and theft were the major constraints facing plantain production in Tai.

RECOMMENDATIONS

On the basis of the findings reached, the study recommends that:

i. Government and civil society should work to enhance security in rural areas to curb the incidence of theft of agricultural produce.
ii. Owing to the profitability of plantain production, government should train unemployed youths on skills necessary to cultivate and manage plantain farms.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study examined the effect of naira-dollar volatility rate on export of ginger and oil Palm in Nigeria from 1988 to 2021.The study adopted quasi-experimental research design and relied on time series data. Pre-estimation diagnostics tests such as unit-root and cointegration test were adopted to check for stationarity of the data and their residuals as well as long run relationship to prevent spurious regression results. The method employed for analyzing the time series data were the fully modified OLS and the Auto Regressive Distributed Lag (ARDL) models regression method. The result showed that a-unit increase in exchange rate brought about 149.2-unit increase in ginger export. Increase in exchange rate brought about a -210.6560-unit reduction in oil palm export value. It was concluded that the naira-dollar exchange rate does not encourage gainful agricultural trading to the Nigerian economy. The study recommended that agricultural production should be increased in the country to meet domestic needs and export so that devalued naira will be beneficial in terms of volume of agricultural commodities exported.
Keywords: *Exchange Rate, Naira, Dollar, Volatility, Export*

INTRODUCTION
The economies of all countries of the world are linked directly or indirectly through asset and goods in the markets. This linkage is made possible through trade and foreign exchange. The importance of international trade in the development process has been of keen interest to development economists. With the implementation of the World Trade Organization (WTO) rules and substantial reduction in trade restrictions, most of the developing countries imports are increasing rapidly. Nigeria's economy is not an exception as it depends on the pattern of world's economy (Abolarin *et al.*, 2022). Export is considered as a major factor that determines balance of payment position of a country. When the value of export of a country exceeds the value of its import, it will improve balance of payment position (Godfrey and Cosmas, 2014). Lack of important resources in some part of the world is one of the reasons that encouraged countries today to engage in international trade transaction (Ramesh and Majed, 2021). In the case of Nigeria, her major exports components come from the agricultural products such as cocoa, palm produce, rubber as well as solid minerals resources such as lead-zinc ores, Limestone, gold among others (Oloyede and Essi, 2017). However, Ramesh and Majed (2021) has pointed out that the impact of exchange rate on export depends on the level of financial development. Mehdi *et al*. (2014) also stated that exchange rate fluctuation lead to an increase in export and economic growth when the financial markets are developed enough. However, when financial markets are undeveloped, exchange rate fluctuations will reduce export and subsequently hinder the growth of the economy.

METHODOLOGY
Study Area
The study on effect of Naira- dollar volatility rate on Ginger and Oil Palm Export (1988-2021) was conducted in Nigeria. It is a tropical land located in West Africa. It extends from about 4° to 14° north latitude, with a north–south span of about 700 miles (1,125 kilometers). In an east–west direction, the country extends from roughly 3° to 13° east longitude, also a distance of about 700 miles. The country's total area of some 357,000 square miles (925,000 square kilometers) is therefore, quite compact in shape. The country's hot and soggy southern border faces upon the equatorial Gulf of Guinea (on the Atlantic Ocean). In the north, Nigeria extends into the Sahel region, nearly reaching the parched Sahara Desert (Zhang *et al*., 2004).

Data Collection
Secondary data was used for this study. Specifically, data on Ginger and oil palm export and exchange rate (Naira to Dollar). All data were gotten mainly from the publications of FAO (2022) on statistics.

Data Analysis

The estimation method adopted for the models were the Auto Regressive Distributed Lag Model (ARDL) and the Fully Modified Ordinary Least Square (FMOLS). In other words, the ARDL method will determine the long and short run impact of exchange rate on agricultural exports in Nigeria.

Model Specification

Model One

GINGEXP = f(EXCHR) (1)

Where; GINGEXP = Ginger Export

EXCHR = Exchange Rate

The single equation Cointegration model of the FMOLS variety of equation (1) is formalized as follows:

$$GINGEXP = \ltimes_0 + \ltimes_1 EXCHR_t + \sum_{p=-y}^{n} \emptyset_1 \Delta GINGEXP_{t-y} + \sum_{p=-y}^{n} \emptyset_2 \Delta EXCHR_{t-y} + \Sigma_t \quad (2)$$

Where: GINGEXP and EXCHR are as previously defined.

$\ltimes_0 = Constant\ Term$

$\ltimes_1 = Long\ run\ Multipliers$

$n\ and\ y = Optimal\ lag\ lenght\ and\ lead\ lengths\ respectively$

$\Delta = First\ difference\ operator$

$\Sigma_t = Statistic\ error\ term$

Model Two

$OILPEXP = f$ (EXCHR) (3)

Where:

OILPEXP = Oil Palm Export

EXCHR = Exchange Rate

Equation (3) is an implicitly expressed econometric model

The model for the regression is specified explicitly as follows

$OILPEXP = a_0 + a_1 EXCHR_t + u_t$ (4)

Where:

a_0 = Constant

a_1 = Coefficients

u_t = stochastic error terms

Specifying equation (4) in ARDL Cointegration model by incorporating the lag and lead of each of the explanatory variables into the model as part of the explanatory variables.

In the short run:

$$\Delta Y_t = \alpha + \sum_{i=1}^{p} \Delta Y_t + \sum_{i=1}^{q} \Delta\beta_1 B_{t-1} + \mu_t \quad (5)$$

Now adopting the model to the study, with indication of co-integration in the long run of the variables we have:

$$OILPEXP_t = \psi + \sum_{i=1}^{p} OILPEXP_{t-1} + \sum_{i=1}^{q} \alpha_1 EXCHR_{t-1} + \mu_t \quad (6)$$

Where: ψ = intercept

β_1 = parameter estimates of the regressors in the short run

u_t = stochastic error terms.

RESULTS AND DISCUSSION

Table 1 presents the time series data of the dependent variables Ginger and Oil Palm Export and the independent variable, Exchange rate.

Table 1 Time Series Data on the Variables Used for Study from 1988-2021

YEAR	EXCHR	GINGEXP	OILPEXP
1988	4.536966667	275	8
1989	7.364735	276	15
1990	8.038285	253	37

1991	9.909491667	628	6

Note: EXCHR: means dollar exchange rate; GINGEXP: means Ginger export; ILPEXP: means Oil palm export

Unit Root Test
The optimal order of lag for each of the variables was based on schwartz information Criterion (SIC) automatic lag selection procedure. The table showed that the variables were stationary at level I (0) and at first difference I (1).

Table 1 Unit Root Test Result

Variable	ADF Levels	Sig.	ADF 1st Diff.	Sig.	Order of Integration
EXCHR	2.212719	0.9999	-3.625471	0.0107	I(1)
GINGEXP	-0.026827	0.9941	-4.284521	0.0020	I(1)
OIPEXP	-3.811844	0.0079			I(0)

Source: Author's Compilation, using E-views 10, 2023

The Augmented Dickey Fuller (ADF) unit root test was the stationarity test type used. The order of integration shows Exchange Rate (EXCHR), Ginger Export (GINGEXP) became stationary at first difference I (1), while Oil Palm Export was stationary at level I (0). The statistical implication of this result is that the regression result will not be spurious and the data set is good for forecasting and examining future trends.

Cointegration Test for Model One

Table 2 Summary of Johansen Cointegration Test Result for Model One

Series: GINGEXP EXCHR

Lags interval (in first differences): 1 to 1

Hypothesized No. of CE(s)	Eigenvalue	Trace Statistic	0.05 Critical Value	Prob.**
None	0.230572	13.15994	15.49471	0.1091
At most 1 *	0.138552	4.772499	3.841466	0.0289
Hypothesized No. of CE(s)	Eigenvalue	Max-Eigen Statistic	0.05 Critical Value	Prob.**
None	0.230572	8.387444	14.26460	0.3407
At most 1 *	0.138552	4.772499	3.841466	0.0289

Source: Author's Compilation, using E-views 10, 2023

From the Johansen cointegration test result in table 2, for model one, the variables were Cointegrated. Both trace and maximum Eigen values showed evidence of Cointegration. Thus, the null hypothesis of no Cointegration was rejected. This implies that the variables in the model have long run relationship.

Cointegration Test for Model Two

Cointegration test for model two was conducted using Bounds Cointegration test. This was so because the variables were stationary at level and first difference.

Table 3 ARDL Bounds Test for Model Two

Test Statistic	Value	Signif.	I(0)	I(1)
F-statistic	0.522840	10%	4.04	4.78
		5%	4.94	5.73
		2.5%	5.77	6.68
		1%	6.84	7.84

Source: Author's Compilation, using E-views 10, 2023

As indicated in table 3, the computed F-statistics (0.522840) is less than the upper and lower bound critical values at 10%, 5%, 2.5% and 1% level of significance, therefore, the null hypotheses of no level relationship could not be rejected. This implies that there was no evidence of co-integration in the model. This implies that there was no long run relationship between the dependent variable (oil palm export) and independent variable (exchange rate). Hence the regression will stop at the ARDL, no need for further testing of the ECM.

Regression Estimation Result for the Models

Table 4 FMOLS Regression Result for Model One

Variable	Coefficient	Std. Error	t-Statistic	Prob.
EXCHR	149.2766	18.51159	8.063954	0.0000
C	-6517.037	3171.651	-2.054778	0.0484
R-squared	0.853437	Mean dependent var		14194.36
Adjusted R-squared	0.848709	S.D. dependent var		17601.40
S.E. of regression	6846.273	Sum squared resid		1.45E+09
Long-run variance	1.29E+08			

Source: Author's Compilation, using E-views 10, 2023

The long run relationship between exchange rate and ginger export was estimated using FMOLS. It was found from the result that exchange rate has a significant positive effect on ginger export in the long run for the period under study. This was so because the p-value of 0.0000 was less than 0.05 at the 5% level of significance.

The result shows that ginger export increased by 149.2766-units as a result of 1% increase in exchange rate. The R-squared (0.853) revealed that the explanatory variable accounted for 85.3% of the overall variations in ginger export. This is an indication that the model is well-fitted.

Table 5 ARDL Regression Result for Model Two

Variable	Coefficient	Std. Error	t-Statistic	Prob.*
OILPEXP(-1)	0.408109	0.191783	2.127974	0.0466

OILPEXP(-5)	-0.357050	0.245238	-1.455932	0.1617
OILPEXP(-6)	0.523793	0.268543	1.950502	0.0660
EXCHR	-210.6560	84.33796	-2.497761	0.0218
EXCHR(-1)	173.8154	95.14031	1.826938	0.0835
C	6259.911	3302.165	1.895699	0.0733
R-squared	0.568399	Mean dependent var		9111.214
Adjusted R-squared	0.386673	S.D. dependent var		9928.038
S.E. of regression	7775.164	Akaike info criterion		21.01035
Sum squared resid	1.15E+09	Schwarz criterion		21.43856
Log likelihood	-285.1449	Hannan-Quinn criter.		21.14126
F-statistic	3.127772	Durbin-Watson stat		2.105095
Prob(F-statistic)	0.019673			

Source: Author's Compilation, using E-views 10, 2023

The result showed that exchange rate (EXCHR) in its current period was negatively significant in influencing changes in oil palm export for the period under study, this is evidenced by the p-value of 0.0218 which is less than 0.05 at the 5% level of significance. The implication of the finding based on the sign and magnitude of the coefficient, is that a unit increase in exchange rate brought about a -210.6560-unit reduction in oil palm export for the period under study. This finding is similar to Endurance and Nsikak (2022) who examined the effect of exchange rate on agricultural exports in Nigeria reported that exchange rate has a negative effect on agricultural exports in Nigeria.

The R^2 which measures the goodness of fit was 0.56. This implies that 56% of the total variation in oil palm export (dependent variable) was explained by exchange rate (EXCHR). The overall model was significant given the F-statistics value of 3.127772 with the probability (F-stat =0.019673). This implies that the explanatory variable was significant in explaining the changes in the dependent variable. The Durbin –Watson value of 2.10 which is not far from 2.0 indicates that there was no problem of serial auto correlation in the model.

From the findings, the exchange rate does not have a stable or predictable effect on international agricultural trading, The study concluded that the naira-dollar exchange volatility rate does not encourage gainful agricultural trading in Nigerian economy. The study recommended that agricultural production should be increased in the country to meet domestic needs and export so that devalued naira will be beneficial to us in terms of volume of agricultural commodities exported

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was carried out to examine the structure of plantain market in Oshimili South Local Government Area, Delta State. Three towns of plantain marketers were randomly selected from four purposively selected towns with a total respondent of one hundred and twenty. Structured questionnaire was used to collect the data. Descriptive statistics, Cost and returns analysis, Return per capital invested were used to analyze the data. The study showed that majority (96%) of the plantain marketers were female. 51.7% are within the active age range of 41-50 years. Most respondents were married and educated having a household size of between 1-10 members. The cost and returns analysis showed that purchased cost, transportation, labour and storage cost constitute the variable cost while rent, tools and market charges form the fixed cost. Furthermore, the findings showed that plantain marketing is profitable with a gross margin of ₦3,867.90 per month from the sales of plantain bunches. Analysis of the profit revealed that plantain marketing is a profitable business. The constraint militating against marketing of plantain in the area were also identified to be high transportation cost, seasonal price fluctuation, rapid deterioration in quality/spoilage, inadequate funds, high initial cost of plantain, poor access road and high market charges. The study therefore recommends that plantain marketers should come together to form plantain marketers' cooperative groups from which members could obtain loans at very low interest rates. Problem of infrastructural facilities such as bad roads should be addressed by all tiers of government.

Keywords: *Economics, Profitability, Marketing, Plantain, Gross Margin*

INTRODUCTION

Plantain (*Musa paradisiaca)* is one of the most important staple food crops for millions of people both in developed and developing countries. It supplies up to 25% carbohydrate for approximately 70 million people in the humid region of Sub-Saharan Africa (Norgrove *et al.,* 2014). Plantain originated from South East Asia and Western Pacific region (John and Marchal, 1995). It belongs to the family of Musaceae, and they are of two types; *Musa acuminate* (genome AA) and *Musa balbisiana (*genome B13). However, a great diversity is said to exist in Central Africa, thus suggesting plantain to be among the oldest cultivated crops in the region (Olumba and Onunka, 2020). The consumption of plantain cuts across social, age, ethnic, religious and geographical barrier. Plantain is accepted and loved by Nigerians. Plantain is a versatile food in the kitchen. It is commonly eaten as fried ripe plantain (dodo), boiled as green plantain and eaten with palm oil or stew or roasted and eaten as snack or as porridge. This reason plus the growing population of Nigeria leads to an enormous increase in demand for the crop in the consumers' market. Plantain is the cheapest staple food crop in terms of production costs per hectare as compared to other food crops like maize and cassava (Source??). It produces fruits all year round, thus playing the role of 'the hunger-gap' between crop harvests. It gives high economic returns, reaches maturity and pays off its cost of establishment within a year. It is an important source of income for the resource-poor rural farmers. Plantain provides household food security and gainful employment to both rural and urban dwellers. Plantain production is environment-friend ly being useful in combating soil erosion and as inter-crop in mixed farming system (Federal Department of Agriculture (FDA, 2015).

Marketing of agricultural products begins at the farm level when the farmer plans his production to meet specific demands and market prospects. Plantain marketing involved all activities and services associated with the movement of produce from farmers' (producers) farms to the consumers. The role of marketing involves assembling of plantain bunches bit by bit by village collectors from the different places of production to the markets in the towns and cities. Like many other agricultural products, plantain is highly perishable. Most plantains are produced by small scale farmers who often do not have the financial resources for sustained production. These physical characteristics and challenges of plantain production present some challenges to its marketing.

Studies on plantain showed that the business of plantain marketing is profitable (Folayan and Bifarin, 2017). High transportation cost, rapid deterioration in quality and spoilage, and seasonal price fluctuations are major challenges to plantain business. Some characteristics of many agricultural commodities such as high perishability and seasonality of the commodities also contribute to the challenges of the plantain marketing business. The need for research on analysis of marketing of plantain became necessary in order to understand plantain marketing situation particularly in Oshimili South Local Government Area (LGA) of Delta State and to achieve good performance and efficiency in its marketing.

Objectives of the Study

The broad objective of this study is to analyze plantain marketing in Oshimili South Local Government area of Delta State. The specific objectives are to; describe the socio-economic characteristics of plantain marketers in Oshimili South LGA of Delta State; determine the market activities and functions performed by plantain marketer; analyse the efficiency of plantain marketing: determine the profitability of plantain marketing and identify constraints to efficient plantain marketing.

METHODOLOGY

The study area was Oshimili South Local Government Area in Delta North Agriculture Zone. Oshimili South LGA occupies a total area of 603 square kilometres and has an average rainfall of 1,765mm and temperature of 29°C. It lies off the shores of the River Niger with an average humidity of 84%. Oshimili South LGA is made up of four (4) towns namely: Asaba, Okwe, Oko and Anwai. Plantain marketers for this study were purposively sampled from three (3) out of the four (4) areas namely: Okwe, Oko and Asaba. These Areas have urban and semi-urban population settlements with markets where plantain marketers trade. The plantain marketers sampled were made up of wholesalers and retailers. Fourty (40) plantain marketers were sampled through random sampling techniques from each of the towns selected giving a total of 120 plantain marketer respondents used for the study. Primary data was used for the study. The data was collected through the use of structured questionnaire. The questionnaire was administered to 120 respondents and there was 100% return rate.

Data Analysis

Descriptive statistics was used to analyze the socio-economic characteristics of plantain marketers. Gross Margin was used to determine the marketing of plantain margin as shown below: Marketing Margin= Pf – Pr. Where Pf. = Producer prices, Pr = Retail price. Net profit equation was used to determine the net return of plantain marketers as shown below:

Marketing Margin = Pf -Pr

Where Pf = Producer prices (N)

Pr= Retail Price (N)

Net profit equation was used to determine the net return of plantain marketers as shown below:

Net profit (NP) =Total revenue - Total cost

i.e. = TR - TC

Shepherd-Futrel model was used to analyze the marketing efficiency of plantain in the study area. This is shown below:

Marketing Efficiency Coefficient: Total Cost/Total Revenue X 100/1

The coefficient showed the proportion of total revenue that was put into the marketing cost. The lower the coefficient the more efficient the market and this expressed in percentage.

The factors affecting the efficiency of plantain in the study area were estimated using the multiple regression model. This is as shown below;

$Me = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + U$

Where;

M_e = Marketing Margin

X_1 = Experience, X_2 = Distance, X_3 = Gender, X_4 = Age, X_5 = Education, X_6 = Household Size, X_7 = Quantity Traded, X_8 = Transportation

β_0 = Intercept term, U = error term

RESULTS AND DISCUSSION

The socio-economic Characteristics result shown in Table 1 reveals that 80% of the respondents were female. This finding agreed with the result of Okezie (2017) in which he estimated that 80% of all trades in food stuff in Nigeria is carried out by rural women. The result also reveals that respondent whose age range between 41- 50years have the highest percentage (51.7%) followed by age range of 51-60 years (22.5%). This is an indication that people whose age range is between 41-50 years are more involved in plantain marketing in the study area. This may imply that people of this age range are likely to be more energetic and willing to take risks involved in plantain marketing.

The result further reveals that 57.5% of the respondents are married with their husband/wives still alive. This implies that plantain marketing is a reliable source of income for the upkeep of the family. The result also reveals that a greater percentage (45%) have secondary education. This finding contrasts with Okezie (2017), in which he estimated that most respondents had no formal education. The implication of this could be that plantain marketing is taking care of unemployment as more educated people are getting involved in the business. The household size of the respondents shows that the highest range was between 1- 4 persons (51.7%) and the least as 7persons and above (20%). The result shows that the trend of having large family size which serves as a source of labour is fast disappearing and this is assumed to be due to adverse economic situation in the country.

Table 1: Distribution by Socio-Economic Characteristics

Variables	Frequency	Percentage (%)	Mean
Sex			
Male	24	20	

Female	96	80	Female
Age			
<40 years	12	10	51.6
41-50 years	62	51.7	
51-60 years	27	22.5	
>60 years	19	15.8	
Marital Status			
Single	31	25.8	Married
Married	69	57.5	
Divorced	5	4.2

4-6	62	51.7	
7 and above	24	20	
Business Experience			
1-10 years	83	69.2	
11-15 years	21	17.5	1-10 years
16-20 years	10	8.3	
Above 20 years	6	5	

Efficiency of Plantain marketers

The effect of the socio-economic characteristics of plantain marketers on marketing margin showed that several variables entered into the model were statistically significant. An R^2 of 0.786 indicated that 78.6% of the changes in market margin of plantain marketers were determined by the various variables entered in the model. The remaining 21.4% were determined by other variables not included in the model. An F-ratio of 14.04 indicated that the overall regression equation is statistically significant at 1% level.

The variables that had significant effect on the dependent variable (Plantain market margin) include: marketing experience, distance, education, quantity traded and transportation.

i. **Marketing Experience:** Marketing experience with a coefficient of 2719.9 and a t-value of 10.45 which is statistically significant at 1% level. It is also positively related to marketing margin. This therefore implies that and increases in the marketing experience of the plantain marketers ceteris paribus will lead to an increase in the marketing margin.

ii. **Distance:** Distance with a coefficient of 2.28 and a t-value of 1.74 indicated that it is statistically significant at 10% level and is positively related to marketing margin.

iii. **Education:** Education with a coefficient of 707.21 and a t-value of 2.45 is statistically significant at 5% level and positively related to marketing margin which implied that an increase in the educational level of the plantain marketer will lead to an increase in the marketing margin.

iv. **Quantity Traded:** Quantity traded with a coefficient of 538.36 and a t-value of 10.40 is statistically significant at 1% level. It is also positively related to marketing margin. The implication is an that and increase in the quantity traded will lead to an increase in the marketing margin.

v. **Transportation**: Transportation with a coefficient of -0.28 and a t-value of -2.86 was statistically significant at 5% level. However, it is negatively related to the dependent variable (Plantain marketing margin). This implied that as the transportation cost increases the marketing margin decreases. A 1% increase in the transportation cost of plantain will lead to a 0.28% decrease in the marketing margin of plantain.

Profitability of Plantain Marketing
The profitability of plantain marketing in Oshimili South Local Government Area of Delta State was determined by finding out the cost and selling price of bunches of plantain fruit.
The cost and return analysis of one dozen (12) bunches of average sized plantain fruit is presented in the table below.

Table 4: Profitability of Plantain Marketing

Variables	Amount in Naira (₦)	
Revenue from sale of average 12 bunches (Total revenue [TR])	9,362.40	9,362.40
Variable Costs		
I. Cost of Purchase	4,874.50	
II. Transport Cost	520.00	
III.Other Cost	100.00	
Total Variable Cost (TVC)	5,494.50	5,494.50
Gross Margin (GM = TR -TVC)		3,867.90
Return on Investment (ROI) = GM/TC		0.704

Table 4 showed that the average variable cost per dozens of plantain bunches is ₦5,494.50 and the average total revenue per dozens of plantain bunches is N9,362.40. The Gross Margin is ₦3,867.90. The return on investment (ROI) is ₦0.704 showing that for every one naira spent plantain marketers in the study area attract a gain of 70 kobo. It can then be deduced from the above result that plantain marketing is a profitable venture. This is in conformity with the findings of Offor (2019), that plantain marketing is a profitable venture.
Constraints of plantain marketing in the study area.
The constraints militating against plantain marketing is presented in Table 5. High transportation cost with a rating of 37.5% constitute a major constraint to plantain marketing and formed one of the highest proportions of the total marketing cost. This is due to the distance traveled to purchase the product from farmers. Another challenge faced by plantain marketers was rapid deterioration in quality or spoilage with a rating of 15%. There is also poor market accessibility which accounts for about 13.3% of the constraints. Access to credits accounted for 11.7% of the constraints.

Table 5. Distribution of Plantain Marketing constraints

Constraints	Frequency	Percentage (%)
Access to credit loans	14	11.7
Security	7	5.8
Inadequate funds	10	8.3
Market Accessibility	16	13.3
Rapid Deterioration in quality/spoilage	18	15
Seasonal price fluctuation	10	8.3
High Transportation Cost	45	37.5
Total.	120	100

CONCLUSION

The findings of the study revealed that plantain marketing is a perfect competitive market. There is no restriction into the business, and it is profitable with moderate net income. However, there are some constraints such as high transportation cost, rapid spoilage, market accessibility, access to credits, inadequate funds, seasonal price fluctuation and security. Findings also revealed that plantain marketing is a profitable venture in the study area.

Based on these research findings, the following recommendations are made: Problem of infrastructural facilities such as bad roads should be addressed by all tiers of government. Bad road should be reconstructed and new ones constructed especially those that link the rural areas with urban areas. This will help in getting the produce to the market places in good quality. It will bring about a reduction in transportation cost and hence the cost of marketing. The marketers should come together to form plantain marketer's cooperative groups from which members could obtain loans at very low interest rates to finance and expand their business. Proper handling during on-loading and/or off-loading as well as good storage facilities will reduce the rapid deterioration in quality and spoilage of the plantain and thereby increasing profit. Development and adoption of better techniques that will simplify plantain processing to reduce the spoilage of overripe plantain and bring about value addition is require.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study analyzed accessibility to USAID MARKETSII project among cassava farmers in Ibarapa Central Local Government Area. A multistage sampling technique was used to select 130 cassava farmers. Structured interview schedule and questionnaire was used to elicit responses from respondents on socioeconomic characteristics, level of accessibility to USAID MARKETSII technologies and constraints faced by participants in accessing MARKETS II package of practice. Data were analyzed using descriptive and inferential statistic at p =0.05. Access to MARKETS II project was more on improved farm inputs (2.70), buyback for MARKETS II cassava (2.66), effective extension service (2.64) and appropriate technology (2.58). Majority (62.3%) had high level of accessibility to MARKETS II Project. Respondents' constraints to MARKETS II project were more on pest and diseases ranked highest (2.23), invasion of cattle into farm land (2.01) and high cost of labour (1.80). A significant relationship existed between constraints (r= -0.459, p<0.05) and respondents' access to USAID MARKETS II project. It is therefore recommended that more effort should be made to make sure that some MARKETS II project that were least accessible (better pesticide management and adequate finance) be made accessible to farmers.

Keywords: *MARKETS II; Accessibility; Project; Invasion*

INTRODUCTION

The Maximizing Agricultural Revenue and Key Enterprise in Targeted Sites (MARKETS II) is USAID/Nigeria's flagship project under their Feed the Future (FTF) Agricultural Transformation Program (ATP) and is a successor to the previous seven years of the MARKETS and the Bridge to MARKETS 2 (BtM2) projects. United States Agency for International Development (USAID) is an international agency that provides foreign aids to needy countries. The agency's intervention in agricultural production is known as Maximizing Agricultural Revenue and Key Enterprises in Targeted Sites (MARKETS). MARKETS is working along the value chain of cassava in order to improve productivity, income, sales, and jobs at firm and farm levels (USAID MARKETS, 2013). USAID MARKETS was initiated in 2005, and designed to expand economic opportunities in Nigeria's agricultural sector. Over time, USAID-MARKETS have grown to provide farmers with assistance such as fertilizer supply and technology development; seed development, and farmers training (USAID, 2013). USAID MARKETS II project was initiated to assist cassava producers with adequate knowledge and skills to enhance cassava productivity, income, and their well-being (USAID-MARKETS, 2014). Cassava (*Manihot esculenta*) is of major economic importance as food crop for approximately 200 million people in sub-Saharan Africa countries, including Nigeria (Afolami *et al.*, 2015). In Nigeria, cassava is a major staple food crop (Ajala *et al.*, 2014). Its root and leaves are valuable and a major source of calories and income for rural households in the country (Afolami *et al.*, 2015). Cassava crop has continued to gain prominence among farmers in Nigeria while the industrial demand is also rising consistently (FAO, 2018). This was further supported by the assertion of Anyeagbunam, *et al*., (2015), that cassava has become a very popular crop in Nigeria and is fast replacing other traditional local staples in the country (Zie *et al*., 2019).

It has been opined that over dependent on traditional technologies by smallholder farmers in Nigeria had continuously subjected them to poor yields and inefficiency (Oyewole and Ojeleye, 2015). Likewise, Nwachukwu (2013) described Nigerian agriculture as being associated with drudgery in which farmers depend heavily on hand-tools in carrying out cultural operations on their farms manually. Hence, MARKETS II technologies through the adoption of best agronomic management practices such as optimal spacing, access to the International Institute of Tropical Agriculture's (IITA's) improved disease-resistant cassava varieties, and the introduction and timely use of NPK, insecticide and herbicide to their fields, etc., is an assured way of progressively maintaining cassava bumper yields. . Nzekwe *et al.* (2015) suggest that regardless of a project's completion time and cost, it can still be considered as failed if the project does not fulfil its required purpose. The potentiality of USAID MARKETS II technologies to enhance greater increase in yield of cassava has necessitated the assessment of accessibility of cassava farmers to USAID MARKETS II technologies in Ibarapa central local government area of Oyo State. This study therefore answered the following research questions; what are the enterprice characteristics of MARKETSII participants in the study area, what is the level of accessibility to USAID MARKETSII technologies in the study area, what are the constraints faced by participants in accessing MARKETS II package of practice in the study area?

METHODOLOGY

The study was carried out at Ibarapa Central Local Government Area of Oyo State, Nigeria. It consists of two towns: Igbo-Ora and Idere. It is located in the Southwest geographical zone of Nigeria with its headquarter in Igbo-Ora. The population of the study were registered MARKETS II Cassava farmers in Ibarapa Central Local Government Area of Oyo State. A multistage sampling procedure was adopted to sample the respondents for this study. The first stage was purposive sampling of Oyo state due to the presence of MARKRTS II**.** There are four ADP zones in Oyo State, the second stage involved random selection of 25% of ADP zones. The third stage involved random selection of 10% of the blocks that participated in MARKETS II project in Ibadan /Ibarapa zones. The fourth stage involved random selection of 30% of the registered farmers from the block which has 432 farmers to give a total of 130 farmers. Data was collected through the use of structured questionnaire and interview schedule. Variables assessed were enterprise characteristics, constraints affecting access to MARKETS II project which was measured using a three-point scale of not a constraint, mild constraint to severe constraint with scores of 0, 1 and 2 assigned, respectively and weighted mean score was calculated in order to ascertain the severity of the constraints. Accessibility to USAID MARKETSII project among cassava farmers was measured on a three point scale of always, sometimes, never and scores of 2, 1 and 0 were assigned respectively. Maximum, minimum and mean score were obtained. The mean score was used to categories respondents into having low or high access. Data was analyzed using descriptive statistics such as frequency counts, percentages, mean scores, while inferential statistics; Pearson Product Moment Correlation (PPMC) was used to analyze study hypothesis.

RESULTS AND DISCUSSION

Enterprise characteristics of Respondents

Result in Table 1 shows that (43.8%) of the respondent earned less than 200,000, (37.8%) of them earned between 200,001-500,000, (11.5%) of them earned between 500,001 – 800,000 while (6.9%) of them earned above 800,001. This implies that the respondents made considerable income annually but still living below $1.90 per day, an indication that they are living below the poverty line. The distribution of mode of land acquisition by the respondents shows that (46.7%) of the respondents acquired the land by renting, (30.0%) of them acquired the land through inheritance and (23.1%) of them got it communally. This indicates that majority of the respondents rented land. This disagrees with the findings of Durojaiye and Ogunjimi (2015) who reported that 64% acquired their land for cassava production through inheritance and the remaining 36% acquired theirs by leasing and renting. The result on cultivated cassava farm size shows that most (91.6%) of the respondents had farm size ranging from 1-10 hectares with mean farm size was 5.45. This finding corroborates with USAID Feed the Future (2017) that through a market-demand value chain orientation, MARKETS 11 focused on the large population of small holders with between1-5 hectares of land under cultivation which makes up the vast majority of all farmland in Nigeria. The Project's systemic approach addressed limitations and opportunities in all of the value chain segments that could have an impact on farmers' food security. Majority of the respondents (94.6%) has less than 10 tonnes output, a few (4.6%) of them had between10-20 output (tonnes) with mean output was 5.40. The study reveals that (33.8%) of the respondents had between 11-15 years of experience in cassava farming. This result is in agreement with the finding of Otubo (2021) who reported his respondents had between 11-20 years of experience in cassava farming. The study reveals (33.1%) of the respondents used hired labour, (23.8%) of them used family and hired labour, (23.1%) of them used self, family and hired labour. This implies that using hired labour is common among respondents. This finding agrees with Abd' Kabir (2021) who reported that most of his respondents (83.75%) used hired labor.

Table 1: Enterprise characteristics of the respondents

Variables	Frequency	Percentage	Mean
Income in Naira			
Less than 200,000	57	43.8	
200,001 – 500,000	49	37.8	
500,001 - 800,000	15	11.5	
Greater than 800,000	9	6.9	
Land Acquisition			
Inherited	39	30.0	
Rent	61	46.9	
Communal land	30	23.1	
Cultivated Cassava Farm Size			
Less than 10 hectares	119	91.6	5.45

10-20 hectares	9	6.9	
Above 20	2	1.5	
Actual output/yield (Tonnes)			
Below 10	123	94.6	5.40
10-20	6	4.6	
Above 20	1	0.8

Accessibility to MARKETS II project

Table2 shows the respondents' accessibility to MARKETS II project. Based on the weighted mean of variable reported, access to MARKETS II project was more on improved farm inputs (2.70), buyback for MARKETS II cassava (2.66), effective extension service (2.64) and appropriate technology (2.58). This implies that better pesticide management among farmers, buyback for MARKETS II cassava, effective extension service and appropriate technology were available and farmers had access to them. They had least access to better pesticide management among farmers (2.45) and adequate finance (2.37). MARKETS II has the ability to link extension to farmers and input suppliers and also ability to link borrowers with lenders. The least accessible MARKETS II Project were better pesticide management among farmers and adequate finance may be because farmers have constraints in accessing better pesticide management and in obtaining collateral security to obtain finance.

Table 2: Accessibility to MARKETS II Project

MARKETS II Project	Always	Sometimes	Never	WMS	Rank
Adequate finance-	46.9	43.8	9.2	2.37	6th
Appropriate technology	60.8	36.9	2.3	2.58	4th
Better pesticide management practice in MARKET II	50.8	42.3	6.9	2.43	5th
Improved farm input in MARKETS II project	71.5	27.7	0.8	2.70	1st
Effective extension service	66.2	32.3	1.5	2.64	3rd
Buy back for MARKETS II cassava farmers	67.7	31.5	0.8	2.66	2nd

Source: Field survey, 2023 Grand mean =2.56

Categorization of level of accessibility to MARKETS II Project

Table 3 further reveals that 62.3% had high level of accessibility to MARKETS II Project while 37.7% of the respondents had low level of accessibility to MARKETS II Project. This implies that respondents experience relatively high level of accessibility to MARKETS II project in the study area.

Table 3: Level of accessibility to MARKETS II Project

Overall level of accessibility	Frequency	Percentage
Low	49	37.7
High	81	62.3
Total	130	100

Source: Field survey, 2023

Constraints faced by cassava farmers in MARKETS II Project

The respondents' constraints to MARKETS II project were explored using weighted mean score as shown in Table 4.Table 4 shows that pest and diseases ranked highest (2.23) among constraints faced by MARKETS II participants. This corroborates the findings of Ayoade (2012) who ranked problem of pests and diseases as second among the constraints encountered by cassava farmers. Invasion of cattle into farm lands ranked second (2.01), the problem of cattle invasion on farm land could be attributed to insufficient pasture for grazing. High cost of labour ranked third (1.80). Inadequate access to credit ranked fourth(1.68), this implies that respondents have difficulties in accessing credit facilities to engage in productive farming which could be attributed to unavailability of sources of credit to the farmers. This is in line with the findings of Okotie (2018) that despite funding from International agencies, farmers are still faced with difficulty in accessing credit facilities. Insufficient physical inputs needed for production ranked fifth (1.63).Poor accessibility of technology to the farmer ranked sixth (1.63). Transportation challenges ranked seventh (1.56), this negates the findings of Ayoade (2012) who ranked poor transportation as third among the constraints encountered by cassava farmers. Irregular rainfall pattern ranked eight (1.55). Poor result demonstration during training ranked ninth (1.51). Inadequate extension contact ranked tenth (1.43) and the least constraint which is gender inequality in input distribution ranked eleventh (1.30).

Table 4: Constraints faced by cassava farmers in MARKETS II project

Constraints	Not a constraint	Mild constraint	Severe constraint	WMS	Rank
Inadequate access to credit	46.2	40.0	13.8	1.68	4th
Poor accessibility of technology to the farmers	40.8	55.4	3.8	1.63	6th
Invasion of cattle into farm lands	19.2	60.8	20.0	2.01	2nd

Correlation between respondents' constraints and access to USAID MARKETS II project

The PPMC result in Table 5 reveals there was a negative and significant correlation between respondent's constraints and their access to USAID MARKETS II project ($r= -0.459$, $p<0.05$). This implies that constraints the respondents faced in cassava production influences their access to USAID MARKETS II project.

Table 5: Correlation between respondent constraints and their access to USAID MARKETS II project

Variables	r-value	P-value	Remark
Constraints	-0.459	0.001	S

Source: Data analysis, 2023

CONCLUSION AND RECOMMENDATIONS

The study concludes that access to MARKETS II project was more on improved farm input, buyback for MARKETS II cassava, effective extension service and appropriate technology. Respondents had high level of accessibility to MARKETS II Project. Respondents' constraints to MARKETS II project using weighted mean score and grand mean shows pest and diseases, invasion of cattle into farm lands, high cost of labour and inadequate access to credit as the major constraints faced by cassava farmers in the study area. There was a negative and significant correlation between respondent's constraints and their access to USAID MARKETS II project. It is therefore recommended that more effort should be made to make sure that some MARKETS II project that were least accessible (better pesticide management and adequate finance) be made accessible to farmers. Ways to tackle invasion of cattle into farmland should be looked into.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analysis of onion marketing in Ungwaggo Local Government Area, Kano State, Nigeria. The study was conducted through a survey of onion marketers. The specific objectives of the study were to describe the socioeconomic characteristics of onion marketers, determine marketing margins, determine marketing efficiency, and describe the problems of onion marketing in the study area. Data were collected through the use of questionnaire administered on 66 marketers (respondents). Data were analyzed using descriptive statistics such as means and frequency distributions, and marketing margins. The results show that most onion marketers in the study area were married (81.8%). About (39.4%) of them were enrolled in non-formal schools. Marketers earned N3,040 per 120 kg bag as profit, accounting for 24.16% marketing efficiency. The hurdle for marketers was little or insufficient understanding of onion marketing. The study also shows that insufficient storage facilities, poor access to credit, lack of market information and poor transportation hindered effective marketing of onions. The study recommends adequate credit facilities, improved market access and market intelligence, and better access to technical resources to improve onion commercialization.
Keywords: *Onion marketing, marketing margin, marketing efficiency*.

INTRODUCTION
Onion (*Allium cepa*) is a vegetable belonging to the Liliaceae family (Alabi and Adebayo, 2008). Also known as "garden onion" or "onion," it is one of the oldest cultivated vegetables. Tubers grow underground and are used to store energy, which can lead to confusion with non-tuberous tubers (Wikipedia, 2010). The leaves are blue-green and hollow, and the tubers are large, fleshy and firm (Azu *et al.*, 2007). It is sold primarily as a fresh fruit vegetable and plays an important role in the preparation of food in most households. It is effective against colds, heart disease, diabetes, osteoporosis, and coughs and sore throats. They are rich in flavonoids, concentrated in the outer layer of the pulp (Nemeth *et al.*, 2007). Hussaini *et al.*, (2000) identified onions as the second most important vegetable after tomatoes. Onions (Allium cepa) are mainly grown in Nigeria, Niger, Ethiopia, Burkina Faso, and Senegal. The cultivation of this crop has grown steadily in the tropics for more than forty years. The total area under onion cultivation in the world doubled to 2.74 million hectares (Pelter *et al.*, 1992; FAO, 2002). In agriculture, horticultural crops, including onions, occupy an important place. Marketing typically begins on the farm when farmers harvest their produce. It is a common issue that the goods, once gathered, are unable to reach their intended purchasers. Harvested products are rarely in a form that is suitable for consumption and must be cleaned, sorted, processed and presented in appropriate amounts and quality for sale to consumers (Asogwa and Okwoche, 2012). Therefore, marketing encompasses all aspects of business operations, including production and the involvement of intermediaries, until the product reaches the end consumer.

Research on food marketing has revealed a direct and causal relationship between the structure of the industry and market conduct. According to Anuebunwa *et al.*, (2006), there exists a causal correlation between the structure of a market and its performance, which can be defined as deterministic in nature. This relationship is influenced by the actions and behaviour of market participants and can be observed through the outcomes and results of the market's operations. When comparing its trade value to that of other produce, such as tomatoes and peppers, the onion (*Allium cepa*) holds its own. It is a crop that garners attention in the market due to its distinct status as a frequently utilized vegetable in virtually every household, as stated by (Dogondaji *et al.*, 2006). Despite the numerous potential benefits of onions in medicine, economics, and industry, there has been no serious marketing studies conducted on this vegetable in the study area. The marketing of crops in Eastern Nigeria is a subject that varies widely depending on the region. However, it is generally understood that marketing strategies for crops are diverse and influenced by factors such as location, infrastructure, and access to markets.The broad objective of this study was the analysis of onion marketing in Ungogo Local Government Area of Kano State, Nigeria. The specific objectives were to: describe the socio- economic characteristics of the onion marketers, determine the marketing margin of the onion and describe the problems of onion marketing in the study area.

METHODOLOGY

The study was conducted in Ungwaggo Local Government Area of Kano State, Nigeria. Ungwaggo local government is one of forty-four local government areas of Kano state. Its headquarters is in *Ungwaggo* town, Two stage sampling techniques were used; these were purposive and simple random sampling in selecting a representative sample of onion marketers in the study area. Ungwaggo local government area was selected for this study because onions were highly marketed in the area. There are eleven (11) wards in Ungwaggo local government area namely; Bachirawa, Gayawa, Kadawa,Karo, Panisau, Rangaza, Rijiyar Zaki, Tudun Fulani, Ungogo, Yadakunya and Zango. Four (4) wards were purposively selected due to the concentration in marketing of onions and 66 respondents were randomly selected from the four wards which include Bachirawa market, Gayawa, Kadawa and Rijiyar Zaki respectively. From each ward in the study area, thirty-six (36) marketers were selected in Bachirawa market due to the higher number of marketers, thirteen (13) respondents in Gayawa, Nine (9) respondents in Kadawa, Eight (8) respondents in Rijiyar Zaki. The analytical tools used were, descriptive statistics and marketing margin. Primary data were used for this study. The primary data were collected with aid of structured questionnaire which was administered on the onion marketers (respondents) in the study area.

RESULTS AND DISCUSSION

Majority in table 1. of onions marketers were youth with mean age of 40 which implies that they were economically active, 93.9% of the respondents were male and 6.1% were female, both male and female were involved but female did not participate in the open market rather they participated in their houses as result of religion and culture of people in the study area. About 81.8% of the respondents were married and 18.2% were single, formal education was generally low whereas most of the respondents attended informal schools in the study area. About 31.82% of the onion marketers fell between 1 to 10 years of experience, majority of onion marketers had household size ranging from 1-5, (53.03%). Table 2. Shows that marketers earned ₦ 3040 per 120 kg bag, Marketing efficiency of onion marketing was 24.16%, meaning that there was high marketing efficiency in the onion marketing in the study. Table 3. Shows the Constraints of onion marketing with 25.23% of the respondents faced inadequate credit facilities which rank first, followed by inadequate storage facilities having 19.16%, Transportation problem having 15.42%, Onion being a highly perishable farm produce, needs to be stored properly to minimize losses due to deterioration in quality. Marketers in some cases suffer losses of between 50% -70% due to inadequate storage facilities. price fluctuation faced 24.30% and 15.89% faced inadequate recent information respectively. This result implied that majority of problem faced of the onion marketers in the study area were inadequate credit facilities. Ungwaggo being a Local Government Area needs to be served by functional transport facilities such as lorries to facilitate easy and timely movement of onion into the State capital. Where the means of transportation are not readily available as is mostly the case, marketers are forced to sell their onion below the market value, as the gloat in the market pull down the price of onion to their disadvantage or stand the risk of losing their investment because lack conventional storing facilities. These problems have adverse effects on the marketer's profit by causing damage due to inadequate storage facilities and increased marketing cost due to inadequate transportation facilities.

Furthermore, lack of capital and credit facilities have effect on the size of marketers holding as well as their marketing scope.

RECOMMENDATIONS

Based on the findings of this study, the following recommendations are made:

i. Marketing loans and credit should be made available to marketers at a low interest rate to help them finance their marketing activity.

ii. To overcome the problem of price fluctuations, the private sector should be encouraged to establish onion dehydration plants to process the onion into more durable product. This may help to enhance the year-round availability of the commodity in addition to preparing it for export.

iii. Transport facilities should be provided either through cooperative efforts or by Government to link the farms with the market as well as the Local Government Area with the state capital to help reduce marketing costs as well as increase marketers' profit.

iv. Adequate and conventional storage facilities should be made available in the market by the government to counteract the problem inadequate storage facilities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study analyzes the effect of COVID-19 pandemic on rice farmers in Ihitte/Uboma L.G.A. The objective of the study was to examine the socio-economic characteristics of rice farmers, ascertain the extent to which COVID-19 has affected rice farming productivity, to determine the constraints faced by rice farmers during the COVID-19 lockdown. Simple random sampling technique was used in selecting a total number of sixty respondents. Data was collected with a well-structured questionnaire and was analyzed using descriptive statistics, Heckman two step selection model and Likert 5 scale. The result showed that majority of respondents were males (96.7%), most of the farmers were between 51 – 60 years in age (50%) and those that attended secondary education (61.6%). Heckman two steps selection model result shows that farm size was found to be significant at 1% and has a positive influence on the extent of rice production during the COVID-19 lockdown. The likert 5 scale result shows that high cost of input, lack of access to input and decrease in demand for rice were the major challenges during the COVID-19 lockdown with a percentage of 4.683333%, 4.283333% and 3.066667% respectively. The research reveals that the COVID-19 pandemic affected the rice farmers in the study area which was due to the fact that there was high cost of farm input, lack of access to the market due to no movement / downsizing policy by the federal government. The study recommends that rice farmers should make use of farm machines so as to ease up the workload of their farms and increase their farm size, this will encourage productivity of rice. The government should subsidize the cost of farm inputs such as fertilizers, insecticides etc. so as to enable rice farmers get these farm inputs at affordable prices.
Keyword: *COVID-19, Rice Farmers, Productivity, Agriculture*

INTRODUCTION

The World Health Organization (WHO) pronounced Covid-19 as a pandemic on March 11, 2020 (Congressional Research Service, 2020). The disease outbreak rapidly spread to all part of the world. The COVID-19 epidemic terrified countries into sudden disruption and successfully put businesses at lockdown. It affected living and all profitable activities particularly business enterprises as well as manufacturing firms (Sansa, 2020 and Ruiz Estrada *et al.,* 2020). Manufacturing firms were heavily affected by the COVID-19 pandemic, due to the closures and reduced working hours recommended to curb the spread of the virus; the covid-19 pandemic had a significant negative impact on manufacturing firm. (IOM, 2020).

Corona virus is a contagious disease caused by severe acute respiratory syndrome corona virus. The first known case was identified in Wuhan, China, in December 2019. The disease had since spread worldwide, leading to an ongoing pandemic Zimmer, *(2021).* Symptoms of COVID-19 often include fever, cough, headache, fatigue, breathing difficulties, and loss of smell and taste. A study by researchers at the University of Southern California found that fever may be the first symptoms followed by cough and muscle pain. After these, those infected with the virus will likely experience nausea, vomiting or diarrhea. These develop first, followed by respiratory symptoms possibly a day later. At least a third of people who were infected don't develop noticeable symptoms. Those people who developed symptoms noticeable enough to be classed as patients, 81% develop mild to moderate symptoms (up to mild pneumonia), while 14% develop severe symptoms (dyspnea, hypoxia, or more than 50% lung involvement on imaging), and 5% suffer critical symptoms (respiratory failure, shock, or multi organ dysfunction). Older people are at a higher risk of developing severe symptoms. COVID-19 transmits when people breathe in air contaminated by the corona virus and small airborne particles. The risk of breathing these particles in is highest when people are in close proximity, but they can be inhaled over longer distances, when people are particularly in door. Transmission can also occur if splashed or sprayed with contaminated fluids, in the eyes, nose or mouth and rarely via contaminated surfaces. People remain contagious for up to 20 days, and can spread the virus even if they do not develop any symptoms (CDC, 2019).

Agriculture is a key sector of the economy in many developing countries and remains the basis of any development strategy. It provides employment for about two-thirds of the continent's working population and for each country, it contributes an average of 30% to 60% of their gross domestic product and about 30% of the value of exports (World Bank, 2020). Agriculture can help reduce poverty, raise incomes and improve food security for 80% of the world's poor, who live in rural areas and work mainly in farm. Agricultural development is one of the most powerful tools to end extreme poverty, boost shared prosperity and feed a projected 9.7 billion people by 2050 (World Bank, 2020). It can therefore contribute towards sustainable development goals and major continental priorities, such as eradicating poverty and hunger, boosting intra-Africa trade and investments, rapid industrialization and economic diversification, sustainable resource and environmental management, and creating jobs, human security and food security. Food a major product of farming and it is important for good health and can help fight diseases. In the agricultural sector, cereal production especially rice, wheat and maize have become essential to food security as they provide more than 60% of daily calorie in developing countries (Mckevith, 2004). The place of diet in good health development is one of the major policy concerns and individual dietary intake and can account for the level of development of the Nation. Rice a major cereal is essential in increasing per calories requirement for the health growth in Nigeria.

Rice is an important staple crop that plays an important economic role and feeds approximately half the world's population (Fahad *et al.,* 2019). Rice represents the staple food for more than 750 million people in Sub-Saharan Africa (USDA, 2018). Rice consumption in Africa is growing faster than other food Staples in every part of the World. However, local rice production in Africa and Nigeria in particular has not kept pace with the increase in demand and the gap is being filled through production of other alternatives whose characteristics are more preferred by consumers (Demont *et al.,* 2013). These renders Africa very vulnerable to international trade disruptions such as the ones currently inflicted by the corona virus disease (COVID-19) crisis (Arouna *et al.,* 2020).

The impact of COVID-19 on agriculture is devastating, complex and varied across diverse segments that form the agricultural value chain. This impact will reverberate across the larger economy and will linger unabatedly than few months. Commercial crops are drastically hit as they tend to be more dependent on farmers who are faced with social distancing, quarantine and lockdown. The Shortage of farmers due to COVID – 19 pandemic has resulted in a sharp increase in daily wages for harvesting crops. In several areas, the rise is as high as 50%, making it un-remunerative for the produce since prices have collapsed due to either lack of market access including the stoppage of transportation and closure of borders. COVID-19 pandemic seems to escalate the already existing food security giving the additional impact it has on both production and marketing segment of rice value chain.

However, as the COVID-19 continues to wreak havoc on many countries and create lots of changes in people's livelihood all over the world, the broader economic crisis is also emerging and creating major challenges to food security and nutrition. Many of the affected countries have implemented a regional lockout policy. This strategy enforced a plethora of COVID-19 security measures such as movement control, as well as supermarket, restaurant and market closure, others are quarantines, supply chain and trade disruption which greatly affected agricultural production, food supply and demand. This study aimed to assess the effect of the COVID-19 pandemic on all rice farmers' productivity in Ihitte/uboma LGA, Imo State. This study established policy dissection in case of future pandemic and suggest way out for farmers who may be trapped in the sudden and harsh security measures that were set-up to arrest the spread of the disease in Nigeria and Imo State in particular. The objectives of this study include to determine the socio economic characteristics of rice farmers in Ihitte/uboma LGA, to ascertain the factors to which COVID-19 has affected rice farming productivity in Ihitte/uboma LGA, Imo State, to determine the constraints rice farmers faced during the period of the pandemic in Ihitte/uboma.

MATERIALS AND METHODS

Ihitte/ Oboma is an Imo State local government area in Nigeria. Its headquarters is located In Isinweke . It has a land area of 104 km^2 and a population of 120,744 people, according to 2006 Census. The postal area's code is 472. Towns and villages in Ihitte/uboma include Amakoha (Amuzu, Ipinweke, Nnacheru, Umuokoroezuka, Umuonyeche, Umuoye). Umue-Zegwu(Umuakpi, Umudibia, Umule/Umuhere, Umuode, Umuokparaka). Ato-Werem (Elugwu, Omuchienta, Umuezina, Umulemaku Umuezea Umuopi). Ikper-Ejere (Umuanyaku, Umudwu, Umuchie, Umuejere, Umuzealaduzuk, Umuoppara-Owerre, Umuehie). Umuihi (Dikenachieze, Emekengwe, Ikenafo, Uhebgu, Uhuanwuse, Umudiaba) etc. Due to the dominance of rice farmers in the study area, a purposive sampling method was adopted to select 6 communities from the study area due to the dominance of rice farmers in the communities. Then a Simple random technique was used to select 60 respondents for the study. 10 rice farmers from each of the communities. The data used in this study were predominantly gotten through primary and secondary data source. The secondary data were gotten from existing literatures, publications, textbooks, journals, and internet. The primary data were gotten from the respondents through the use of structured questionnaire. The data collected were analyzed with the use of descriptive statistic method, Heckman two step and Likert scale.

Total	60	100

Source: Field survey data 2022

Table 1 shows that a percentage of (55%) of the respondents had family size of 4-6 members, 38.4% of respondents had family size of 7-9 persons. This is good because farmers with large number size of household members tend to be positive for Agricultural productivity since more hands are needed to increase production. 61.6% of respondents spent 7-12 years in school, which is secondary education while 35% spent 1-6 years in school, which is primary education. This simply implies that secondary school, rice farmers have enough skill to increase productivity and rice farming is a business that doesn't really require certificate to run. 96.7% of the respondents are males while 3.3% are females. This implies that rice of farming in Ihitte/Uboma is dominated by males. Majority of the rice farmers (50%) are between the ages of 51-60, 26.6% of rice farmers are between the ages of 41-50 years. This simply implies that rice farming in Ihitte/Uboma is predominant with matured or middle-aged people who are active individuals. Majority of the rice farmers (60%) has between the farm size of 1.1-2, 21.7% of rice farmers has between 0.1-1of the farm size. The farm size can affect the total output of production and income of farmers. 58.3% of farmers have rice farming experience of between 11-20 years, followed by 26.7% with farming experience of between 21-30 years. This implies that majority of rice farmers have more years of experience.

Table 2 shows that **Farm size (X_6)**: Farm size was found to be significant at 1% level and has a positive influence on the extent of rice production during COVID - 19 Pandemic. This implies that an increase in farm size increases the extent of rice production in the study area during the COVID - 19 pandemic.

Table 3 Result of Likert 5 scale on the constraints faced by rice farmers during covid-19 period

Constraints faced by farmers	SA	A	N	D	SD	MEAN SCORE	RANK
Lack of labour	14		3	16	15	2.1	8
Lack of access of inputs	29	25	1	4	1	4.2	2

Confiscation of goods by law Enforcement agencies	0	0	26	0	34	1.9	10

Source: Field survey data 2022

Table 3 shows the Result of Lirkert 5 Scale on the constraints rice farmers faced During the Pandemic, from the analysis above it is clear that high cost of input was the most pressing major constraints during the covid-19/lockdown faced by rice farmer in the study area, lack of access to input followed as a major constraint, Decrease in demand for rice followed as a major constraint, this implies that the revenue of rice farmers was affected negatively. Reduction of farm revenue followed due to low sales caused by decrease in demand of rice produce during the period. lack of transportation was another major problem because of ban on movement during the lockdown, followed by international trade disruption and the least is lack of rice processing mills.

CONCLUSION

This research reveals that the covid-19 pandemic affected the rice farmers in the study area. And this is due to the fact that there was high cost of farm input, lack of access to the market due to no movement/downsizing policy by the federal government and decrease in the demand of rice, as people were restricted in carrying out their daily business activities it led to shortage/decrease of money to spend on food which rice is not exempted. It is recommended that 1. Rice farmers should make use of farm machines so as to ease up the workload of their farms and increase their farm size, this will encourage productivity of rice productivity. 2. The Government should subsidize the cost of farm inputs such as fertilizers, insecticides etc. so as to enable rice farmers get these farm inputs at affordable prices 3. The Government should make an exemption for agricultural produce for easy access and transportation most especially for staple foods such as rice etc., if at all any incident that will warrant closures of markets and movement of citizens re-occurs.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study assessed the costs and returns of poultry entrepreneurs in Abia State, Nigeria. Primary data were collected with the aid of a questionnaire from 120 poultry farmers selected using multistage sampling techniques. The data were analyzed using the profit function and simple descriptive tools like tables, and percentages. Results revealed that 63% of the respondents were male with a significant proportion (72%) married with a household size of 1-5 persons. The majority (72 %) of the farmers had one form of education or the other. About 13% of the poultry entrepreneurs engaged in breeding/hatchery and day-old chicks' distribution (Br/H/D), 16% engaged in production, live-bird/egg trading, processing, and transportation (P/L/E/Pr/T), 21% engaged in feed milling and transportation (Fm/T), 21% engaged in feed milling, production, processing and transportation (Fm/P/, Pr/T) while 29% engaged in processing and barbeques (Pr/B). The results of the profitability/cost and returns analysis of various poultry value chain activities revealed that operators that combined Br/H/D had ₦ 5000 as net profit, P/ L/E/ Pr/T had ₦ 7000 as net profit, Fm/ T had ₦ 6000 as net profit, Fm/ P/Pr/T had ₦ 9000 as net profit and operators that combined Pr/B had ₦ 4000. The value given was based on a single unit of commodity and not the entire system. Poultry operators in the study area were seen to be profitable and operators that combine feed milling, production, processing, and transportation had the highest net profit of ₦9,000 followed by ₦7,000 for a combination of production, live bird/egg trading, processing, and transportation, the least was ₦4000 for processing and barbeque operators. It is thus; recommended that poultry farmers be encouraged to join FM/P/Pr/T because of its high returns if they want to engage in poultry-related businesses. Age of farmer, sex, educational status, experience, household size, operating expenses, cost of feed, and membership in cooperative society were the factors influencing the profitability of poultry production in the study area
***Keywords**: Poultry entrepreneurs, profitability, transportation*

INTRODUCTION
Livestock production constitutes an essential part of the agricultural economy of Nigeria, It provides meat, clothing, fuel, fertilizer, and draught power to sustain the economy and also serves as additional income earning activities to small and marginal farm families. (Yusuf and Olorunwa, 2018). According to Ekunwe and Soniregun (2007), Poultry production is the management of birds for food, income, and other purposes. It has incredible potential for expanding protein supply in Nigeria and plays a significant role among the livestock-based vocations, this is because of its enormous potential to bring about rapid economic growth and quick returns to investment. Apart from supplying protein, poultry is also a good source of lipids and vitamins of high zoological value to man (Bamiro. 2006). Available information shows that Nigeria hosts more than 45% of the poultry in the West African sub-region and its poultry population is estimated at 140-160 million comprising 72.4 million chickens, 11.8 million ducks, 4.7million guinea fowl, 15.2 million pigeons, and 2 million turkeys (Ebukiba and Anthony, 2016). The demand for poultry products is progressively increasing in as meat consumers' preference for white meat arises. High cost and poor quality of feeds, inadequate finance, poor access to credit facilities, high rate of disease infestations, and high cost of drugs and vaccines are some of the constraints to the growth and profitability of poultry enterprises in the country (Emokaro and Erhabor, 2014; Mamman, 2016; Ebukiba and Anthony, 2019). Therefore, this study seeks to evaluate the profitability of poultry enterprises in Abia State, Nigeria. Specifically, it sought to describe the socio-economic characteristics of poultry farmers and estimate the cost and returns of poultry value chain activities of the entrepreneurs in the study area

METHODOLOGY
This research was conducted in Abia State, the Southeast geopolitical zone of Nigeria. Primary and secondary data were employed in this investigation. A well-structured questionnaire was used to extract primary data from 120 poultry operators in the study area. Secondary data were collected from yearbooks, magazines, journals, and work downloaded from the internet. The multi-stage sampling procedure was adopted in this study. The first stage involved the purposive selection of

three Local Governments Areas (LGA) with relatively high involvement in poultry and poultry-related activities. Ikwuano, Bende, and Aba South were chosen from Umuahia, Ohafia, and Aba respectively. The second stage involves a random selection of 40 operators from the list of poultry operators in the selected LGAs. Thus, the sample size of the study is 120 respondents.

Method of data analysis

Data were analyzed using the profit function. The profit function is given as:

Π = TR – TC

Where:

Π = Profit

TR = Total Revenue

TC = Total Cost =TVC +TFC

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents

The result on the socio-economic characteristics of the respondents revealed that the majority of the poultry entrepreneurs in Abia state are married men in their active years with a form of education and experience in the poultry business. Table 1 indicates that the majority (48%) of the respondents were within 40-49 years, 28% were between 20-39 years and 23% were more than 50 years, implying that the poultry farmers were within their economically productive age. The result revealed that 63% of the respondents were male with a significant proportion (72%) married. The Table further indicates that 71% of the respondents had a household size of 1-5 members; implying that poultry entrepreneurs would require hired labor (other than relying on family labor) for poultry activities. A vast majority of poultry farmers in the state were educated and experienced in the poultry business. A notable share of the respondents (46%) had secondary education, 29% had primary education, 13% had tertiary education, and 13% had no formal education. The Table shows that 37% of the respondents had work experience of 6 to 10 years. This implies that the poultry farmers were well-groomed and experienced in their business. A significant proportion of poultry operators (63%) were members of cooperatives.

Distribution of poultry value chain combined activities carried out in the study area

Poultry entrepreneurs in Abia state have a combination of value chain activities, Table 2 presents the distribution of poultry value chain combined activities in the study area. The value chain activities identified include Breeding, Hatchery, and Day old Chick Distribution (Br/H/D); Production, Live-bird/egg Trading Processing and Transportation (P/L/E/Pr/T); Feed milling and Transportation (Fm/ T); Feed milling, Production, Processing and Transportation (Fm/P/Pr/T) and Processing and Barbeque (Pr/B). The percentage of entrepreneurs involved in the value chain activities are 13%, 16%, 21%, 21%, and 29% respectively. It implies that operators who combined only the processing and preparation of chicken barbeque were the highest. Br/H /D was done by few operators because of the associated risks in breeding which therefore required the services of experts.

Cost and Return Analysis Results for various poultry value chain activities

Poultry production is a profitable business in the study area. The cost and returns analysis of the respondents is presented in Table **3.** The Table revealed that operators that combined Br/H/D, P/L/E/Pr/T, Fm/T, Fm/P/Pr/T, and Pr/B had ₦5,000, ₦7,000, ₦6,000, ₦9,000, and ₦4,000 net profit respectively (the value given was based on a single unit of commodity and not the entire system). Fm/ P/ Pr,/T had the highest net profit (₦9,000) followed by P/ L/E/ Pr, (₦7,000),the least was (₦4000) for Pr,/B

Average total fixed cost (₦)	7,000	8,000	6,000	11,000	4,000
Average return from the sale (₦)	27,000	32,000	19,000	40,000	15,000
Average total cost (₦)	22,000	25,000	13,000	31,000	11,000
Average net returns (₦)	5,000	7,000	6,000	9,000	4,000

Source: Field survey,2016

CONCLUSION

Entrepreneurs that combined processing and preparation of chicken barbeque were the highest while Breeding/Hatchery and distribution of day-old chicks distribution were done by few operators because of the associated risks in breeding which therefore required the services of experts. This research also revealed that poultry and poultry-associated activities in the study are profitable. operators that combine Feed milling, Production, Processing, and Transportation (Fm/P/Pr/T) had the highest net profit of ₦9,000 followed by ₦7,000 for a combination of production, live bird/egg trading, processing, and transportation (P/L/E/Pr/T), the least was ₦4000 for processing and barbeque (Pr/B) operators. It is recommended that poultry farmers be encouraged to join Feed milling, Production, Processing, and Transportation (FM/P/Pr/T) because of its high profitability returns if they want to engage in poultry and poultry-related businesses.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Profitability of abacha processing in South East, Nigeria was studied using 120 sampled processors. Structured questionnaire was used to collect primary data. Percentage responses and Net farm income were used to address the objectives of the study. The result of data showed that abacha processing was profitable in the study area with Net Farm Income of N36,800.and return on investment of 0.49. Also, the major constraints to abacha processing were; poor access to credit, high cost of cassava roots, drying method and high cost of labour. The need to enhance processors' access to credit, labour saving devices and drying machines were recommended.
Keyword: *Profitability, Tapioca 'Abacha', Processing, South East, Nigeria.*

INTRODUCTION
Cassava is the basic staple food for more than 70% of the Nigerian population, particularly in North Central, South East, South South and South West, Nigeria (food and Agriculture Organization, (FAO),2017). Cassava can be processed into varied forms. However, the form in which cassava is processed depends on cultural food habits, tastes and preference of the people as well as the variety of cassava and age at harvest of roots (International Institute for Tropical Africa (IITA, 2014). In South East, Nigeria, abacha is amongst the commonest form cassava roots can be processed into (Nweke, Ngoram, Dixon, Ugwu and Ajobo, 2001). Abacha may be consumed with coconut and with sauce for taste According to Alinnor, (2002) abacha can be processed by washing of cassava roots – peeling - boiling for 20 minutes - shredding - soaking of the shredded cassava in water for 12-24hours - water will be changed for about 2-3 times during the period. These processing technology according to Ume, et al; (2020).was disseminated to processors for onward adoption through extension arm of Agricultural Development Programme in the States concerned. The abacha processing has encountered lots of problems that affect its productivity negative. IITA, (2014) enumerated the problems to include, high price of cassava roots, irregular / seasonal supply of cassava roots, low price of abacha, high cost of sieving baskets, water scarcity and high cost of firewood. Therefore, there is need to assess the processors' productivity in terms of profit accruing from the processing in the study area. This could aid in formulation and implementation of policies that would propel the processors to improve on their productivity and among others. Specifically, the objectives of the study were to determine the profitability and constraints to abacha processing in the study area.

MATERIALS AND METHODS
The study was conducted in South east of Nigeria. The zone lies between 5 9'and 7 75'N of equator and longitude 6 85' and 8 46' East of Greenwich meridian time. .It has a population of 16,381.729 people (NPC, 2006)and total land area of 10952400 hectare. It comprises of five states; Imo, Anambra, Ebonyi, Abia and Enugu. Four states (Enugu, Abia, Imo and Anambra) were purposively chosen based on intensity of 'abacha' processing. Multi stage sampling technique was employed in selecting 30 processors from each State, making a total of 120 respondents. The primary data for the study was obtained using questionnaire and oral interview schedules Percentage responses and net farm income were used to capture the processors' profitability and constraints to the processing in the study area.

Model Specification
Gross Margin Analysis Model
Gross margin analysis is the difference between the total revenue (TR) and the total variable cost (TVC)

G.M. = TR – TVC…………………………….……(1)

i.e.G.M= $\sum_{1-1}^{n} P_1 Q_1 - \sum_{j-i}^{m} r_i x_i$ ....(2)

The net farm income can be calculated by gross margin less fixed input. The net farm income can be expressed as thus:

NFI = $\sum_{1-1}^{n} P_1 Q_1 - \left[\left(\sum_{j-i}^{m} r_i x_i \right) + k \right]$ ....(3)

Where: GM = Gross margin (₦), NFI = Net farm income (₦), P1 = Market (unit) price of output (₦), Q = Quantity of output (kg), ri = Unit price of the variable input (kg), xi = quantity of the variable input (kg), K = Annual fixed cost (depreciation) (₦), i = 1 2 3 …….. n , j = 1 2 3 ……m

RESULTS AND DISCUSSION

Table 1 Costs and return of processing 1000kg of cassava roots to tapioca "abacha"

Item	Unit	Price/ unit	Quantity	Value
Revenue				
Tapioca "Abacha"	Kg	300	250	75,000
Total Revenue				75,000
Variable Cost				
Inputs				
Cassava tuber	Kg	30	1000	30,000.
Transportation and firewood				2400
Sub Total				32,400
Labour for the various ·processing operations for tapioca product ion				4,200
Total Variable Cost				36,600
Fixed Cost				1,600
Total Fixed Cost				1,600
Total Cost				38,200
Net return				36,800
Return on investment				0.49

Source; Field Survey, 2022.

Table 1 show that 250kg of tapioca was produced from processing of 1000kg of cassava roots. A kilogram of tapioca was sold at N300 and for 250 kg, a total revenue of N75,000 was obtained. The total cost consists of total variable cost and total fixed cost was N38,200. The cost of inputs was N30,000 which accounted for about 78.53% of the total cost. The competition in cassava root uses among humans and agroindustry could be attributed to high cost of the resource (Nweke, *et al*; 2001). The cost of labour was N4,200, constituted about 11% of total cost of production. The high cost of labour in the study area according to Ume, *et al*;(2020) could be attributed to economic meltdown in the country, leading labourers charging very high to survive. Net returns for 250kg of tapioca processed from 1000kg of cassava root was N36,800. The return on investment was 0.49, implying that in every N1invested 49 kobo accrued. This finding concurred with Alinnor, (2002), who return on investment of 0.52.

Table 2 Constraints to Tapioca processing in the study area

Variable	Frequency	Percentage
Poor access to credit	100	83.33
Poor pricing of products	80	66.67
Irregular supply of roots	98	81.67
Poor road network	45	37.5
High cost of Labour	94	78.33
Drying problem	68	56.67

*Multiple Responses
Source, Field Survey, 2022

Table 2 shows that most (83.33%) of the respondents complained about poor access to credit. The poor access to credit could be related to processors' inability to produce the required collateral as demanded by lending agencies, high interest rate of the loan and ignorance of loan facility in the banks (Ume, *et al;* 2020). Credit could aid in procurement of apart processing equipment, procurement of raw materials and in payment of labour (Nweke, et al; 2002). The least, problem of poor road network were reported by 37.5% of the respondents. This could be related to recent massive rural roads rehabilitations ongoing by various States government in the zone.

CONCLUSION AND RECOMMENDATION

Based on the study, the following conclusions were derived; Tapioca processing was profitable in the study area. More so, the constraints to tapioca processing were poor access to credit, high cost of labour, poor pricing of products, irregular supply of cassava roots and drying problem. Based, on the conclusions, the following recommendations were proffered;(I) Cassava processors should be exposed to credit facilities by commercial banks and microfinance bank at reduced interest rate.(ii)Labour saving devices should be developed and disseminated to the processors at subsidized price (iii)The need to ensure that processors have access to improved drying technologies such as solar drying system to aid in the adequate drying of their products at subsidized cost

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Diversification is an important platform for risk minimization and income complementation. The study assessed income diversification activities among smallholder maize farming households in Bunkure LGA of Kano State, Nigeria. Multi-stage sampling technique was used to select the 60 farming households used in the study. The first stage involved purposively selection of four (4) communities due to large number of farmers. The second stage involved a random selection of fifteen (15) farming household from each community given a total of sixty (60). Primary data was collected from smallholder farming households with structured questionnaire. The data collected was analyzed using descriptive and inferential statistics. The result indicated that about 35.5% of the respondents were between the ages of 35 and 44years; about 59.4% had household size of between 6 and 10 persons. The result of the regression analysis reveals the relationships between most of the variables are significant. There is a significant relationship existing between socio-economic characteristics and income generating activities of the rural respondent in the study area at 1%, 5% and 0%. The result of the research reveals that Access to credit was found to be negatively related to performance of income generating activities. It is therefore recommended that micro-credit should be made accessible for the farmers too should form a body (association, group, cooperative) and farmers so that the credit facility can be easily accessible.

Key words: *Income diversification, livelihood, smallholder, farming household*

INTRODUCTION

Income generation simply means gaining or increasing income or money that an individual or business receives in exchange for providing good or service after investing capital for improvement of livelihood and diversification in other business activities. To achieve this, the sources of income must be diversified. Therefore, income diversification if often referred to as a risk management and coping strategies meant to cushion the effect of economic hardships especially in rural area. It can also be seen as an increase in the number of income or the balance among the different sources of income. When linked to farm and off-farm activities in the rural areas, income diversification is often used to describe expansion in the importance of non-crop and non-farm income. Nonfarm income includes both off-farm wage labor and non-farm employment (Adelekan and Omotayo, 2017). Adekunle and Shittu (2014) states that most rural households adopt multiple income generating activities in order to manage risk in terms of weather change or other factors, to meet household consumption needs in the face of high transaction costs, to take advantage of positive externalities among activities, and to respond to diseconomy of scale.

Statement of the Problem

Multiple motives prompt households and individuals in the area to diversify incomes generating activities. The first set of motives comprises of what are traditionally termed push factors, risk reduction, response to diminishing factor returns in any given use such as family labor supply in the presence of land constraints driven by population pressure and fragmented landholdings, reaction to crisis or liquidity constraints, high transactions costs that induce households to self-provision in several goods and services. Similarly, the current challenges affecting farming household dependent on wet season agricultural production which has been insufficient to cover the food and non- food expenditure of the households despite various income generating alternatives in rural communities in addition to increasing male migration to cities which force women to become sole producers of food for the maintenance of the family. To address these issues, the following objectives were achieved. The broad objective assessed income diversification activities among small holder maize farming households while the specific objectives are to;

i. describe the socio-economic characteristics of the small holder maize farming households,

ii. describe the level of access to productive resources,
iii. describe the type of income diversification activities engaged by the farming households; and
iv. determine the factors influencing their income generating activities in the study area.

Justification of the Study

Diversification of Income generating activities is an essential livelihood component that can help in improving the living standard of smallholder farming households. The study investigates various income generating activities and factors influencing income diversification by realizing the potential and opportunities associated with that for better economic engagement among farming households in the study area. The findings can equally be use by policy makers and development partners for intervention toward improvement of living standard, poverty reduction and reduce the migration of youth to cities for employment which exposes them to danger. In addition, researchers can equally use the findings to fill the gap and make contributions to the existing knowledge.

METHODOLOGY

Study Area

The study area has it coordinates as $11^0$42'N and $8^0$33'E with land area of 9911.22 Km^2. It comprises of (15) fifteen wards with an estimated population of 170,891 in 2006 census. The weather and climate of the area play a great role on the agricultural practices and are favorable to large scale cultivation of cereals, groundnuts, beans and vegetables. The people of the area engaged in crop production and off farm activities during wet season and irrigation activities during dry season as their primary occupation while the secondary occupational include civil service, animal husbandry and marketing of agricultural products (Maryam, *et al.*, 2014)

Sampling Techniques

Multi-stage sampling technique was used in selecting the households. The first stage involves purposive selection of four (4) communities due to large number of farmers. The second stage involved random selection of fifteen (15) farming households from each community and lastly a total of one hundred and fifty-six respondents were interviewed from sixty farming households as presented in table1 bellow

Table 1sampling techniques

S/N	Communities	Households Size	Sample Size
1	Bunkure	15	58
2	Shiyye	15	40
3	Kumurya	15	30
4	Gurjiya	15	28
	Total	60	156

Data Collection and Analytical Techniques

Primary data was collected from smallholder farming households with the use of structured questionnaire. Both descriptive and inferential statistics was used in analyzing the data. Objective1, 2 and 3, were analyzed using descriptive statistics while objective 4 was analyzed using and multiple regression. The explicit form was stated below.

$Y = f(x_1, x_2, x_3, x_4, x_5, x_6, x_7 + e)$

Were,

Y = Dependent variable (number of incomes generating activities engaged in)

$X_1 – X_7$ (independent variables)

Were,

X_1 = Age (Years)

X_2 = Marital status (Dummy variable, married 1; otherwise, 0)

X_3 = Household size (Number)

X_4 = Education (Number of years)

X_5 = Access to credit (access 1; no access 0)

X_6 = Years of experience (Number of years)

X_7= Access to productive resources (effective 1; otherwise, 0)

X_8= Farm management practices (effective 1, otherwise 0)

e = Error term

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Maize Farming Households

Age

The results in table 2 shows minimum age of the people engage in other income generating activities was 24 years and the maximum was 65years. The findings also indicated the sustainability of engagement in income generating activities among the farming household with the engagement of people that are in economic productive age as stated by Onu and Edon (2009) younger farmers have the tendency to operate more efficiently than the older ones because they are more agile and energetic to work.

Marital Status

The findings also revealed that majority (81.1%) of the members within the farming household were married. This implies that there were more married individuals involved in income generating activities than those that are single. This could be associated with the need to support and sustain their families.

Household Size

It was found from the results that the minimum household member found in the households that engaged in income generating activities was 1 with maximum of 15 members. The size of the household may contribute positively to their involvement in the various income generating activities. Ibrahim (2002) reported that family size is relevant to any activities engaged by that household in term of production and other income generating activities.

Educational Level

The findings from the study shows that majority (56%) of the people found within the maize farming household can be able to read and write in western language while (44%) can do that in Arabic language. This implies that the entire respondents had different education background and may be the basis for their engagement in various income generating activities. Muhammed *et al*. (2009) in their studies asserted that level of education is expected to influence farmers' adoption of agricultural innovations, involvement in other income generating activities and decisions on various aspects of farming for sustainable agricultural growth.

Level of Access to Productive Resources

The findings from Table 3 reveals that majority (65.4%) of people found within the maize farming household that engaged in other income generating activities beside production of maize had full access to land as one of the resources used in production. Having access to farmland in rural areas may be associated with the fact that the primary activities of the people in rural areas is farming and they can obtain the lands through inheritance. Similarly, 60.9% of them had full access to labor for production of maize. This is attributed to the fact that, farmers within the communities used family labor in their production activities. The findings further revealed that majority of the farmers within the farming households had no access to capital that aid in production activities in which all other activities rely on. This may necessitate the people to engage in to other income generating activities to be able to compliment in their primary production.

Table 2: Socio-Economic Characteristics of Members of Maize Farming Households

Age of maize farming households	Frequency	Percentage
24-30	15	9.40
31-37	50	32.4
38-44	45	28.8

Income Generating Activities Engaged by Members of Maize Farming Households

Result in table 4 shows various income-generating activities engaged by people within the maize-farming households in the areas. It can be seen clearly that most (33.5%) of the members engaged in livestock rearing. The livestock were fed with the left over from farming activities. Others (30.7%) engaged in trading of different commodities. Processing of agricultural product more especially among the women was found to be among the activities engaged by the people. The entire activities engaged by the people have in one way or the other relation with their primary activities (farming).

Table 4: Income Generating Activities Engaged by Maize Farming Households (N= 156)

Income generating activities	Frequency	Percentage
Processing of Agro Products	67	26.1
Trucks Driving	25	9.7
Trading	79	30.7
Livestock Rearing	86	33.5
Total	257	100

Factors Influenced Maize Farming Households to engaged in other Income Generating Activities

Table 5: Factors influenced maize farming household to engaged in other income generating activities

Variables	Coefficient	Standard error	T-value	Sig.
Constant	52.702	3.126	15.58***	0.000
Age	4.221	1.352	3.12**	0.034
Access to Credit	-0.173	0.066	-2.25^{NS}	0.291
Access to Productive Resources	0.105	0.934	0.82^{NS}	0.382
Marital Status	0.091	1.262	0.94^{NS}	0.218
Years of Experience	0.132	0.070	1.77*	0.078
Household Size	0.070	0.151	0.46^{NS}	0.898
Education Status	0.873	0.250	0.34^{NS}	0.695
Farm Management Practices	0.366	0.138	2.67*	0.095
R^2	0.72			
R-Adjusted	0.82			
F-ratio	3.38			

Source: Field survey , 2021 *** = Significant at 1% ** = Significant at 5% * = Significant at 10% NS =Not significant

The result of the regression analysis on factors that influenced maize farming household engagement in other income generating activities reveals that the coefficient of age (4.221) was positive and significant at 5% probability level. This implies that the older the person, the more he/she engaged in other income generating activities. Similarly, the coefficient of years of experience (0.132) was found to be positive at 10% probability level implying that more years of farming experience led to engagement in other income generating activities. In addition, the coefficient (0.366) of good farm management practices was also found to be significant at 10% level of probability. This indicates that good farm management practices enhance better productivity and attracting more income from the harvest resulting to saving and use for engagement in to other business for income generation. The coefficient of multiple determination (R^2) value of 0.72 indicates that about 72% of variations in factors was explained by the explanatory variables while the remaining 28% was due to other factors not specified in the model.

CONCLUSION

Based on the findings of the study, it was concluded that maize-farming households engaged in other income generating activities, which were influence by their age, farming experience and good farm management practices for improvement of their livelihood. It was recommended that government and development partners should improve and support access to credit through the establishment of micro-credit scheme and co-operative banks, which will encourage savings and lend loans at low interest rates and establish skills acquisition and entrepreneurial centers where young adults could be trained on the skills and operations of different non-farm activities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Finance in terms of credit plays central role in any given investment especially in agriculture and a catalyst for improving the entire agricultural value chain. The purpose of this study was to investigate the effects of micro-credit on vegetable production in Ido Local Government Area of Oyo State. Specifically, the study described the socio-economic characteristics of the respondents, identified the sources of micro-credit that were available to vegetable farmers and examined the effect of micro-credit finance on vegetable farmers' in the study area. A multi stage sampling technique was used in selecting 110 respondents for the study. The data-collecting instrument used for the study was interview schedule. The data were analyzed using frequency and percentages, Mean and linear regression. The study revealed that majority of the vegetable farmers were between the ages of 41and 50 years. They realised annual income ranging from ₦101,000 to ₦200,000. It was also established in the study that there were various sources of fund available to vegetable farmers such as micro finance banks, cooperative societies, and bank of agriculture amongst others. Financing of vegetable production maximally (WMS= 5.0) was one of positive effects of micro finance while loss of valuable properties due to bankruptcy (WMS= 5.0) was one of negative effects of micro finance. The study concluded that vegetable farmers do enjoy this micro finance but effect on farming operations is not encouraging as expected. The study therefore recommended amongst others that programmes that will lead to increase in productivity and considerable policies that will enhance accessibility of loans should be in place by the government.

Keywords: *Micro-credit, vegetable production, effects and farmers.*

INTRODUCTION

Micro-credit is a common form of microfinance that involves an extremely small loan given to an individual to help them become self-employed or grow a small business (Olajide *et al.,* 2012). Micro-credit is also known as "micro lending" or "microloan." The importance of agricultural credit to the overall welfare of farmers is that credit is required to purchase improved technologies like seeds, fertilizers, herbicides, pesticides, agricultural machinery, equipment etc needed for increased productivity and the overall expansion of the farm. Credit is needed to pay salaries of regular staff and wages of farm labour hired for major seasonal tasks. The role of agricultural credit is not restricted to production alone (Boateng and Oduro, 2013). Adegeye and Dittoh (2015) observed that consumption credit, especially to small farmers is a necessity as it provides the necessary impetus to increase labour productivity on farms as well as feeding money before the outright harvesting of crops. Agriculture's contribution to the development process of providing food, capital and labour to the industrial sector and increasing the size of products at the international market is hinged on the availability of credit to farmers (Ikpi and Olayemi, 1994). However, In Nigeria, the government has been a major player in micro-finance services. Government intervention has been due to a lack of modern technology in agriculture, limited savings capacity and the predominance of informal service providers as the sole source of capital. The Nigerian Agricultural and Cooperative Bank (NACB) and other credit enhancing schemes such as the Nigerian Agricultural Credit Guarantee Scheme (NACGS), Nigerian Agricultural Insurance Scheme (NAIS) and the Family Economic Advancement Program (FEAP) are important instruments designed to provide rural and poor economic agents with access to credit (Olawuyi *et al.,* 2010). Poor population possess the capacity to implement income-generating activities but that the main limitation to their initiative is the lack of access to capital. It is based on this background that the study examined the effect of micro credit finance on vegetable production in Ido Local Government Area of Oyo State while specific objectives were to: describe the socio-economic characteristics of the vegetable farmers, identify the sources of micro-credit that were available to vegetable farmers and examine the effect of micro-credit finance on vegetable production in the study area.

METHODOLOGY

Ido is a Local Government Area in Oyo State, Nigeria. Its headquarters is in the town of Ido. It has an area of 986 km²; with and an estimated population for year 2022 to be 148,800 (CityPopulation, 2023). The targeted population of study were the entire vegetable farmers in Ido Local Government. A multi stage sampling technique was used in selecting respondents from the study area. According to Independent National Electoral Commission (INEC), Ido Local Government has Ten (10) wards. Hence, at stage 1, all the ten wards were identified and selected for the study. At stage 2, the number of polling units were collated and identified in each of the wards as follows; Ward 1: Six (6) polling units, Ward 2: Twelve (12) polling units**,** Ward 3; Eight (8) polling units**,** Ward 4: Forty Eight (48) polling units**,** Ward 5: Eight (8) polling units**,** Ward 6: Ten (10) polling units**,** Ward 7: Twenty two (22) polling units**,** Ward 8: Eleven (11) polling units**,** Ward 9: Thirty Nine (39) polling units and **w**ard 10: Thirty One (31) polling units**.** Hence, total number of one hundred and ninety five (195) polling units were identified. At stage 3, based on major crop cultivated, vegetable farmers were purposively selected in each of the 195 polling units. At stage 4, simple random sampling technique was used to select 10% of vegetable farmers selected in each of the 195 polling units to arrive at 110 respondents used for the study. Data collected were analysed using both descriptive and inferential statistics such as frequency and percentages and hypothesis was analyzed using linear regression.

RESULTS AND DISCUSSION

Table 1 revealed that the mean age of the respondents was 45years. This result is similar to a study conducted by Adeyemi and Ogazi (2013) where the mean age was 45.4 years and respondents were said to be in their active age. The Table further revealed that 60.9% were female. This implies that vegetable production was female dominated occupation in the area. Majority (72.7%) of the respondents were married, 11.8% were widow, 8.2% were single and 2.7% were separated. This implies that there is likelihood of family labour availability. About 73.2% of the respondents had secondary school education while 23.6% had no formal education and 3.6% had tertiary education. This implies that majority of vegetable farmers in the study area had one form of education or the other which could assist them to understand what innovation to adopt and practice. Table 1 also revealed that 54.6% were realizing ₦101,000 - ₦200,000. However, 19.6% of the respondents were making ₦51,000 – ₦100,000, while 8.2% were earning ₦301,000 – ₦400,000 and 7.3% made less than ₦50,000 but only 4.5% realized over ₦400,000 as their annual income from vegetable production. This implies that vegetable farmers were realizing various degrees of money from sales of vegetables.

Table 1: Distribution of respondents according to Socio-economic characteristics

Socioeconomic characteristics	Frequency	Percentage	Mean
Age (Years)			
20 -30	11	10.0	
31 -40	32	29.1	
41 – 50	57	51.8	45 years

Sources of micro-credit available

Data in Table 2 showed the sources of micro-credit available to the vegetable farmers in the study area. The results revealed that all (100%) the respondents claimed that microfinance banks and cooperative societies were readily available sources of micro-credit for their vegetable production. However, 96.4%, 81.8%, and 54.6% asserted that thrifts/contributions, family and friends and informal financial institutions, respectively were the readily available sources of fund. This implies that there were various sources of fund available for them for their farming enterprise. This corroborate Olaitan's (2011) position that universal/development banks, specialized institutions and micro finance banks were the major sources of micro credit.

Table 2: Distribution of Respondents according to sources of micro-credits available

Sources of microcredit *	Yes	No
Bank of agriculture	31(28.2)	79 (71.8)
Commercial banks	10 (9.1)	100 (90.9)
Microfinance banks	110 (100)	0 (0.0)

Effects of microcredit finance on vegetable production

Data in Table 3 revealed positive or negative outcome on vegetable production in one way or the other. It was observed that microcredit financed vegetable production maximally as it was ranked 1st. This is in consonant with Shepher (2013) that credit has been recognized as an essential tool for promoting small and medium scale enterprises as well as agricultural production. Loss of valuable properties was ranked 2nd. High interest rate and access to better farming facilities were ranked 3rd and 4th respectively while procurement and sufficient use of inputs was ranked 5th amongst others.

Table 3: Distribution of respondents according to effects of microcredit finance on vegetable production

Effects of microcredit *	**SA**	**A**	**U**	**D**	**SD**	**Wms**	**Ranks**
Helps to finance vegetable production maximally	110	0	0	0	0	5.0	1st
Loss of valuable properties due to bankruptcy	108	1	1	0	0	4.97	2nd
Attracts high interest rates	106	2	1	1	0	4.94	3rd
Helps in procuring and sufficient use of inputs	102	0	6	0	2	4.82	5th
Access to better farming facilities/equipment	100	5	1	2	2	4.81	4th
Assists vegetable farmers to finance farming operations	99	2	6	1	2	4.77	6th
Increased vegetable production	94	10	2	3	1	4.76	7th
Ensures all year round vegetable production	96	4	3	5	2	4.74	8th
Increase in monthly/annual income	82	8	11	3	6	4.43	9th
Better access to education	23	61	16	9	1	3.87	10th
Makes farmers to become perpetual debtors	0	90	12	6	2	3.73	12th

Enhances households' varietal consumption	10	9	41	10	40	2.45	15th

Source: Field survey, 2023 * Multiple responses; WMS = Weighted Mean Score

Data in Table 4 established a significant relationship between farming experience (0.00218 **), income (0.01566*) and effect of micro-credit on vegetable production. Farming experience was significant at 0.01 level and income (0.01566*) was significant at 0.05 level. This implies that farming experience and income contributed to micro-credit financing of vegetable production.

CONCLUSION

Based on the findings of the study, it was concluded that Micro-credit is a life wire for vegetable farmers but farmers' accessibility to other micro credit finance institutions other than cooperative societies needs to be worked on. It was recommended that provision of educational programmes and accessible credit schemes that can facilitate vegetable production should be encouraged. Programmes that will lead to increase in productivity and considerable policies that will enhance accessibility of loans should be put in place. Having realized the effect of micro-credit finance on vegetable farmers, it is highly necessary for all extension agent to encourage the vegetables farmers to join cooperative societies in order to get credit facilities to finance their farming operation. Government should interfere on high interest rate being charged by Micro Credit Institutions.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was on the socio-economic characters of the beneficiaries of BOA agricultural loan and the challenges facing them in Benue state, Nigeria. The study used multistage sampling technique to select 100 respondents and data gotten was analysed with the use of descriptive statistics. Results indicate that the respondents were of active age, male dominated, married, educated with vast experience in farming, large household size, and small scale. Socio-economic characteristics of beneficiaries have great influence on their quest for loan and beneficiaries are faced with myriad of problems. The study recommends the reduction of interest rate to single digit, effective supervision of the credit beneficiaries, and timely disbursement of funds among other things.
Keywords: *BOA, agricultural credit, beneficiaries and loan*

INTRODUCTION
Agriculture in developing countries is characterized by low farm incomes, low level of capacity to satisfy the food and fibre needs of the country and primitive techniques of production. Against the background of the current global food crisis resulting from escalating oil prices and increasing use of food crops as bio-fuels by the industrialized countries, there is need for sustainable agricultural practice and policies that would elevate the nation to the status of self -reliance in food production (Ogah, 2011). Agriculture in the country is under threat due to neglect of the farmers, lack of adequate information and inadequate infrastructure for farming activities and lack of credit facilities which have retarded farmer's effort. (Ogah, 2011). Dwindling budgetary allocation from both federal and state government which is less than 3% of the national budget and the lack of support by the government is part of what is making farming unattractive to vast majority of farmers.

In most developing countries and Nigeria in particular where majority of the farmers are small-holders, the task of agricultural development demands the adoption of new technologies such as the use of improved seeds, fertilizers, herbicides and tractors. To actualise this requires a significant degree of financial commitment. However, because the average Nigerian farmer is poor, they do not have enough capital to adopt these new technologies, the only alternative left for them therefore is credit (Yakubu, 2002). Access to credit will alleviate the capital constraints on agricultural households as expenditures on agricultural inputs must be incurred during the planting and growth periods of crops, while returns are received only after the harvest several months later, therefore to finance the purchase of inputs, the farm household must either dip into their savings or obtain credit (Ogah, 2011).

Realizing the critical nature of agriculture and credit, the Federal Government of Nigeria came up with the strategy of transforming the economy on improving the rural agriculture. One of the measures is the establishment of the Nigerian Agricultural Cooperative and Rural Development Bank (NACRDB) now bank of agriculture (BOA), the single largest agricultural development financial institution in Nigeria which is one of the efforts of the federal government of Nigeria aimed at boosting the delivery of agriculture macro and micro credit to improve agricultural development thereby alleviating poverty among the rural and urban poor Nigerians.

Small scale farmers involved in processing, storage and marketing are faced with enormous difficulties in acquiring credit facilities such as late disbursement of agricultural loans, non-fulfilment of security collateral requirement, diversion of funds by banks management for non-agricultural purposes and inability of the banks to reach small scale farmers at the grass root. Lack of savings and capital make it difficult for many poor farmers to become self-reliant and to undertake productive employment generating activities to increase their income and productivity. Providing credit seems to be a way to generate self- employment opportunities for the poor farmers. Ahmad (2007) had stressed the need for the provision and proper use of credit for small holder to alleviate poverty in in their midst and prevent social unrest. The situation is quite apt for Nigeria where past government policies were highly skewed in favour of investment in construction, transport and commercialization sectors with higher returns to the detriment of the primary sectors with slow or low returns. The result is huge accumulated deficit in funding/ investment needs for agriculture in order to stimulate growth.

This action is also compounded by liberal import tariff policies, weakened manpower status of the rural agriculture sector which encourage rural urban migration, expansion of monetary supply with its attendant inflationary pressure on the economy all of which combine with above to retard progress in the agricultural sector, perpetuate poverty, ill health, poorly educated populace of Nigeria leaving credit as the only option available. Researchers like Awotodunbo, (2008), Olagunju, (2007) and Sisay, (2008) focused on financial constraints to small scale farming, impact of credit use on resource productivity and determinants of small holder farmer's access to formal credit thereby creating a vacuum on the socio-economic characteristics of the beneficiaries of bank of agriculture agricultural credit in Benue state, Nigeria, which is the gap to be filled. The study has the following objectives: to describe the socio-economic characteristics of the beneficiaries of BOA credit and the constraints they faced.

METHODOLOGY

The study was conducted in Makurdi Local Government Area of Benue State, Nigeria. The area was chosen because of the location of BOA in the area. It lies between latitude $7^0 38'$ N and $7^0 50'$N and between longitude $8^0 54'$ E and $8^0 38'$E with usual temperature of 32.5 degree cencius. It has an estimated population of 300,377 (NPC, 2006) and covers a land mark of 835,624km sq. It experiences a typical climate with two distinct seasons, rainy season, which lasts between April and October and the dry season which is characterized by harmattan dry wind from November to March. The area is inhabited by the Tivs, Idomas, Igedes, Jukuns, and other ethnic groups like Hausas, Yorubas, Ibos, Anglo, Akwenyas, Etulos among others. The people are predominantly farmers who engage in agriculture and grow wide range of crops like yam, maize, sorghum, cassava, sweet potatoes, rice soybeans etc. The area was chosen because of the activities of the cooperatives.

A multi-stage sampling technique was used in the selection of the small scale farmers that formed the sample. In the first place, five council wards were selected by means of simple random sampling, in the second stage, 20 small scale farmers from each of the council ward were selected proportionately by means of random sampling to give the total of 100 respondents for the study. Data were collected from primary source with the use of questionnaire to illicit the needed information for the study. The data collected were analysed with the use of descriptive statistics like frequency distribution, percentages, mean and the use of tables.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Beneficiaries of BOA Agricultural Credit

The results of the socio-economic variables of the respondents are presented in Table 1. From the results, most of the beneficiaries (43%) were in the age bracket of 41-50 years. This is not unexpected as population within this age limit is an active and productive population that can engage in farming activities. This corroborates the findings of Ogah et al (2021) that this age group is a productive population. The mean age of 43 years is an indication that BOA like other financial institutions will only extend credit to agile and productive population. From the analysis, most of the beneficiaries are males (81%) while females are 19%. As noted by John, (2015), females are under the direct legacy of their husbands and therefore cannot acquire credit from the banks without the approval of their husbands. From the results, 98% of the respondents have one of education or the other. This is in important as the loan terms will have to be read and understood. Specifically, 18% have primary education, 35% have secondary education, 45% have tertiary education while only 2% do not have any formal education. This is in line with the findings of Ogah et al (2018) that most loan beneficiaries in Benue state are educated. Further scrutiny on Table 1 indicates that 9% of the beneficiaries have been farming for less than 5 years, those with 5-10 years of experience are 19% while 33% have been farming for more than 21 years. The mean farming experience of 13 years is an indication that the beneficiaries are not novice in the use of credit. This agrees with the findings of Ogah et al (2017). From Table 1, the mean household size is 7 persons for the beneficiaries this is large and will help in farming business and serves as support to the agricultural credit. Ogah et al (2021) have noted large household size for the farming communities in Nigeria. From Table1, it can be seen that most of the beneficiaries are small holder with 78% cultivating 1-3 hectares. The mean farm size of 1.5 hectares is a testament on why agricultural credit is needed to support their production. Collaborating this, Ogah et al (2018) asserted that majority of Nigeria farmers are small holders. Analysis from Table 1 revealed that most of the beneficiaries are married and this constitutes 75%. In other categories, the singles are 11%, divorced 8% and widowed 6%. The high proportion of the married is an indication that they are responsible and will make use of the credit judiciously. Under African culture as noted by Ogah et al (2017), marriage is a sign of responsible individual and maturity and therefore people that are married command more respect and can access credit easily.

Constraints faced by Beneficiaries in Obtaining Agricultural Credit from BOA

Table 2 provides detail analysis of constraints faced by the respondents in their quest for agricultural credit. From Table 2, the high-ranking problem is the interest rate which is 90%. Most of the respondents complained of high interest rate as the rate is double digit instead of single digit. The matter is made worse with the increasing inflationary rate which washed off the value of the naira. Most of them advocate for single digit rate for them to break even This collaborates the findings of Thirumalaisany *et al* (2016) who reported high interest rate as problem facing farmers. Another serious constraint faced by the beneficiaries in the study area was delay in approval of loan as the loan is not given in time to meet up with the farming activities. The study revealed that 80% of the respondents complained of this problem.

The issue here is that sometimes the farming season might have gone before the loan is disbursed and therefore farmers could not invest the loan on agricultural activities and will have to wait till another farming season. This issue often leads to diversion of loan for other use. This agrees with the findings of Ogah, (2011) who noted that agricultural credit farmers in Katsina and Kaduna states, Nigeria have problem of delay disbursement of loan. Another issue of concern to the beneficiaries is the problem of having to meet the minimum saving amount before the credit is disbursed. As most of the farmers are small scale there is barely enough to eat not to talk of saving to meet the minimum saving required by the bank. From the analysis, 65% of the respondents had this problem. Other problem is lack of supervision by the bank staff which constitutes 52%. According to the beneficiaries, they are often left unattended to and no supervision by the bank staff to ascertain whether the credit has been utilised or not. This could actually lead to diversion of the loan funds. This is in agreement with the findings of Ogah, (2011). Other concerns are insufficient amount which is 48%, short repayment period 42%, administrative bottleneck 37% and too many trips to the bank which constitutes 28% responses.

Table 2 Distribution of Respondents Based on Constraints Faced in the Study Area

Problem	Frequency	Percentage
High rate of interest	90	90
Delay in loan approval	80	80
Minimum saving requirement	65	65
Lack of supervision	52	52
Insufficient amount	48	48
Short repayment period	42	42
Administrative bottle neck	37	37
Too many trips to bank	28	28

Multiple responses, Source: Field survey, 2022

CONCLUSION AND RECOMMENDATIONS

Socio-economic characteristics of BOA agricultural credit beneficiaries have great influence in loan disbursement as BOA tends to skewed funds disbursement towards active and productive population. The beneficiaries of the agricultural credit are faced with myriad of problems which could militate against effective use of the agricultural credit. The study recommends the reduction of interest rate to single digit, effective supervision of the credit beneficiaries, timely disbursement of funds to meet up with farming season and smoothening of administrative procedures for the beneficiaries. Having these in place, BOA will rightly be placed to live up to the expectations of Nigeria farmers.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study assessed the degree of commercialization of selected staple crops among farming households in Southern Agricultural Zone of Borno State, Nigeria. A simple random sampling technique was used to select 180 respondents for the study. Data collected were analyzed using descriptive and Double-Hurdle Model. Results revealed that majority (78.9%) of the respondents were male while only 21.1% were female. A large proportion (64.4%) of the respondents were within the age bracket of 31-50 years. most (51.1%) of them had between 6-10 persons per household. Many of the respondents (36.7%) had between 21-30 years of farming experience; majority (60.0%) of them were educated and most (85.6%) of the farmers did not belong to any cooperative association while More than half of the farmers (52.8%) hard between1-2 hectares of farm land. The most commercialized crop was cowpea with a commercialization index of 0.84. This was followed by groundnut (0.74) and maize (0.73). The least commercialized crop was rice with an index of 0.65. The variables that affected commercialization of smallholder staple crop were marital status, household size, and membership of farmers association and were significant at 1%, 5%, and 1% respectively. Constraints to staple crop commercialization among farmers were poor market information, low output prices, inadequate transportation facilities, unfavourable contract farming agreements, and high post-harvest losses. Conclusively, cowpea enterprise has the highest commercialization index (0.85), while rice has the least (0.65). It was recommended that more extension agents be trained so that more farmers could be reached, and good storage facility should be made available to reduce post-harvest losses.
Keywords: *Commercialization, Staple crops, Smallholders*

INTRODUCTION
According to conventional wisdom, the transition from subsistence (or semi-subsistence) to commercial agriculture represents a key ingredient for the economic development of low-income countries. By exploiting comparative advantages, food crop commercialization enhances trade and efficiency, leading to economic growth and welfare improvement at the national level. This is further expected to initiate a virtuous cycle which raises household income, thus improving consumption, food security and nutritional outcomes inside rural households (Carletto, 2017). The Agricultural sector grew by 4.88% in third quarter of 2016, and recorded 26.06% in 2020, suggesting immense unrealized potentials (Adepoju, 2018). Participation in commercialized agriculture holds considerable potential for unlocking suitable opportunity necessary for providing better income and sustainable livelihood for small scale farmers (Adenegan, 2011). Commercialization among smallholder farmer in developing countries has often been signalled as being a vital tool for the upliftment of countries economic condition and food security of the farmer's household (Dioula, 2013).
Agriculture continues to be a strategic sector in the development of Nigeria where smallholder farming is the dominant livelihood activity for the rural areas (FAO, 2018). Moreover, the rate of agricultural growth depends on the speed with which subsistence oriented production system is transformed into a market orientated production system (Diro, 2016). Consequently, agricultural commercialization remains a widely pursued approach in development projects to improve food security in low-income countries (Linderhof, 2019).). By so doing, it does not only bring the welfare benefits of market-based exchange economies to this group, but is central to an inclusive development process (World Development Report, 2016; Arias, 2013; Gezachew, 2018). Despite the importance of smallholders and commercialization in inconomic and income generation, the traditional system of agriculture stii prevails with it's characteristics of low technological base, high reliance on manual labor hence low resource productivity. Bridging the gap of paucity of information about the degree of commercialization among smallholder crop farmers necessitated this study. The objective was to assess the degree of

commercialization of selected staple crops production among farming household in southern agricultural Zone of Borno state, Nigeria.

METHODOLOGY

The study was conducted in selected local Government areas of southern Agricultural Zone of Borno State, Nigeria. The selected local government areas were Askira/Uba, Biu and Hawul because most farmers in the selected areas grow and market the selected crops. Borno State is lying within latitude 11. 8846^{0}N, 11.4959.99^{0}N and longitudes 13.1520^0'E and 13.900^{0}E, of the Greenwich Meridian, which has an area of 61,435sqkm. The rainfall is highly seasonal with marked wet and dry seasons.. Normally the rainy season begins in June and terminates in September or early October (between 4 - 5 months) while the dry season begins in October and terminates in May (between 7-8 months).

A simple technique was used for the study. Purposive selection of three (3) LGA Areas from the nine LGA in the study area. Three districts each LGAs and two villages from each districts were purposively selected. Ten (10) registered farmers were randomly selected from each villages making a total number of One hundred and eighty (180) respondents.

Data Analysis

Descriptive statistics such as frequency distribution tables, means, percentages and standard deviations, Household crop output commercialization index (HCOCI) and Craig's double hurdle model were used.

The Craig's double hurdle regression models were specified as follows:

$$P(y=0|x)=1-\mu(x\alpha)$$

$$\log(y|x,0)=1(y=0)\ln\left[\mu,\left(\frac{x\beta}{\delta}\right)\right]+1(y>0)\ln\left|\frac{\mu(x\beta)}{\mu\left(\frac{x\beta}{\delta}\right)}\right|+\ln\left[\frac{1}{\delta\sqrt{2\pi}}\exp(-\frac{1}{2\delta^2}(y-x\delta^2))\right]$$

HCOCI = Household crop output (production) commercialization index

a = gross value of crop sale

b = gross crop production value Y =Participation for the crops production commercialization (maize, rice, cowpea and groundnuts) (=1 if participated in the production, 0 otherwise)

RESULTS AND DISCUSSION

Socio-economic Characteristics of Respondents

Socioeconomic Characteristics of the Respondents are Presented and Discussed as Follows:

Age: The information from table1 revealed that larger proportion (32.2%) of the respondents were within the age bracket of 31-40 years. The mean age was approximately 42 years implying that the respondents were active individuals of economic phase.

Gender: Majority (78.9%) of the respondents were male while only 21.1% were female. This implies that the proportion of male-headed households is higher than that of female-headed households...

Marital Status

The marital status result revealed that majority (75.0%) of the respondents were married, while 20.6% were single. Similarly, 3.3%, and 1.1% were widowed and divorced respectively.

Farming Experience

Shows that larger proportion of the respondents (36.7%) had between 21-30 years farming experience, while 28.9% had between 11-20 years of farming experience.

Years of Formal Education

Information on the respondents' years of formal education shows that majority (60.0%) had spent between 13-18 years in formal education. This implies that the respondents were literate and hence, can read and write

Level of Commercialization of Selected Crops

The level of commercialization of selected crop is shown in Table 2 showed that the most commercialized crop was cowpea with a commercialization index of 0.84. This may be due to the high price and income generated in the sale of this crop compared to other crops produced in the study area. This was followed by groundnut (0.74) and maize (0.73). The least commercialized crop was rice with an index of 0.65.

Table 2: Level of Commercialization of Selected Crops

Gross Values	**Maize (₦)**	**Groundnut (₦)**	**Cowpea (₦)**	**Rice (₦)**
Gross value of Crops sold (a)	735,742.62	175,417.78	198,822.69	106,700.13

Determinants of Staple Crop Commercialization Decision of Farmers

The variables that affect commercialization of staple crop were determined using the Double-Hurdle Regression Analysis. Table 3 shows a log likelihood of 73.994626 and a chi-square of 47.54 both at 1 percent level of significance.. From the results, marital status (-0.0589738), household size (-0.0100916), and membership of farmers association (-0.1436261) were the only significant variables influencing household commercialization decision at 1%, 5%and 1% level of significant respectively.

Table 3 Determinants of Factors that Influence Commercialization Decision of Farmers

Variable	Coefficient	Std. Err.	z- Statistic	Prob.

Pseudo R^2 = 0.7683.

CONCLUSION AND RECOMMENDATIONS

Based on the findings of this study, it can be concluded that the level of commercialization of selected crops was high with cowpea having the highest commercialization index. Socioeconomic characteristics of the farmers such as their marital status, household size, and farmers association strongly influenced commercialization decision of the respondents in the study area. Based on the findings, the following recommendations were made; To mitigate post-harvest losses, farmers need to be provided with enough and good storage facilities to ensure that food crops produced in excess are stored in order to make it available throughout the year at an affordable prices.Supports in forms of credit facilities and input subsidy be provided to the farmers so that they can produce large quantities for commercialization. Various governments and NGOs concerned should assist in providing an accessible road network that can help farmers move their produce easily.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Rice is an important staple food crop and Nigeria has the capacity to be self-sufficient in rice production. However, production capacity is far below national requirements; domestic production and enterprise profitability are critically constrained. Therefore, this study analyzed profitability and rice productivity among smallholder farmers in Riyom, Plateau State, Nigeria. For this study, 108 respondents were selected using a multistage sampling method. Collected data were analyzed using farm budgeting and total factor productivity techniques. The estimated total and net returns were respectively ₦243,200 and ₦103,700 per hectare; indicating a profitable enterprise, with potentials for improved economic prospects. Additionally, the benefit-cost ratio was estimated to be 0.74. Further, the majority of rice farmers (53.7%), whose TFP indices were below the optimal scale, were producing sub-optimally; due to an inefficient mix of inputs and the high cost of factors of production. Therefore, this study recommends improved access to agricultural credit and farm capital; improved cooperative activities, input supply and subsidies, policy modifications, development and adoption of agricultural production technology, improved extension service delivery and farmer sensitization.
Keywords: *Benefit-cost, productivity index, small holder farmers, rice production*

INTRODUCTION
Rice belongs to the genus *Oryza* and the family *Gramineae*. Rice is the world's important staple food crop. Rice is mainly produced and consumed by small-scale farmers in low income and developing countries such as Nigeria (NBS, 2012). Rice (*Oryza spp*.) is the fourth major cereal in Nigeria after sorghum, millet, and maize in terms of farm output and cultivated land area (RIMIDAN, 2012; Shehu *et al*., 2007). Rice is a basic food for most households in sub-Saharan Africa and Nigeria in particular. A shift in the demand for rice has changed the perception of it being a luxury food to a major source of calories for most households in Nigeria (Osawe *et al.*, 2017). The leading world producers of rice are Japan, Indonesia, Taiwan and Brazil (FAO, 2016; FAOSTAT, 2013). In Africa and particularly sub-Saharan Africa, Nigeria is the largest producer of rice, producing an average of 3.2million tonnes of rice (Obianefo *et al.*, 2019). Rice cultivation is wide spread within the country extending from the northern to southern zones with most rice grown in the eastern and middle belt of the country. Nigeria has the capacity to be self-sufficient in rice production. Virtually all ecologies in the country are suitable for rice cultivation. Rice in Nigeria is typically grown all year round in Nigeria, either as rainfed or by irrigation. In Nigeria rain fed lowland system account for approximately 25% of the harvested area: rain fed upland system account for 50%; irrigated system account for 16%; and deep water or mangrove swamp account for less than 10% of the total rice production area (Obianefo *et al.,* 2019). Moreover, there are over 20 species of rice, however, only two are cultivated types, the rest are wild species. The cultivated species are *oryza sativa* and *oryza glaberrima* (FAO, 2016; FAOSTAT, 2013). The two species are believed to have originated separately: *Oryza sativa* from Asia (India and China), while *oryza glaberrima* from Africa (West Africa) (FAOSTAT, 2013; RIMIDAN, 2012; Shehu *et al*., 2007).

Although rice contributes a significant proportion of the food requirements of most households, the production capacity is far below national requirements; and despite the rise in cultivated area, demand for rice relative to other major staple food continuous to rise above the level of domestic production; with consumption broadening across all socio-economic classes (Osawe *et al.*, 2017). In Nigeria, rice output is low and declining; the decline is traceable to inefficient use of farm resources, labour shortages and scarcity and high cost of farm inputs, poor management practices and inadequate farm capital. Domestic production is also constrained by low input and poor crop management techniques by small-scale farmers as well as inadequate water control techniques. To meet the increasing demand, the importation of milled rice was used to bridge the gap between domestic demands and supply (CBN, 2012). A major reason for this trend was adduced to a sizable rice yield gap between attainable and actual farm yield. Nigeria has depended heavily on imported rice to meet her consumption needs and has become the world's largest importers of rice, with well over ₦150.15billion expended annually on rice importation; indicative of the declining self-sufficiency in rice production (CBN, 2012). Small-scale farmers have attempted in achieving efficient rice production but lack modern inputs and capital to exploit the economic potentials of their farmlands. Additionally, most farmers do not keep farm records, which affects research aimed at assessing the profitability of agricultural production by comparing the cost of input and output level (Onuwa *et al*., 2022). Thus, it becomes imperative to analyze the profitability and index of rice productivity in Riyom, Plateau State, Nigeria. This study will provide useful recommendations, which will go a long way to facilitate improved yield in rice production. Based on the foregoing, this study aims to provide answers to the following research questions: (a) Is rice production profitable? (b) What is the index of rice productivity?

METHODOLOGY

The Study Area

The study was conducted in Ganawuri district, Riyom Local Government Area (LGA) of Plateau State. The LGA has a total land area of about 807km^2 (NBS, 2012). Riyom LGA consists of three (3) districts namely Riyom, Bachit and Ganawuri, with two major ethnic groups (Berom and Aten). The LGA is located at Northern Guinea savannah, with coordinates at longitude 9^{o}38'N and latitude 8^{o}46'E (NBS, 2012). Annual rainfall varies between 1000mm and 2000mm, with a mean temperature of 25^{o}C. Most of its population are farmers, cultivating food crops such as rice, maize, fonio, Irish potatoes, cabbage, etc.

Sampling Procedure

Multistage sampling procedure was used to draw sample for the study area. In the first stage, Riyom LGA was purposively selected, based on the intensity of rice production in the area. The selection was done to reflect the most typical situation for rice based farming systems. In the second stage, Ganawuri district was purposively selected. This is the major rice producing district in the study area. The third stage involved random selection of respondents from a list of rice farmers complied by trained enumerators from the selected district. In all, 108 respondents were selected for the purpose of this study and validated using the raosoft sample size calculator with a confidence level of 95% and a margin of error of 10% adapted from Onuwa *et al*. (2022).

Method of Data Collection

Structured questionnaires designed in line with the objectives of the study were used for data collection.

Analytical Techniques

Primary data collected were evaluated using farm budgeting model and Total Factor Productivity (TFP) technique. The farm budget technique (costs and returns analysis) was used to determine the costs, returns and profitability of rice production in the area. The Total Factor Productivity (TFP) technique was used to estimate agricultural productivity by comparing an index of agricultural inputs to an index of outputs. Therefore, a combination of statistical and budgetary techniques was used in the analysis of the collected data as adapted from (Onuwa and Wuyep, 2023; Onuwa, 2022).

Farm Budget (Profitability) Analysis

The farm budgeting models used are presented in Equations (1), (2), (3) and (4), respectively as adapted from Onuwa and Wuyep (2023):

NR=TR-TC …….. (1)

Where: NFI= net return; TR=Total return (₦); and TC=Total cost (₦)

$TR = P_Y.Y_I$ …….. (2)

Where: P_Y = output unit price (₦); and Y_I = output quantity (kg)

Total Cost (TC) =TVC+TFC …….. (3)

Where: TC = Total cost (₦); TVC=total variable cost (₦); and TFC=total fixed cost (₦)

$TVC = P_X. X_I$ …….. (4)

Where: P_X = variable input unit price (kg or liter) [Seed (₦), fertilizer (₦), labour cost (₦), and agrochemicals (₦)]; and X_I = Input quantity (kg or liter); and TFC = Total fixed cost (₦) (farm tools and equipment's). To further substantiate the profitability of this enterprise, the benefit-cost ratio (BCR) was also estimated and specified in Equations (5), as adapted from (Onuwa *et al*., 2022; Onuwa, 2022):

Benefit-cost ratio (BCR) = Net return /Total cost …….. (5)

Total Factor Productivity

By comparing an index of agricultural outputs to an index of agricultural inputs, total factor productivity (TFP) can be used to calculate agricultural productivity. This can be computed following Onuwa and Wuyep (2023) in equation (6):

$$\frac{TFP}{TVC}=\frac{Y}{TVC}=\frac{Y}{\sum PiXi} \text{ ……… (6)}$$

Where: Y = quantity of output; TFP = Total Factor Productivity; TVC = total variable cost; Pi = unit price of the ith variable input; and Xi = quantity of ith variable input. This method does not take into account the role of total fixed cost (TFC) because it does not affect the conditions for resource-use efficiency or profit maximization. The TFP index can be interpreted as follows:

(< 0.1) = Sub-optimal; (1.0 – 1.09) = Optimal; and (≥ 1.10) Super-optimal.

RESULTS AND DISCUSSION

Costs and Return of Rice Production

The cost and returns analysis in Table 1 shows that the total cost of producing rice per hectare in the study area was ₦ 139,500,while the average total and net return were ₦243,200/ha and ₦103,700/ha, respectively. The components of variable costs comprised 85.7% of the total production cost, while total fixed cost components comprised 14.3%. Also, the estimated benefit cost ratio was 0.74 (BCR<1), which indicates that rice production is a relatively profitable enterprise in the study area. Thus, the farmer earned ₦0.74 on every naira spent on rice production. Hence, rice production in the study area is a very viable farm enterprise with prospects of improved economic potentials. This conforms to Onuwa and Wuyep (2023); Onuwa (2022); Obianefo *et al.* (2019) who, in their respective studies on agricultural profitability, reported outcomes that were comparable.

Table 1: Cost and returns analysis for rice production (₦/ha)

Variables	Amount (₦/ha)	%
A. Returns		
(i)Total output (tonnes/ha): 1.9		
(ii)Price (₦/ton):128,000		
(iii) Total return = ₦243,200		
B. Variable cost:		
(i) Fertilizer	55,000	39.4
(ii) Agrochemicals	32,000	23
(iii) Seed	14,500	10.4
(iv) labour	18,000	12.9
Total Variable cost	119,500	85.7
C. Fixed cost		
(i) Farm tools & equipment	20,000	
Total fixed cost	20,000	14.3
D. Total cost	139,500	100
E. Net return	103,700	
F. Benefit-cost ratio:	0.74	

Source: Field survey, 2016

Total Factor Productivity Analysis

According to the summary statistics of the total factor productivity result in Table 2, the majority of rice farmers (53.7%) were producing less than optimally because their TFP indices were below the optimal scale. This indicates that the production process did not allocate the right mix of inputs. According to their TFP indices, 31.5% were optimally productive, while 14.8% were found to be super-optimally productive because their TFP indices were higher than the optimal scale. The low output in the various cucumber farms in the study area could be attributed to a sub-optimal input mix and high production input costs. This corroborates with Onuwa *et al.* (2022); Cechura *et al.* (2014) whose studies on agricultural productivity profiles yielded comparable findings.

Table 2: Distribution based on total factor productivity of rice farmers

Productivity index	Frequency	Percentage
Sub-optima (<1.00)	58	53.7
Optima(1.00-1.09)	34	31.5
Super-optima (>1.10)	16	14.8

Source: Field survey, 2016

CONCLUSION

The findings showed that rice farming was moderately profitable, with possibilities for improved economic prospects. Additionally, the majority of cucumber farmers' TFP indices were below the optimal range, indicating sub-optimal productivity owing to sub-proficient information, poor innovation reception and significant expense on production inputs. The study recommended: (a) Strengthens policies to improve access to agricultural credit for smallholders; (b) Public-Private sector partnerships that ensures adequate provision and distribution of production inputs/technologies at subsidized rates; and (c) Improved farm cooperative activities that facilitate access to inputs such as fertilizers, herbicides, seeds, etc., as well as efficient produce marketing. Inaddition, adoption of modern practices and technology that automates production; minimizes labour costs and optimizes productivity, agricultural extension activities in the study area need to be strengthened to provide improved agricultural techniques to farmers, and modifications to tenure policies to reduce farmland fragmentation; and increased sensitization on modern management practices that mitigates farm risks (pest/disease outbreaks) and improves productivity.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The work was carried out to examine the economic superiority of FARO 68 to other rice varieties and checks in Nigeria. The results of the On-station trials in 2019 and 2020 shows that genotype ARS161-3-5-3-B-BD was late (82 days) to reach 50% flowering, had the highest number of tillers per square meters and was late (109 days) to maturity. It also recorded the highest grain yield of 6974.50kg/ha. The mean performance of yield and some traits of lowland genotypes and checks during multi-locational trials at 9 locations for 2 years were observed. The genotype ARS161-3-5-3-B-BD recorded clear lead in the grain yield value (7165.95kg/ha). The highest single year grain yield recorded by ARS161-3-5-3-B-BD was 11556.22kg/ha at Edozhigi, Niger State in the 2021 cropping season. However, the combined means of yield performance showed that ARS161-3-5-3-B-BD recorded the highest yield of 10194.78kg/ha at Edozhigi according to Table 3. The On-farm Trials were conducted by14 farmers (14 sites) across 11 States in 2021; the result is presented in Table 4. The monetary value and economic gain of ARS161-3-5-3-B-BD is also presented in Table 5 below and proof to be superior over others.
Keywords: *Checks, economics, faro 68, genotype, superiority*

INTRODUCTION
The present rice cultivated may hardly be enough for the country to be self-sufficient in food consumption for population growth now and in future to come. If the growth in demand and consumption is more than production, there will be shortage, which endangers the security of food in the nation (Familusi and Oranu, 2020). The rice demand projection for 2030 is 19,796,832,353 kg equivalent to 67.35% growth in 2030 (Familusi and Oranu, 2020). The total supply projection of rice in Nigeria is at 8,773,617,507 kg equivalent to 56.92% in rice production coming 2030, while estimated population size stand at 26.60% by 2030. The expected estimated for demand and consumption for rice is higher by 2.26% than the nation production of rice, therefore there is need to increase the rice production. The area expansion of rice production is no longer solution to increase rice availability, but through frontier technologies. The potential yield of the commercial variety in lowland ecology is about 10 tons per hectare in the country. However, National Cereals Research Institute (NCRI) with national mandate on genetic improvement and development on rice, in collaboration with African Rice Centre in Cotonou and the Rice - maize Centre, Ibadan have developed some lowland rice genotypes that have agronomical superiority and better grain quality to the varieties in farmers' fields. In addition, the new genotypes could outperform the available national checks in yield and resistance to prevailing biotic and a biotic stresses in the country. The developed genotype ARS161-3-5-3-B-BD is having superior agronomic traits, comparative nutritional attributes to the checks and average grain yield advantage of 32.92% and 58.09% over and above the FARO44 and FARO 67 respectively as national checks. The objective is to quantify the economic value in monetary term the superiority of FARO 68 (Plate 1) over other varieties.

Plate 1. FARO 68 plant and Grains are shown above

METHODOLOGY

On-station trials On-station evaluations were carried out at the Fadama Rice Research fields of National Cereals Research Institute Headquarters, Badeggi, Niger State, Nigeria in the 2018 and 2019 growing seasons. The selected genotypes and two (2) popular national checks (FARO 44- high yielding, FARO 67- recently released) were evaluated for yield and yield-related agronomic traits. The experiments were in Randomized Complete Block design, replicated three (3) times.

Multi-location trials were conducted by NCRI in 2020 and 2021. The experiments were carried out in nine sites namely; Wushishi (Niger), Badeggi (Niger), Kebbi (Kebbi), OLAM (Nassarawa), Warri (Delta), Akure (Ondo), Numan (Adamawa), Edozhigi (Niger) and Abakaliki (Ebonyi) state respectively,

Seven (7) selected genotypes (ARS 161-3-5-3-B-BD, ARS 563-14-B-ED, ARS 150-TGR-10-NCRIB-12, ART 64-26-1-1-B-B-ED, D 56-NCRIJ-1-1, ART 90-46-1-1-B-B-ED, ART 739-2-6-B-BD) and two (2) national checks (FARO 44, and FARO 67) were evaluated for their yield performance. The trials were laid out in a randomized Complete Block Design. Each entry was planted in a 4 x 3m^2 plot size in three replications, the nursery was raised and three weeks old seedlings were transplanted in single seedling per stand. Fertilizer application was at 80, 40 40 kg per ha of N, P_2O_5 and K_2O, with N applied at two splits at 21 and 42 days after transplanting (DAT). Weed was controlled by Propanil and 2-4-D formulation at 4 liters per hectare of Orizo Plus, with supplementary hand weeding through GGE Biplot to identify ideal and stability of the genotypes across environments was also carried out. Reactions to biotic and abiotic stresses were scored.

On-farm trials were conducted by National Rice and Maize Centre (NRMC) in collaboration with National Cereals Research Institute, (NCRI) Badeggi at the respective State Agricultural Development Projects (State ADPs). Fourteen farmers in eleven States of the Federation were randomly selected. Three best genotypes (ARS 161-3-5-3-B-BD, ART 739-2-6-B-BD, and ARS 563-14-B-ED) selected from the multi-location trials were composed for the On-farm trials alongside farmers' variety (FARO 44) as check. This was conducted using farmers' fields and planting methods. In conjunction with Extension Agents of respective States ADPs, field days and Participatory Varietal Selection (PVS) to assess the Farmers' Preference and Ranking of criteria for the genotypes and check were conducted in Niger, Ebonyi, Oyo and Kebbi States.

RESULTS AND DISCUSSION

The results of the On-station trials in 2019 and 2020 are presented and the combine means are in Table 1.The genotype ARS161-3-5-3-B-BD was late (82 days) to reach 50% flowering, had the highest number of tillers per square meters and was late (109 days) to maturity. ARS161-3-5-3-B-BD also recorded the highest grain yield of 6974.50kg/ha followed by ARS563-14-B-BD (5917.50kg/ha) and D56-NCRIJ-1-1 (5429.5) and FARO 67 (5415.00).

Table 1: Combined Mean Performance of agronomic traits for Lowland Rice Genotypes during On-Station trial at Badeggi in 2018 and 2019

S/No.	Genotypes	DFF	PH (cm)	PL (cm)	NTPMS	NPPMS	DM	GY (kg/ha)

DFF= Days to 50% flowering, NTPSM = Number of tillers per square meter, NPPSM = Number of panicles per square meter, PH = Plant height (cm), PL = Panicle Length (cm), DM = Days to maturity, GY = Grain yield (kg/ha). FARO 44 and Faro 57 = Checks.

Table 2 indicates the mean performance of yield and some traits of lowland genotypes and checks during multi-locational trials at 9 locations for 2 years. Significant differences were observed for all the traits studied. Means were separated using Llkeast significant difference at 5% probability and the values are indicated. The genotype ARS161-3-5-3-B-BD also recorded clear lead in the grain yield value (7165.95kg/ha) followed by ART 739-2-6-B-BD(5765.97kg/ha).

In Table 3 the highest single year grain yield recorded by ARS161-3-5-3-B-BD was 11556.22kg/ha at Edozhigi, Niger State in the 2021 cropping season. However, the combined means of yield performance showed that ARS161-3-5-3-B-BD recorded the highest yield of 10194.78kg/ha at Edozhigi according to Table 3, while FARO 67 recorded the least value (3253.46kg/ha) at Badeggi also in Niger State.

The On-farm Trials involved 14 farmers (14 sites) across 11 States in 2021, the result is presented in Table 4.ARS161-3-5-5-3-B-BD showed clear yield (6637.82kg/ha) superiority over other selected *lowland rice* genotypes and the national commercial check, followed by ART 739-2-6-B-BD (4875.97kg/ha). The analysis of variance showed significant differences amongst the *lowland* genotypes and the check variety.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examines the productivity and profitability of IFAD beneficiaries under Tunga-kawo irrigation scheme Niger State. Multi-stage sampling techniques were used to select 118 beneficiaries and 119 non-beneficiaries on which primary data were elicited with the aid of a structured questionnaire complemented with interview schedule. Data were analyzed using descriptive statistics (such as frequency, percentage and mean), Farm budget technique and total factor productivity. The study revealed that the average age of rice farmers in the study area was 38 with average farming experiences of 24 years. The beneficiaries had at least secondary education while the non-beneficiaries had at least primary education. The cost and return revealed that rice production in the study area was productive with a net farm income of ₦1,783,543.22 and ₦550,788 for both beneficiaries and non-beneficiaries respectively although the beneficiaries demonstrated higher levels of productivity compared to non-beneficiaries. Also, the mean TFP index for beneficiaries and non-beneficiaries were 8.82 and 3.40 respectively. The study recommended that to further enhance rice productivity in the study area, efforts should be made to expand access to improved seeds, irrigation facilities, and extension services not only for beneficiaries but also for non-beneficiaries. This can be achieved through government programs and partnerships with agricultural organizations.
Keywords: *IFAD-VCDP, Farm Budget Technique, Total Factor Productivity, rice farmers*

INTRODUCTION
Rice is a critical food crop for millions of people in Nigeria and Africa, providing essential food security, nutrition, and income for many households in the region (FAO, 2018). In Nigeria, rice is a major staple food and is consumed by millions of people, but the country still faces a significant gap between domestic rice production and consumption, leading to a high level of dependence on imported rice (International Rice Research Institute (IRRI), 2017). To address these challenges, the agriculture sectors in Nigeria have placed a high priority on increasing rice production in the region. This is achieved through various initiatives aimed at boosting rice production, such as improving irrigation systems, developing improved rice seed varieties, and providing support for small-scale farmers (Babatunde and Oyebanji, 2017). One of such initiatives is the International Fund for Agricultural Development (IFAD) Value Chain Development Programme (IFAD-VCDP) which aims at improving cassava and rice value chains for smallholder farmers in 9 States. Tungan Kawo Irrigation Scheme is one of the intervention areas under IFAD-VCDP in Niger State. Despite these efforts, Nigeria faces significant challenges in meeting the food demands of its growing population. The population growth rate stands at 3.2% annually, while food production is increasing at a slower rate of 2.5% per year (National Bureau of Statistics (NBS), 2022). It is against this background that this study was carried out to describe the socioeconomic characteristics of rice farmers in study area; determine the net returns from rice production for beneficiaries and non-beneficiaries of IFAD-VCDP intervention in the study area; and determine the productivity level of both the beneficiaries and non-beneficiaries of IFAD-VCDP in Tunga-Kawo Irrigation intervention.

METHOLOGY
The study was carried out in Niger State which is located within 8^0 22'N and $11^0$30'N and Longitudes 3^0 30'E and 7^0 20'E with an average annual rainfall in the State is 1,219 mm. The State covers an estimated total land area of 74.244sq.km, which is about 8% of Nigeria's total land area with a 3,950,249, comprising 2,082,725 males and 1,867,524 females (National Population Commission (NPC), 2006). The projected population of the State as at 2021 was 5,644,139 at 3.2% population growth (NBS, 2022).

Multi-stage sampling procedure was employed in the selection of 118 beneficiaries and 119 non-beneficiaries of IFAD-VCDP farmers under Tungan-Kawo Irrigation Scheme, Niger State. Primary data were elicited from the respondent with the aid of a structured questionnaire complemented with interview schedule. Descriptive statistics (such as mean, frequency distribution count, and percentages) were used to analyze the data collected. Farm budgeting approaches and total factor productivity were utilized to describe the enterprise's profitability and productivity.

RESULTS AND DISCUSSIONS

Socioeconomic and demographic characteristics of respondents

Table 1 revealed that the average age of beneficiaries and non-beneficiaries rice farmers in the study area was 38 years. This implies that the respondents in the study area were in the prime of their productive years with the energy required for labour-intensive agricultural activities. Also, younger farmers may be more flexible in their decisions to adopt new ideas and practices. Result in Table 1 also reveals that majority (93.2%), (91.6%) and (92.4%) of the beneficiaries, non-beneficiaries and the pooled sample respectively were married. This implies that married rice farmers dominate rice production in the study area. Marriage often signifies the establishment of a household, and in many agrarian societies, family members actively participate in farming activities. This finding corroborates with that of Aminou *et al*. (2019) who reported that majority of rice farmers in Niger were married. Results from the study also reveals that the average farming experience of beneficiaries, non-beneficiaries and the pooled sample were 24, 23 and 24 years respectively. This implies that experienced rice farmers dominate rice production in the study area which is expected to enhance the productivity of rice production in the study area. The results also revealed that most (61.0%) of beneficiaries had one forms of formal education or the other with an average of 8 years of formal education. Also, 53.6% of non-beneficiaries had formal education with an average of 5 years of formal education. This implies that rice farmers in the study area had moderate level of education with at least secondary and primary education for beneficiaries and non-beneficiaries respectively. This is expected to enhance the productivity of rice farmers in the study area. The result in Table 1 revealed that all the beneficiaries of IFAD-VCD programme had access to extension while only few (1.7%) had extension in the last farming cycle. This suggests that access to agricultural extension services is significantly higher among beneficiaries of the IFAD-VCD program compared to non-beneficiaries. Table 1 revealed that nearly half (44.9%) of beneficiaries and 25.2% of non-beneficiaries had access to credit. This implies that beneficiaries of the IFAD-VCD program have a higher percentage of access to credit compared to non-beneficiaries although access to credit among the two groups is below average. The higher percentage of beneficiaries with access to credit suggests that the IFAD-VCD.

Cost and returns from rice production for beneficiaries and non-beneficiaries of IFAD-VCDP intervention

Table 2 present cost and return of rice production for both beneficiaries and non-beneficiaries in the study area. The Table revealed that the average Total Variable Cost (TVC) of beneficiaries and non-beneficiaries were ₦326,688.14 and ₦211,707 respectively, which accounts for 91.76% and 89.14% of the total cost of rice production for both group respectively, while the Total Fixed Cost (TFC) of beneficiaries and non-beneficiaries was ₦29,318.64 and ₦25,799.7 respectively accounting for 8.24% and10.86% of the total cost incurred by both beneficiaries and non-beneficiaries respectively. The calculated gross margin was ₦1,812,861.86 and ₦576,587 for both beneficiaries and non-beneficiaries respectively. It is significantly higher for beneficiaries as compared to the non-beneficiaries. This suggests that the intervention has positively impacted the productivity and profitability of rice farming for the beneficiaries.

Similarly, the net income was ₦ 1,783,543.22 and ₦ 550,788 for both beneficiaries and non-beneficiaries respectively**.** The net farm income was positive for both groups which imply that rice production in the study area is generating profits, although the beneficiaries had higher NFI compared to the non-beneficiaries. The estimated rate of return was 5.01% for beneficiaries and 2.32% for the non-beneficiaries This indicates that for every unit of cost invested in rice production, beneficiaries are generating a return of 5.01% while non-beneficiaries generating 2.32% but to a lesser extent compared to beneficiaries. The benefit cost ratio was 6.01 and 3.32 both beneficiaries and non-beneficiaries respectively. This implies that for every unit of cost invested in rice production, beneficiaries are generating a return of 6.01 units in terms of benefits. Also, non-beneficiaries had positive benefit-to-cost ratio, but to a lesser extent compared to beneficiaries. Gross ratio of 0. 17 indicates that for beneficiaries, the total costs incurred are 83% of their total returns. In other words, beneficiaries can retain 17% of their total returns as gross margin while the gross ratio of 0.30 for non-beneficiaries suggests that their total costs constitute 70% of their total returns, allowing them to retain 30% of their total returns as gross margin.

Table 2: Cost and returns from rice production for beneficiaries and non-beneficiaries of IFAD-VCDP intervention

variable cost	Amount	% of Total Cost	Amount	% of Total Cost

Productivity level of both the beneficiaries and non-beneficiaries of IFAD-VCDP in Tunga-Kawo Irrigation intervention

The result in Table 3 presents the productivity level of both the beneficiaries and non-beneficiaries of IFAD-VCDP in the study area. The Table revealed that majority (**96.61%)** of beneficiaries was within the super-optimal level, indicating that most beneficiaries are achieving high productivity levels while above average (**63.87%**) of non-beneficiaries fall in the sub-optimal categories indicating that a significant proportion of them experience moderate levels of productivity. The mean TFP index for beneficiaries and non-beneficiaries were 8.82 and 3.40 respectively. The mean TFP index of 8.82 for beneficiaries signifies that, on average, the group experiences a notably higher level of total factor productivity.

Table 3: Productivity level of both the beneficiaries and non-beneficiaries of IFAD-VCDP in Tunga-Kawo Irrigation intervention

TFP index	Frequency	Percentage	Frequency	Percentage
	Beneficiaries		**Non-beneficiaries**	
Sub-optimal (0.1 – 2.9)	2	1.69	22	18.49
Optimal (3.0 – 4.9)	2	1.69	76	63.87
Super-optimal (5.0 and above)	114	96.61	21	17.65
Total	118		119	
Mean	8.82		3.40	
Minimum	.58		1.99	
Maximum	63.55		6.92	
Standard deviation	8.38		1.08	

Source: Field survey, 2023

CONCLUSION AND RECOMMENDATION

Based on the findings of the study it can be concluded that beneficiaries demonstrated higher levels of productivity compared to non-beneficiaries. They had a higher average level of formal education with access to extension services. The study recommended that to further enhance rice productivity; efforts should be made to expand access to improved seeds, irrigation facilities, and extension services not only for beneficiaries but also for non-beneficiaries. This can be achieved through government programs and partnerships with agricultural organizations.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study analyzed the economic effects of livelihood income activities on food security status of rural farming households in Niger state, Nigeria. Undertaking diverse livelihood income generating activities is one of the key strategies often adopted to tackle the challenge of food insecurity in Niger State by rural farmers. Three Local government areas were randomly selected namely: Mokwa, Mashegu and Paikoro from the three Agricultural zones in Niger State. Primary data were used only for the study, The data were obtained with the aid of structured questionnaire. Data collected were analyzed using descriptive statistics such as frequency counts, percentages and mean, and inferential statistics. The specific objectives of the study were to; describe the socio-economic characteristics of respondents, identify their various livelihood activities, determine their food security status, identify the determinants of householdfood security of the respondents and lastly, identify the constraints to diversifying livelihood sources in the study area. A multistage sampling technique was used to collect primary data from 240 rural household heads using structured questionnaire. Data collected were analyzed using descriptive and inferential statistics. The result revealed that 90% of the respondents were male and 88.57% were married. Majority (70%) were educated and are mostly small scale farmers (about 96%). Similarly, they undertake other diverse livelihood income activities whichare mostly unskilled non-farm activities. The mean per capita food expenditure per month was estimated to be ₦12,588.12 and the value was used to establish the food security line which showsthat 68.7% of the households were food secure. The binary logit regression analysis showed thatthe coefficients of education level(X_5), number of income generating activities(X_6), remittance(X_9) and farmsize(X_{10}) were positive and significant at $p<0.1$ and $p<0.05$ respectively, while that of household size (X_4) was significant but negative. The major constraints to diversifying livelihood income activities include; inadequacy of funds, infrastructural problems, and lack of awareness/training. The study recommended that, effort should be made by all development actors to; improve access to credit by farmers, provide basicinfrastructure in the area, and lastly integrate awareness creation on diversifying livelihood income activities into extension massages.

***Keywords**: Livelihood income, households, food security*

INTRODUCTION

In many developing countries, and particularly in Africa, agricultural income represents an essential component of rural households' subsistence. However, this type of income exhibits a high seasonality and leads to uncertain outcomes, mainly due to market prices volatility and environmental hazards. Consequently, household members partly allocate their working time to activities which provide a more stable income so as to cope with adverse shocks (Ellis, 2000). In Nigeria and some other developing countries traditional image of farm households has been that,they focus almost exclusively on farming and undertake little rural off-farm economic activities (Reardon *et al*., 2006). Successive governments in Nigeria have made efforts to achieve food security in the country by trying to boost food production through the setting up of a number of Agricultural Development Institutions, and Special Programmes and Projects. In recent decade, such effort in that regard include: the National Agricultural Development Fund [NADF] in 2002; National Special Programme on Food Security [NSPFS] in 2002; National Food Crisis Response program [NFCRP], Food Security Thematic Group [FSTG] in 2009, and the present administration's Growth Enhancement Support [GES] under the Agricultural Transformation Agenda [ATA] in 2011. Sanchez (2005) defines food security as a situation where people do have physical and economic access to sufficient, safe, nutritious and culturally acceptable food to meet their dietary needs to lead a healthy and active life. Off-farm income activities generally plays a vital role in sustainable development and poverty reduction in rural areas (Shehu and Abubakar, 2015). It reduces the pressure of unemployment and the demand for land by the poor in rural areas; contributes to breaking down the vicious cycle of poverty among the rural populace and the income obtained from off-farm activities can significantly increase total household income and hence enhance the investment capacity in farm activities (Babatunde *et al.*, 2010). Therefore, off-farm income activities is often a source of savings, which plays an important role in food security and livelihood. The households that diversify their income by participating in off-farm income activities are more capable of overcoming negative shocks from poor harvest (Myyra *et al.*, 2011).

However, despite these government efforts, empirical records of many of these initiatives are not impressive enough to have achieved the objectives for which they were initiated, leaving an overwhelmingly large proportion of Nigerians food insecure (Idachaba, 2004; Azubuike, 2012; Jerome, 2012; Adepoju and Adejere, 2013). Agriculture being the traditional livelihood source has failed to guarantee sustainable livelihood opportunities for these farmers in this country and in many other developing nations (Barrett and Reardon, 2000; Kydd, 2002; Davis and Bezemer, 2004; Muyunda, 2009; Dary and Kuunibe, 2012; Babatunde, 2012; Uche, 2012).

Improved food security is important for global reduction of hunger and for economic development. In the year 2000, world leaders committed themselves to the Millennium Development Goals (MDGs) and one of their aims is to eradicate poverty and hunger, and "reduce by half the proportion of people who suffer from hunger" between 1990 and 2015. Currently, 820 million people are affected by hunger in developing countries and the number of hungry people in the world is growing at an alarming rate of four million a year; this trend is not falling quickly enough to achieve the food security goals particularly in Africa and southern Asia.

Despite the growing world abundance of food, food-related crises continue to occur. Differences in food security statuses within countries are common, even if the country has sufficient food in aggregate during normal periods. There have been increased observations of inequalities in the sufficiency of food intake by certain groups despite overall adequacy of supply. However, since the World Food Conference of 1974, the focus on the topic "Food security" has moved from a global and national perspective to that of households and individuals. Food security as a complex and multidimensional phenomenon alongside poverty is nowadays defined as "A situation when all people at all times have physical and economic access to safe, efficient and nutritious food needed to maintain a healthy and active life". Nord and Hopwood also defined it as "An access by all people at all times to enough food for an active life.

Food insecurity is closely linked with poverty. The average income and poverty measures, however, do not provide clear information about food security. It may, therefore, be incorrect to assume that a state, country, region, community or household's poverty prevalence rate is the same as its food insecurity or hunger prevalence rate, since the relationship between poverty and food insecurity is not a consistent one. A wider definition of food security incorporates quality of life indicators. Accordingly, food security implies livelihood security at the level of each household and all members within, and it involves ensuring both physical and economic access to a balanced diet, safe drinking water, environmental sanitation, primary education and basic health care. An important aspect of the wealth of a nation is its ability to make food available and accessible to its populace. The social and economic development of a nation is dependent on the quality of its human and non-human resources. The productivity of a nation's human resources is, however, a function of how well fed the citizens are and how healthy they are at all times.

In Nigeria, the percentage of food insecure households was reported to be 18% in 1986 and over 40% in 2005. Howbeit, figures released by Food and Agricultural Organization in 2005 on the state of food insecurity in the world indicated that about 29% of the Nigerian population was chronically undernourished between 2000 and 2002 . This was less than the regional average of 33% for sub-Saharan Africa. However, the 29% or about 40 million undernourished Nigerians translate to about 5.4% of total number of undernourished people in sub-Saharan Africa as a whole.

The main objective of this study is to analyze the economic effects of livelihood income activities on the food security status of rural farming households in three Local Government Area of Niger state, Nigeria. The specific objectives to be achieved are to :

i. describe the socio-economic characteristics of the respondents;
ii. identify the various livelihood income activities among the respondents;
iii. determine the food security status of the respondents;
iv. identify the determinants of household food security of the respondents; and

MATERIALS AND METHOD

The study area.

The study was conducted in Niger State, it is located between Latitudes $8^0 22^/$N and $11^0 30^/$N and Longitudes $3^0 30^/$E and $7^0 20^/$E, and covers 76,363 square kilometers of land mass which makes it the largest Nigerian State by land mass. However, using the population growth rate of 3.2%, the projected population of the State was 6,764,755 as the end of 2021.

Method of Data Collection

Primary data was used for the study. The data were collected using a well-structured questionnaire administered to the respondents by the researcher through multi stage sampling techniques

Analytical Techniques

Combinations of analytical techniques were used to analysed data collected from the field. It include descriptive statistics and inferential statistics. Multi-stage sampling technique was employed in selecting the representative households used for this study. Three Local Government Areas in the Niger State namely Mokwa, Mashegu and Paikoro from the three Agricultural zones were selected randomly in the first stage. Simple random sampling were used to select twelve (12) rural settlements from the wards selected in the second stage. The last stage was the selection of household heads from the chosen settlements. 240 respondents were drawn from the chosen settlements proportionate to size. Descriptive statistics such as frequency distribution, means and percentages were used to achieve objectives I and II.

Model Specification

Food security line

Household's expenditure on food which has found wider application in several empirical studies (Omonona and Agoi, 2007; Bamou and Mkononga, 2008; Iheke and Arikaibe, 2012) were used to achieve objective III. The food security line was estimated as two-third of mean per capita monthly expenditure of all respondents. Households were then classified into their food security status as food secure and food insecure households based on the food security line.

The formula is given as;

$$FSi = \frac{\text{per capta food expendture for the th household}}{\frac{2}{3}\ \text{mean per capta food expndture of all households.}}$$

Where;

FSi= food security index

FSi ≥ 1 food secure ith household.

FSi < food insecure ith household. …………………… (1)

A food secure household is that whose per-capita monthly food expenditure is above or equal to two-thirds of the mean per-capita food expenditure, while a food insecure household is that whose per-capita monthly food expenditure falls below two-thirds of the mean monthly per-capita food expenditure.

Binary logit regression model

Following Adeniyi and Ojo (2013), a binary logistic regression model was used to examine the determinants of household food security of the respondents in the study area. The food security status of households which is bivariate, taking the value of 1 for food secure households and 0 for food insecure households was used as the dependent variable. Socio-economic variable as well as food security indicator variables were used in the Logit regression analysis and specified explicitly in the model as:

$$FSi = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + \beta_9 X_9 + 10X_{10} + U \ldots \quad (2)$$

Where;

FSi = Food security index (ratio)

β_0 = Constant

X_1 = Age of the household head (years)

X_2 = Gender of the household head (Male=1: Female=0).

X_3 = Marital status of the household head (Married=1: Single=0).

X_4 = Household size (Number).

X_5 = Educational status of the household head (Number of years).

X_6 = Number of income generating activities (Number)

X_7 = Quantity of own production (kg grain equivalent)

X_8 = Membership of cooperatives (Yes=1: No= 0)

X_9 = Remittance (1= if they receive in cash or kind. 0 = otherwise)

X_{10} = farm size (Ha)

U= Error term

RESULTS AND DISCUSSIONS

Socioeconomic Characteristic of Farmers in the Study Area

The findings from the field survey reveal some personal and household characteristics of the respondents in this study are presented in Table 1. Results in Table 1 show that majority (36.7%) of the respondents were within the age group of 26 – 35 years with mean age of 38 years. This implies that the respondents were in their active and productive age where they could diversify into off-farm income generating activities to improve their livelihood. This finding is in agreement with that of Odoh and Nwibo (2017) who reported that the majority of household in South-Eastern Nigeria that diversified into off-farm income are younger and active in their respective occupations. That greater proportions (68.8%) of respondents were male whiles (31.3 %) were females. This implies that male are the dominant gender in off-farm activities in the study area. This could be due to the fact that they are major decision makers regarding off-farm income generating activities. This agrees with the findings of Okere and Shittu (2012) who revealed that the males dominated the work force in Nigeria's agricultural communities. Majority (40.2%) of the respondents had household size of less than 11 people with a mean household size of 7 people implying a relatively large household size which is very important in agricultural production. This result agrees with the findings of Okere and Shittu (2012) who posited that larger households are likely to diversify into off-farm income activities than smaller households.

Years of farming experience reveals tha (22%) of the respondents had farming experience between > 21 years with a mean of 12.5 years of farming experience. This implies that the small-scale crop farmers in the study area are relatively experienced and exposed to various forms of off-farm activities that could enhance income and livelihood. This finding is in consonance with that of Babatunde and Qaim (2009) who reported that highly experience farmers diversified into non-farm income activities in Nigeria. Also More than half (30%) of the respondents had farm size between 1.1 – 2 hectares with a mean of 2.1 hectares. This implies that the respondents are actually producing crops on a small-scale. This finding agrees with that of Adeoye *et al.* (2019) who reported that larger proportion of households in Nigeria operate on small scale.

Table 1: Distribution of respondents according to socioeconomic characteristics (n=240)

Distribution of Respondents Based on Livelihood Activities

The results of this study shows that many rural areas in Niger State and Nigeria, different households had highly diversified income-generating activities. From the findings, different farming and non-farming income livelihood activities of household heads were identified. However some of the activities identified in the study area are presented in Table 2 and 3 as farming and off-farm/Non-farm activities respectively. They are classified into four groups namely; farming, trading, skilled non-farm, and low skilled non- farm activities. In all the settlements, it is evident that farming is the most important livelihood income source as all households participate in farming on a commercial and or subsistence basis. The result shows that majority of the respondents 58.3% are into crop farming while livestock rearing has 33.3% participation rate with fishing farming having 8.3%. This finding is in line with those of Arene and Anyeaji (2010) and Oni and Fashogbon (2013) who said that, rural Nigeria is characterized by small scale agrarian livelihood as well as certain other primary production activities. Low skilled off-farm/non -farm activities is the second largest activity with about 43.57% participation rate. It represent a very low cost, low return niche occupied by respondents with very low human capital accumulation in either formal education or vocational training. Activities that fall under this category include artisans, motor cycle transport (Achaba), casual wageworkers or labourers and all other menial tasks. Skilled non- farm activities refer to occupations for which requisite training is received by the respondents in the form of formal education or vocational training, which could be in the formal or informal sector. It encompasses the range of occupations found among the respondents, which includes civil service, carpentry, masonry, mechanic/electricians, photography, clergy, blacksmithing, and sewing. This category is ranked third among the respondents having a participation rate of about 20%. Trading is the least among the categories of activities with about 12.14% participation rate. This can be attributed to the fact that most of these settlements do not have functioning markets couple with their low population and other constraints.

Table 2: Distribution of Respondents According to their Farm Activities

Activity(ies)	Frequency	Participation Rate (%)
Crop farming (wet and dry season farming)	140	58..3
Livestock farming	80	33.3
Fishing farming	20	8.3

Food Security Status of the Respondents

Food security index estimation using expenditure method was used to classify the respondents into food secure and food insecure households in a bid to establish the food security status of the individual households. This is shown on Table 4. A food secure household is therefore, that whose per capita monthly food expenditure is at least two-third of the mean per capita monthly food expenditure. On the other hand, a food insecure household is that whose per capita monthly food expenditure is less than two-third of the mean monthly per capita food expenditure. The mean per capita food expenditure per month was estimated to be ₦12,588.12 and this value was used as food security index. The food security line was ₦6,235.07. This implies that, all respondents whose per capita monthly food expenditure falls less than ₦6,235.07 was regarded as being food insecure. This is because; it is an indication that these households were unable to meet their expectedfood expenditure. Respondents with values equal or above ₦6,235.07 are regarded as beingfood secure. The findings on Table 4 indicates that 68% of the respondents were food secure while 31% were food insecure. This implies that, the incidence of food insecurity among the respondents is high and this is in agreement with the findings of Adepoju and Adejere (2013) who reported that, there is high incidence of food insecurity in rural Nigeria with North East sub-region having about 56% food insecure households.

Table 4: Distribution of Respondents According to Food Security Status

Food Security status	Frequency	Percentage (%)
Food Insecure	75	31,3
Food Secure	165	68.7
Total	240	100

Households' own perception of food security status

Table 5 showed the perception of the respondents to food security. They were asked whether their own households had sufficient food between the previous year and now. The result indicated that majority 67.7%) of the respondents were of the view that they had enough food during the period. However, 33.3% of them felt their household had food security problem during the period. This finding has an important implication as it shows the presence of transitory or even chronic food security challenge among the study population.

Determinants of Household's Food Security of the Respondents

In explaining the determinants of food security among the respondents, the Binary Logic regression model used gave results of the parameter estimates of these variables as presented in Table 6. The model gave the McFadden R-square as 0.617, which impliesthat all the explanatory variables included in the model were able to explain to about 62% of the variability in food security status of households in the study area. The variables that were found to significantly influence food security status included; household size, educational status, number of income generating activities, remittance and farm size.

The finding reveals that household size (X_4) has a coefficient of -0.1673 and significant at 5%. This implies that there is an inverse relationship between household size and food security. In other words, an increase in family size would lead to a decrease in household food security status. Specifically, a member increase in household size decreases the probability of household being food secure by 0.1673. This is in agreement with Ikpi and Kormawa (2004), Haile *et al.(*2005), Adebayo (2012), Bashir *et al*. (2012) and Adepoju and Adejere (2013) who found that an increase in one family memberincreases the chances of a household becoming food insecure by indirectly reducing income per head, expenditure per head, and per capita food consumption. This may be attributed to the fact that household size exerts more pressure on consumption than it contributes to production (Paddy, 2012). The coefficient of years of formal education (X_5) is statistically significant at 5% level and has a positive relationship with household food security. Specifically, the probability of being food secure is increased by 0.6255 for households whose heads had higher level of formal education. This suggests that, increase in years of formal education increases the likelihood of households to be food secured and vice versa. This is asexpected, since the level of education should positively affect the income earning capacity and level of efficiency in managing the household's food resources. The result coincides with those of Omonona *et al*. (2007), Asogwa and Umeh (2012), Adebayo (2012), Adepojuand Adejere (2013), and Oni and Fashogbon (2013**)**. The coefficient of number of livelihood activities (X6) of household is statistically significant at 1% and exhibits a positive relationship with food security status. This impliesthat, increase in the number of livelihood activities increases the possibility of a household becoming food secure by 0.3495. Therefore, households involved in diverse activities tend to be more food secure than those who are into fewer activities. This is because diversification is one of the livelihood strategy that provides additional income to rural household. It enhances household economy and food security by giving additional income and decrease food deficit when agricultural production falls short and also minimizes the sales of farm produce that should be consumed. Alternative income sources outside farming provide enhanced security for household livelihood. This is in line with the *a priori* expectation and the findings of Joshi *et al*. (2004), Babatunde and Qaim (2009), Aidoo *et a*l. (2013), Awotide *et al. (*2012), and Frimpong and Asuming-Brempong (2013).Remittance (X9) has a positive and statistically significant (5%) relationship with food security. This signifies that for a unit rise in transfer income, the level of food securitywill increase by 0.001768. This implies that, an increase in the amount of transfer increasesthe possibility of a household becoming food secure. This is due to the fact that remittancescontribute to household income and would lead to increase per capita food expenditure andconsequently improved food security status of the households. This finding corroborate those of Asogwa and Umeh (2012) and Adepoju and Adejere (2013) who revealed that, households with access to remittances have a lower probability of being food insecure. The coefficient of farm size (X10) was positive and statistically significant at the 1%level. This means that as a household's farm size increases, food security tends to increase. Specifically, the probability of being food secure increases by 0.8621 for every hectare increase in farm size. That is, households with larger farm sizes tend to be more foodsecure than those with smaller sizes, and vice versa. This can be attributed to the greater efficiencies in the use of resources associated with the large farms than those with small farms as observed by Reddy *et al.* (2004). Consequently, small farm holdings may result tolow productivity, low income, and the incidence of food insecurity among the farm households. This outcome is consistent with the finding of Asogwa and Umeh (2012) who opined that household food security increases with increase in area under cultivation.

CONCLUSION AND RECOMMENDATIONS

From the result of this study, it shows that participating in diverse livelihood income activities have an important influence on household food security status. The analysis and findings in this study have shown that food insecurity is a problem in the study area as measured and also opined by the respondents. Similarly, the respondents have shown great interest to diversify their livelihood sources, but are constrained by many factors. Hence, the need to assist these rural residents to overcome these constraints so as to promote remunerative and also diverse livelihood income activities which will in turn improve their food security status.

The preceding analysis has brought out some findings that have important implication on policy formulation. Based on these findings, the following recommendations are proffered towards promoting diverse livelihood income activities and food security in the study area:

i. To address the resource acquisition constraints faced by the respondents, there is the need for rural development actors to improve access to credit by rural farmers. Innovative micro-credit packages should be introduced so as to promote remunerative livelihood income activities. Such initiative should be self-sustaining and whose savings and loan schemes are organized to suite rural residents.

ii. In order to encourage diverse livelihood income activities, it is important that development actors focus on providing basic infrastructure such as electricity, good access roads, portable drinking water, health facilities, schools among others. Such infrastructure has an immense potential to facilitate improved rural livelihoods and poverty reduction through promoting integration with national economies, transfer of information, efficient markets, improving the working mobility of people, resources and outputs.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Food security is a basic human need and its absence can lead to hunger and poverty in any developing country, in 2015, the number of people living in hunger in Nigeria seemed to be declined but started increasing gradually from 2016 till date. Today, two billion people are still living in severe food insecurity and this implies that 820 Million of these two billion facing food insecurity are living in hunger and poverty. A nation is said to be prosperous, once it is able to make environment conducive and a sustainable atmospheric standard of livings among the citizens. The prosperity of a nation must be in line with its Social Progress Index (SPI) that measures the extent to which countries provide for the social and environmental needs of their citizens. This implies that the ranking should be based on wealth, economic growth, education, health, personal well-being, and quality of life obtainable in the country. National prosperity is a man made and not inherited. It does not only grow out of a country's natural endowments, its geography, labour pool, interest rates or its currency's value, as some scholars suggested. National prosperity is created from the efficiency and transparency of the people living in a country. In view of this, this paper holistically looked into why agriculture fails in the developing nation like Nigeria. In the course of the study, the research found that agriculture collapsed in Nigeria due to the followings: Conflicts, natural disasters, policy inconsistencies, corruption, political institutions and leadership system, gender inequality, noninvolvement of farmers in policy-making processes, death of infrastructures, poverty and hunger, ineffective career guidance, poor marketing and media relation, climate change and deterioration in science and technology. In the light of these, it becomes very obvious that agriculture has been neglected and needs to be addressed in terms of straightening the key roles of agriculture in eliminating poverty, hunger and rural development, ensuring access to agricultural inputs through comprehensive approaches to affordable prices, prioritization of equitable development and gender equality in agriculture, embracing sustainable agriculture through climate sensitive, investments in agriculture and revival of agricultural sector, reinforcing resilience to disasters and application of biotechnology in agriculture.
Keywords: *Good governance, agricultural growth, investment, poverty, food insecurity*

INTRODUCTION
Nigeria as of today depends heavily on oil sector for her economic growth and this imposed illusions on the citizens' mind that government relying highly on oil income to take care of various problems in Nigeria is possible (World Bank, 2020). Because of this, agriculture that supposed to be the major contributor to Nigeria's economic growth has been relegated and sidelined. Agriculture is the source of income for many Nigerians before the advent of oil boom. Despite being an overall rich country with oil assets, Nigeria's economy has not provided more job opportunities ,except only a few people that benefit from it (World Bank, 2019).However, about 96 million people and 48%, of the population are extremely poor (Otekunrin *et al.*, 2019; World Poverty Clock, 2020). Since the population is growing geometrically and the percentage of people living in poverty is changing drastically, the accurate number of people in poverty is increasing geometrically as well, and this causes more people to suffer from food insecurity (Ugwoke *et al.*, 2020).

In November,1996 World Food Summit held in Rome, all heads of government and their representatives at the summit were supported and agreed to achieve global food security and alleviation of hunger with the aim of reducing the population of undernourished persons by the year 2015 (Matemilola and Elegbede, 2017). Despite this development by international institutions, the population of the undernourished people in the world remains a major problem in most parts of the world especially in Africa. According to 2015 assessment of the Food and Agriculture Organization of the United Nations (FAO), around 795 million people in the world remained undernourished and the figure represents 167 million and 216 million reduction in the last decade and 1990 respectively (Matemilola and Elegbede, 2017).

According to World Bank (2019), development of agriculture remains one of the most effective tools to end extreme poverty, boost prosperity and feed a projected 9.7 billion people by 2050. To meet the demand, agriculture in 2050 will need to produce almost 50 percent more food, feed and bio-fuel than it did in 2012 (FAO, 2017).Agricultural productivity in Sub-Saharan Africa has continued to fall short of expectations. Stagnant production growth and sharp annual fluctuations in output have been the chronic problem of developing economies, hence constituting the main cause of their persistent poverty and rising of food insecurity in the continent. In the light of this, Etuk,and Ayuk (2021), cited that significant progress in promoting economic growth, reducing poverty and enhancing food security cannot be achieved in developing economies without strategically developing fully the productive capacity of the agricultural sector.

Sequel to the above, food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life (Matemilola and Elegbede, 2017). From this definition, four components of food security emerged: availability, access, utilization and stability of food. Therefore, for a country to be food secured, all the four components must be satisfied simultaneously to meet the objectives of food security. Putatively, our economy is in a mess today because we lost what it takes to be great than what it takes to be a minority in the social system. Agriculture, which is the pillar of all nations and the root of all products on earth, has seriously been neglected because of oil exploration and pseudo democracy. For this country to cure her problem and be free from incessant economic recession, agriculture should be prioritized as our major source of income. In the light of the above, it behooves this study to do an analytical review on why agriculture fails in the developing nations: the case of poverty, prosperity, and hunger and food insecurity in Nigeria.

The Collapse of Nigerian Agriculture in the 21st Century

Many factors could be associated with the collapse of agricultural sector in Nigeria but the most important ones are highlighted as follows:

Conflicts: The ethnic or religious conflicts imposed devastating effects on agriculture, especially in the areas that are prone to conflict. Agricultural sector like other sectors in an economy requires security. This is not only essential but is critical because it can discourage development. However, one of the strongest and recently recurring factors that seem to threaten agriculture productivity in Nigeria is the state of insecurity in the country. Local or foreign business investors are not motivated to invest in an unsafe and insecure environment (Okonkwo *et al.*, 2015).They look forward to both high returns in investments and a safe environment for their investment. In the view of this, security is freedom from danger or threats to a nation's ability to protect and develop itself, promote its cherished values and legitimate interests and enhance the well-being of its people. It connotes protection against all forms of harm whether physical, social, environmental, political, economic or psychological and safety from all forms of harmful disruptions to peaceful coexistence (Umaru *et al.*, 2015). It will be wrong to say there is peace in such a country like Nigeria where Boko Haram and other sects are threatening the unity of the country (Anwana *et al.*, 2019).

Natural disasters: Frequent climate changes such as shortage of rainfall, drought, flooding, excessive rainfall and flood in some regions of the country contributed immensely to low food production in Nigeria and this may serve as a threat to agricultural growth in Nigeria.

Policy inconsistencies and corruption: Frequent policy summersault and poor performance of legislators assigned to implement food and agriculture policies impose serious setback on food production and agricultural growth in Nigeria. Once a new government assumes power, the previous agricultural policies and programmes are abandoned and new ones are put in place; not that the new ones are better than the old ones but it is in a bid to create opportunities for embezzlement. However, abandonment of some of the past programs like Operation Feed the Nation, Green Revolution, River Basin Development Authorities (RBDAs) as well as agencies like National Agricultural and Land Development Authority (NALDA) and the Directorate of Foods, Roads and Rural Infrastructure (DFRRI) have led to low agricultural and food productivity in Nigeria.

Political institutions and leadership system: Leadership, whether bad or good, must reflect either negatively or positively on a state's socioeconomic and political environment. Good governance has been equated to the realization of sustainable human development. It was seen as the bedrock of all development initiatives and fundamental steps to any form of sustainable growth in the country. As a result of bad leadership in Nigeria, most of our leaders have no sense of commitment to development. Our politicians lacked vision of development to improve the efficient resources they inherited. They were interested in access to power and privileges but not development. Lack of continuity and frequent change of government policies among politicians affect the nation's agricultural sector. Several attempts had been made to encourage productivity in the agricultural sector, but the frequent changes in government and subsequent government policy changes reduced agriculture finally to its knees. Various governments in Nigeria to address agriculture and rural development problems have adopted many strategies; the story remains the same due to rapacious nature of our politicians. Based on this, there are still inequality and poverty particularly in the rural areas and this constitutes a threat to Nigeria's vision of becoming one of the twenty strongest economies (Tiri *et al.*, 2017).

Gender Inequality: Gender inequality is one of the major challenges in agricultural sector. In some countries of the world, women have less access than men to agricultural assets, inputs and service do. However, agricultural crops are gender-specific in some communities, women do not have access to land owing to their culture and this imposes danger to agricultural growth in Nigeria. Based on this, analysts were of the view that, if women grant the same access to productive resources as men, women would have boost yield by 20 – 30 percent, raising the overall agricultural output in developing countries by two and half to four percent, this could lessen the number of hungry people in the country. Therefore, balancing gender inequality and recognizing the contribution of women to agriculture is essential to achieving global food security, and this proves the evidence that when the status of women is improved, agricultural productivity increases, poverty is reduced and nutrition improves (Anwana *et al.,* 2019).

Non-involvement of farmers in policy-making processes: Farmers need to be part of dialogues focusing on agricultural policies. If we acknowledge their vast population dynamics, surely, we need to include them in the formulation and implementation of policies affecting their future. More so, there is also a need to look into new policies that best reflect the current economy and agricultural practices as regards to current climate change; this replaces the needs to be invested in the implementation of some policies as in some instances that may not see the light of the day (Udemezue, 2019).

Dearth of Infrastructures: Rural areas are some times more deficient in physical and social infrastructure than urban areas; this may lead to rural-urban migration with the attendant removal of youths from the rural areas where agriculture is mostly practiced. As long as urban areas offer a more attractive destination for young people's desired lifestyles, more youths will continue to leave the rural areas. Availability of good roads, constant electricity, recreational facilities, internet, potable water, affordable housing and qualitative healthcare in rural areas will go a long way in retaining youths in rural areas and improving their engagement with agriculture, if properly rehabilitated (Udemezue, 2019).

Poverty and hunger: Poverty begat hunger and hunger is a barrier to economic development because it prevents people from working hard to increase productivity. Agricultural productivity is capital and labour intensive. The poor peasant farmers, due to their level of poverty, produce the bulk of food needs in Nigeria and they find it very difficult to care for themselves and their family members, let alone getting the necessary inputs and energy to produce for others. Because of this, the growth of a sustainable agriculture in the developing country like Nigeria may be threatened.

Ineffective Career Guidance: The absence of effective career guidance in schools is one factor that derails youth participation in Agriculture. The poor promotion of agriculture in schools as a tertiary study unit is another key component that shifts the minds of the youths from agriculture. Therefore, institutions that promote agriculture need to hold career expos in rural and urban settings to promote agriculture as a study unit, they need to make electronic and print media available to the youth. To promote the growth of agriculture in Nigeria there should be effective career guidance among youths, awareness should be created telling the youth that agriculture is a business on its own and not a punishment per say.

Poor Marketing and Media Relations: Another challenge is the poor promotion of agriculture. There is a need to create programming that makes agriculture to look cool and attractive to people. The internet, particularly, social media can also be good tools to promote agriculture if used effectively. With the surge of internet access among the youth, institutions promoting agriculture need to acknowledge the youth's shift from traditional media especially newspapers. Nowadays, most young people get their information from the internet so the internet would be one of the best platforms to market and promote agriculture to reach the youth demographically (Udemezue, 2019).

Climate change: Climate change is a general issue that affects every country in Sub-Saharan African States. In the year, 2012, there was one of the worst floods in Nigeria and this led to the loss of many lives, displacement of people, and farmland being washed away (Nkechi *et al.*, 2017; Kralovec,2020). In the year, 2022 the same incidence reoccurred and claimed lives and properties. Therefore, climate change does not affect all States at the same time. Nigeria has four different geographical climate zones: 'the warm desert climate in the Northeast, the warm semiarid climate in the other parts of the North, the monsoon climate in the Niger-Delta, and the tropical savannah climate in the middle belt and parts of the southwest' (Akande *et al.*, 2017). Rainfall is low in the North and high in the South, which leads to shorter rain seasons and desertification in the North and floods in the South. The coastal area in the South has furthermore to deal with the sea level rise. However, all in all, the North is more vulnerable to climate change. Desertification coupled with too much rainfall can lead to damages in cultivation and displacement of people. Therefore, the whole country is hit by climate change (Abdulkadir, 2017; FAO, 2017; Kralovec, 2020).

Deterioration in Science and Technology: In Africa and other third world countries, Nigeria inclusive, agricultural technologies are in constant deterioration and stagnation due our build and collapse mentality syndrome, which has long been identified as one of the reasons for poor agricultural production performance in Africa. It has been observed those indigenous techniques like crop rotation and other cultural farming practices, which have been used to maintain the soil structure and its fertility do not seem to be enough in the current efforts to boast food production in most developing countries to meet up with population increase. This calls for application of science and technology to promote agricultural production in Nigeria.

The Origin of Poverty, Prosperity and Hunger in Nigeria

The state of agriculture and its prosperity in Nigeria today is in shambles. It is nothing to cheer about and this has led the country to the level of importing millions of metric tons of food such as rice, wheat, floor, vegetable oil, beefy, chicken, fish, among others from foreign lands,. In spite of great potentials in agriculture (Dangana, 2011). Food security is a basic human need and its absence can lead to hunger and poverty in any developing century like Nigeria (Kralovec, 2020). According to FAO *et al.* (2019), in 2015, the number of people living in hunger declined but has started increasing from 2016 till date. Today, two billion people are still living in severe food insecurity, since they do not have regular access to food, and this implies that 820 Million of these two billion facing food insecurity are living in hunger and poverty (FAO et al., 2019).

Poverty refers to as before not having enough resources to provide the necessities of life such as food, clean water, shelter and clothing. However, looking at the things of modernity, it can be extended to lacking access to health care, education and security. Poverty could be seen as absolute poverty or relative poverty depending on the metric used by each country. Based on this,World Bank uses a metric called the International Poverty Line ,as of 2015, world bank set the definition of extreme poverty as those who live on less than US$1.90 per day while those living on between $1.90-$3.10 per day are classified as the moderate poor. This figure is based on the monetary value of a person's consumption rather than income alone. Common perceptions of poverty consider income and consumption alone but there are other significant factors that should be considered since money does not tell the whole story about what poverty is. Poverty goes beyond not having enough money to solve problems. It could be seen using the Multidimensional Poverty Index (MPI) and the Human Development Index (HDI) approaches. Based on these, poverty can be measured across three dimension such as health, education and standard of living. According to the World Poverty Clock, the population of Africans living in "extreme poverty" per continent is 430.3.As of 2023, the three countries with the greatest number of people living in extreme poverty are: Nigeria (71 million), Democratic Republic of Congo (68 million) and India (44 million) (*Charizze and Judy, 2023*).

At the societal level, high poverty rates can be a damper on economic growth and be associated with problems like crime, unemployment, urban decay, education, and poor health. This could be the reasons our youths engaged in various criminal activities to sustain their livings. To address the issue, governments often put social welfare programs in place to help lift individuals, families, and communities out of poverty (James, 2023). Therefore, a poor nation is not prosperous because it assumes poor in all ramifications, which could be because of its political institution or ideologies. Sequel to this, a nation is said to be prosperous, once it is able to create a conducive environment and a sustainable atmospheric standard of livings among the citizens. The prosperity of a nation must be in line with its Social Progress Index (SPI) that measures the extent to which countries provide for the social and environmental needs of their citizens. This implies that the ranking should be based on wealth, economic growth, education, health, personal well-being, and quality of life obtainable in the country. According to Olufemi (2022), national prosperity is a man made and not inherited. It does not only grow out of a country's natural endowments, its geography, its labour pool, its interest rates or its currency's value, as some scholars suggested. National prosperity is created from the efficiency and transparency of the people living in a country. This reminds us that Prosperous nations are not those with large populations or small populations; they are not those endowed with natural resources but those which can use their population, irrespective of the size,(whether small or big), and natural resources to increase the efficiency of the people through research and development to maintain a lead. However, two types of economy are essential to national prosperity :(a) Knowledge economy and (b) Agrarian economy. (a) Knowledge economy or advanced economy describes the use of commodity and economic value derived from research and development.(b)Agrarian economy is an economy which is highly dominated by primary industries like farming, fishing, lumbering, etc and subsistence means of production. Therefore, wealth of a nation depends on the type of the above economy used by a country. What makes the difference between wealthy and poor nations is how they are able to organize their factors of production to generate wealth (that is, how they are able to develop their land, entrepreneurs, capital and machinery to create wealth).

A nation can prosper through the exploitation of comparative advantages. In this case, differences in national values, geographical location and culture in the world can be exploited to develop the wealth of nations. According to Olufemi (2022) no nation with over 40 per cent youth unemployment rate, as can be seen in most African countries, can prosper. Government has to add to the value chain of the nation by helping the people to be able to fend for themselves and this is done by exploiting nations' comparative advantages. In Africa, some nations have comparative advantages in agriculture and our government should see it as comparative advantages for means of employment generation and national prosperity. Contrary to this, Acemoglu and Robinson (2013) pointed out that economic prosperity of a country is not determined by geography and culture as pointed above, but rather a matter of institutions and politics.

According to them, "Countries rise when they put in place the right pro-growth political institutions and they fail—often spectacularly—when those institutions ossify or fail to adapt. Powerful people always and everywhere seek to grab complete control over government, undermining broader social progress for their own greed. Keep those people in check with effective democracy or watch your nation fail."

Sustained economic growth in countries with extractive institutions is never possible, because elites limit access to economic institutions for a large part of the population. Sustained growth requires innovation, and elites generally oppose this, as it may threaten their economic and political prerogatives. Moreover, conflicts will inevitably arise between different competing elite groups that will destroy economic growth (Acemoglu and Robison, 2013).Temporary economic growth, is possible under extractive institutions, due to its clear limits. Sustained growth requires innovation, and elites generally oppose this, as it may threaten their economic and political prerogatives. Therefore, to have a sustained agricultural growth in Nigeria with extractive institution is hardly possible because income and wealth distribution are always related to the vicious circle, and this is done as to impoverish their citizens. In the agricultural sector specifically, one critical condition for growth is good governance structure and related policies at all levels. Therefore, unless effective governance systems are in place, agricultural reforms, food security, poverty reduction and development will remain a tall dream. Through institutional and human governance capacities, public policies and strategies effectiveness can be achieved and better public decisions are made and implemented (Anwana *et al.,* 2019).

To through more light on the nation's prosperity, Abraham Maslow's theory of needs states that human need are insatiable but predictable, and should be exploited by all nations at their benefit to increase their values. Human beings need food, water, shelter and clothing (psychological needs); security and safety of lives and properties, job security and environmental peace and order (safety needs); friendship, recognition, being loved and loving somebody (love and belonging needs); confidence (self-esteem needs) and fulfillment (self-actualization needs). This implies that we are motivated by the above needs as human beings. Therefore, if our basic needs are unmet, definitely, we would be unable to meet our societal needs. The constitutional role of every government is to ensure that everybody is psychological and safety needs are met but this is an opposite case in African continent. This theory is therefore used to justify why Africans are mostly not innovative and inventive, and why they remain poor (Olufemi, 2022).

Adam Smith on his book, usually referred to as The Wealth of Nations held that wealth was fixed and finite and that the only way to prosper was to hoard gold and tariff products from abroad. This theory was of the view that nations should sell their goods to other countries while buying nothing in return to have monopoly of trade. However, this could be impossible because no nation is an island on its own. To be specific, nations that want to create wealth and prosper must have surplus 'balance of trade' compared with other nations. Such a nation must be able to identify his areas of comparative advantage and judiciously develop these comparative-advantage activities to its benefit. Therefore, a nation like Nigeria with arable land should develop its agriculture to sustain agricultural growth, while a nation that has spiritual and religious history should develop its tourism potential. No nation can prosper by allowing its markets to be turned into dumping grounds and this interests us to know that without healthy competition with other developed nations, no nation can prosper.

According to World Bank reports, human development index in Africa is abysmal due to politics and corruption. Life expectancy is in the decline, poverty increases daily, death rate increases, decrease in standard of living and infrastructural designs are in dilapidation (Kuka, 2007;Udemezue *et al.,* 2017).everywhere in the world go today, Africans record failure in all spheres of life like political, economic, social and morally otherwise. Ideally, Africans should not be blamed in any political computation because; the continent is naturally blessed with oil and mineral resources. What could be the cause of our failure? Is it the way we play politics and corruption handlings that has placed us on the front lines food insecurity rating before the world. In view of these, our failure stems from bad governance and corrupt politicians that have inability to carry on the torch of independence and civilization, which was handed over to us through the founding fathers of our nations by our civilized colonial masters. The civilization, which they left behind for us, was the structure of governance and was at a time become inoperative and collapsed. With this, one can say that our problem is failure of leadership. Based on this, Ogara (2011), pointed out that the trouble with Nigeria is that it is governing by a breed of rapacious politicians, political vultures who impoverish the country and enrich themselves at the detriment of people. To his extension, there are two leaders in power; leaders committed to the common good and leaders derived by ambition and self-seeking. These two leaders behave according to their kindness and self-aggrandizement. Leaders in the first group are good and popular while those in the second group are bad and notorious.

As a matter of the above, our agricultural sector fails to grow just like other countries of the world simple because we have extractive politicians and not inclusive politicians that bring sustainable agricultural growth to the nation. Government institution in Nigeria is an extractive institution and not inclusive that carries everybody along in the affairs of government. For the country to be liberated from these shackles of leadership, all the political action committees must be duly dissolved, otherwise this may call for military inversion as have done in most of the African countries today. The question is who will bell the rat? This is subject to further research. Subject to these, Acemoglu and Robinson (2013) said that Inclusive institutions are institutions that safeguard not mainly the interests of the ruling elite, but which are open to larger groups in the society. These types of institution create incentives for people to save, invest, and innovate, while extractive institutions, on the contrary are institutions that harm the interests of the majority of the society because they aim to enrich only the ruling classes. In this type of institution, property rights are not sufficiently protected for most of the populaces, except for the elites who know that their interests are secured by force or power.

Bad governance has made development elusive in Africa and Nigeria in particular. Poor governance and corruption particularly in Nigeria has been responsible for the fall of the agricultural sector. The various river basins development authority and other agricultural establishments are not functional to supply food to the nation. They do not produce food, they are more or less exists, as bureaucracy where there are workers that receive salary every month, but the production of food is absent. However, those government establishments failed in Nigeria because of corruption and extractive politicians who keep their eyes open always to see where opportunity exists to divert money into their private pockets. Nigeria is in visible ruins and the results of these problems are reflecting in every sphere of our national existence. It is only the beneficiaries of these corruptions can see and say that the country is in the best shape while opposite is the case. Our leaders often deliberately offer a false image of peace, unity, stability, progress and development in the country through diplomatically deceptive speech as to outshine the eyes of other nations (Udemezue *et al.,* 2017).

Good governance and effective leadership are stepping-stones to sustainable development. Studies on the Nigerian economy have proven leadership problems as a major cause of the country's inability to mobilize her resources. Leadership problem has hindered the country's progress in the political, economic, military, socio-cultural sectors (Ogbeidi, 2012) .Nigeria's expectations at independence were high, and the possibilities for greatness were grossly assured. The leaders had a supreme confidence of greatness considering the vast resources endowed with, but with things of regret, the Nigerian economy has hit below the expectations because of massive underutilization of resources occasioned by bad governance. Leadership and lack of transparency in public spending have resulted in massive looting of the national treasury and gross mismanagement of public enterprises which this has led the nation into the arrays of agricultural failure and economic dwindling (Balogun *et al.,* 2021).There is an organic interconnection between quality of governance and capacity to drive a sustainable development. Good governance was seen as the bedrock of all development initiatives in a country and a fundamental prerequisite to any form of sustainable growth or meaningful development in the country (Balogun *et al.,* 2021). Concisely, what determine the prosperity of a nation and development are political institution, culture, history/linage, geography, economic resources, ideology and agriculture.

Agriculture remains an everlasting panacea to the well-being of Nigeria; this is because every nation has the responsibility to feed her citizens and any nation that cannot feed her citizens adequately is vulnerable to unrest and cannot have peace and stability. Therefore, for a nation to be able to feed her citizens, it must strengthen its agriculture and produce sufficient food. To do this, it requires a lot of inputs which only government has the resources to coordinate and provide (Udemezue *et al.,* 2017).Agriculture is the main root of economic building and whatever affects agriculture indirectly, affects economy directly. Therefore, the primary expectation of agriculture is to maintain the economic building of nation's development. However, diversification of Agricultural inputs and budgets made for agricultural production by corrupt government officials and politicians could cause poor building of Nigerian economy as well as agricultural failure thereafter.

Nigeria is not beyond redemption, let us put hands together and rebuilds this country from these ruins. In this case, this paper hereby advice leaders to enthrone good governance, ensure justice in the country and mobilize the teeming youths to harness their talents in national productivity and wealth generation. If leaders in Africa fail to stop looting of the countries common wealth, this continent will gradually be tamed by the angry youths to the level that there will be no hiding place for the rapacious leaders in Africa.

Way forward on enhancing agricultural growth in Nigeria

The basic approaches for enhancing agricultural growth and prosperity in the developing countries include the followings:

Straightening the key roles of agriculture in eliminating poverty, hunger and rural development: The roles of agriculture in nation building and poverty reduction have to be straightened there by empowering the smallholder farmers who are the major contributors to food production in the country. Provision of necessary support to raise rural incomes and productive capacities to enable smallholder farmers participate and benefit from national and international markets are prerequisite to agricultural prosperity in the developing countries.

Ensuring access to agricultural inputs through comprehensive approaches to affordable prices: Cost of agricultural inputs is so high that the majority of the farmers cannot afford them; this has led to migration of some youths from rural areas to the urban. Access to agricultural inputs will bring more hands into agriculture since the majority of our youths left the system not just that they lack interest, but because of the high cost of farm inputs. Based on this, government should therefore, subsidize agricultural inputs to be affordable by the farmers who are the end users of the products. This movement and initiative will not only boost food production but also enhance agricultural growth in a country.

Prioritization of equitable development and gender equality in agriculture: Equitable development and gender equality, especially empowerment of women since they are the most marginalized and vulnerable set of people in agriculture can reduce the menace of food insecurity that leads to agricultural prosperity in totality. More so, if women can give the same access to productive resources as men, agricultural yields and output would increase and there would be a significant reduction in the number of impoverished people. In the light of this, Akinyetun (2018) pointed out that there will be surplus food for the nation if women could be granted access to; and control over land and other productive resources; empowering women smallholder farmers to overcome institutional, social, and economic bottlenecks, and participation of both women and men in decision-making at all levels.

Embracing sustainable agriculture through climate sensitive: Climate change is one of the factors working against food production in the world today. Food demand in the world today increases because of population growth, urbanization, and changing dietary habits and this implies that greater attention should be given to some uncertainties in agriculture like climate change to sustainable agriculture. Sustainable intensification of agriculture requires increases in productivity, while adapting to climate change and reducing greenhouse gas emissions. Therefore, Climate-sensitive agriculture makes growth more sustainable, while improving the management of ecosystems, including soils, forests, water, fisheries, oceans, watersheds and biodiversity.

Investments in agriculture and revival of agricultural sector: Investments in agriculture and revitalization agricultural sector in Nigeria contribute to major societal benefits, including inclusive growth, and creation of decent jobs. Reasonable investment in agriculture can be strengthened starting from the recognition that the main investors in agriculture are the farmers themselves, engaging small producers and their organizations fully in the design and implementation of national strategies for agriculture and food security will help in regernerating the confidence of the farmers. Similarly, ensuring their land tenure system land and improving their access to improved technology and innovation, ensuring they benefit from key public goods such as market infrastructure, price stabilization instruments for both producers and consumers, affordable financial services, and functioning extension services. This calls for an integration of public and private investment that includes farmers' associations, agri-businesses, government, civil society groups and sources of financing.

Reinforcing resilience to disasters: Poor rural and urban farmers face challenges such as volatile food prices and climatic shocks that threaten their food price and productivity. However, the sustainability and resilience of their livelihoods can be reinforced through developing a range of capacities and entrepreneurial skills; promoting non-farm rural employment; empowering small producers to diversify their on-farm and off-farm activities; including the most vulnerable in sustainable development processes, and investing in social protection such as food assistance, safety nets and targeted transfers.

Application of biotechnology in agriculture: Biotechnology represents a scientific advance in agriculture with far reaching potentials in increasing food production in an environmentally sustainable manner. Agricultural biotechnology includes using genetics to modify crops and plants to produce more nutritious food, cloning of livestock; tissue culture technique and genetic engineering (Akinyetun, 2018).Therefore, application of it in our daily farming will help to boost agriculture in the country.

CONCLUSION

Bad governance has been a stagnant to agricultural development in Nigeria. Poor governance and corruption particularly in Nigeria has been responsible for the fall of the agricultural sector. In view of this, this paper holistically looked into why agriculture fails in the developing nation like Nigeria. In the course of the study, the research found that agriculture collapsed in Nigeria due to the following: Conflicts, natural disasters, policy inconsistencies, corruption, political institutions and leadership system, gender inequality, non-involvement of farmers in policy-making processes, dilapidated infrastructures, poverty and hunger, ineffective career guidance, poor marketing and media relation, climate change, deterioration in science and technology. In the light of these, it becomes obvious that agriculture has been neglected and needs to be addressed in terms of straightening the key roles of agriculture in eliminating poverty, hunger and rural development. Also ensuring access to agricultural inputs through comprehensive approaches to affordable prices, prioritization of equitable development and gender equality in agriculture, embracing sustainable agriculture through climate sensitive, investments in agriculture and revival of agricultural sector, reinforcing resilience to disasters and application of biotechnology in agriculture.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cucumber (Cucumis sativa L.) is a nutritious crop whose production and utilization gives greater satisfaction for food security, employment and health needs of Nigeria. An average farmer achieved a gross margin per hectare of ₦2,680,580.00; incurred a total variable cost of ₦706,300.00 per hectare and had a return on investment of ₦3.64. R-square value of 88% which was significant at 5% level of probability showed that the regression coefficients of specified variables were significantly positive, less than unity, and thereby sufficiently explained the cucumber output in the study area. The resource use efficiency of cucumber production implied that fertilizer, labour and land resources were under-utilized while the one for seed resources were over utilized. The major constraints to cucumber production were inadequate storage facilities and inadequate water and irrigation facilities. The study recommended the deployment of more qualified and experienced extension agents for the farmers and the formation of farmers into cooperatives to build on their social capital values and to actively advocate and or solicit for government support.

INTRODUCTION
Cucumber (*Cucumis sativus* L.) is one of the exotic and refreshing vegetable crop in Nigeria. It is consumed as a healthy food and as a valuable source of conventional anti-oxidant food rich in vitamin C, beta-carotene and manganese (Sambou *et al*., 2023). Cucumber is low in cholesterol and sodium; and it is a rich source of prophylactic and therapeutic ingredient for daily bodily need (Suma *et al*., 2019). Furthermore, Cucumber was said to being consumed since ancient times, eaten as traditional food and used for treating constipation (Pan *et al*., 2022). Its consumption helps to maintain hydration, relieves constipation and helps to reduce the risk of cardio vascular diseases as well as many types of cancer (Mallick, 2022).
Cucumber (*Cucumis sativus* L.) belongs to the family of cucurbitaceae and is an important vegetable crop (Eifediyi and Remison, 2010). Cucumbers are long, cylindrical green fruits that contain about 95% of water, and are for this reason it is often recommended as natural diuretics and helpful for body building (Wilcox *et al*., 2015). The production of cucumber is complex and very technical in handling. It is a tender and frailly crop that requires serious management focus, attention and technology (Rahman *et al*., 2020) as one grows the crop from seedling to maturity. The commercialization of this crop therefore requires that farmers have requisite skills and resources to provide high cost of inputs such as irrigation, fertilizer, and labour in other to achieve surpluses (Rahman.*et al*., 2020) However, for farmers around water bodies and those that can afford small scale irrigation farming would possibly have considered this, as an adaptation strategy for coping with rainfall variations. However, the interruption of rains within growing season and the adverse effects of drought upon soil conditions render crop failure for most farming households that lives in rural areas in particular.
Cucumbers thrive best at relatively high temperatures, between 75 to 85 degrees F. The plants do not tolerate frost. Since they are a quick-growing crop, they must be well supplied with moisture and plant nutrients throughout the growing season. Water is especially critical for cucumbers during the fruiting stage. Cucumber plants like sun, but are prone to scorching, so some shade is preferable. Encourage greenhouse varieties to climb to boost yields. Harvest fruits early in the day while it's cool. Harvest frequently to get more fruits during the season. Along with seasonal production, cucumbers are also successfully grown in off season under greenhouse due to its suitability to thrive under high light intensity, high humidity, high soil moisture, temperature and fertilizers condition. Cucumber farming is considered as an essential part of agriculture and its noteworthy contribution in raising the foreign exchange earnings for Nigeria. In addition, since it's a labour intensive enterprise and thus offer a considerable promise for generating rural employment opportunities, especially for unemployed women and youth in the study area.

Among the vegetables in various regions of Nigeria, the most studied include tomato, pumpkin and watermelon, among others (Oguniyi and Oladejo , 2011; Adenuga *et al*., 2013; Ayinde *et al*., 2011; and Adeoye *et al*., 2011); only few studies existed on the resource-use efficiency of smallholder cucumber production in Kaduna state. Cucumber is one of the most important exotic vegetables in Nigeria. Its profile is rising due to widespread knowledge of its health benefits and to sustain the availability of the crop supply and meet with its increasing demand, there is the need to understand the economics of its production and resource use efficiencies as a way to understand achieving its productivity. This study avails itself to achieve in Sabon-gari LGA of Kaduna State, the following specific objectives are stated as follows: (i) analyze the costs and returns of cucumber production, (ii) estimate the input-output production function of cucumber production, (iii) estimate the resource use efficiency of cucumber production, (iv) identify problems encountered in cucumber production by farmers,

METHODOLOGY

The study was conducted in Sabon-Gari Local Government Area of Kaduna state of Nigeria; located in the Northern Guinea Savannah Zone of Kaduna state. The Local Government Area is situated on a plateau of a height of about 700m above sea level of latitude 110 12' N and longitude 70 8'E. The study area has two distinct seasons which are dry and wet seasons. The rainfall extends from April to October and average annually between 100 to 1000mm with a mean temperature ranging from 27.20 ^{0}C to 35 ^{0}C in the month of April. The local government area has an estimated population of farming families of about 246,544. It consists also of 12 Districts including Samaru, Jama'a, Bassawa, Hanwa, Dogarawa, Chikagi, Muchia, Zabbi, Jushi , Angwa-gabas, Angwan-godo and Bomo. The predominant language is Hausa and majority of the populace are Muslims. The major crop grown in this area includes Maize, millet, groundnut, cowpea, sugarcane, rice and vegetables such as cucumber, tomato, onion, and pepper are cultivated. The major livestock kept are goats, sheep, cattle and poultry. The farmers in the study area use simple farm implements such as hoes, cutlass and human labour mostly. The farm economy is characterized by small size and fragmented land holdings.

The study adopted a multi-stage cross-sectional sample survey design. The population of farmers involved in the study were Cucumber farmers in Sabon Gari Local Government Area of Kaduna state. The multistage approach used, firstly involved a random selection of 4 district/villages from the twelve district listed above. Secondly, a random selection of 30 farmers from each of the villages making a total of 120 farmers, who were actively involved in the cultivation of cucumber were selected and interviewed. A well-structured and pretested questionnaire, was administered by trained enumerators. The data collected include those of socio-economic characteristics of respondents, revenue and cost variables and of other factors affecting Cucumber enterprise in the study area.

The study employed descriptive statistic including use of frequency distribution, percentages and means to describe the socio-economic characteristics and constraints farmers faced in Cucumber production. Also, inferential statistic such as multiple regression analysis was used. The profitability of cucumber production was estimated on per hectare basis using farm budget techniques; including the estimation of gross return, gross cost, gross margin, net return and benefit-cost ratio (undiscounted). The formulas used for the calculation of profitability include: Gross return, GR = P×Q; where, P = Selling price of the product (Naira); Q = Yield per hectare (Kg). Total cost TC = TFC + TVC; where TFC = Total fixed cost (Naira); and TVC = Total variable cost (Naira). Gross margin, GM = GR – TVC. Net return, NR = GR – GC; and Benefit-cost ratio = Gross benefit / Gross cost. The production function and resource use efficiency of Cucumber production was carried out using Multiple Regression Analysis: - The model in its general implicit form is;

$Y = F\ (X_1, X_2, X_3, X_4, e_t)$; Where, Y = output of cucumber (kg), X_1 = Seeds (kg), X_2 = Fertilizer used (kg), X_3 = Labour input (man/hr) X_4 = Land (ha), e_t = error terms.

Among the functional forms tried, the best fit Cobb-douglas double-log form was used; and the explicit forms of the model is; $\log Y = a + b_1 log X_1 + b_2 log X_2 + b_3 log X_3 + b_4 log X_4 + e_t (Double\ Log\ ) \ldots\ldots\ldots\ldots Eqn\ 1$

The Resource-use efficiency, stated as; $r = \frac{MVP}{MFC} \ldots\ldots\ldots.. Eqn\ 2.$ Where, MVP = Marginal value product of a variable input, MFC = Marginal factor cost, r = Efficiency ratio. The MVP was estimated as follows;

$MVP = MPP.P_Y \ldots\ldots\ldots Eqn\ 3.$ Where, P_Y = Price of output, and MPP is the marginal physical product. The decision rule implies that; if r =1, resources are efficiently used. If r > 1, resources are underutilized, if r<1, resources are over utilized.

RESULTS AND DISCUSSION

Profitability of cucumber

The estimate of the costs and returns of cucumber production in study area was indicated in Table 1. below; and showed that an average cucumber farmer, growing cucumber on an average of an hectare of land, incurred a total variable cost of ₦706,300.00. He incurred a total cost of ₦ 728,800.00 which by breakdown consisted of; seed cost of ₦394,800.00 (54%), fertilizer ₦76,500.00 (10.5%), labour cost of ₦ 200,000.00 (27.4%), transportation cost of ₦ 35,000.00 (4.8%), Rent on land cost of ₦ 20,000.00 (2.7%) and Depreciation of farm tools costing ₦ 2,500.00 (0.3%). The cost items analysis indicated that cost of seed ₦394,800.00 (54%) was the highest percentage of cost of production used. This was so because cucumber crop is an exotic one in Nigeria, and the farmers have one-off use of the seed for planting. These hybrid seeds are packed in counts and in sachets of about 10g weight, being sold to farmers only by agro-allied companies like East-West Seed Company. Again, these seeds can only be planted, directly and or as transplanted seedlings raised from nursery beds. The cost of labour ₦ 200,000.00 (27.4%), was second in consideration owing to the fact that the crop needs intensive attention from land cultivation, to tendering the climber vines and plant on supports of strands or staking materials. Also, for cucumbers, harvesting activities are also not done as a one off activities, but rather, the crops are often harvested fortnightly throughout an extensive harvesting period; among others. Therefore, lots of man-hour was deployed. Also, the negligible percentage of depreciation cost (0.3%) revealed that most farmers are smallholders who uses simple and costless traditional implements in farming, rather than the use of capital intensive machinery that would have warranted a significant depreciation value. This justifies the use of gross margin in determining the viability of smallholder farmers in the study area (Olukosi and Erhabor, 2005). However, an average cucumber farmer is profitable in the study area with a gross margin of ₦ 2,680,580.00, and a Net farm income of ₦2,658,080.00. This is in line with Adeoye and Balogun (2016), they found that cucumber production was profitable among smallholder farmers in Oyo state, since their total cost of production was less than the total revenue obtained. Also, a return on capital of 3.65, was obtained by an average farmer, which implies that for every ₦1 invested in cucumber production, an average farmer gets back in return ₦ 3.65 only. Also, close result to Adeoye and Balogun (2016), found that the rate of return of cucumber production among smallholder farmer was 1.26, meaning for every ₦1 invested in cucumber production, ₦1.26 was obtained in return.

Table 1 – Estimated costs and returns per hectare for maize-groundnut production

S/n	Variables	Unit/ha (Kg/ha)	Unit price (₦/kg)	Value/ha (₦/ha)	Percentage (%)
1.	Variable Cost:				
a.	Seed (Kg/ha):	0.282	1,400,000.00	394,800.00	54

Production function analysis of cucumber production

The results of the multiple regression analysis presented in Table 2. Showed the variation in cucumber production among the farmers which was explained by some of the independent variables seed, fertilizer and labour costs included in the Cobb-Douglas model, in which they are positive and significant effects on cucumber output at 5%, 10% and 5% respectively, while the factor land was not significant neither at 5% nor 10%. This status was affirmed by an R-square value of 88% which implies that the independent variables actually influences the result of the dependent variable in the model. However, the result of input and output resources used were also as describe in Table 3, in which the mean values of input resource per hectare used, and the mean yield achieved by an average farmers was as indicated.

Table 2: Estimated co-efficient of Cobb-Douglas production function for cucumber farming

Variables	Regression Coefficient	Standard Error	t-value	Level of Significance
Constant	452.13	211.42	2.138	0.00

Resource use efficiencies in Cucumber production

The production function for cucumber production indicated the physical relationship between input and output as shown in Table 2 above. The resource use efficiency of cucumber production was determined as a ratios of marginal value product to marginal factor cost. All the resources used, except that of seed input, were greater than unity, Table 4; revealing that the resources were used at sub-optimal levels for cucumber production. The resource use efficiency for seed input was less that unity and thus, over utilized.

Table 4. Marginal physical and marginal value product for the inputs used in cucumber production

Input	MPP (Kg/Unit of input used)	MVP (₦)	MFC (₦)	MVP/MFC
Seed	20.82	202.4	212.2	0.95
Fertilizer	225	1452	987.3	1.47
Labour	320	2154	448.2	4.80
Land	1.05	19.3	12.4	1.55

Constraints to Cucumber production among smallholder farmers

Majority of the small holder cucumber producers' constraint in the study area was inadequate storage facilities (19.8%). They expressed that cucumber does not stay fresh for more than a week after harvest and thus, requires that, provision of adequate storage facility to farmers would go a long way to assist them balance the variation in market conditions after products'harvests; and thereby allow them make more profit and not always to lose out of business. This is in line with the report of Okonkwo-Emegha *et al*. (2019) that the cost incurred during the post-harvest contributes to low profit. Next in frequency of complaint by farmers is inadequate water and irrigation facility (17.7%). They explained that cucumber needs more water, and more water, throughout its stage of production and so that, it is being better still if farmer have irrigation facilities to help them maximize the yield potential of their crop via more irrigation facilities and more water for their grown plants.

Table 5. Constraints to cucumber production among small-scale farmers

Constraints	Frequency	Percentage
Inadequate storage facility	110	19.8
Inadequate Transportation	92	16.6
Inadequate credit facility	75	13.5
Unstable market forces	88	15.8
High cost of production input	94	16.9
Inadequate water and Irrigation facility	98	17.7
Total	555*	100

Source; field survey data 2023.
*Multiple responses.

CONCLUSION WITH RECOMMENDATIONS

Cucumber is a special nutritious vegetable crop that means many things to many people. However, an average cucumber farmer in the study area with a gross margin income of ₦ 2,680,580.00, a Net farm income of ₦2,658,080.00. and a return on investment of 3.63; is profitable in the study area. Some input resources employed which are underutilized including fertilizer, labour and land should be increased up to economic optimum level where resource use efficiency equals unity. Also, the major constraint to Cucumber production is inadequate storage facility and and inadequate irrigation facility. The farmers should form themselves into cooperatives, and develop their own social capitals and approach banks and government for loan facilities, adequate storage facilities and irrigation facilities needed to increase productivity and profitability of Cucumber production in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23^{rd} – 27^{th} Oct., 2023

ABSTRACT
The study investigated the production function and profitability of sweetpotato production in Sabon-Gari Local Government Area of Kaduna state. An average farmer incurred a total variable cost of ₦218,000.00 per hectare and realized a total revenue of ₦375,000.00. His sweetpotato average yield was 5000kg per hectare. A gross margin of ₦157,000.00 per hectare was achieved; and this makes the enterprise a profitable one. The Cobb-douglas regression estimates indicated an R-square value of 0.75 implying an 75% variation in total farm output of sweetpotato among the sampled farms were explained by the production inputs specified in the model. The major constraint faced by an average sweetpotato farmer is inadequate storage facilities. The study recommends that farmers form themselves into cooperative in order to benefit from government facilities and credit necessary to meet their storage and other problems.

INTRODUCTION
Sweetpotato (*Ipomoea batatas* (L.) Lam) is classified as a root and tuber crops that are notably grown in the sub-Saharan Africa (SSA), owing to its adaptive nature and appreciable productivity per unit area and time. (NRCRI, 2005). Sweetpotato thrives well and produce high yields even on marginal soils. Although it was recently being grown in Nigeria as commercial crop as well (Kisiangani and Pasteur, 2008); it was commonly grown by most smallholder farmers as an insurance crop, should other crop fail to yield well. It also serves for them as a crop to rely on for their subsistent living (Low *et al.* 2007).
Sweetpotato crop means many things to different people in Nigeria. It is often consumed boiled or fried and sometimes; being processed into various confectionaries like cakes, pancakes, rolls, buns, and puff puff ; and can also be made into sweetpotato gari (Odebode, 2004). The roots and tops could be made into a dried meal and fermented silage to feed livestock like pigs, cattle and poultry. Also, its vines, leaves and roots can be processed to animal feeds to feed sheep, goat, rabbits (Tewe *et al*. 2003), Also, the crop can be processed into ethanol and biofuel at economic scale. Sweetpotato can yield 137 litres of ethanol per metric tonnes of sweetpotato tubers (Akorado, 2009).
However, the almost static food growth rate in the face of explosion in population growth rate has been the main food problem in Nigeria. This has also leads to rises in food prices over the years. Ohajianya (2014), posited that the main food problems are food supply deficits, poverty and uneven distribution of income in terms of ability to buy food. Adequate production of most Nigeria staple crops such as sweetpotato which is consumed in many parts of the country, and which can be processed into wide range of food and utility products will contribute positively to the agricultural sector. The general objective of farmers is sustainable production at reasonable levels and at minimal risk, to satisfy their subsistence and commercial needs (Beets, 2010). Although, recent research works on sweetpotato might have concentrate more on the bio experimental researches on the crop, this study is focused on production function and profitability of Sweetpotato in the study area. The specific objectives of the study are to; i. determine the input-output relationship in sweetpotato production in the study area; ii. estimate the cost and returns of sweetpotato production; and iii. examine the constraints of sweetpotato production in the study area.

METHODOLOGY
The study was conducted in Sabon-Gari Local Government Area of Kaduna state of Nigeria; located in the Northern Guinea Savannah Zone of Kaduna state. The Local Government Area is situated on a plateau of a height of about 700m above sea level of latitude 11^0 12^1 N and longitude 7^0 8^1E. The study area has two distinct seasons which are dry and wet seasons. The rainfall extends from April to October and average annually between 100 to 1000mm with a mean temperature ranging from 27.20 ^{0}C to 35 ^{0}C in the month of April. The local government area consists of 12 Districts including Samaru, Jama'a, Bassawa, Hanwa, Dogarawa, Chikagi, Muchia, Zabbi, Jushi , Angwa-gabas, Angwan-godo and Bomo; and has an estimated

population of farming families of about 246,544. Majority of the farmers grows sweetpopato, irish potato, maize, millet, groundnut, cowpea, sugarcane, rice and vegetables such as cucumber, tomato, onion, and pepper are cultivated. The major livestock kept are goats, sheep, cattle and poultry.

The study adopted a multi-stage cross-sectional sampling survey design. Firstly, a random selection of 4 district/villages from the earlier listed 12 district was carried out. Secondly, a random selection of 30 sweetpotato farmers from each of the villages, making a total of 120 sweetpotato farmers were selected and interviewed. A well-structured and pre-tested questionnaire, was administered by trained enumerators. The data collected include those of socio-economic characteristics of respondents, input and output quantities used, revenue and cost variables and major constraints to sweetpotato production in the study area was gathered.

The study employed descriptive statistics including use of frequency distribution, percentages and means to describe the socio-economic characteristics, input-output of sweetpotato production and constraints farmers faced in sweetpotato production. The profitability of sweetpotato production was estimated on per hectare basis using farm budget techniques; including the estimation of gross return, gross cost, gross margin, net return and benefit-cost ratio (undiscounted). The formulas used for the calculation of profitability include: Gross return, GR = P×Q; where, P = Selling price of the product (Naira); Q = Yield per hectare (Kg). Gross cost, GC = TFC + TVC; where TFC = Total fixed cost (Naira); and TVC = Total variable cost (Naira). Gross margin, GM = GR – TVC. Net return, NR = GR – GC; and Benefit-cost ratio = Gross benefit / Gross cost.

Also, multiple regression analysis was used to analyse the production function, and estimation of the physical and economic relationship between the input and output factors in sweetpotato production. **-** The model in its general implicit form was; $Y = F\ (X_1, X_2, X_3, X_4, X_5, e_t) \ldots\ldots\ldots Eqn\ 1$; Where, Y = output of sweetpotato (kg), X_1 = Seeds (kg), X_2 = Fertilizer used (kg), X_3 = Pesticides (l), X_4 = Labour input (man/hr) X_5 = Land (ha), e_t = error terms. Among the functional forms tried, the best fit Cobb-douglas double-log form was used; and the explicit forms of the model is; $\log Y = a + b_1 logX_1 + b_2 logX_2 + b_3 logX_3 + b_4 logX_4 + b_5 logX_5 + e_t (Double\ Log\ ) \ldots\ldots\ldots\ldots. Eqn\ 2$

RESULTS AND DISCUSSION

Table 1 shows the result of input and output resources for sweetpotato production per hectare in the study area. An average farmer who cultivated an hectare of land uses 25kg and 200kg of seedstock (planting propagules vines) and fertilizers respectively. Also, 2.0litres and 152Man-hour of pesticides and labour respectively was used. However, Table 2. Show the estimated Cobb-Douglas production function result that, except for the coefficient log of seeds, that was not significant; all other coefficients of variables log fertilizer, log pesticides, log labour and log land are positive and significant at 5%, 5%, 10% and 10% respectively. The substantial R-square value of 75% also indicated that each of the specified explanatory variables actually well explained the output of sweetpotato per hectare in the study area.

In Table 3, the results of costs and returns analysis of an average smallholder sweetpotato producers in Sabon-Gari Local Government Area of Kaduna State were as shown below. The result revealed that, the enterprise is profitable in the area, with an average gross margin of ₦157,000.00 per hectare achieved and the average total costs of production of ₦235,600.00 per hectare was incurred to achieve this feat. The rate of returns on investment which was 0.59 means that, for every naira invested, the farmer will make ₦ 0.59 profits. These findings agreed with Alabi and Ajooku (2012), and Njoku and Offor (2016).

RECOMMENDATION AND CONCLUSION

The study found that the production of sweetpotato is profitable in the study area. It also showed that variables including fertilizer, pesticides, labour, and land are important determinant of output levels achieved. And that the major constraint to production is lack of storage facility. The study recommends the formation of farmers into cooperative group and for government interventions of loans to farmers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
In the agricultural marketplace, raw agricultural products and their value chains are developed through post-harvest activities, value chain processing, technology transfer and business models. Three selected agricultural crops, namely cassava, oil palm and rice were assessed in the light of these major tools for their market development. The selection of these three agricultural crops was based on their demand and versatility amongst Nigerians. Post-harvest activities entail the operations after harvesting, preventing damage; thereby increasing their shelf life. Value chain processing entails the processing of these crops from raw agricultural products to end-use consumption. Technology transfer includes technologies such as disease-resistant seed varieties, high oil-yielding seed varieties of these crops to realize optimal production after value chain processing. Business models involve the selection of private sector-led business model for accelerating the market development of harvested products of these agricultural crops. Cassava farming, oil palm farming and rice farming has been done successfully for several years in Nigeria and therefore poses no new investment risks. This paper ended by outlining sustainability concerns of these crops and recommendations towards market development of these selected agricultural crops in Nigeria.
Keywords: *Cassava, Market Development, Oil Palm, Rice, Value chain.*

INTRODUCTION
The primary and secondary processing of selected agricultural crops have a relatively high potential for use in energy supply and value chains (Thessa *et al.,* 2016). This is because in the production of primary agricultural products, relatively little energy is used. Also, in primary and secondary processing, large amounts of energy are used, and agricultural feedstocks and residues are often available at the processing location (Thessa *et al*, 2016). In tertiary processing, large amounts of energy are used but very limited feedstocks and agricultural residues are available. In some cases, primary processing is done by farmers. In these cases, this reduces the potential for using agricultural residues for energy supply. In addition, most primary and secondary processing is done in the vicinity of locations where the primary products are produced in order to avoid transportation of large volumes of primary products. These primary products are produced in rural areas with poor access to energy supply. Tertiary processing is often done in close urban areas and/or industrial areas, close to the customer base or transportation hubs, with better access to energy supply (Ladan, 2017). In Nigeria, with the availability of biomass at processing locations and existence of medium and large processing companies, the value chains of these three agricultural crops have best potentials for energy supply (GNESD, 2011). Despite geographic differences, this review discussed ways to enhance agricultural production, optimize processing activities and accelerate business models for market development of selected agricultural crops, namely cassava, oil palm and rice as well as their value chains in Nigeria.

Cassava (*Manihot esculenta*):
Food and Agricultural Organization (FAO) projected that by Year 2025, about 62% of global cassava production will come from sub-Saharan Africa (Adelekan, 2012). Cassava is an important staple crop in Nigeria and is Africa's second most important food staple in terms of calories consumed per capita and a major source of calories for roughly two out of every five Africans (Scarlett et al, 2020). Cassava is a staple of choice across cultures and social divides in Nigerian households. Much of the tuber produced from this root crop is consumed locally as traditional meals. It is the most important crop by production and the second most important by consumption (FAO, 2013). Cassava is grown in all agro-ecological zones of Nigeria but thrives better in the rainforest and derived savannah areas. Production is highest in the North Central and South-South regions of Nigeria. Nigeria is facing significant future demand for processed cassava; the cassava sector is expected to reach €7.2 billion in value by 2020. Cassava is important in Nigeria, not just as a food crop but even more so as a major

source of cash income for households. As a cash crop, cassava generates cash income for the largest number of households, in comparison with other staples, contributing positively to poverty alleviation. Cassava is usually consumed in processed forms, its processing by traditional methods is labour intensive but the applications of improved processing technology has reduced processing time and labour, thereby encouraging further production. Industrial utilization of cassava products is increasing but this accounts for less than 5% of total production (Sanni, *et al.*, 2012). For many years, the government of Nigeria is stimulating the cassava value chain, as cassava production and processing is a viable option to boost employment in the county. Measures taken to stimulate market growth in the cassava sector include institution of up to 40% of high-quality cassava flour requirements in wheat bread and 10% ethanol requirements in gasoline (of which 50% is from cassava). Cassava waste products are suitable for power generation as it contains large amount of starch; 20–35% fresh and 80.6% dry weight (Okudoh et al, 2014).

Production Chain:

Cassava is regarded as a staple food in Nigeria, as it is used to produce 'gari', 'fufu', and 'lafun'. Besides 'garri', cassava is used to produce 'Atteke', a cassava product. Cassava is used for animal feed, cassava starch, flour, ethanol, adhesives, and bread. The production chain shows the processing of cassava to "Garri" and "Atekke". The production chain shows that cassava starch is produced from cassava. From both production chains, substantial residue streams become available when processing cassava. The amount of residue becoming available in the different cassava processing steps provides an excellent basis for energy production.

Technology: To produce energy from cassava residues, several energy conversion technologies can be utilized, depending on the type of residue and energy requirements of the processor. Also, wastewater from cassava bagasse and starch residues can be used for energy production. Processing technologies and conversion processes for energy generation from cassava waste streams are impressive. Combustion and digestion can be used at relatively small scales. Cogeneration and gasification usually require somewhat larger-scale energy input for cost efficiency. Fermentation technology can be used to convert cassava into bioethanol. This technology usually uses the entire cassava and not only the residues. The selection of the most appropriate technology depends on scale of operation, availability of sufficient space for installation and energy demand of companies.

Figure 1: Processing of Cassava

Business models: Potential business models for the realization of sustainable energy supply from cassava depend on the size of the cassava processing company. Large-scale, well-equipped cassava processors can develop, build, maintain and operate power generation. These companies can bear the capital investments required to build a power system and are likely to have the knowledge and experience needed. Another option for these companies is to engage in a Design-Build-Operate-Maintain (DBOM) or a Build-Own-Operate-Transfer (BOOT) contract with third parties. With third parties, a Power Purchase Agreement (PPA) can be negotiated by cassava processors. That way, these cassava processors can receive steady energy supplies, without having to manage the plant itself. For medium- and small-scale cassava processors, it will hardly be feasible to develop and build a captive power plant internally. This can be ascribed to two facts. Firstly, the capital investments required for a captive power plant will most likely be too large for a medium- or small-scale entrepreneur in the cassava processing industry. Secondly, they usually do not have the required knowledge and skills within their firm, to develop, build, operate and maintain a waste to energy captive power plant.

Cassava Processors: Cassava is mainly cultivated in Anambra, Delta, Edo, Cross River, Imo, Oyo, Ogun, Niger, Rivers, Kwara and Benue States (Daniels *et al.,* 2011). There are about 1,200 large scale farmers (10 to1000 hectares and 5,000 medium scale farmers (6 to10 hectares in Niger Delta, supplying a handful of large processing industries and about 50 small-medium scale industries (PIND, 2011b). The National Cassava Processors and Marketers Association (NCAPMA) mentioned 65 members on their website (http://ncapma.org/directory/listing/). Large agri-food processing companies in the cassava sector have been identified in Cross River, Ogun, and Niger States.

Oil Palm (*Elaeis guineensis*):

Nigeria produced nearly 8 million tonnes of oil palm fruits (resulting in about 1 million tonnes of palm kernel) and is the third largest producer of oil palm in the world (FAO, 2009). Oil palm processing offers the empty fruit bunches, the processing waste effluent and palm kernel shells as options for energy supply. About 80% of Nigeria's palm oil production comes from scattered smallholder farmers spread over an estimated 1.6 million hectares of land. Oil Palm Plantations occupy between 200,000 and 360,000 hectares of land. Oil palm provided direct employment and income to about 5 million Nigerians (FAO, 2009). Oil palm is grown abundantly in southern Nigeria, with majority of large and small holder farms found in South-east and South-south Nigeria. The Niger Delta's nine states (Akwa Ibom, Abia, Rivers, Edo, Imo, Ondo, Bayelsa, Cross River and Delta) account for about 80% of total Nigerian palm oil production (Thessa *et al.*, 2016). But this production is dominated by the collection of palm fruits such as Fresh Fruit Bunches (FFB) from wild groves (74% of area and about 50% of supply of FFB), followed by production from private plantations (small, medium, and large farmers, 19% of area and 34% of supply of fruit) and large corporate and government owned plantations (about 7% of area, 25% supply of fruit). Other important oil palm producing states are: Ekiti, Ogun, Enugu, and Oyo. In 2012, the Government of Nigeria initiated the Agricultural Transformation Agenda for increasing palm oil production in the country (FAO, 2009). Government has distributed hybrid oil palm seedlings to farmers to replace the low-yielding and old trees; government is collaborating with farmers and private sector organizations to expand oil palm plantations. Some production increases have been recorded from this initiative. The government also supports domestic production through research.

Production Chain:

The Nigerian palm oil processing industry is made up of four identifiable channels including:

Channel 1: Traditional TPO (Technical Palm Oil)

Channel 2: Medium Technology TPO

Channel 3: Medium Technology SPO (Special Palm Oil)

Channel 4: Integrated

Channel 1 is the largest of the four channels, but it is shrinking. It is dependent on the wild grove harvest and tens of thousands of small processors, each producing between 40 and 200 litres poor quality product, produced with traditional production techniques. In this channel the end markets /end-users are food vendors, hoteliers, and households. Channel 2 is driven increasingly by improved farming techniques (commercially oriented) and by an improved processing technology for crude palm oil. The channel is comprised of the larger private producers of FFB who are integrating vertically into using more efficient processing technologies. Channel 2 is attracting the more commercially oriented actors from Channel 1 to upgrade and move into a more productive segment. It is generally expected that Channel 2 will become the dominant channel in Nigeria's oil palm value chain. This channel is already handling more than 50% of all the oil palm that is mechanically processed and commercially marketed. It has more than a thousand processors around the Niger Delta Area alone. Channel 3 represents an intermediate technology between the semi-improved processing and the expensive modern methods. Most oil palm estates produce Special Palm Oil (SPO). The channel has different actors in all the functions from input supplier, producer, processors, wholesalers, retailers, and end-users so the vertical coordination is complex. The channel is growing gradually due to high demand for the product in Nigeria. Channel 4 is comprised of the large estates with vertically integrated through processing with fully automated processing plants. Some companies like PRESCO, take the product all the way through to the fractionated Oleins and Stearins, while others sell their SPO to the secondary processors for fractionating. This channel is the model being used by the largest industries in the world from Malaysia and Indonesia, which can control the production of the fruit, the timing of its delivery to the mills, and the access to end markets. Medium and large-scale farmers in both the TPO and SPO channels seem very suitable to adapt to energy production.

Technology: To produce energy from oil palm residues, different energy conversion technologies can be utilized, depending on the type of residue and energy requirements of the oil palm processor. There are suitable processing technologies and conversion processes for energy generation from oil palm residues. The selection of the most appropriate technology depends on the scale of operation, availability of sufficient space for installation and the specific energy requirements of companies.

Business Models: Potential business models for the realization of energy production depend on the size of the oil palm processing company. Large and automated palm oil processors usually can develop, build, maintain and operate power generation. These companies can bear the capital investments required to build a power system. The most suitable business model for these oil palm processors is using the DBOM model, having third parties exploiting power plants and supplying energy to oil palm processors under PPA agreements. Both business models show a commercial potential.

Oil Palm Processors: Two companies in channel 4 are currently at the fore front in the production of SPO. These companies are PRESCO & Okomu Oil, both located in Edo State. Other actors in this channel are Golden Oil company and Envoy Oil Industries located in Anambra State, Agro Ideas International located in Akwa-Ibom State, EFB Industries Limited in Abia State and Sudit Oil in Oyo State.

Rice (*Oryza sativa L.*):

Rice production in Nigeria seems to have increased in recent years to 6.7 million tons in 2014 (Scarlett et al, 2020). Estimates indicate that over 90% of domestic rice production comes from resource poor and weakly organized small-holder farmers. Niger State produces the largest amount of rice paddies in the North Central zone at 473,000 tonnes paddy per annum (GIZ, 2015b). In the last few years, integration in the form of installation of rice mills and direct farming seems to be gaining more ground. Good examples of these are Olam and Dangote. In 2015, Olam Nigeria has invested €94 million in an integrated farm and milling facility in Nasarawa State. One of the biggest commitments for investing in rice processing was made in 2014 by Dangote Group. This Nigerian conglomerate committed to spending more than N165bn (€750 million) in rice mills, farms, and related infrastructure in a bid to supporting Nigeria's goal of becoming a net-exporter of rice (GIZ 2014). Dangote Group acquired farmland in five states, which will be used for the commercial production of rice paddy. It will also set-up two rice mills with an installed capacity of 240,000 tonnes of rice per day.

Production Chain: The Nigerian rice value chain is made up of five different channels. The integrated industrial processing mills seem the most suitable to adapt to energy production.

Processing Technology: To produce energy from rice residue, different energy conversion technologies can be utilized, depending on the energy requirements of processors. As straw is usually not available at the milling site, this residue is not a suitable feedstock for energy production at the mill location.

Business Models: For large scale rice millers, it is possible to install and manage power generation facilities internally. The large milling companies can bear the relatively high capital investments required to start energy generation using rice husk. Moreover, these companies are likely to have access to the knowledge required to build, own, maintain and operate a power plant. Another option for these companies is to appoint third parties that will be responsible for energy generation. With these third parties, a PPA can be negotiated. That way, the processors can receive steady energy supplies, without having to manage the plant itself. For medium scale rice millers, it will hardly be feasible to develop and build a power plant internally. This can be ascribed to two facts. Firstly, the capital investments required for a power plant will most likely be too large for these companies. Secondly, they usually do not have the required knowledge and skills within their firm, to develop, build, operate and maintain a waste-to-energy energy production plan. Most suitable business model for these rice millers is using a DBOM model, having third parties design, build, operate and maintain the power plant, supplying energy to rice processors under PPA agreements (GIZ, 2015). Some might prefer to use the BOOT model. For small rice millers only the DBOM model seems suitable. All business models show a commercial potential.

Rice Millers: In recent years, significant investments have been made in increasing the rice processing capacity in Nigeria. According to the Rice Millers, Importers and Distributors Association of Nigeria, the number of rice mills resulting from one plant five years ago is twenty-four at present (Simonyan and Fasina, 2013).

CONCLUSION AND RECOMMENDATIONS

The roadmap toward a future where primary production and value chain processing of these selected agricultural crops will be developed including an agricultural productive use component has been discussed. Based on this review, there are agricultural activities to prioritize and business model options that will enable better agricultural productivity. These business models include significant private sector participation to align with the private sector-led approach of the Nigerian energy sector and to reduce dependency on donor funding, ensuring long-term sustainability of these crops and their end-products. Their sustainability concerns include wastewater from effluent from their processing; indirect emissions emanating from land use changes due to crop production; water consumption; food security issues; biodiversity concerns; impact of agrochemicals on human health and ecosystems; long-term soil quality and conservation; social impacts; deforestation of natural areas. Therefore, it is important for these sustainability concerns to be taken into consideration in future for the market development of these selected agricultural crops. There is need to demonstrate returns of investment (via equipment purchases and feasibility studies) for the selection of business models to de-risk (risk factors of cultivation, storage, marketing) and attract private and foreign direct investments. These deliverables from combination of cross-sectoral engagement across the agricultural and value chain sectors alongside pilot tests is needed to drive findings and approaches identified in this review. Findings from this review showed some interesting developments and success stories in the value chain processing of these crops for socio-economic development of rural communities in developing countries like Nigeria. The recommendations of this review are:

1. Convene a working group across the agriculture and value chain sectors to coordinate, guide, and promote activities required to achieve long-term commercial viability.
2. Implement pilot tests and feasibility studies for agricultural production activities and collect operational data to refine financial models.
3. Use pilot data to design and implement recommended commercial business models and develop financial instruments for the market development of these selected agricultural crops.
4. Use lessons learned from pilot tests and feasibility studies to implement, deploy strategies, formalizing the structures needed to finance and support wide-scale policy instrument for improved agricultural production.
5. Deployment of these strategies for agricultural production activities; addressing identified barriers to agricultural development; addressing future investment risks and harnessing opportunities in the agricultural and value chain sectors with stakeholders in the industry.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The production of yam is beset by many problems which include weed pressure, decline in soil fertility, soil borne pests and diseases, storage pests, high labour cost of land preparation and maintenance, staking and barn making among others. The objective of this study is to generate mini tubers from yam slips to help solve the problems presented by insufficiency in yam planting materials. Five yam cultivars: TDr 89/2660, Hembakwase, Ame, Adaka, and Nwopoko were planted in the experimental site of the National Root Crops Research Institute, Umudike, in a 2 x 1 m plot size, at a planting spacing of 20cm, replicated 3times in a Randomized Complete Block Design. The seed yams were dusted with aldrex –T to prevent seed borne disease attack. Weeding was carried out at 4, 8 and 12WAP. Fertilizer NPK 15:15:15 was applied at 400kg/ha at 8WAP after the second weeding. Staking was done using trellis method of yam staking. Periodic monitoring and training of the vines was also done. Data were collected on stand count at harvest, number of seed yams, weight/plot (kg) and were subjected to ANOVA and means were compared using LSD under GenSTAT statistical software. The result showed that the available planting materials sprouted well and this may be due to the treatment with the Aldrex-T used which prevents soil borne disease attack. It also showed that the staking is a factor which promotes number of tuber and tuber size. The increase in the growth of the tuber size was also attributed to timely application of manures in form of N:P:K fertilizer and other cultural practices that was carried out timely. This study showed that, yam slips provide alternative means of generating yam mini tubers. To get good tuber size of yam, clean planting materials, timely maintenance and operations is the key.
Keywords: *Partial sectioning technique, Yam minisett, Minitubers, Yam slips*

INTRODUCTION
Yam (*Dioscorea* spp.) is generally classified under the genus *Dioscorea*, family *Dioscoreaceae*, and order *Dioscoreales*. Yams are the second most important tuber crop in the whole world after cassava, in terms of production and utilization (11TA, 2013)**.** One of the earliest attempts at partial sectioning technique was in 1975 by Nwosu (1975) at the National Root Crops Research Institute (NRCRI), Umudike, Nigeria. This method involves selecting an average sized seed yam of 300 – 400g. The proximal region including the corm was cut off to remove apical dominance. The tuber was sectioned into partially cut setts using incisions that are 1cm deep to mark out sett areas of 3 x 3cm on the tuber. In marking out each incised sett, the sectioning was first done longitudinally and then horizontally. The sectioned tuber was buried whole in a fertile compost mixture. Within few weeks, the incised part struck with vigorous roots arising from the base of the sprouting points. The sprouted sections were cut out from the tuber body and planted in the fertile field. This technique appears to double the multiplication rate from 1:5 to 1:10.
Ten years after the introduction of the partial sectioning technique for seed yam production, NRCRI, Umudike successfully developed the yam minisett technique for rapid, high volume seed yam production (Okoli *et al.*, 1982). This technology has not only increased the multiplication ratio in seed yam production to 1:30 but has reduced the cost of seed yam production. Yam minisett technology has been found to be economically viable and an easy alternative to solve the challenges presented by insufficient yam planting materials (Ironkwe *et al*., 2007). and it has been widely adopted not only in Nigeria but also across the yam belt of West Africa. In furtherance to reducing high cost of seed yams and insufficiency in availability of yam planting materials, investigations have been carried out this time, on the use of yam slips in mini tuber production. The objective of this study is to generate minitubers from yam slips to help solve the problems presented by insufficiency in yam planting materials.

MATERIALS AND METHODS
Planting materials, Design and Cultural practices:
Five yam cultivars: TDr 89/2660, *Hembakwase, Ame, Adaka*, and *Nwopoko* were planted in the experimental site of the National Root Crops Research Institute, Umudike, in a 2m x 1m plot size, at a planting spacing of 20cm, replicated 3times in a Randomized Complete Block Design. The seed yams were dusted with aldrex –T to prevent seed borne disease attack.

Weeding was carried out at 4, 8 and 12WAP. Fertilizer NPK 15:15:15 was applied at 400kg/ha at 8WAP after the second weeding. Staking was done using trellis method of yam staking. Periodic monitoring and training of the vines was also done. Which year was the experiment carried out.

Data Collection and Analysis:
Data were collected on stand count at harvest, number of seed yams, weight/plot(kg) and were subjected to ANOVA and means were compared using LSD under GenStat statistical software.

RESULTS AND DISCUSSION

Germination Rate (%):
The result on Table 1 and figure 1 showes that there was no statistically significant (P>0.05) difference among the treatment means in the germination percentage for both year 2011 and 2012. Similarly, the comparison of the varieties across the two years also showed no Significant (P>0.05) difference for percentage germination rate. However, in the year 2011 and 2012, Nwopoko and Hembamkwase gave the best promising germination rate of 22.38% and 21.72% respectively, while, *TDr 89/02660* and Ame gave the least (22.33% and 16.31% respectively) percentage of germination rate. This is an indication that the available planting materials sprouted well and this maybe due to the treatment with the Aldrex-T used which prevents soil borne disease attack. This agrees with Damudi (2013) who stated that for any planting materials to germinate and sprout well, they need to be adequately treated with recommended chemicals in which Aldex-T dust is inclusive.

Number of Seed Tuber:
The result on Table 1 and Figure 2 showed there was significant (P<0.05) difference in the number of seed tuber in year 2011 but there was no significant (P>0.05) difference in 2012. The interaction of the varieties across the two years showed no significant (P>0.05) difference. However, in the year 2011 and 2012, Nwopoko and Hembamkwase gave the best promising number of seed tuber of 28.00 and 26.00 respectively, while, *Adaka* and *Ame* gave the least (23.00 and 21.70 respectively) number of seed tuber. This is an indication that the staking is a factor which promotes number of tuber and tuber size. This is in agreement with Akoh, (2012); Manu, (2010) and Ajih, (2009), they observed that staking process assist in tuber elongation and size increase in tuberous crops.

Weight of tuber (Kg):
The result on Table 1 and Figure 3 showed there was significant (P<0.05) difference in the number of seed tuber in year 2011 but there was no significant (P>0.05) difference in 2012. The interaction of the varieties across the two years showed significant (P<0.05) difference. However, in the year 2011 and 2012, Hembamkwase gave the best promising tuber weight of 5.70Kg and 3.93Kg respectively, while, *TDr 89/*02660 and *Adaka* gave the least (3.73Kg and 2.00Kg respectively) tuber weight. The increase in the growth of the tuber size can also be attributed to timely application of manures in form of N:P:K fertilizer and other cultural practices that was carried out timely. In support of this, Adejoh, (2013); Daluba, (2010); Edibo, (2008); Ezekiel, (2006) and Olazide (2004) stated that fertile topsoils, mulches, organic manure with proper staking and weeding help to boost the tuber yield of yams most especially in tropical zones.

Table1: Stand count, number of seed yams/plot and weight of seed yam/plot on the use of yam slips for mini tuber production in 2010 cropping season

	Yield parameters					
	2011			2012		
Treatment	Stand count	Number of seed yams	Weight (kg)	Stand count	Number of seed yams	Weight (kg)
Adaka	22.67	23.00	3.80	25.7	26.00	2.00
Ame.	24.33	24.33	4.60	19.3	21.70	2.97
Hembamkwase	24.33	24.67	5.70	27.0	28.70	3.93
Nwopoko.	27.00	28.00	4.23	22.0	22.70	3.57

CONCLUSION

Many problems beset yam production in Nigeria, ranging from weed pressure, decline in soil fertility, soil borne pests and diseases, leaf and shoot diseases, storage pests, high labor cost for land preparation and maintenance, staking, harvesting, barn construction and tuber quality deterioration. The contributions of the National Root Crops Research Institute, Umudike to yam improvement is highly commendable. However, the tasks before it and collaborating crop research institutes, and crop breeders are the development of alternative planting materials which do not compete with human food, non-stake yam varieties, weed tolerant, pest and disease resistant and highly adaptable yam genotypes/varieties for Nigerian farmers. The need for the adoption of molecular techniques in addition to the conventional breeding techniques cannot be over emphasized. This trial showed that, yam slips provides alternative means of generating yam mini tubers. To get good tuber size of yam, clean planting materials, timely maintenance and operations is the key.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Factors influencing participation in contract farming among tomato farmers in Ankpa Local Government Area of Kogi State were assessed in this study. Multistage sampling technique was employed for selecting sample of 150 respondents. Primary data was used for the study. Data were collected using a structured questionnaire. Probit model and Likert Scale were used to analyse data collected. The results showed that Sex (0.008) was statistically significant at 1% alpha level, while marital status (0.049), co-operative membership (0.019) and extension services (0.034) were statistically significant at 5% alpha level in influencing participation in contract farming. Inadequate credits with the mean score ($\bar{X}$=1.61), pest and diseases attack ($\bar{X}$=1.71), high cost of labour ($\bar{X}$=1.47), poor transportation network ($\bar{X}$=1.66), long distance from the farm to the market ($\bar{X}$=1.74), inadequate co-operative societies ($\bar{X}$=1.66), high cost of agrochemicals ($\bar{X}$=1.34), irregular extension visits by extension agents ($\bar{X}$=1.34), prevalence of adulterated agrochemicals ($\bar{X}$=1.10), lack of irrigation ($\bar{X}$=1.30), and untimely supply of inputs by contracting firm ($\bar{X}$=1.32) were the serious constraints faced by tomato farmers in the study area. Contracting individuals/firms should ensure timely delivery of inputs to farmers to ensure effective operations and timely delivery of produce, extension agents should pay more visits to tomato farmers since increased frequency of visit by extension workers was found to increase participation in contract farming. Also, necessary measures should be taken by the government against the circulation of adulterated agrochemicals among farmers in the rural areas of Nigeria.
Keywords: *Contract, farming, Participation, Analysis, Factors, Influencing, Tomato, Farmers*

INTRODUCTION
Contract Farming is an agreement between farmers, processing and/or marketing firms to produce and supply specified crop(s) under forward agreements mostly at pre-determined prices (Will, 2013). Tomato farming generates profits for the farmers and thus improve their living standards, create job opportunities in agriculture and agro-allied sectors thereby boosting the overall economy of Nigeria. This provides stimulus for agricultural innovation, increasing capital for agricultural investment which could result in the development of rural economies. Buyers of the specified crop(s) may provide embedded services such as upfront delivery of inputs, pre-financing of input, delivery on credit and other non-financial services (such as extension service, provision of training for farmers, transport and logistics). Tomato farming generates profits for the farmers and thus improve their living standards, create job opportunities in agriculture and agro-allied sectors thereby boosting the overall economy of Nigeria (Nwigwe *et al.*, 2020). Small scale farmers in the rural areas of Nigeria suffer from marketing risks associated with the sale of their produce, price volatility which sometimes discourage farmers from production and poor market linkages. These have increased poverty level as well as food insecurity among rural farmers especially in the study area. Hence, this study was designed to assess factors influencing participation in contract farming among tomato farmers in Ankpa Local Government Area, Kogi State. The following are salient research questions: (i) what factors influence the participation in contract farming among farmers in the study area? and (ii) What are the constraints faced by tomato contract farmers in the study area? The objectives of this study were to:

(i) analyze the factors influencing participation in tomato contract farming in the study area
(ii) describe the constraints faced by contract tomato farmers in the study area.

Hypothesis:
H_0: socio-economic characteristics of farmers do not influence participation in contract farming
H_1: socio-economic characteristics of farmers influence participation in contract farming

METHODOLOGY
This research was conducted in Ankpa Local Government Area, located on the A233 high way in the Eastern part of Kogi State. It is found between latitude 70 15" North and 70 37" North of the Equator and longitude 70 30" East and 70 and 37"

East of the Meridian (NPC, 2006). It has an estimated population of three hundred and nine thousand, nine hundred and thirty (309, 930) people and a land mass of two hundred and sixty-two (262) square kilometre (NPC, 2006). Crops grown are Tomato, Okra, Yam, Maize, Cassava, Cowpea, Citrus, Oil Palm, Mango, and Cashew. Major livestock are goats and poultry which are reared extensively. Multistage sampling technique was used to select 150 respondents for the study. In the first stage, the three (3) major districts namely; Ankpa, Enjema and Ojoku districts were purposively selected. The second stage involved random selection of two (2) communities from Ankpa district, two (2) communities from Ojoku district and four (4) communities from Enjema district based on the prevalence of tomato farmers in those areas. The third stage involved the use of proportional sampling technique to select 10% of the respondents from the sampling frame, as shown in Table 1 below. Primary data were used for the study. Data were collected using a structured questionnaire.

Table 1: Distribution of Tomato Farmers in the Study Area

Districts	Communities	Sampling Frame	Sample Size (10%)
Ankpa	Ikanekpo	85	8
	Ogodo	40	4
Enjema	Inye	800	80
	Ofugo	107	10
	Agbeneba	90	9
	Enelie	300	30
Ojoku	Ochunobi	31	3
	Ojoku	60	6
Total		**1,513**	**150**

Analytical Techniques

Probit Regression was used to analyse objective (i) while objective (ii) was analysed using three point Likert scale.

Probit Regression Model

Probit Regression Model was adopted for the analysis of factors influencing participation in contract farming because the dependent variable (Participation in contract farming) was a binary variable. This was adopted following Ebuenyi *et al* (2020), who applied the Probit Regression Model to assess agricultural credit Sources and accessibility in Nigeria

The implicit form of Probit model is as follows:

$$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, X_9, X_{10}, X_{11}) \quad (1)$$

Where:

Y = Participation in contract farming (a Binary variable; 1, for participation in contract farming and 0, for non-participation in contract farming)

X_1-X_{11} = Vector of explanatory variables (predictors)

The model is specified explicitly as:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + \beta_9 X_9 + \beta_{10} X_{10} + \beta_{11} X_{11} + \mathcal{E}_i \quad (2)$$

Where:

Y=Dependent variable (Participation in contract farming) which is a binary response variable predicted by the model (with responses coded as Yes=1, No=0)

β_1-β_{11}=Coefficients of the explanatory variables

β_0=Constant

X_1=Age of farmer (years)

X_2=Sex of farmer (Male=1, Female=0)

X_3=Marital Status (Single=1, Married=2, Divorced=3, Widow=4, Widower=5)

X_4=Educational Level (No formal education=1, primary education=2, secondary education=3 and tertiary education=4)

X_5=Household size (Number of persons)

X_6=Farming experience (Years)

X_7=Co-operative membership (Yes=1, No=0)

X_8=Farm size (hectares)

X_9=Annual income (₦)

X_{10}=Access to agricultural credit

X_{11}=Access to extension service

$\mathcal{E}_i$=Error term.

The constraints to tomato farmers were assessed using Mean scores of responses obtained from three point Likert scale:

Serious=1

Undecided=2

Not Serious=3

Mean score of each item was determined using the formula:

$$\bar{X} = \frac{\Sigma FX}{N} \quad (3)$$

Where:
$\bar{X}$ = Mean of responses
$\sum$= Sigma (Summation)
F=Frequency
X=Numerical value of the scale point
N=Number of respondents.
The numerical value of the scale points and their respective real limits are as follows:
Serious constraints = 1-1.70
Undecided = 1.80-2.49
Not serious constraints = 2.5-3.00
This means that any mean score between 1 to 1.70 depicted 'Serious constraints'
Mean score from 1.8 to 2.49 was considered as 'Undecided' while Mean score of 2.50 to 3.00 was considered 'Not serious constraints'.

RESULTS AND DISCUSSION

Factors Influencing Participation in Contract Farming among Tomato Farmers in the Study Area

The results of Probit Regression estimate on factors that influence tomato farmers' participation in contract farming in the study area is presented in Table 2. Participation in contract farming was the dependent variable while the independent variables were age, sex, marital status, level of education, household size, farming experience, membership of co-operative societies, farm size, extension services, annual income and access to credit. The result showed that the value, Prob > chi^2 (0.0348) is significant at 5% alpha level. This implies that the null hypothesis that the socio-economic variables do not influence participation in contract farming is rejected. It further implies that the independent variables in the model were jointly statistically significant in influencing farmers' participation in contract farming. Sex of the respondents which was significant at 1%, marital status (5%) co-operative membership (5%) and access to extension services (5%) were the principal determinants of participation in contract farming among tomato farmers in the study area.

The coefficient of sex is negative and significant at 1% alpha level. This implies that sex of the farmers negatively influence the participation in contract farming. This implies that male farmers are more involved in tomatoes contract farming than female farmers in the study area. This was even evidenced by the fact that majority of farmers in the study area were male. This tallies with the a priori expectation that there will be more males in tomato contract farming than females.

The coefficient of marital status was negative and significant at 5% in influencing farmers' participation in contract farming. This means that marriage negatively influences farmers' participation in tomatoes contract farming in the study area. It implies that married farmers were less likely to participate in contract farming than single farmers. This could be because married farmers have larger households and as such, higher responsibilities than unmarried farmers. This could make delivery of the crop difficult. That is, married farmers may easily breach the contract compared to unmarried ones. This is similar to the findings of Ahamefule *et al.* (2018) who reported that married smallholder farmers are 66.32% less likely to be able to repay their loans than single small holder farmers.

Membership of co-operative societies has a positive coefficient and was significant at 5%. This implies that a unit increase in the number of co-operative societies to which a farmer belongs, will lead to an increase in the probability of farmers participating in contract farming. This is perhaps because co-operative society is a medium through which contracting individuals or firms negotiate with potential contract farmers. Such co-operative societies also facilitate timely and effective dissemination of information among members. This result is similar to findings of Assogba *et al.* (2017), who reported that belonging to farmers' cooperatives associations was found to increase the likelihood of farmers' access to formal and semi-formal credit.

The coefficient of extension services was positive and significant at 5% level of significance. This means that the frequency of contacts with extension agents positively influences the participation in contract farming. This implies that if the village extension workers increase their frequency of visits to farmers' farms, the probability of participation in contract farming will be higher. It also implies deploying more extension agents to the rural areas will positively affect the probability of involvement in contract farming. This implies that extension agents educate farmers on the benefits of participating in contract farming. This is similar to Ahamefule *et al.* (2018) who reported that the number of supervisory visits is positively related to small holder farmers' ability to repay their loans and that increasing the number of supervisory visits will increases the probability of a farmer been able to repay his/her loan.

Constraints Faced by Contract Tomato Farmers in the Study Area

The result of the analysis on constraints faced by contract tomato farmers in the study area is shown in Table 3. The result shows that inadequate credits with mean score ($\bar{X}$=1.61), pest and diseases attack ($\bar{X}$=1.71), high cost of labour ($\bar{X}$=1.47), poor transportation network ($\bar{X}$=1.66), long distance from the farm to the market ($\bar{X}$=1.74), inadequate co-operative societies ($\bar{X}$=1.66), high cost of agrochemicals ($\bar{X}$=1.34), irregular extension visits by extension agents ($\bar{X}$=1.34), prevalence of adulterated agrochemicals ($\bar{X}$=1.10), inadequate flow of information ($\bar{X}$=1.67), lack of irrigation ($\bar{X}$=1.30), and untimely supply of inputs by contracting firm ($\bar{X}$=1.32), were the serious challenges faced by tomato farmers in the study area. But farmers were not decisive about theft ($\bar{X}$=1.91) being a constraint or otherwise. Inadequate market information ($\bar{X}$=2.50) was not a serious constraint to the tomato farmers in the study area. This findings is consistent with Enemosa *et al.* (2022) who reported that inadequate credits, shortage of funds, Lack of technical knowledge, Knowledge and skills limitation and High cost of post-harvest materials were severe constraints to post-harvest management training needs for tomatoes farmers in Niger state, Nigeria. Enemosa *et al.* (2022) also reported that inadequate market information and theft of produce were not severe constraints to post-harvest management training needs for tomatoes farmers in Niger state, Nigeria.

Table 3: Estimate of Constraints Faced by Tomatoes Contract Farmers

Constraints	Serious	Undecided	Not serious	Mean	Decision
Inadequate credit facilities	*83(69.2)*	*0(0.00)*	37(30.8)	1.61	Serious
Inadequate market information	*30(25.0)*	*0(0.00)*	90(75.0)	2.50	Undecided
pest and diseases attack	74(61.7)	*6(5.00)*	40(33.3)	1.71	Serious
High cost of labour	91(75.8)	*0(0.00)*	29(24.2)	1.47	Serious
Poor transportation network	77(64.2)	*5(4.20)*	38(31.6)	1.66	Serious
Long distance from the farm to the market	52(43.3)	*46(38.3)*	22(18.3)	1.74	Serious
Inadequate co-operative societies	80(66.7)	*0(0.00)*	40(33.3)	1.66	Serious
High cost of agrochemicals	99(82.5)	*0(0.00)*	21(17.5)	1.34	Serious
Irregular extension visits by extension agents	91(75.8)	*15(12.5)*	14(11.7)	1.34	Serious
Prevalence of adulterated agrochemicals	107(89.2)	*13(10.8)*	7(9.30)	1.10	Serious
Inadequate information flow	79(68.5)	*0(0.00)*	41(34.2)	1.67	Serious
Lack of irrigation	100(83.3)	*2(1.70)*	18(15.0)	1.30	Serious
Untimely supply of inputs by contracting firm	99(82.5)	*2(1.70)*	19(15.8)	1.32	Serious
Theft	60(50.7)	*5(6.00)*	10(41.7)	1.91	Undecided

Source: Field Survey, 2022

CONCLUSION

In conclusion, sex, marital status, membership of co-operative society and extension services were the principal factors that influence/determine participation in contract farming among tomato farmers in the study area. Inadequate credit facilities, pest and diseases attack, high cost of labour, poor transportation network, long distance from the farm to market, inadequate co-operative societies, high cost of agrochemicals, irregular extension visits by extension agents, prevalence of adulterated agrochemicals, inadequate information flow, lack of access to irrigation, untimely supply of inputs by contracting firm were the serious constraints to contract tomato farmers in Ankpa Local Government Area of Kogi State.

RECOMMENDATIONS

Based on the findings of this study, the following policy recommendations were made:

(i) Contracting individuals/firms should ensure timely delivery of input to the farmers to ensure effective operations timely delivery of produce.

(ii) Necessary measures should be taken by the government against the circulation of adulterated agrochemicals among rural farmers.

(iii) Extension agents should be charged to intensify their activities and as such pay more visits to tomato farmers since increased frequency of visit by extension workers was found to increase participation in contract farming

(iv) Since membership of co-operative society increases participation in contract farming, formation of more co-operative societies by the farmers is highly imperative.

23rd – 27th Oct., 2023

ABSTRACT

Information and communication technology (ICT) has helped in developing tools that are capable of identifying crop diseases and pests damage, but faces a greater challenge due to the variability of symptoms. However, several novel techniques for diseases and pests identification that use image recognition systems have been developed. This study was conducted to assess the efficacy of NURU smartphone application in identification and management of cassava viral diseases. PlantvillageNURU is an application that can be used in an android phone to detect and diagnose viral diseases on cassava. Data from 100 respondents were collected using amulti-stage sampling technique and analyzed using descriptive statistics. The findings revealed that most (92.0%) of the respondents reported that they would be inclined to confirm cassava virus when plants have stunted leaves or yellow leaves. With regards to management of the cassava diseases, most (51.0%) of the farmers mostly practiced removal of infected stems. But the introduction of NURU application was perceived to play a vital role in determining and monitoring diseases from cassava farm with a mean of 4.41 ($\bar{X}$ = 4.41), and WAVE Participatory surveillance effectively managed the viral diseases affecting cassava thereby increasing cassava yield with a mean of 4.47 ($\bar{X}$= 4.47). However, the capability of NURU application as a tool to detect cassava diseases and pests was excellent. The implication of this study is that, NURU can be an effective tool for in-field diagnosis of cassava diseases and has the potential to be a quick and cost-effective means of disseminating knowledge to farmers, particularly on the identification of disease symptoms and their management practices. Hence, the need for creation of more awareness on the use of NURU in cassava diseases diagnosis is necessary.

Keywords: *Identification, NURU Application, Cassava, Diseases, Management*

INTRODUCTION

Cassava has a wide range of pests and diseases that constrain its production, but the two virus diseases, Cassava mosaic disease (CMD) and Cassava brown streak disease (CBSD) are the most economically damaging in Africa. Nigeria is the leading producer of cassava in the world (Ezedinma *el al.,* 2007). The production of cassava is concentrated in the hands of numerous smallholder farmers located primarily in the south and central regions of Nigeria. According to (FAO. 2003), about 50% of cassava harvested is wasted due to production and postharvest inefficiencies at the farm level. The rest is consumed as food in a few, limited ways as its production is not commercially oriented to serve the needs of industry. However, successive virus disease pandemics have resulted in losses worth hundreds of millions of dollars each year, threatening the livelihoods of all those who depend on this source of calories. To this end, participatory surveillance in collaboration with Plant Village of Pennsylvania State University (USA) was commenced through regular cassava disease diagnostics based on the use of an intelligent application called NURU. This application is used in other parts of Africa and Asia but not frequently used in Nigeria. Currently Plant Village is a public good resource built at Pennsylvania State University for diagnosis of viral diseases. These include the viral diseases of cassava (CMD and CBSD) and the damage caused by CGM.

Statement of the Research Problem

Cassava products are increasingly becoming popular in Nigerian food and agricultural markets. Cassava production is currently threatened by cassava mosaic disease (CMD) and cassava brown streak disease (CBSD) both largely propagated through the exchange of infected planting materials among farmers, and resulting in losses of over 1 billion USD annually (Legg *el al.,* 2015). Awareness raising and training of cuttings multipliers and cassava producers in the use of healthy planting material is the best alternative for disease leaching and can lead to significant production improvements. To this end, Participatory surveillance in collaboration with Plant Village of Pennsylvania State University (USA) through regular cassava disease diagnostics based on the use of a smartphone application called NURU. The application is used in other parts of Africa and Asia but not frequently and adequately used in Nigeria. NURU is a deep learning object detection model for diagnosing plant diseases and pests developed as a public good by Plant Village (Penn State University). In addition to providing instant pest/disease diagnosis, the application hopes to provide guidance on control, and helps farmer to source healthy planting material of improved varieties by linking users to the International Institute of Tropical Agriculture IITA Seed Tracker application.

METHODOLOGY

The study area was Kebbi State, Nigeria. Multi-stage sampling technique was used in this study to select actors who are in cassava production. Primary data were used for this study and they were collected by means of structured questionnaire. The analytical tools that were used include descriptive statistics (frequency, percentage, mean, standard deviation and ranking)

RESULTS AND DISCUSSION

Traditional Approach in Identifying Cassava Viruses

Most (92%) of the respondents reported that they would be inclined to confirm cassava virus when plants show stunted leaves or yellow leaves (8%) (Table 1). This shows that farmers have prior knowledge of cassava diseases. With regards to management of the disease, farmers mostly practiced removal of infected stems (51.0%). Other farmers (32%) used insecticide to control insect vectors, while a small fraction (4%) of the respondents used clean planting material. These results indicate that the respondents in the survey area lacked adequate knowledge on management aspects. Providing the farmers with extension services only does not always lead to increased land productivity since many farmers still do not have sufficient technical knowledge and they faced shortage of farm labour (CUTS, 2011).

Table 1. Traditional Approaches Used in Identifying Cassava Virus Diseaes

Variable	Frequency	Percentage
Traditional ways used to confirm cassava virus		
Leaves stunted	92	92
Yellowish leaves	8	8
Total	**100**	**100**
Management		
Removing infected plant	51	51
Use of insecticide to control	32	32
Crop rotation	2	2
Use of clean planting material	4	4

Perception of Farmers in Identifying Cassava Diseases Using NURU Application

The result presented in Table 2 shows that after rating the perception of respondents in identifying cassava diseases using NURU application. All the perceptions agreed with the following statements, potentiality of the application to improve yield of cassava production ($\overline{X}$ = 4.54), Using NURU is better than traditional diagnosis ($\overline{X}$ = 4.54), Using NURU application tool can monitor and manage cassava farm from diseases ($\overline{X}$ = 4.54), the new application could be used to diagnose disease on cassava farm ($\overline{X}$ = 4.47), usefulness of the application ($\overline{X}$ = 4.46), the capability of NURU to determine cassava pests and diseases symptoms in cassava production ($\overline{X}$ = 4.44) and impact of the application to determine disease ($\overline{X}$ = 4.41) as well as the rate capability of the application is the best ($\overline{X}$ = 4.41). These results indicate that NURU has potentials to be applied to a wide range of disease and pest problems that affect farmers and also the application will improve planting material to enhance their output. In addition, the application is capable of diagnosing cassava diseases in cassava production in order to improve their family livelihoods. These findings confirm the findings of Souter *et al.* (2005) and Sife *et al.* (2010), who both asserted the potential of mobile phones application in reducing vulnerability.

Table 2: Perception of Farmers in Identifying Cassava Viruses Using NURU

	Statements	Mean	SD	Remark
1	Potentiality of the NURU application	4.54	0.67	Agreed
2	The use of NURU is better than traditional diagnosis	4.54	0.65	Agreed
3	NURU tool can monitor and manage cassava farm from diseases	4.54	0.65	Agreed
4	The New application could be used to diagnose disease on your cassava farm	4.47	0.64	Agreed

5	Useful of the application	4.46	0.65	Agreed
6	capability of the application	4.44	0.63	Agreed
7	Impact of the application to determine disease	4.41	0.63	Agreed
8	The rate capability of the application is the best	4.41	0.67	Agreed

Source: Field Survey, 2022

CONCLUSION AND RECOMMENDATION

It was concluded that farmers confirmed cassava diseases only when the plants become stunted or show yellow leaves and mostly managed cassava diseases by removing infected stems or use of insecticide to the control vectors. NURU application can be an effective tool for in-field diagnosis of cassava diseases, particularly on the identification of disease symptoms and their management practices. Therefore, it was recommended that creation of more awareness on the use of NURU is necessary in cassava diseases diagnosis.Farmers should be encouraged to use NURU application to control and manage CMD and CBSD in their field.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study examined Arable crop farmers' information needs in using soap opera for sourcing Agricultural Information in Oyo State, Nigeria. Using a multistage sampling procedure, 120 farmers were randomly selected across the study area. Data were collected with the use of interview schedule on farmers' enterprise characteristics, information needs and perceived constraints to the use of soap opera for sourcing agricultural information. Data were analyzed using descriptive (means and percentages) and inferential (Chi-square) statistics at p=0.05. All the respondents (100%) were involved in crop production. Crop produced by farmers varied from cereals (40%), Tuber crops (26.7%), vegetables (20.8%) and legumes (12.5%). Higher proportion (95.3%) of farmers would like the soap opera to cover crop planting procedure (29.2%), future market price (42.5%), marketing strategies (30.8%) and daily rainfall prediction (40.0%), land and boundary dispute (53.33%), ethnic dispute resolutions (46.67%). Unstable power supply (52.5%), unfavourable broadcasting hour (50.0%) and irrelevant information (48.3%) were identified as constraints to the use of soap operas for agricultural enterprise promotion. It is recommended that soap opera for agricultural enterprise promotion should focus on crop with emphasis on preferred agricultural information types.

Keywords: *Soap Opera, Agricultural Information, Arable Crop farmers*

INTRODUCTION

Information in agricultural development is very critical because, it serves as a tool for communication between stakeholders and also a channel for assessing trends and shaping of decisions (Darshan *et al*., 2017). Farming requires timely and technical information hence, the need for extension services. However, due to some factors extension services are not readily available to farmers. A consensus exists that extension services, if functioning effectively will lead to improve agricultural productivity hence, providing farmers with necessary information that will help them optimize their limited resources (Muyanga and Jayne, 2006). The basic information needs of farmers are information on crops, production techniques, production equipment and agricultural inputs, market information, and weather forecast among others (Milovanović, 2014). Soap opera, sometimes called "soap" for short, is an ongoing episodic work of dramatic fiction presented in a serial format on Television or radio. The name soap opera stems from the original dramatic serial broadcast on radio that had soap manufacturers such as Procter & Gamble, Colgate-Palmolive and Lever Brothers as sponsors and producers. Soap opera forms an integral part of modern mass media messages and it follows that, sources on mass media are valuable. It is a branch under Entertainment Education being a strategy for development communication that shares behavior change premises with other development communication theories and strategies (Buenting and Brown, 2013; Brown and Singhal, 1993). It is trans-cultural and encapsulates a universal appeal that fascinates members of most culture in which it incorporates both imagery and dialogue, this is because soap opera is a combination of the visual image and linguistic (Marx, 2007). Soap opera on television as a medium of disseminating information can be fully utilized to channel new technologies and innovations related to agriculture to farmers that will further increase their productivity.

Problem Statement

The power of entertainment in shaping the perceptions and practices of viewers and listeners cannot be overemphasized. Both the radio and television Entertainment-Education (EE), shows programs, movies, and music that do not only command attention of their audiences, but also reinforce their existing positive behaviors by demonstrating new behavior that affect audience emotions (Coleman 1986; Olajide and Yahaya 2003). The importance of information in every society cannot be overemphasized. The agriculture sector in developing countries is becoming increasingly knowledge intensive and researchers at the global, regional, and national levels continue to generate new information but due to various factors, extension services are not readily available to all farmers. However, not all institutions have fully embraced social media as a tool for disseminating information or sharing research outputs.

However, little evidence exists on the information needs of farmers in the use of soap opera utilization for sourcing timely agricultural information useful for promotion and development. It is against this background the study tends to achieve the following objectives.

The broad objective of the study is to assess arable crop farmers' information needs in using soap opera for sourcing agricultural information

The specific objectives include:

- described socioeconomic characteristics of the respondents
- identify farmers' sources of information
- ascertain enterprise information that arable crop farmers uses soap opera to address
- identify the constraints in the use of soap opera by arable crop farmers

METHODOLOGY

Multi stage sampling procedure was used to select respondents for this study. The first stage involved purposive selection of 2 Local Government Areas from each senatorial district of the state with the highest number of registered farmers. The second stage involved random sampling of 50% of the registered farmers from the selected LGAs, and the third stage involved selection of 10% of the registered farmers were randomly selected to give a total of 120 farmers used for the study. Frequency counts, means and percentages were used to examine the various data of respondents.

RESULTS AND DISCUSSION

Table 1 show that majority (94.17%) of the respondents were males while 5.83% of them were females. This implies that male farmers were more involved in farming than females in the study area. The result supported the findings of Edeoghon *et al*., (2008) which says that males were more involved in arable cropping than females in Edo State. The result shows that age range of 31 to 59 years were the majority with 55.83%, followed by those above 60 years with 35.83%, and 8.33% were less than 30 years respectively. This implied that most of the people were active people who can still practice arable crop production. Also findings in the Table showed that majority (99.17%) were married while (0.83%) are singles. The result agreed with the findings of Onasanya (2007) who reported that most crop farmers in Ogun State are married; and Soyebo *et al.* (2005) stated that agriculture is very much practiced by married people to make ends meet and cater for their children. Furthermore, many of the respondents (54.16%) were Muslims, followed by Christians 45.01% while the remaining 0.83% practiced traditional religion.

The table further shows that many of the respondents (42.5%) has a household size of less than 6 persons, 36.7% had a household size of between 6-10 members, and 20.8% had above 10 household size respectively.. Also the table further revealed that 16.6 % of the respondents had no formal education, 46.7% had primary education, 25.8% had secondary education and 10.9 % had other educational qualifications respectively. Finally, the result shows that majority (62.5%) had 6-10 years' experience, 30% had farming experience of 1 to 5 years, while 7.5% had above 10 years of farming experience respectively

Table 1: Socioeconomic characteristics of the respondents

Variables	Frequency	Percentage	Mean
Sex			
Male	113	94.17	
Female	7	5.83	
Age			
≤30	10	8.33	
31- 59	67	55.83	
>60	43	35.83	
Marital status			
Single	1	0.83	
Married	119	99.17	
Family size			
1-6	51	42.5	
7-10	44	36.7	
Above 10	26	20.8	
Educational level			
No formal	20	16.6	
Primary school	56	46.7	

Secondary school	31	25.8
Others	13	10.9
Farming experience		
1-5	36	30
6-10	75	62.5
Above 10	9	7.5
Primary occupation		
Farming	120	100.0

Source: Field survey, 2018

Table 2 shows that 37.5 % of the respondents got information through the radio, 8.4% of the respondents in the study area got information from extension agent, 33.3% got information from Farmer's Association, and 20.8% received information from television. This is in line with Churi *et al*. (2012) who stated that majority of the farmers mentioned radio broadcast as their sources of agricultural information.

Table 2: Sources of agricultural Information (n=120)

Sources of information	Frequency	Percentage
Radio	45	37.5
Extension agent	10	8.4
Farmers association	40	33.3
Television	25	20.8

Field survey: 2018

Table 3 shows that 40.0% of the respondents produced maize only, 26.7% produced cassava only, 20.8% produced (maize and cassava, and 12.5% produced other arable crops respectively. This is in agreement with the findings of Olajide (2017), which stated that most of the farmers are involved in more than one type of crop (mixed Cropping) in other to diversify their means of livelihood. Results in Table 4 show that 29.2% of the farmers' crop based information were on crop planting procedures, 25.8% on fertilizer application, 20% on pest and disease management, 11.7% were on harvesting techniques, and 13.3% on storage facilities respectively. The Table revealed that 42.5% of the respondents sought information on the future market prices of their products, 30.8% sought information on marketing strategies while 26.7% sought information on the current prevailing market prices of their products. Furthermore, the table revealed that 40.0% sought information on daily weather forecast, 33.3% on seasonal rainfall pattern and 26.7% on drought prediction respectively. Finally, 53.33% sought information on land and boundary dispute while 46.67% on ethnic dispute resolution.

Table 3: Crops produced by the respondents (n=120)

Type of Crops	Frequency	Percentage
Maize only	48	40.0
Cassava only	32	26.7
Maize and cassava	25	20.8
other arable crops	15	12.5
Total	120	100

Field survey: 2018

Determining the perceived constraints of using soap opera for sourcing agricultural information dissemination

Table 5 shows the perceived constraints associated with the use of soap opera for sourcing agricultural information in the study area. The result shows that 52.5% of the respondents identified unstable power supply as a severe constraint, 50.0% identified unfavorable broadcasting hours as a severe constraint, 48.3% of the respondent sees irrelevant information as a severe constraint, while 60.0% and 42.5% sees inability to comprehend soap opera message and language barrier as mild constraints, respectively.

Table 5: Distribution of respondents based on perceived constraints of soap opera (n=120)

Constraints	Severe constraints	Mild constraints	Not at constraints
Language barrier	32 (26.7)	51 (42.5)	37 (30.8)
Unstable power supply	63 (52.5)	45 (37.8)	12 (10.0)
Uninteresting story line	32 (26.7)	48 (40.0)	40 (33.3)
Unfavorable broadcasting hours	60 (50.0)	45 (37.5)	15 (12.5)
Irrelevant information	58 (48.3)	34 (28.3)	28 (23.3)
Untimely agricultural information	46(38.3)	39(32.5)	35(29.2)
Inability to comprehend soap opera message	21 (17.5)	72 (60.0)	27 (22.5)

Source: Field survey, 2018 * Multiple responses

CONCLUSION

Farmers' information need in soap opera utilisation for agricultural enterprise promotion include crop planting procedure, future market price, marketing strategies, daily weather forecast, land and boundary dispute, and ethnic dispute resolutions. The use of soap opera for enterprise promotion may be constrained by unstable power supply, unfavorable broadcasting hours and irrelevant information.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted in Enugu State using 120 respondents. Primary data were obtained using questionnaire and oral interview. Percentage, frequency, mean and logistic model analysis were used to analyze the data. The result of the logistic regression model shows that the coefficients of educational level (0.764364) and access to extension services (0.43241) were positive and significant. Furthermore, the constraints to attainment of food security were high cost of labour, poor access to land and credit. The need to enhance the farmers' access to credit facility, labour saving devices and extension services were recommended.

Keywords: *Determinant, Food insecurity, Farmers, Enugu State, Nigeria.*

INTRODUCTION
In sub-Saharan Africa countries, the roles of agriculture in economic growth and development are well documented in recent literatures (FAO, 2004; Graaff *et al*., 2011).) However, the gain does not significantly manifest on the people and the economy due to numerous constraints in agricultural production, with resultant miserable crops yield and food insecurity (Ibrahim *et al*., 2009, Delvaux and Paloma, 2018). The consequences of food insecurity, particularly the chronic type within certain populations according to FAO (2004) perpetuates socioeconomic inequalities and limits the potential for social and economic advancement within the societies. However, Food security is built on four main dimensions – food availability, accessibility, utilization and stability. In this sense, people are food secure only when there is stability of food availability, accessibility and proper utilization over time (Kaine and Ume, 2017).

In Nigeria, successive governments have embarked on numerous policies and programmes which included Agricultural Development Programmes (ADPs), Operation Feed the Nation (OFN), and so on among others, in order to boost farmers' farm productivity for enhanced food security. Yet food insecurity, hunger and poverty continued to multiply at alarming rate in the country (Abu and Soom, 2017). The farmers whose income and livelihood depend on agriculture were worse-off (Babatunde *et al*., 2007). This study is geared towards investigating food insecurity of the farmers in relation to their socioeconomic characteristics for policy formulation and implementation. Specifically, the objectives are to: (i) describe the socioeconomic characteristics of the farmers, (ii) determine the effect of farmers 'socioeconomic characteristics on their food insecurity and (iii)identify constraints to attainments of food security in the study area

MATERIALS AND METHODS
Enugu State lies between latitudes 6°30'N and 7°10'N of Equator and longitudes 6°35' E and 7°30' E of Greenwich Meridian. The state has an estimated population of about 4.1671 million people (NPC, 2006) and land area of 16,727 square kilometers (km^{2}). The inhabitants were mainly agrarians and still engage in non-agricultural activities. A well-structured questionnaire was used to collect data for the study. Random sampling technique was used to select one hundred twenty farmers who were respondents for the study.

Method of Data Analysis

The objectives of the study were achieved using simple descriptive statistics such as percentage, frequency and Logit Regression Model.

Model Specification

Logit regression model:

The logit regression model was used to examine the determinants of food insecurity of the farmers. The model, as given by Kaine and Ume, (2017) is expressed thus:

$$P_r(Y = 1/X_i) = in\left(\frac{Y}{1-Y}\right) = a + b_1X_1 + \dots \dots \dots \dots + b_7X_7 + U \quad \text{…………………..(1)}$$

Where: Y is Food security status of the ith farmer (food secure = 1, food insecure = 0),
P (Y = 1/*X*) is the Probability of Y (attaining r *I* food security) occurring, given that X has occurred, *a* is constant intercept, b1 - b7 are coefficients of the independent variables to be estimated and X - X are explanatory variables defined as follows: is X_1 = age (years), X_2 = Level of education (years*)*, X_3= Membership of Organization(member =1, otherwise = 0), X_4 = Access to extension services (access = 1 and otherwise = 0) and *U* is error term.

RESULTS AND DISCUSSION

Table 1 indicates that 31.67% of the respondents were between 20 to 40 years, while 68.33% were 41 years and above .This infers that most respondents were youthful and *they were* expected to have a positive effect on labour supply which should in turn contribute to increase in farm productivity and food security (Ogbonna and Ume, 2022). Also, majority (70.83%) of the respondents attained various forms of formal education, while 29.17% had no formal education. Education attainment enhances individual's resource prudency and risk averse in adopting improved technologies to boost their food security through high outputs (Abu and Soom, 2016). Moreover, 83.33 % of the populations studied were members of different cooperative organizations, while only 18.67% were not. Cooperative according to Babatunde *et al.* (2007) aids in improving her members' farm productivity for enhanced odds of being food secure through training and credit access. Table 1 showed that only 33.3% of the respondents had contacts with extension agents, while the majority (66.7%) had no contact. This indicated that extension outreach was poor; which implies poor access to improved technologies for high productivity, leading to high propensity to be food insecure (Delvaux and Paloma, 2018).

Table I: Distribution of Respondent According to Socioeconomic Characteristics

Variables	Freq.	Percentage
Age		
20 – 40	38	31.67
41 and above	82	68.33

No	100	83.3
Extension Services		
Yes	40	33.3
No	80	66.7

Sources: Field survey, 2022.

The Logit regression model was used to identify factors that determine cooperative members' access to loan. . The age of the farmers' coefficient was negatively signed, indicating that aged farmers were more food insecure than youthful ones. The aged farmers are usually not strong enough to tackle farming that is usually tedious and energy sapping. Also, the educational level of the farmer was positively signed, indicating that farmers that acquired formal education are more food secured than their counterpart. Literatures show that educated people are more receptive to innovations for high farm outputs (Kaine and Ume, 2017). Further, the coefficient of access to extension services was positively signed, connoting that farmers with access to extension services have high farm outputs. This may probably be due to access to improved technologies and provision of technical assistants by the change agents compare to farmers without access (Ibrahim *et al.*, 2009). Most (31.50%) of the respondents had poor access to credit and hence poor food security. The poor access to credit could be related to high interest rate as charged by lending agencies (Babatunde; *et al;* 2007). The least (14.65%) had poor access to extension services (Table 3). This could be related to wide ratio of farmers to extension officers (Ogbonna and Ume, 2022).

Table 2 The Logit regression results

Variable	Coefficient	**Standard Error**	t-value	P>|t|

*Multiple Responses

Source: Field survey 2022

CONCLUSION AND RECOMMENDATIONS

The food insecurity of the farmers was positively and significantly influenced by educational level and access to extension services. The factor limiting food security were access to credit, land and high cost of labour.

Based on the results, the following recommendations were made:

(i)There is need to enhance farmers access to educational programmes such as adult education, seminars and workshop in order to boost their production and productivity.

(ii) Extension agents should be motivated to be responsive to their duties through payment of enhanced salaries and other fringe benefits on time.

(iii)There is need to develop labour saving devices such as hand driven ploughs and distribute them to farmers by government agencies concerned and even Non –governmental Organization(NGO).

(iv)The land use act of 1976 should be revisited, thus making land available to genuine farmers to cultivate.

(v) There is need to enhance farmers' access to credit through commercial banks at reduced interest rate.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analyzed the effects of adoption of improved rice varieties on rice farmers' livelihood in Kwara State of Nigeria. Three-stage sampling technique was used to select one hundred and nine (109) rice producers in the study area. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected were analyzed with the aid of descriptive statistics (frequency, percentages and mean) and inferential statistic (Tobit Regression Model). Finding showed that FARO 57 (75.2%) and FARO 54 (74.3%) were the dominantly adopted varieties of rice. The coefficient of number of improved varieties (0.0590437), farm size (0.0412416) and farming experience (0.0031312) statistically ($p<0.05$) influenced increase in the livelihood of rice farmers. The major constraints to the adoption of improved rice varieties were poor road network (83.5%) and poor output (79.8%). It was recommended that feeder roads should be constructed by State and Local Government authorities in order to ease the movement of farmers' produce from farms to points of processing. Furthermore, farmers should be sensitized on how to boost their output for better livelihood status. Lastly, more lands should be committed for rice production.

Keywords: *Adoption, Improved, Rice varieties, Farmers' Livelihood status*

INTRODUCTION
Rice (*Oryza sativa*) is one of the most cultivated crops in the world. It is the third most important cereal grown and consumed globally after wheat and maize (Agro-Nigeria, 2018). In Nigeria, rice is cultivated in almost all ecological belts of the country as they all provide favourable environment to support the crop's cultivation (Agro-Nigeria, 2018). Rice is the staple food for many African countries and constitutes a major part of the diet for many others. During the past three decades, the demand for rice has increased steadily, playing a major role in the strategic food security planning policies of many countries in sub-Saharan Africa (WARDA, 2011). Evidently, development, food security and livelihood status cannot be achieved without rapid agricultural growth, hence assisting the rural poor to enhance their livelihoods and food security in a sustainable manner is a great challenge. Many improved rice varieties exist that can be grown in Nigeria. For instance, the National Cereal Research Institute (NCRI), Baddegi had released many improved rice varieties that are suitable for cultivation in different agro-climatic conditions. The varieties were classified into four main groups namely; early maturing varieties (FARO 27 and FARO 44), medium maturing varieties (FARO 29, FARO 35, FARO 37, FARO 50, FARO 51, FARO 52 and FARO 57), and the late maturing varieties (FARO 7, FARO 8, FARO 12, FARO 14 and FARO 15 and deep water (floating) areas, FARO 7, FARO 14 and FARO 15, respectively (NCRI, 2009). FARO 44 is one of the many developed rice varieties that is widely distributed and highly adopted compared to other developed varieties (Adesina, 2012). It is, therefore, necessary to determine the effect of adoption of improved rice varieties on farmers' livelihood status in Kwara State. The objectives of the study are to identity the improved rice varieties adopted and determine the effects of their adoption on farmers' livelihood status.

RESEARCH METHODOLOGY

This research took place in Kwara State. The State, which is located in the North Central Nigeria, lies between latitudes 8º-10ºN and longitude 2º45'-6º4'E of the Greenwich meridian. It covers an estimated land area of about 36,825 square kilometers or 8% of the total area of Nigeria. According to National Population Census (NPC) (2006), the state has a population of 2,591,555 peoples, spread across the sixteen Local Government Areas, which was projected to be 3,005,409 as at 2017 using an annual population growth rate of 2.5% (World Bank, 2013). The major food crops produced in the state are mostly cereal crops namely rice, maize, sorghum, millet, cow pea, melon and they constitute the main staple food, aside root and tuber crops (Ajadi *et al.*, 2011). Multistage sampling technique was employed in this study to select the sample size. This involved four stages of selection. The first stage involved random selection of two Local Government Areas (LGAs) in the State. In the second stage, three (3) villages were randomly selected from each LGA, making a total of six (6) villages. In the fourth stage, a proportional sampling was used to select 10% of the respondents from the sampling frame to give a total sample size of one hundred and nine (109) farmers. Primary data were used for this study. Data were collected by the researcher, assisted by trained enumerators, using structured questionnaire and complimented with interview schedule. Descriptive statistics such as mean and frequency distribution was used to analyse objective (i). Effects of adoption of improved rice varieties on rice farmers' livelihood objective (ii) was achieved using Tobit regression model. The implicit and explicit forms are specified as follows:

$$Y = \alpha + X_i \beta + \varepsilon_i \quad (1)$$

$$Y = a + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 \ldots \beta_n X_n \quad (2)$$

Y=livelihood status index (LSI)

X_1 = number of improved varieties adopted, X_2= farm size (ha), X_3= farming Experience (years)
X_4 = number of training, X_5 = annual income (₦), X_6= cooperative membership (number), X_7= Credit (amount received), X_8= Access to extension (number), X_9 = fertilized used (kg), X_{10} = Agrochemical used (litre), X_{11} = Simpson index (Amount).

RESULTS AND DISCUSSION

Improved Varieties adopted by the Respondents

Table 1 showed that majority (75.2%) of the rice farmers adopted FARO 57. This may not be unconnected with high yielding and early maturity experienced with FARO 54. Also, 74.3% of rice farmers adopted FARO 54. Furthermore, 71.5% of the rice farmers adopted FARO 44. This might be owing to some favourable qualities exhibited by FARO 44 such as high yield, early maturity, and high resistance to pest and diseases and market acceptability. This finding agreed with Tsado *et al.* (2018), who reported that majority of the rice farmers in Niger State adopted FARO44 improved rice. The least adopted improved rice variety in the study area was FARO 62. This might be due to the relatively newness of the variety, which made the farmers to shy away from it; it could also be due to lack of familiarity, as farmers were yet to find it compatible with their existing practices or lack of awareness of it.

Table 1: Distribution of respondents according to improve varieties adopted (n=109)

Variables*	Frequency	Percentage
FARO 44	78	71.5
FARO 54	81	74.3
FARO 57	82	75.2
FARO 60	76	69.7
FARO 62	68	62.4

Effects of Adoption of Improved rice Varieties on Farmers' Livelihood Status

The result of regression analysis in Table 2 showed the effects of adoption of improved rice varieties on farmers' livelihood in the study area. The result showed that the Pseudo R^2 value was 0.9626, implying that about 96.3% of the variations that occur in improved rice varieties were explained by the independent variables included in the model, while the remaining 24.3% were due to external factors not captured by the researcher. The coefficient of number of improved varieties (0.0590437) was significant at 1% level of probability. This signifies that more access to improve rice varieties tend to increase outcome and income of farmers and have positive effect on their livelihood. The coefficient of farm size (0.0412416) was positively significant at 5% level of probability. This signifies that increase in size of farm land will lead to increase in the livelihood of improved rice adopters. This finding agreed with Afodu *et al.* (2020) who reported that increase in farm size reduces food insecurity among rice farmers in Ogun State, Nigeria. The coefficient of farming experience was negatively significant at 5% level of probability, implying that as farmers experience increases, there is tendency for the livelihood to be affected.

Table 2: Effects of adoption of improved rice varieties on farmers livelihood (n=109)

Variables	Coefficient	Z-value
Number of improved rice varieties	0.0590437	4.68***
Farm size	0.0412416	2.18**
Experience	0.0031312	2.30**
Access to training	0.0449753	1.31

Annual income	1.99e-07	1.83
Cooperative membership	-0.0131772	-0.89

Constraint Facing Adoption of Improved Rice Varieties

The result in Table 3 revealed that poor road network (83.5%) was the major constraint facing the adoption of improved rice varieties in the study area. Lack of good road is obvious and peculiar to most of the rural areas where rice is been produced. Another constraint was poor output (79.8%), implying that rice farmers, despite adopting improved rice varieties could not get the desired output. This agreed with Mohammed *et al*. (2019), who reported that inadequate output and inadequate improved varieties were among the challenges to adoption of Faro (39) Rice Project Technology by farmers' in Agricultural Zone 1 of Niger State, Nigeria. The problem associated with land is common among farmers in North Central due to the activities of Fulani herdsmen and other forms of land encroachment that reduce farmers' access to adequate farmland for farming activities. This agreed with Zalkuwi (2019), who reported that land tenure problem is one of the challenges to rice production in Nigeria. Also, incentive like agrochemicals and fertilizers could not be accessed by rice farmers due to the non-availability or that the available inputs were mostly hijacked by political heads and distributed by those loyal to them.

Table 3: Constraints facing adoption of improved rice varieties

Variables	Frequency	Percentage	Rank
Poor road network	91	83.5	1st
Poor output	87	79.8	2nd
Land tenure system	72	66.1	3rd
Labour and youth migration	66	60.6	4th
Processing problem	65	59.6	5th
Seasonal attack of pest and diseases	61	55.9	6th
Inadequate improved varieties	34	31.2	7th

Sources: Field survey 2019

CONCLUSION AND RECOMMENDATIONS

Based on this finding, it can be concluded that majority of rice farmers adopted FARO 57, FARO 54 and FARO 44. The coefficient of number of improved rice varieties, farm size, and farming experience had effect on the adoption of improved rice varieties on farmers' livelihood status. The major constraints to the adoption of improved rice varieties were poor road network, poor output and land tenure system. It was recommended that feeder roads should be constructed by State and Local Government authorities in order to ease the movement of farmers' produce from farms to the point of processing. Also, farmers should be sensitized on how to boost their output for better livelihood status. Lastly, more lands should be committed to rice production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT.

This study assessed the impact of Covid-19 on the farm output among Cassava farmers in Lafia Local Government Area. The specific objectives were to describe the socio-economic characteristics of the cassava farmers, estimate the costs and returns in cassava production, analyze the impact of Covid-19 farm output among cassava farmers and identify the constraints faced by cassava farmers in the study area. The data for this research work were obtained through primary source by the used of structured questionnaire, to elicit useful information from the practicing cassava farmers interviewed schedules was used as well. The data were collected with the used of multistage random sampling technique. The result revealed that cassava farmers were in their active year, also cassava production was a profitable enterprise in the study area. Results in Table 3 further revealed that 31% of variation of farm output among cassava farmers were caused by the explanatory variables included in the multiple regression model. While 69% was not explained by the explanatory variables. The F-value was 2.45 and significant at 5% probability level, this implies that there is significant relationship between Covid-19 and selected explanatory variables. Results further revealed that cassava farmers faced multiple constraints. Based on the findings of this study, it is concluded that Cassava farmers were in their active years, considering the age percentage of 70% for the range between 18 -55years in the study area, The study also indicated that Cassava production was a profitable enterprise, there is relationship between Covid-19 and farm output in cassava production and cassava farmers also faced some production constraints in the study area. It is recommended that there is need to encourage practicing and prospective entrants into the business by making production resources available and accessible to the practicing farmers. This will enhance production, reduce widespread poverty, create job opportunity and better the lives of the citizenry. There is need for Government and Non-Governmental Organizations (NGOs) to coordinate more research into latest varieties of cassava, production techniques and Covd-19 to serve as extension packages since extension contact was found to affect the farm output of cassava farmers. Government and community leaders should try and establish more markets for cassava commodities for farmers to sell their products to avoid glut.

Keywords: *Impact of Covid-19, Cassava Farmers, output.*

INTRODUCTION

Cassava is a very important crop to the economy of Nigeria. It is estimated that about 30 million farmers grow cassava with average yields of about 11 metric tons per hectare and annual output exceeding 33.8 million metric tons. Estimate of output in 2011 was over 52 million metric tons (FAO, 2013). Apart from being a source of food to about 200 million people in the sub-Saharan Africa, cassava can contribute to employment creation, income generating capacity and food security for many households in Nigeria (Ogunleye and Ojedokun, 2014). An Italian who works in Nigeria flew into Lagos from Milan on 25th February 2020 and had contact with a Nigerian from Ogun state, and on 27th February 2020, he was diagnosed with covid-19. This was announced as the index case being the first recorded case of Covid- 19 in the country (Bernard, 2020). The news came not as a surprise because earlier before that date a legislative member at the national Assembly in Abuja raise alarm over the absence of security personnel at the various international airports in Nigeria whose responsibility ordinarily should be to conduct a routine check of every passenger on arrival. Following this development there was the enforcement of a 2-week lockdown on 30th March 2020 for three very busy commercial region of the country, namely Ogun State. Lagos state, and the Federal capital Abuja following the advice offered to the Nigerian president by the National centre for disease control {Bernard, 2020].

The lockdown of these three states was followed by other state in Nigeria in order to forestall the chances of contracting and spreading the deadly virus. These was the prohibition of interstate travel and general restrictions on the movement of goods and services with the exception of essential services (Been and Aziz, 2020), Scholars have researched on Covid-l 9 pointing it devastating impact of the disease on the economy as well as the health-care delivery system. As it is, Nigeria is divided into six geopolitical zones, namely, north- east, north- west, north- central, south- west, south- south, and south- east. The Igbo ethnic nationality, our primary focus in this study, occupies the south east with states such as Imo, Anambra, Abia, Enugu, and Ebonyi State. There are other Igbo- speaking groups in Rivers, Delta, and Edo state, respectively, in south- south Nigeria.

The Igbo of south eastern Nigeria has no access to the sea and thus landlocked with all their coastal neighbors in Calabar or Bonny having no linguistic sameness. This was the circumstance that made it possible for the federal military government to enforce the food blockade policy against Biafra that yielded defeat for secessionist in 1970. The federal government greatest weapon amidst machine guns was hunger. The same inability of the region to cultivate sufficient food for it populace is still much of a challenges to the collective survival of the population. The southeast region currently suffers from a food deficit in terms of producing crops such as onions, tomatoes, yam, potatoes, carrot, oranges, and other crops. The major source of protein such as cows, goats and the aforementioned crops is supplied from the northern region of Nigeria. The various established cases of clashes in Igbo land between farmers and herders stem from the wanton destruction of crops by cattle among other causes.

The covid-19 outbreak with all it challenges is indeed a clarion call and pointer to the reality of food insecurity in Igbo land creating an imperative for immediate response. In spite of the federal government directive that vehicles and lorries carrying food, water, and other essential services should be allowed free movement , the corrupt nature of the security agents such as the police, army, civil defense corps, federal road safety corps, and neighborhood watch securities at the various security posts on the federal highways made this impossible. After extorting so much from Lorries carrying food, the prices of commodities skyrocketed and the population suffered for their overdependence on food coming from the northern region of Nigeria. The population claims of the food supply in the form of palliatives to the region from the federal and state governments were only heard on radio and television, respectively, while the voting population languished into total lack.

The importance of food cannot be overemphasized. It is an essential ingredient needed by all living beings for survival, and it availability determines the standard of living of the people at all times (Iwuagwu, 2008). The environment and geography of people determine what food they eat and it availability at all times within this context is the issue of climate and it suitability to agriculture. This is closely linked to soil fertility evidenced in land context made possible by rainfall. In essence, there is an evident nexus between agriculture and the physical environment of Igboland (Uzozie, 1979). Igboland is peopled by subsistence farmers with emotional ties to the attributes of their land notably "soil type, climate and vegetation" (Iwuagwa, 2008). The aim of this study is to analyze the impact of Covid-19 on farm output among cassava farmers in the study area. The specific objectives are to: describe the socio-economic characteristics of cassava farmers in the study area, estimate the costs and returns among cassava farmers in the study area, analyze the effect of Covid-19 on the farm output among cassava farmers in the study area and identify the constraints faced by cassava farmers in the study area.

METHODOLOGY

This study was conducted in Lafia Local Government Area of Nasarawa State. Lafia is located within Longitude 08°32 East of Greenwich Meridian and Latitude 08°33 north of the Equator. It has a land area of 2,73755sqm and altitude of 181 .53 (570tf) and shares boundaries with Obi Local Government Area to the South , Nasarawa-Eggon local Government Area to the North, Doma Local government area to the west, and Quanpan local government area in Plateau State to the East (Nasarawa State, 2006). Lafia Local Government Area has a distinct wet season which commences in March and ends in October, and dry Season Starts from November and ends in February. The average annual rainfall is approximately 151.9mm and temperature is high throughout the year with an annual maximum mean range of 34.3 Celsius and annual minimum mean range of 22.8 Celsius (Nasarawa State, 2006).

Lafia Local Government Area is made up of eight (8) Districts among which are: Lafia east, Lafia West, Kayarda, Agyaragun Tofa, Akunza, Awuma, Agyaragu and Ashangwa. The soil texture is sandy loam and very fertile for crops like sorghum, cowpea, cassava, rice, yam, groundnut among other are cultivated in the area. There are tree crops such as cashew, mango, palm tree, oranges that are grown in the area. Other economic activities carried out in the .Lafia local government Area are: trading, hawking, food vendors, artisans, transporters etc. Based on the 2001 population census, the estimated figure was 215,145 people. The major tribes found in the local government are: Eggon, Kanuri, Migili, Gwandara, Hausa/Fulani, Alago, Mada, Igbo, Yoruba and others. A Multistage sampling techniques was used, the first stage involved selection of 5 districts out of twelve districts. The second involved random selection of two villages each from the five districts to give a total of ten (10) villages. Third stage was random selection of 2 households from each of the 10 villages to give the total of twenty (20) as the sample size of the study. Primary data for the study was collected from the respondents using structured questionnaire and oral interview. The questionnaire contained questions covering all the objective of the study such as socio-economic characteristics, costs and returns, impacts of Covid 19 on farmers' outputs and constraints faced by the respondents. The following analytical techniques were used, frequency distribution tables, percentage, arithmetic mean, variance and standard deviation was used to achieved objectives i and IV

Budgeting Techniques: Gross Margin Analysis: This is the difference between the Gross Farm Income (GFI) and the Total Variable Cost (TVC).

GM = GFI – TVC

Where GM = Gross Margin, GFI = Gross Farm Income, TVC = Total Variable Cost.

(b) Net Farm Income: It is the difference between the Gross Margin (GM) and Total Fixed Costs (TFC).

NFI = GM – TFC

Where NFI = Net Farm Income, TFC = Total Fixed Cost and GM is as previously defined. This tool was used to achieve objective ii of the study.

In order to achieve objective III which is to analyze the effect of Covid-19 on the cassava farmers output multiple linear regression model was used. The implicitly functional form is specified as: $Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7)$…….. ei

Where

Y = Cassava yield (dependent variable)

X_1 = Covid-19 impact

X_2 = Educational level (years spent in school)

X_3 = Access to credit (Dummy variable, 1 for yes, 0 otherwise)

X_4 = Extension visit (Number of times)

X_5 = Input price (₦)

X_6 = Transportation cost (₦)

X_7 = Medication (₦)

e_i = Error term

RESULTS AND DISCUSSION

The socio-economic characteristics of respondents such as age, sex, marital status, educational level, farming experience, household size, land acquisition, source of labour, farm size, membership of cooperative ad extension contact were analyzed using simple descriptive statistics are presented in table 4.1. Age refers to the number of years person has lived and it is determinant factor of the quality labour supply in farming enterprise. The result presented in table 1 revealed that most (75.0%) of the respondents were within the age bracket of 18-55 years. This is an indication that a large proportion of the farmers in the study area were in their productive years. Production was dominated by male (80.0%) farmers. The females (20.0%) are usually single parent. Generally, female members of households usually engage in domestic responsibilities as well. Most (85.0%) of the respondents were married. Married couples contribute significantly to the general progress of farm enterprises and where wives are given separate portions of land to produce crops, increase in output can be substantial. Educational attainment levels of the farmers was relatively high as 79.5% of them had one form of education or the other. It will be easier for educated farmers to adopt the latest extension packages in the study area. Result presented in table 1 showed that 95.0% of the respondents had household size between land 10, 19.0% accounted for 11-20 while 1.0% and 21.30 0.0% of the farmers had household sizes respectively. Result in table 1 further reveals that a largest proportion of the respondents (40.0%) had years of farming experience of between 1.10, 30.0% accounted for 11-20, 40.0% while 21.30, 25.0% of the farmer had farming experience of 31-40, 5.0% respectively. The various methods of land acquisition by the respondents are also presented in table 1. Inheritance (40.0%) and rented (40.0%) has topped the list, while the least method was through purchase (20.0%) in the study area. The result in table 4.1 revealed that most 80.0% of the respondents engaged in source of labour family labour has 20.0% while hired labour has 80.0%. Result in table 4.1 further revealed that a large proportion of the respondents (95.0%) had farm size of between 1-10 hectares

The profitability assessment of cassava production in the study area was done using Gross Margin (GM) analysis. The estimated costs and returns of cassava farmers are presented in Table 4.2. The total variable cost in cassava production was ₦195,712.33 per hectare, comprising of 20.4% of labour cost, 10.6% cassava cuttings, 6.5% of herbicides cost, 16.8% of fertilizer cost and transportation cost accounted for 44.5%. The fixed costs of cassava production per hectare was ₦2,491.31, comprising of 0.3% of hoes while 0.5% accounted for axes and cutlass each respectively. The total cost of production for a typical cassava farmers was ₦198,203.64 per hectare. It is clear from the analysis that cassava production needs large capital in order to increase the profitability level of the cassava farmers as well as increasing the living standard of the farmers in the study area. The average gross returns obtained by cassava farmers was ₦372,425.34 per hectare. The net farm income was ₦177,221.75 per hectare. The return per naira invested was ₦1.89. This implies that cassava production was profitable in the study area. Therefore, there is need for cassava farmers to expand their production scope so that they can obtained more returns in order to better their living standard in the study area. This study agrees with the findings of Okoye *et al.* (2010) that the production of cassava was profitable in South-Eastern Nigeria.

Table 2: Average Costs and Returns per Hectare of Cassava Production in the Study Area

Costs and Returns	Amount (₦)	% of total cost
(A) Variables Cost		
Labour	40,463.85	20.4
Cassava cutting	21,024.62	10.6
Herbicides	12,773.85	6.5
Fertilizer	33,304.62	16.8
Transportation	88,145.39	44.5

Multiple linear regression model was used to examine the impact of Civid-19 on the output among cassava farmers in the study area. The results is presented in Table 4.3. The estimated parameters with positive signs indicates that variables contributes negatively to increase the output of farmers while positive signs is the reverse. The mean Covid-19 (X_1) had positive sign and significant at 1% probability level. This implies that a unit increase in Covid-19 led to decrease in output among the cassava farmers in the study area. Furthermore, the coefficients of education and extension contact also had expected positive signs and were significant at 1% and 5% probability levels respectively. This is an indication that change in education and extension contact influence the output among cassava farmers in the study area.

On the other hand, access to credit had negative sign and significant at 5% probability level. This signifies that as respondents increase in access to credit, it led to decrease on the farm output of the respondents. Results in Table 3, further revealed that 31% of variation of farm output among cassava farmers were caused by the explanatory variables included in the multiple regression model. While 69% was not explained by the explanatory variables.

The F-value was 2.45 and significant at 5% probability level, this implies that there is significant relationship between farm output and selected explanatory variables.

Table 3: Regression Results of impact of Covid-19 on the Cassava farmers output.

The study observed that farmers encountered various constraints in their cassava production activities. The constraints faced in the study area are presented in table 4.3. The results revealed that stealing (95%) ranked first, inadequate storage facility, shortage of inputs, unfavourable weather (85%) ranked second on the other hand, outbreak of disease ranked least the low ranking of outbreak of disease could be due to the fact that farmers in the study area may have several means of curtailing them.

Table 4: Distribution of respondents according to the constraints faced by farmers

Constraints	Frequency	Percentage
Stealing	19	95
Inadequate storage facility	17	85
Shortage of inputs	17	85
Inadequate transport facility	17	85
Lack of market for product	14	70
Unfavourable weather	14	65
Low produce price	12	60
Outbreak of disease	6	30
Total	115

CONCLUSION AND RECOMMENDATIONS

Based on the findings of this study, it is concluded that Cassava farmers were in their active years, considering the age percentage of 70% for the range between 18 -55years in the study area, The study also indicated that Cassava production was a profitable enterprise, there is relationship between Covid-19 and farm output in cassava production and cassava farmers also faced some production constraints in the study area. Cassava production was found to be a profitable enterprise in the study area. Therefore, there is need to encourage practicing and prospective entrants into the business by making production resources available and accessible to the practicing farmers. This will enhance production, reduce widespread poverty, create job opportunity and better the lives of the citizenry. There is need for Government and Non-Governmental Organizations (NGOs) to coordinate more research into latest varieties of cassava, production techniques and Covd-19 to serve as extension packages since extension contact was found to affect the sustainability of farm level practices. Government and community leaders should try and establish more markets for cassava commodities for farmers to sell their products to avoid glut.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Striga generoides (Willd) is a major destructive parasitic weed of Cowpea (Vigna unguiculata L.) which causes substantial yield reduction in West and Central Africa. The trial involving 10 improved varieties in 2019 aimed at evaluating Cowpea genotypes resistant to Striga generoides was evaluated using Randomized Complete Block Design (RCBD) replicated three times at the Research Farm and Botanical Garden of the Department of Plant Science and Biotechnology, Nasarawa State University Keffi. Data collected on grain yield and yield components were subjected to Analysis of Variance (ANOVA). There was variability in number of days to 50% flowering among the genotypes studied. New sources of resistance were not found in this screening. However, the number of days to 50% flowering varied from 49 to 62 days with the mean of 51 days. The number of days to 50% flowering was highest in B5/15/2627(51 days) and was lowest in IT98k-205-8(49 days). The three resistant check (IT93K-593-2, IT99K573-1-1 and IT 98K-205-8-) had no emerged Striga shoot while varieties 291-171, 2472-154, and survita-2 were significantly different from that of susceptible check (IT90K-372-1-2) and they were identified as moderately resistant to Striga with low Striga shoot. Varieties (B2/19/2405-87, B1/18/2542 and B4/7/2338-20) were described as tolerant with high Striga shoots but no significant yield loss was observed. Therefore, the genotypes IT93K-593-2, IT99K573-1-1 and IT 98K-205-8 were confirmed as potential donor sources for incorporating resistant genes into adapted and farmer preferred varieties. The cultivars B2/16/2378, B1/13/2614-296 and B1/18/22542 were also identified as donor parents in breeding cowpea for yield improvement.

Keywords: *Genotype, Evaluation, Screening, Resistance, Variety, Striga and Cowpea*

INTRODUCTION
Cowpea (*Vigna unguiculata* (L.) Walp) is considered the most essential leguminous grain in the dry Savannas of tropical Africa. It is also known as the black- eyed pea or southern pea and is cultivated in a range of ecologies and cropping systems in the tropics. It originated from the semi-arid areas of West Africa and has been cultivated for human consumption for more than 4,000 years. (Tweneboah, 2000). Cowpea is a member of the Phaseoleae tribe of the Leguminosae family (Timko *et al.*, 2007). It was reported that Nigeria, being the largest producer of cowpea in the world accounted for 2.2 million tons of dried grain in 2010. The temperature varies 20-36 degree Celsius. The brief period of hot and dry weather occur between March to April with the temperature between 38-42 degree Celsius while the wet weather from May to October will long term annual rainfall of about 1040mm (Adejuwon, 2004). The average yield per hectare of cowpea in Nigeria was only 417kg per hectare (Abiola *et al.*, 2010). Regardless of the significance of black-eyed pea in West Africa; its production is still impeded by a myriad of abiotic factors. Biotic components, for example, pests and diseases, and parasitic weeds cause serious threat to cowpea production. The parasitic angiosperm *Striga gesnerioides* (Willd) is one of the significant limitations to cowpea cultivation particularly, in the Guinea Savanna agro-ecology. The parasitic weed *S. gesnerioides* is an obligate root-parasitic blossoming plant of the Scrophulariaceae family.
Methods need to be adopted for easy and less expensive for the identification cowpea genotypes that are resistant to *Striga gesnerioides* to boost production index of cowpea among local farmers. Due to ineffectiveness of the existing strategies for the control of infestation cause by *striga* specie for rural farmer the easier and inexpensive method of controlling *Striga* species is screening of cowpea genotypes for the best resistant to *Striga* infestation. The genotypes were classified as resistance or susceptible using the scale described by Emerchebe and florin (1997). The objectives of this study were to Identify: Cowpea genotypes resistant to *Striga gesnerioides* and Estimate genetic variability.

MATERIALS AND METHODS

The trials was carried out during the 2019 rainy seasons at the Research Farm and Botanical Garden of the Department of Plant Science and Biotechnology, Nasarawa State University, Keffi. The area is geographical located at latitude 0.833.766N and longitude 0.833.00E (Malunax, 2005).The climatic condition is characterized by two seasons: the dry and wet season. The rainy season last up to six-seven months and dry season usually last for about six months. Cold weather is usually experience between November to February which emanate from the influence of Northern-Easter Wind (Harmattan) which control the tropical continental air mass coming from the Sahara desert. The germplasm used comprised of 10 improved varieties from IAR Zaria. The experiment was conducted using Randomized Complete Block Design (RCBD) with three replications. Each plot comprised two rows of 3 m long with inter-row spacing of 0.80 m, and intra-row spacing of 0.50m. Three seeds were planted per hill and were thinned to one per hill two weeks after seedling emergence, resulting in a total of 14 plants per plot. Super single phosphate cowpea. Two hoe – weeding was done before *striga* emergence. The pesticide applied was dimethoate ($C_5H_{12}NO_3PS_3$) at pre-flowering and after pods formation to control insects and encourage pollination. Data was collected for Number of days from planting to 50% flowering, *Striga* shoots per plot, S*triga* density, *Striga* dry biomass, Grain yield, One hundred seed weight, Fodder yield.

RESULTS

The number of days to 50% flowering result shows that (Table 1) varied from to 49 to 62 days with a mean of 51 days. The number of days to 50% flowering recorded the highest result in B5/15/2627 2R (62 days) and was the lowest in IT98K-205-8 (49 days) throughout the period of observation. The three resistant checks (IT93K-693-2, IT99K-573-1-1 and IT98K-205-8) had no emerged *Striga* shoots m^{-2} (Table 1). The *Striga* shoots m^{-2} was low in lines of 291-171, 2472-154 and suvita-2 with values of 0.43, 0.74 and 0.87 respectively. These values were significantly different from that of the susceptible check IT90K-372-1-2 (7.84 *Striga* shoots m^{-2}). Varieties 2491-171, 2472-154 and Suvita -2 were identified as moderately resistant to *Striga*. Three lines of (B2/16/2378, B6/3/39274, and B3/13/2399-81A) described as tolerant had high *Striga* density (DS) of 2.53 to 8.77 *Striga* shoots m^{-2}, but no significant yield loss was observed. Cowpea grain yield varied from 54.88kg ha^{-1} to 691.63 kg ha $^{-1}$ for line 2510-192 and for line B1/18/2542 with an average yield of 246.12 kg ha^{-1}. Only five genotypes (6%) had yields exceeding 500 kg ha^{-1} while 35 (44%) had yield less than 200 kg ha^{-1}. The result (Table 1) shows that the yield reductions were significantly high (79% and 66%) in the susceptible cowpea lines as compared to the tolerant and resistant lines. In contrast, it was observed that the yield of tolerant cultivars (441.17 kg ha $^{-1}$ to 691.67 kg ha $^{-1}$) was higher than those of the resistant lines (276.63 kg ha $^{-1}$ to 380 kg ha $^{-1}$) *Striga* dry biomass (SDB) varied from 0.00 (IT93K- 693-2, IT99K-573-1-1 and IT98K-205-8) to 52.88 g (B6/2/2516). The overall genotype mean for SDB was 17.91 g per plot. One hundred seed weight (100-SW) varied from 7.3 g (2512-192) to 22.25 g (B4/13/2563-245-IR) with a mean of 14.91 g. Cowpea pod weight ranged from 50.93 g (2429-111) to 548.07 g (B1/18/2542 2R) with an average of 195.52 g per plot.

DISCUSSION

There was variability in the number of days to 50% flowering among the genotypes. This is in line with the findings of Tiwari *et al.,* (2019).This variability may be due to climatic conditions or the genetic background of the varieties. In this study the number of days to 50% flowering ranged from 49 to 62 days after planting with a mean of 51 days while it varied from 32.72 to 54.84 days after planting (DAP) with a mean of 44.31 DAP in the study by Egbe *et al.* (2010). This showed that there were no extra early maturing varieties in the germplasm screened. Only three genotypes (IT99K-573-1-1 and IT98K-205-8) include as resistant checks were free of *striga* emergence in this study. The resistance in IT93k-693-2 confirmed the result of Singh (2002) and Boukar *et al*. (2004) who reported that this genotype was resistant to all the five known *striga* races in Africa. Recently, Tignegre (2010) found similar result with the races prevailing in Burkina Faso. The resistance observed in IT99K-573-1-1 and IT98K-205-8 in line with the finding of Tchiagam *et al.* (2010) who observed no *Striga* emergence from the two genotypes screened for resistance to race 5 in Cameron. Though, these genotypes were highly resistant to *Striga* in this studies there grain yields were very low as compared to their yields obtained from studies in Cameroon. IT99K-573-1-1 and IT98K-205-8 yielded 1042.75 kg ha $^{-1}$ and 871.10 kg ha^{-1} respectively in plot 1versus 340.74 kg ha $^{-1}$ and 276.63 kg ha $^{-1}$ in plot 2. The line IT93K-693-2 yielded 911.60 kg ha $^{-1}$in this study. These differences observed may be attributed to genotypes response to climatic conditions and soil types. The genotypes are well adapted to the conditions in both plots.

CONCLUSION

New sources of *Striga* resistance were not found in this screening. However, the genotypes IT93K-693-2, IT99K-573-1-1 and IT98K-205-8 were confirmed as potential donor sources for incorporating resistance genes into adapted and farmer preferred varieties. The cultivars B2/16/2378, B1/18/2542 and B1/13/2614-296 were identified as donor parents in breeding cowpea for yield improvement. The best combination of crosses to incorporate *Striga* resistance into adapted lines would be IT93K-693-2 as donor parent and the top three farmers' preferred varieties while IT90K-372-1-2 and IR88-63) as recurrent parents.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study on the impact of National Root Crops Research Institute (NRCRI) on agricultural practices was conducted in Umuahia agricultural zone, Abia State, Nigeria. By purposive and random sampling techniques, ninety (90) farmers were selected for the study. A well-structured questionnaire was used to elicit information from the respondents. The data was analyzed using descriptive statistics such as frequency counts, and percentages. The findings revealed that a majority of the respondents were in their active stage of their life in which they can effectively adopt improved innovations that would change their farming practices and result in increased productivity. However, most of the farmers recorded high impact in their farming activities and productivity through the adoption of improved farm technologies from NRCRI. It was recommended that the institute should sustain the esteemed record of impacting positively on the farming activities and productivity of the farmers in the study area. Efforts should be made by the institute to impact positively on the farming activities and productivity of over 90% of the farmers in the study area.

INTRODUCTION
The National Root Crop Research Institute (NRCRI), which has the mandate for the genetic improvement root and tuber crops such as yam, cassava, cocoyam, sweet potato, Irish potato and ginger, rizga (Livingstone potato), sugar beet and Turmeric has great potential for contributing to national economic development. The Institute also researches into the farming systems and researh-extension farmer input linkages (REFILS) for crop cultivation techniques, storage, processing and utilization of the crops for farmers in the south-east zone of Nigeria. The Institute runs a diagnostic survey of the farming systems of the zone to obtain information on status of agricultural activities and to identify production constraints and opportunities, conduct of up-stream (on-station) research to tailor down commodity research results to suit farmers' conditions, conducts Monthly Technology Review Meetings (MTRMs), where scientists from research institutes and universities train the Subject Matter Specialists (SMSs) from the state Agricultural Development Programmes on improved technologies (Udealor, 1999). The Institute also provides training of middle level agricultural workers, awarding National Diplomas and Higher National Diplomas and providing specialized vocational training to farmers.
The National Root Crop Research Institute (NRCRI) helps in the development and transfer of production packages-crop varieties, optimum spacing, optimum rate and time for fertilizer application, weed control measures and crop compatibilities, stacking methods in yam-based systems, harvesting for maximum productivity of technologies, weed control in root and tuber crops-based mixtures, cocoyam/maize/pigeon pea at 2.0m inter-row and 1.0 inter-row spacing and development of complementary use of both cassava composite root meal and cassava composite meal with commercial feed in the feeding of broilers and laying birds (Udealor, 2001). This study was therefore initiated to to assess the impact of NRCRI on agricultural practices in the Umuahia agricultural zone, Abia State, Nigeria.

METHODOLOGY
The study was conducted in Umuahia Agricultural zone in Abia State, Nigeria. The zone is made up of six (6) Local Government Areas: Umuahia North, Umuahia South, Isiala Ngwa North, Isiala Ngwa South, Ikwuano and Umunneochi. About 60-70% of the population are engaged in agriculture primarily for crop production and animal rearing (Nnamerenwa, 2012). Umuahia North and Ikwuano Local Government were purposively selected due to their proximity to NRCRI Umudike. A total of 90 respondents were randomly selected and interviewed. Forty-five (45) farmers were chosen from three (3) communities in each of the two (2) Local Government Areas selected for the study. The farmers were selected based on their involvement in root and tuber crops production. Both qualitative and quantitative information was elicited from the farmers using a well-structured questionnaire and the data collected was analysed with descriptive statistics like mean, frequency, percentage and Likert-scale methods.

RESULTS AND DISCUSSION

Demographic characteristics of Farmers: (n=*90)*

Table 1 provides a frequency distribution of the respondents based on various demographic variables. The results show that majority of the sampled respondents were female (62.2%), while men constituted 37.8% implying that women are more involved in the production of root and tuber crops more than men in the study area.

The mean age of the respondents in the study area is 48.8 years implying that agriculture as a business is dominated by middle aged people. The result further shows that the majority of the respondents (64.5%) were married. This may be an added advantage in the sense that supportive spouses could be a major source of encouragement and motivation in ensuring that innovations are adopted in the study area. The result also indicates that more than half (61.1%) of the respondents have a household size of 6-10 members. This result indicates that the respondents had household sizes above average. This number of household members may lead to increased output and income generation from their farms. In terms of education, about (37.8%) of the respondents attained primary, secondary (32.2%), 20% had tertiary educational while 10 percent had no formal education. The farmers may thus be considered literate. This is an advantage in that education should assist these farmers to understand better the farming innovations being introduced to them. This is consistent with the findings of Adedoyin *et al*. (1999) who identified education as a foundation for farmers' use of agricultural innovations. The result shows that the mean farm size is 1.8 hectares. Majority of the respondents (86.7%) had farm sizes of 2 hectares and less, implying that the study area is characterized by small, fragmented and non-contiguous farm holdings. The small farm sizes may also affect their farm output and hence low farm income. Only 28.9% had less than 5 years of farming experience, 53.3% had between 6-10years of experience, 10.1% had between 11-15 years' experience, while 6.7 percent had above 16 years of farming experience in the study area.

Farmers Understanding of Reasons for the Establishment of NRCRI Umudike.

The result for Table 2 shows that 35.6% of the respondents understood the establishment of NRCRI Umudike by the government to be for the identification of solutions for major constraints to root and tuber crops production, followed by the development and distribution of improved planting materials to farmers to increase their agricultural productivity (31.1%). 20% of the respondents had the understanding that NRCRI Umudike was established to advice farmers on the best agronomic practices to adopt and to assist farmers in the control of post-harvest losses (13.3%). The result implies that the respondents had better understanding of the reason behind the establishment of NRCRI Umudike and would better assess the performance of the Institute in meeting up with such mandate.

Table 2: Distribution according to reasons for the establishment of NRCRI

Reasons for the establishment of NRCRI	Frequency	Percentage
To identify solutions for major constraints to Root and Tuber crops production	32	35.6
To advice farmers on the Best Agronomic Practices	18	20
For development and distribution of improved planting materials	28	31.1
To assist farmers in the control of post-harvest losses	12	13.3

Source: field survey 2017

Farmers Visitation by NRCRI Extension Staff

Table 3 shows that majority of the farmers (72.2%) had at most three visits from the extension staff of the Research Institute. The mean number of visits to the farmers by staff of Research Institute was once per farming season. This implies that in a year, most of the farmers had very few visits from the extension staff of NRCRI Umudike and may therefore not have benefitted from the knowledge they are supposed to gain from them. Knowledge is in form of new agricultural innovations and technologies, improved crop varieties, better farming practices and advice on better farm management practices may not have been disseminated effectively to the farmers in one visit only.

Table 3: Respondents according to number of NRCRI staff visits they received.

Number of visits	Frequency	Percentage
≤ 3	65	72.2
4-6	22	24.4
>7	3	3.3
Mean	1.8	

Source: Field survey 2017.

Reasons for Visit by NRCRI Extension Staff to the Farmers

The result in table 4 shows that majority (44.4%) of the farmers were visited by the extension staff only to distribute improved farm inputs to them. This was followed by extension staff (24.4%) who visited the farmers to establish demonstration farms, (20%) who visited the farmers to invite them for seminar, and, (10%) who visited the farmers to inspect their farms**.**

Table 4: Distribution according to their reasons for visit by NRCRI extension staff

Reasons for visit	Frequency	Percentage
To supply improved farm inputs	40	44.4
To invite for seminar	18	20
Establishment of demo farm	22	24.4
To inspect farm	10	11.1

Source: Field survey 2017.

Level of Impact of NRCRI on Agricultural Practices and Productivity of Farmers in the study area.

Table 5 showed that majority (44.4%) of the farmers recorded high improvement in their farming activities and productivity despite their access to improved farm inputs from the research institute, while only 38.9% of them recorded low improvement. However, fewer (16.7%) did not record any significant improvement in their farming activities and productivity of the farmers in the study area.

Table 5: Level of impact of NRCRI on agricultural practice and productivity of farmers

Level of impact	Frequency	Percentage
High improvement	40	44.4
Low Improvement	35	38.9
No Improvement	15	16.7

Source: Field survey 2017.

CONCLUSION AND RECOMMENDATION

The study findings revealed that most of the respondents were in their active stage of life in which they can effectively adopt improved innovations that would change their farming practices and result in increased productivity. Majority of the farmers understood the reason for the establishment of NRCRI Umudike by the government to be mainly for the identification of solutions for major constraints to root and tuber crops production and for developing and distributing improved farm inputs to farmers in other to increase their agricultural productivity. Most of the farmers recorded high improvement in their farming activities and productivity through the adoption of improved farm technologies from the institute. The institute impacted positively on the agricultural activities and productivity of farmers in the study area.

This study therefore recommends that the extension staff of NRCRI should be encouraged to take the farming-visiting aspect of their training very seriously especially in the study area. Efforts should be made by the institute to impact positively on the farming activities and productivity of over 90% of the farmers in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was on the production of fabric design using banana stalk gum. The practical was carried out at the Department of Home and Rural Economics, Oyo State College of Agriculture and Technology, Igboora. The objectives were to study the structure and physical properties of procured banana stalk gum, applied design on fabrics using banana stalk gum and determine the level of acceptability of fabrics produce. The data was collected through well-structured questionnaires administered to twenty one (21) respondents (staffs and students) to receive their view about the product produced in term of colour, texture, appearance, design, functionality and overall acceptability of the products. The data collected from this study were used to analyze the frequency count and percentage to explain the characteristics of the respondents with the use of table to relate one variable to another. From the result, the fabrics produced using banana stalk gum was rated in the order: extremely, like very much, like moderately and like slightly in term of colour, texture, appearance, design, functionality and overall acceptability. From the finding, it was observed that the fabrics produced with banana stalk gum is well acceptable by the respondents. The findings recommend that sap from banana tree which contains tannins can be used to make fabric design. Also, Farmers should be encouraged by the government to embark in production of banana trees for its sap (tannis) collection like sugar cane which is produced because is third content. (Sucrose).
Lastly, the youth should be trained in line with the usage of tannins to produce designs on fabric for the production of different dresses.

INTRODUCTION

Natural fibres have under intensive study worldwide due to their continuous supply, safe handling biodegradability and nontoxicity. They are usually low-cost fibres with low density with high specific properties (Santosha et al., 2018). Banana belongs to the family Musaceae, genus Musa, is a general term embracing a number of species or hybrids in this genus. Currently, throughout the world, it is widely cultivated in tropical and subtropical regions as one of the important staple food and commodities. (Boonruangrod, 2009). Almost each and every part of banana plant gives fibres of various strength, colour and long staple length. It is also sustainable, biodegradable, strong, fine, and could be an alternative to silk (Ebisike *et al.*, 2013). Subsequently a dead waste product from banana production, which is already being grown on a large scale globally, can be turned into fabric. Banana stalk gum can be made into a textile that can be used in multiple applications. However, it is a very obscure textile in the fashion industry, even with the rise in sustainability awareness. Further the companies that have been using banana stalk gum have not been doing so for a lengthy time. This study therefore aimed at producing textile from banana stalk gum.

MATERIALS AND METHOD

This research work was carried out in the department of Home and Rural Economics, Oyo State College of Agriculture and Technology, Igboora, Oyo State.

Research Design

The design for the study is a combination of experimental and survey design methods.

Population of the Study

The population of the study was the total number of student in the department of Home and Rural Economics which is 205 students and 10 lecturers from the department of Home and Rural Economics, Oyo State College of Agriculture and Technology, Igboora.

Sample Size and Sampling Technique

Random sampling techniques was used to select the sample size which was 10% of students and 10% lecturers was used for data analysis which is 20.5 students. Therefore, the research used twenty one (21) respondents

Procedures for Data Collection

The data was collected through the use of some samples of fabrics design with banana stalk gum and well-structured questionnaire was also administered to the respondent to receive their view about the product produced.

Materials for the production of fabrics design using banana stalk gum

Materials	Quantity (ies)
• Fabric	15 yards
• Dyes	150 g
• Caustic soda	50 g
• Hydrosulphite	150 g
• Corn Starch	50 g
• Scissors	1
• Hand gloves	2
• Bucket	1
• Bowl	1
• Stove/Gas	1
• Kettle/Pot	1
• Stirring rod	1
• Nose cover	1
• Starch	50 g

Production Procedure

1. Washing of the fabrics to remove industrial starch and dry
2. Application of banana stalk gum to the fabrics

3. Prepare the chemical
4. Dye the fabric

5. Wash thoroughly and dry
6. Application of starch to the fabric and sundry
7. Ironing of the fabric
8. Packaging of the design fabric

Method of Data Analyses

Primary data obtained for the study was analyzed and presented using tables. The data collected was synthesized for any ambiguities that may exist, coded and analyzed using the Statistical Package for Social Science (SPSS).

Presentation of Analyses and Discussion of Findings

Table 4.1 Distribution of Result Generated from Tie-Dye Produced using Banana Stalk Gum

Distribution of Result Generated from Tie-Dye Produced using Banana Stalk Gum

Colour:- The table shows that 52% of the respondents scored the colour of the tie-dye as like extremely, 39% scored it as like very much while the remaining 10% of the respondents scored it as like moderately. This show that majority of the respondents accept the colour of tie-dye produced with banana stalk gum as like extremely, like very much and like moderately.

Texture:- the result reveals that 52% of the respondent scored the texture of the tie-dye produced with banana stalk gum as like extremely, 33% of the respondents scored the texture of the tie-dye as like very much while the remaining 15% of the respondent scored the texture of the tie-dye produced with banana stalk gum as like moderately.

Appearance:- The table below shows that 76% of the respondents scored appearance of the tie-dye as like extremely while the remaining 24% of the respondents scored it as like very much, in term of appearance of tie-dye produced with banana stalk gum.

Design: the table below shows that 48% of the respondents scored the design of the tie-dye produced with banana stalk gum as like extremely, 33% of the respondents scored it as like very much, 10% scored it as like moderately while the remaining 10% scored the design of the tie-dye produced with banana stalk gum as like slightly.

Functionality: 52% of the respondents scored the functionality of the tie-dye produced with banana stalk gum as like extremely, 43% of the respondents scored it as like very much while the remaining 5% scored the functionality of the tie-dye as like moderately.

Overall Acceptability:- the result in the table below shows that 95% of the respondents scored the overall acceptability of the tie-dye produced with banana stalk gum as like extremely, while the remaining 5% said they like it very much. This reveals that there is acceptability of the tie-dye produced with banana stalk gum among the sampled respondents.

CONCLUSION AND RECOMMENDATIONS

In line with the findings of this study, the following conclusions and recommendations were made;

i. Banana stalk should be made use of in the production of quality fabrics
ii. It is recommended that sap from banana tree which contains tannins should be used to make best fabric design.
iii. Farmers should be encouraged by the government to embark in production of banana trees for its sap (tannis) collection like sugar cane which is produced because is third content. (Sucrose)
iv. The youth should be trained in line with the usage of tannins to produce fabric and to produce different dresses.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This paper aimed at understanding the motivating force behind competitive tea production in Nigeria. Secondary data from Mambilla Beverages Nigeria Limited annual reports were used. A dynamic panel regression method was used to examine factors influencing competitiveness of tea productions in Nigeria. The results showed that training ($p \leq 0.05$), working years ($p \leq 0.05$) and labour cost are major($p \leq 0.05$)determinants of tea competitiveness while factors such as gender, household size, age and religion are not critical to tea competitiveness.
Keywords: *Competitiveness, Dynamic Panel Regression, Private Cost Ratio, Tea, Nigeria*

INTRODUCTION
Tea (*Camellia sinensis*) is one of the most popular lowest cost beverages in the world; it is consumed by people from all races and ages (Raj, 2020; FAO, 2022). Tea demand is increasing around the world, resulting from increased sensitization of the health benefit, new client and new market; owing to this increasing demand, tea is considered a major component of world beverage market (Raj, 2020). In the past decades, the tea industry worldwide recorded speedy progress, with a rising amount of clients worldwide as well as many domestic markets (FAO, 2022). The international tea market is described by increasing income and tremendous revenue sectors and related health beneficial potentials, consumers increasing demand for natural organic, locally sourced drink in varied flavor, blend and environments. There is also, growing interest in quality specialty teas, locally sourced with particular flavours, and growing numbers of young customers and an emerging middle class.

The Federal Ministry of Agriculture and Water resources introduced tea production to Nigeria in 1972. Research activities onto the potential of tea growth on the Mambilla Plateau was carried out and report submitted in 1973 which recommended among other things the establishment of a tea estate and a land area of 700 hectares were acquired and in 1975, the first tea estate was established by the government. Tea varieties were imported from Kenya and research into development and establishment of clonal material commences. Commercial production of tea started in 1981 on the Mambilla plateau of Taraba State. To meet the processing demand of the tea company, the arrangement was made for out growers small scale farmers who sell their green tea leaves to the company.

The annual demand for green leaves increases with increases in processing companies in the country. This is equally accompanied by increased consumption leading to increase demand for made tea. On the average, there is annual tea requirements of ten million (10,000,000) kilogram in Nigeria, out of which only 1,640,000 Kilogram (10%) of this requirements is being met annually on the Mambilla Plateau (Omolaja *et al.*, 2012;Oluyole,*et al*, 2017; NBPC, 2016, 2017, 2018, 2019). Government intervention in tea sector resulted into expansion of areas cultivated with tea on the Plateau thereby more than double tea output in Nigeria. Also, the increases in areas cultivated with tea addresses the problems of dependence on tea importation and remove the heavy burden of foreign exchange outflow resulting from tea importation into the country (Adulagba, 2010). Nigeria now becomes' exporter of tea and earn foreign currencies and increased profitability; Tea production, processing and marketing has great potential for economic growth, hence the need for assessing determinants of competiveness to understand point of entry (Oluyole *et al.,* 2017, 2018; NBPC, 2019).

CONCEPTUAL REVIEW
CONCEPT OF COMPETITIVENESS
Competitiveness has been the basis of analysis when there is interest on issues bordering on allocation of assets in order to guarantee social welfare, better living standards and great employment rates as well as determining what a sector contributes/can contribute to the country's GDP (Ilchenko, *et al*, 2021). The Organization for Economic Cooperation and Development (OECD) defined competitiveness as "the ability of corporations, businesses, states, countries to produce, while trading in international market, a reasonably high income level and factor employment levels on a sustainable basis" (Saptana, *et al*, 2022). The EC (2018) defines competitiveness as "the ability of a country to provide its inhabitants with high

and increasingliving standards and high employment rate on a sustainable basis". Others relate this meaning to profitability (Long, 2021).

Competitiveness is a relative measure, depending on the purpose of study, the level of analysis, and the commodity being study. Several methodologies have been used to estimate competitiveness (Saptana, *et al*,2022; Dildora Nurmatovna *et al.*, 2020; Long, 2021; OCDE, 2021). Broadly, competitiveness has been classified into two main discipline namely: The Neoclassical economies who place emphasis on trade and export and measure competitiveness with comparative advantage, exchange rates and exports or imports indices (Yulin, 2021) and the Strategic Management that focuses on firm's structure and strategy, as well as the firm's competitiveness using indicators such as productivity and efficiency (Raji and Omotosho, 2006).This study adopted Porter's measure of competitiveness, competitiveness advantage described as country ability to produce a good or services at a lower cost domestically; approach described by Monke and Pearson, (1989)

Theoretical Framework

Theory of Competitive Advantage

The theory of competitive advantage was proposed by Michael Porter in the year 1985 and the theory seeks to address some of the criticisms of comparative advantage. Competitive advantage is the strategic advantage one business entity has over its rival entities within its competitive industry (Porter, 1985; Pressman, 1991). Porter believes that to get more than its fair share of profits, a company has to be able to do things that its competitors cannot do thus making such a company to have a competitive advantage over the others. There are two drivers of competitive advantage as far as Porter is concerned: cost advantage and differentiation. In cost advantage, one needs to incur lower costs than any other competitor. That advantage allows one to either price his/her products lower than anyone else or just to match prices and take the difference in profits. Differentiation just means meeting some customers 'need better than any competitor and getting a premium price in return. Porter identified attributes of nation which either promote or impede its competitive advantage and this includes factors condition, demand conditions, firm strategy, structure & rivalry, government role and element of chance.

Factor conditions: When a country is endowed with human resources, physical resources, knowledge resources, location, capital resources and infrastructure, it plays a significant role in determining its national competitive advantage. Also, basic factors such as natural resources, climate, advanced factors such as skilled labour, communications infrastructure, and technology are the crucial determinants of the nation's capabilities and competitiveness. Advanced factors are declined by the efforts of the individuals, firms, institution and government in a country.

Demand conditions: The demand conditions in home market are important in stimulating domestic firms to undertake innovation and improve quality of products. When domestic buyers are sophisticated, a pressure in the market is created for the domestic firms to meet high standards of quality demanded. Government's role: This can influence each of the other determinants of competitiveness. Government can influence the supply conditions of key factor s of production, demand conditions in the home market, and competition between firms. Government interventions can occur at local, regional, national or supranational level. Firm strategy, structure and rivalry: The way in which companies are created, set goals and are managed is important for success. But the presence of intense rivalry in the home base is also important; it creates pressure to innovate in order to upgrade competitiveness. Element of Chance events: These are occurrences that are beyond the control of a firm. They are important because they create discontinuities in which some gain competitive positions while others lose. In the present study, productivity, economies of scale, factor conditions, demand conditions and ability to obtained adequate price are major determinants of competitiveness of the value chain which are embedded in Porter competitive advantage theory.

METHODOLOGY

Secondary data for tea production 2015 to 2018 from Mambilla Beverages Nigeria Limited annual report was used. Competitiveness of tea production was determined using; a dynamic panel through the system generalized method of moments (SGMM) and combined with Policy Analysis Matrix (PAM) specified as follows:

$$PCR_{it} = \alpha_1 PCR_{it-1} + \alpha_2 X_{it} + (\varepsilon_i + \mu_{it}) \qquad (i)$$

Where:

PCR is the ratio of domestic cost and to value created at private prices, *i* indicate a vector of cross-section of producer at period *t*., X represents a vector of exogenous variables, indicators like religion, gender, training, age, and household size, number of household income earners, labour cost, and working years.,ε_i is an error term capturing the unobserved and fixed time-specific effect of producers, μ_{it} is an endogenous error term (Roodman, 2009; Azimi, 2022). Furthermore, equation 1 assumes a random walk, and PCR is persistent.α_1 yield unbiased and efficient in finite samples through the system GMM rather than the differenced GMM (Arellano and Bover, 1995; Blundell *et al*., 2001; Roodman, 2009), especially since the data of the variables are collected for specific period.

This study utilized the system generalized method of moments (SGMM) and conducted various investigations to select the best suitable model specification. Estimation of SGMM can either be one-step or two-step (Hansen, 1982; Erickson and Whited, 2002). While the One-step SGMM involves estimating the parameters of the model in a single step by minimizing the moment conditions based on the data, the two-step GMM takes the process further by minimizing the distance between the moment conditions and the sample moments of the estimated parameters (Arellano and Bond, 1991; Wooldridge, 2010). However, the one-step GMM is adopted in this study because the model is correctly specified, and the moment conditions have no measurement errors. Also, this study relies heavily on efficient and faster computation of parameters, which is a major advantage of one-step SGMM over the two-step SGMM.

Furthermore, to examine the presence of serial correlation in the residuals, the Arellano-Bond test is utilized while assuming the absence of order serial correlation of first (AR1) or second (AR2) (Roodman, 2009). The Hansen test of over-identifying restrictions to detect potential endogeneity bias and specification issues during model estimation (Hoeffler *et al.,* 2001) was employed in this study. Following Roodman (2009), the instrument matrix is collapsed to prevent having numerous instruments, which may arise from the Arellano-Bond estimation approach of using a lagged level as valid instruments.

RESULTS AND DISCUSSION

The result of the system generalized methods of moment (SGMM) approach is as presented in Table 1. From the table, the result of difference-in- Hansen test statistics show that the null hypothesis which stated that there is no serial relationship between instruments and error terms cannot be rejected, signifying that the over-identifying restriction are valid. Also, the Arellano- Bond test for AR(1) provides strong evidence that the residuals are negatively correlated which corroborate the first-difference process in the SGMM methods. Similarly, the null hypothesis of zero correlation in the first differenced at order 2 (AR2) is not rejected, a necessary requirement for constant results.

Adopting the policy analysis matrix approach to PCR values, the higher the PCR (PCR >1) the smaller the competitiveness. Hence, a positive calculated figure signifies that the independent variable rises the PCR and has a negative effect on competitiveness. However, a negative estimated coefficient shows that the explanatory variables decreases the PCR and thereby has a positive influence of competitiveness. From table 1, the PCR value is less than 1, indicating that tea production is competitive in Nigeria.

The result from the table further shows that, the estimated coefficient of training variable is significant at 5% level. The result show that each additional cost incurred in getting trained increases competitiveness. Tea production requires continuous training to improve performance, and efficiency in operations. Training lead to access to economic benefit, improved technology, information, improved methods of operations, reduction in various costs and consequently, higher competitiveness.

The result of the SGMM also shows that number of working years significantly influenced competitiveness at 5% level. The higher the number of years used in tea production, the more the competitiveness. This is a result of training attended and improvement leant over the years which affect the profitability of actors. The result equally shows that labour cost coefficient is significant at 5% levels. This is an indication of strong relationship between labour costs to increase in competitiveness. An additional cost incurred on labour increases profitability. The labour cost involved in tea activities is small as confirmed by the PAM results and this increase profitability.

Source: Field survey, 2021 Note: ** and *** indicate 5% and 1% significance levels, respectively. Values in the squared bracket are probability values.

CONCLUSION AND RECOMMENDATION

Result of the dynamic SGMM showed that, training, number of working years, and labour cost are main determinants of competitiveness. The estimates further revealed that age, gender, household size are not important factor for tea competitiveness. It is therefore recommended that government should enhance the participation of actors in tea value chain in relevant training to increase the competitiveness of tea sector.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The agricultural sector's significance as a driver of economic growth and development has led successive administrations in Nigeria to prioritize interventions in this domain since the 1970s. The understanding of agricultural pivotal roles, including food supply, raw material provision, job creation, savings, tax generation, and foreign exchange earnings drives this focus. The sector's importance is underscored by the fact that, without developing agriculture, achieving economic growth in Nigeria is nearly impossible due to its 70% population employment. The paper discusses several challenges facing smallholder farmers in Nigeria, focusing on economic difficulties, insecurity, and the impact of climate change. It highlights the vital role of farming in feeding the global population and introduces the various ecological and economic challenges farmers have historically faced. The economic overview section emphasizes the economic hardships in Nigeria, including income loss, inflation, and unemployment, which impact farmers' ability to access financial resources and improve their yields. It points out that despite some projected economic growth, issues such as inflation and reduced liquidity could continue to affect the non-oil sectors and macroeconomic stability. The socioeconomic situation in Nigeria, characterized by poverty and limited human capital development, is also discussed. Climate change is discussed as another significant challenge affecting Nigerian farmers. The paper notes that rising temperatures, drought, and changing rainfall patterns impact agricultural productivity and food security. The effects of extreme precipitation events and flooding on agriculture are highlighted, with recent flood events causing displacement, destruction of farmland, and potential increases in food prices. The paper further discussed the Prospects of Agricultural development and Pro-poor intervention by the Federal Government of Nigeria through the Central Bank of Nigeria. Climate Smart Agriculture (CSA) and Good Agricultural Practices (GAP) are highlighted, with CSA addressing food security and climate change challenges, aiming for increased productivity, enhanced resilience, and reduced emissions. GAP involves voluntary audits to ensure safe and sustainable food production. While challenges like climate change and insecurity persist, government policies, financial support, improved inputs, and technological advancements are proposed as solutions. Farmers' resilience and persistence remain crucial in sustaining Nigeria's agricultural sector's contributions to the national economy and food security. The paper highlights the multifaceted challenges faced by smallholder farmers in Nigeria, encompassing economic difficulties, insecurity, and the effects of climate change. It underscores the urgent need for interventions to support farmers in overcoming these challenges and improving their livelihoods.

***Keywords**: Climate Smart Agriculture, Good Agricultural Practices, Food security, insecurity, climate change, Pro-poor intervention*

INTRODUCTION

Farming is indubitable a noble and vital profession; because without farming, the whole world would starve to death. However, farming as we know is a uniquely challenging profession. For Millennia, farmers have struggled to find creative solutions to a variety of ecological and economic challenges. The various challenges affect feeding an expanding global population to meeting rising demands which involves producing more foods on lesser acres to the detriment of using less arable land, producing high quality and bountiful yields, rearing healthy and numerous livestock. Throughout the record of history there has never been a time when farmers had absolutely no worries. Till date farmers are faced with those perennial risk, yet they have been survivors and most of you farmers are no exceptions.

According to Mbenka and Mbah (2016), smallholder farmers operate at subsistence, smallholder level, with intensive agriculture being uncommon. A characteristic feature of the agricultural production system in Nigeria is that a disproportionately large fraction of the agricultural output is in the hands of these smallholder farmers whose average holding is about 1.0 - 3.0 hectares. According to the Federal Office of Statistics (1999) smallholder farmers are those with land holdings ranging from 0.1 to 4.99 hectares. Access to new enhanced technology is extremely limited, and their overall situation does not always warrant real investments in cash, inputs, and labor. These farmers lack agricultural information and this is a factor that encourages ignorance of contemporary farm technologies in the farmers, consequently the issue demands more attention than it already gets. These farmers also face high production costs, which affect both commercial and smallholder farmers, as well as other restraints affecting smallholder farmers. The Nigerian Small holder farmers have limited access to loans, which significantly decreases their production (Mgbenka and Mbah, 2016).

Economic Overview

Economic hardship resulting from income loss, recession, unemployment, price inflation, and economic insecurity affects a country generally. As these and many other lapses occur it affects farmers and farming practices, putting farmers in situations where they need financial support to enable them grow, expand and improve their yields. There are various micro-financing institutes in operation today in Nigeria but so many farmers still cannot access them and others encounter delayed financing. For example, seeds such as hybrid or certified seeds yield better and are more tolerant and disease resistant than others but they are sold at higher prices than the regular seeds.

According to World Bank (2022) Nigeria's economic growth improved after the pandemic-induced recession in 2020, but macroeconomic stability deteriorated. Inflation is skyrocketing, forcing millions of Nigerians, especially smallholder farmers who are mostly unnoticed, into poverty as a result of global commodity shocks, weakening currency, trade restrictions and deficit monetization. Nigeria has also been unable to benefit from rising global oil prices since 2021, as oil production has dropped to historic lows and petrol subsidies continue to eat a higher share of total oil revenues. In 2018, 40% of Nigerians (83 million people) were regarded as been poor and another 25% (53 million) were found to be vulnerable. The number of Nigerians living in extreme poverty is expected to rise by 7.7 million between 2019 and 2024, as population growth continues to exceed poverty reduction

Even though, the economy is anticipated to expand by an average of 3.2% in 2022 – 2024, adverse risks to the growth outlook include additional drops in oil production and increased insecurity. Meanwhile, continued currency shortages and reduced liquidity could have an impact on non-oil sector economic activity and jeopardize macroeconomic stability as a whole. Along with persistent budgetary and debt pressures, high inflation is also anticipated to accompany the uncertainty. While Nigeria has made some progress in socio-economic terms in recent years, its human capital development ranked 150 out of 157 countries in the World Bank’s 2020 Human Capital Index (World Bank, 2022).

Insecurity

According to World Bank report (2022) the battle against Boko Haram and other terrorist groups in the northeast, as well as ongoing occurrences of banditry and kidnappings in the north-west and parts of the southwest, has changed the security environment since 2011. The southeast is still experiencing unrest as a result of separatist agitations (unknow gunmen). In 2021, Nigeria was ranked 6th in the world terrorism index (Fig. 2 and Table 1) and 3rd in African after Somalia and Burkina Faso. In recent times, Nigeria has witnessed an unprecedented level of insecurity. This has made national security threat to be a major issue for the government (Achumba *et al*., 2013).

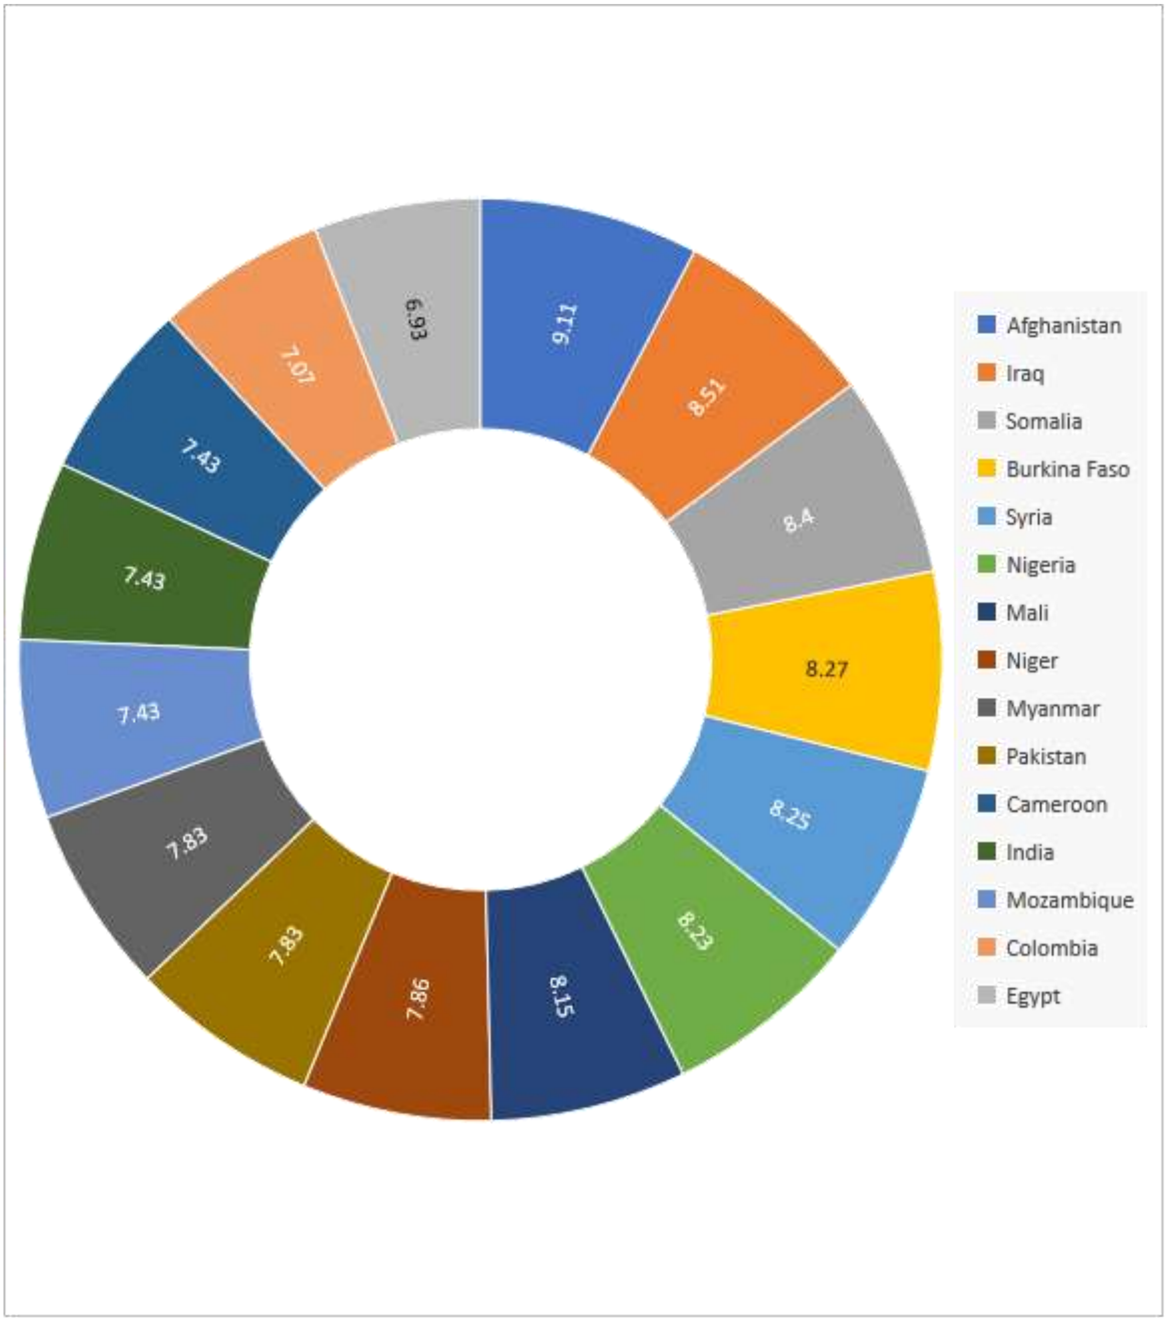

Fig. 1. World Terrorism Index.
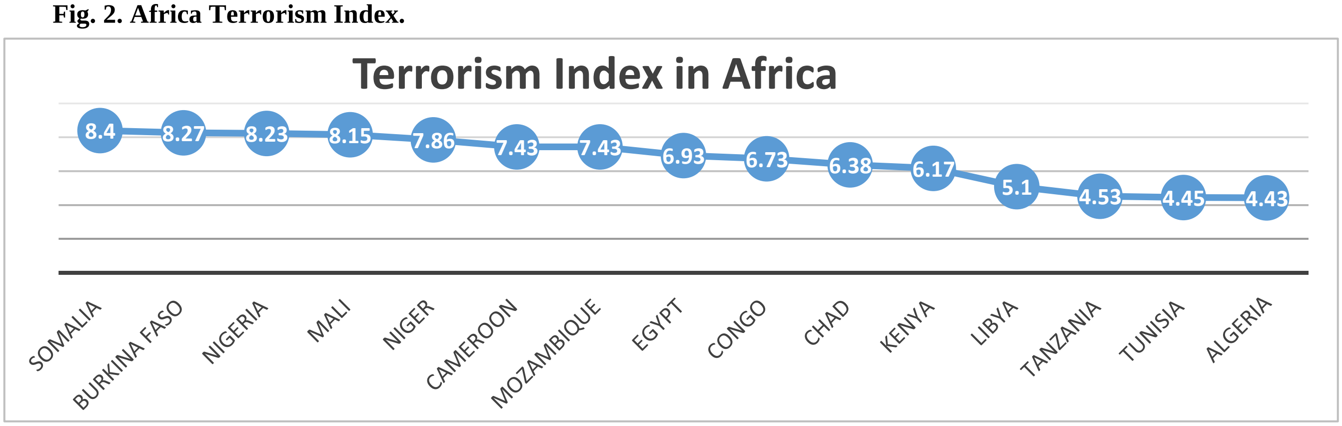
Source: Trading Economics (2022).
Fig. 2. Africa Terrorism Index.



Source: Trading Economics (2022).

Thus, the challenges of agricultural sector in the twenty first century due to the activities of cattle herdsmen rustling and terrorist insurgence have imposed more security threats than safety to the mankind because they have created a severity of untold hardship to farmers in particular and a nation at large. According to Bolarinwa *et al*. (2012) Nigeria has recorded several violent conflicts in many rural communities from 1999 till date; conflicts that have resulted to over 10,000 deaths and internal displacement of over 300,000. These situations have resulted in distortion in farmer's livelihood since they live and earn their living from rural areas. Farmers are vulnerable to the effects of shocks from physical and social environments because they suffer huge crop and livestock losses due to insecurity challenges. Majority of those engaged in agriculture are poor and therefore, engulfed in serious financial obstacle to escape the vicious circle of poverty (Obamuyi, 2008). A lot of the farmers have resorted to the use of some adaptive measures in order to cope with shocks from insecurity.

For the last 5 years, the Boko Haram crisis has had a profound impact on northern Nigeria, specifically the North Eastern states of Adamawa, Bauchi, Borno, Gombe, Taraba and Yobe while in the last couple of years, the following North Central states: Benue, Kaduna, Katsina and Niger, Plateau and North western states: Kebbi, Sokoto and Zamfara are ravaged. Fig. 3. shows the terrorism index calculated for Nigeria form 2011 – 2019. As the sects rampaged through these areas, communities were destroyed, millions of people (farmers) were displaced from their communities and cut short of their livelihood; insecurity spread across the region; cattle rustling increased, farm lands were abandoned, farmers or communities were taxed exorbitantly by the rampaging bandits. A land mass that is almost 15% of Nigeria has essentially become a no – go area for nomadic herdsmen and farmers.

Fig. 3. Terrorism Index in Nigeria, 2011 – 2019.

Source: Trading Economics, (2022).

The North Eastern region of Nigeria has some of the richest foraging stock in the country – and much of that is no longer available for use – because of the Boko Haram crisis. The implication has been a downward, southwards movement by nomadic Fulani herdsmen as they move in search of water and foraging resources for their cattle and this has led to intensification of resource pressures on north central and southern communities, culminating in violent clashes. Indiscriminate cattle grazing has also contributed to the destruction of vegetation and wildlife habitats, and led to the pollution of farms, rivers and waterways with cattle manure across many communities. However, Communities have experienced ecological and economic devastation as a result of this crisis. Therefore, the combination of a growing cattle population, the effects of climate change on the availability of water and forage crops, as well as the lack of access to North Eastern foraging grounds due to the Boko Haram crisis are the proximate causes of the increasing tensions between farming communities and cattle herdsmen.

Many disputes occur during dry seasons when farmers are planning to harvest crops and at the same period, the herdsmen are wandering to feed their cows on the crops. However, if crop damage occur, farmers may claim right to fight that the herdsmen should stop destroying their crops and when this happens, the herdsmen may also perceive this act as an intimidation to them. More so, conflicts could also erupt when some vegetable farmers living around riverside claim right to grow vegetables around the water side that the herdsmen should not destroy their vegetables in order to give their cattle water. There is lack of agreement in the principles of land use as the cause of the conflict between farmers and pastoralists occur (Agboola and Eniola, 1992).

In an extension to the cause of conflict between Fulani herdsmen and farmers, it appears to be no consensus among both groups as to the cause of their mutual conflicts. According to Dehaan (2002) destruction of crops by cattle and other farming properties (irrigation equipment and infrastructures) by the cattle herders themselves were the major causes of conflicts cited by the farmers. Burning of range land, blockage of the stock route and water points were another cause of conflicts reported by the cattle herders. Whatever the causes of farmers-herdsmen conflicts may be, it is evident that conflicts have been of great negative effects (loss of income/resources yield) to physical effects (such as home/farm destruction, body injury or death of family members) and socio-psychological effects like emotional exhaustion, job dissatisfaction, among others (Adisa, 2011). Banditry has posed a serious threat to farming communities in the northern parts of the country. This is because most of the farmers in agriculturally famous community of the middle belt, northwest and northeast have abandoned their farms and migrate to other communities in seeking safety for their lives hence leaving their farms fallow and unharvested crops which would pose adverse effect on the farming system.

Climate Change

A report on climate change by the USAID (2022) indicated that Nigeria has the largest economy in Africa, the most people, and a wealth of natural resources, mainly oil and natural gas. Its diverse natural zones have given rise to a diverse set of livelihoods, agricultural techniques, and commodities, all of which are vulnerable to climate change and shocks. Rising sea levels endanger southern cities like Lagos and coastal communities, making them more vulnerable to flooding and waterborne disease. Drought and decreasing rainfall, combined with rising temperatures, suffocate the country's hydropower systems and impede agricultural productivity and fisheries and aquaculture, diminishing food security and having a detrimental impact on health and nutrition. Nigeria's greenhouse gas (GHG) emissions are mostly caused by the energy sector, deforestation and land-use change.

In the report of the World Economic Forum (WEF), one of the effects of climate change is that a warmer atmosphere creates more intense precipitation events. This occurs because warmer air can hold more moisture. The amount of water vapor that the atmosphere can contain increases by about 7% for every 1.8 degrees Fahrenheit (1 degree Celsius) of increase in atmospheric temperature. Research has documented that this increase in extreme precipitation is already occurring globally and it impede agricultural activities thereby affecting food security (Table 1). The fact that the world has experienced multiple record of flooding events in recent years – including catastrophic flooding in Australia, Western Europe and China – is not a coincidence. Climate change is making record-breaking extreme precipitation more likely. Severe floods in Nigeria since September have caused the deaths of over 600 people and displaced 1.3 million from their homes, according to a government minister, in the most devastating episode of seasonal floods Nigeria has seen in a decade. Heavy rains combined with poor urban planning have made parts of Nigeria more susceptible to flooding. Around the River Niger bridge which joins Lagos to Onitsha and the rest of eastern Nigeria, sizable portions of surrounding communities have been submerged under water, crippling economic activity for many small traders and farmers (WEF, 2022).

In Anambra state, 76 people died trying to flee the flood after an escape boat capsized. More than 200,000 houses and 266,000 acres of farmland have been completely or partially damaged and yet the people were warned that more floods would still come. This has led to an increase in outbreak of water-borne diseases. The last major flood emergency experienced was between July and October in 2012, when the Niger and Benue rivers overflowed their banks. The reported death toll at the time was under 500, but it displaced a similar number of people as that of this year. But in addition to state governments failing to prepare early for seasonal floods, this year's events have also been blamed on the release of excess water from Cameroon's Lagdo dam in the middle of September. Nigeria does not have a buffer dam to prevent this flow though, this need has existed since 1982 when the Lagdo dam was completed. Some big agricultural businesses are feeling the heat and that could increase food prices in the coming months. Olam Nigeria, which produces a quarter of Nigeria's rice, says 10,000 acres of its farmland have been submerged and washed away, leading to a shortfall in harvest and this could raise prices of rice produce. "We should expect an increase in rice prices in December. Of course, that goes without saying, because the entire crop has been lost," said Ade Adefeko, the company's Vice-President for Corporate and Government Relations (WEF, 2022). The same trend was experienced in most rice growing states like, Kebbi, Nasarawa, Niger, Kogi, Kwara, Jigawa and Zamfara. The current flood has affected nearly all 36 states in the country. President Muhammadu Buhari, President of the Federal Republic of Nigeria, tweeted on October 16, 2022:

"All Federal agencies dealing with rescue and disaster management have been directed to scale up response and intervention efforts to support the victims of flooding across the country, as well as all the affected State Governments – 33 states so far affected and the FCT".

Table 1. Effects of flood on farmlands/cultivated lands coverage

Extent flood affect farmlands include:	N = 632				Total	
	AA	A	S	NA		Decision
Washing away of farmlands by flood leads to severe hunger and starvation	144 (22.8%)	247 (39.1%)	106 (16.8%)	135 (21.4%)	632 (100%)	*
Farmers in the community experience very poor harvest ofcrops after flood incidents	272 (43.0%)	163 (25.8%)	73 (11.6%)	124 (19.6%)	632 (100%)	*
Households or residents find it difficult accessing food after every flooding incident	159 (25.2%)	203 (32.1%)	117 (18.5%)	153 (24.2%)	632 (100%)	*
Growth and development of crops is affected when flood washes away farmlands	213 (33.7%)	229 (36.2%)	93 (14.7%)	97 (15.3%)	632 (100%)	*
Flood washes away the fishing nets or traps in the fishing ports/gardens	140 (22.2%)	100 (15.8%)	214 (33.9%)	178 (28.2%)	632 (100%)	#
Basic food is scarce after all flood incident	247 (39.1%)	229 (36.2%)	84 (13.3%)	72 (11.4%)	632 (100%)	*
Flood makes individuals not to gain from the crops planted in farms or gardens	166 (26.3%)	292 (46.2%)	77 (12.2%)	97 (15.3%)	632 (100%)	*
Flood brings up the issue of food insecurity and stealing of food in the community	268 (42.4%)	216 (34.2%)	83 (13.1%)	65 (10.3%)	632 (100%)	*
Flood rises the harvesting of immature crops	221 (35.0%)	172 (27.2%)	111 (17.6%)	128 (20.3%)	632 (100%)	*
Illegal trespassing into other persons farms/fishing areas increases after every flood	171 (27.1%)	213 (33.7%)	131 (20.7%)	117 (18.5%)	632 (100%)	*

Prospects

Agricultural Development and Pro-poor Interventions

The agricultural sector has been a major focus of the interventions of the Central Bank of Nigeria since the 1970s. The interventions which are driven by the development finance mission of the apex bank are motivated by the recognition of the critical role's agriculture plays in economic growth and development. These roles, according to Kinderberger *et al*. (2021) include: Supply of food to the population; Supply of raw materials for the non-agricultural sector; provision of employment; provision of investible surplus in the form of savings and taxes; and also, foreign exchange earnings through export. Stressing the importance of agriculture to the economic growth of Nigeria and hence the need for increased investment in the sector, Odetola and Etumnu (2013) of the International Food Policy Research Institute (IFPRI), Nigeria, said: "In Nigeria, because 70% of the population is employed in the agriculture sector, economic growth will be almost impossible to achieve without developing the sector.

a. **Agricultural Credit Guarantee Scheme Fund (ACGSF):** The interventions of the CBN in the agricultural sector started in 1977 with the introduction of the Agricultural Credit Guarantee Scheme Fund (ACGSF). The Fund was designed to encourage banks to lend to farmers. Under the scheme, the CBN through the Fund, guarantees loans to farmers up to 75% of the amount in default net of any security realized. According to data from the CBN, the ACGSF since inception till March 2021, has facilitated 1.180 million loans valued N122.632 billion to farmers across the country (CBN, 2022).

b. **Agricultural Credit Support Scheme (ACSS):** Another intervention of the CBN in the agricultural sector is the Agricultural Credit Support Scheme (ACSS). ACSS was introduced to enable farmers to exploit the untapped potentials of Nigeria's agricultural sector, reduce inflation, lower the cost of agricultural production (i.e., food items), generate surplus for export, increase Nigeria's foreign earnings as well as diversify its revenue base. ACSS funds are disbursed to farmers and agro-allied entrepreneurs at a single-digit interest rate of 8.0 percent. At the commencement of the project support, banks will grant loans to qualified applicants at 14.0 per cent interest rate. Applicants who pay back their facilities on schedule are to enjoy a rebate of 6.0 per cent, thus reducing the effective rate of interest to be paid by farmers to 8.0 per cent (CBN, 2022).

c. **Commercial Agriculture Credit Scheme (CACS):** In a bid to encourage commercial farming on a large scale, the CBN in collaboration with the Federal Ministry of Agriculture and Water Resources (FMA&WR) in 2009 established the Commercial Agriculture Credit Scheme (CACS) to provide finance for the country's agricultural value chain namely production, processing, storage and marketing. The CBN explained that increased production arising from the intervention would moderate inflationary pressures and assist it to achieve its goal of price stability in the country. Under the CACS, loans are provided to commercial farmers at a maximum interest rate of 9 percent.

   The scheme also allows for moratorium in the loan repayment schedule taking into consideration, the gestation period of the enterprise. Data for the CBN shows as at January 2021, banks under the CACS have disbursed N672.9 billion loans to fund 636 commercial farming projects while total loan repayment stood at N443.9 billion (65.96% repayment). In terms of employment, the CBN disclosed that the firms that benefited from the CACS recorded net job increases of 24,457 between 2009 and 2018 (CBN, 2022).

d. **Anchor Borrower Programme (ABP):** Following the sharp decline in crude oil prices in 2014 and the resultant decline in foreign exchange earnings and reserves, the CBN took radical measures to address the huge food import bill as a means of preserving the nation's external reserves. Thus, in addition to the foreign exchange restrictions placed on 41 items (which were mostly food items), the CBN introduced another intervention in the agricultural sector to boost local food production. Thus, the birth of the Anchor Borrowers Programme (ABP) which was launched by President Mohammadu Buhari in 2015. According to the CBN, the ABP is intended to create a linkage between anchor companies involved in the processing and small holder farmers (SHFs) of the required key agricultural commodities. The programme thrust of the ABP is provision of farm inputs in kind and cash (for farm labour) to small holder farmers to boost production of these commodities, stabilize inputs supply to agro processors and address the country's negative balance of payments on food. At harvest, the SHF supplies his/her produce to the Agro-processor (Anchor) who pays the cash equivalent to the farmer's account.

e. **FGN/IFAD LIFE-ND:** The Livelihood Improvement Family Enterprises Project for the Niger Delta (LIFE-ND) is a project of the Federal Government of Nigeria (FGN) designed in collaboration with International Fund for Agricultural Development (IFAD) and Niger Delta Development Commission (NDDC). The project is in response to the limited readily available options for the "disadvantaged" (youth and women) in the rural and suburban communities to improve their means of livelihood and help them to live decent lives. LIFE-ND promotes community-based on-farm and off-farm business activities along key agricultural value chain as a mechanism for job and wealth creation amongst unemployed and underemployed youths and women-headed households. The LIFE-ND Project adopts an Incubator model at the community level of the Local Government Areas, targeting core commodities of comparative advantage in such communities. LIFE-ND community beneficiaries are identified, trained and supported in different segments of Agriculture along the entire value chain. This support includes access to affordable agricultural inputs for sustainable production, agro-processing & packaging, transportation and link to competitive financing and markets. Through the LIFE Project, a robust production to marketing system that reduces food wastage and increase farm earnings for rural families is ensured. According to LIFE-ND (2022). The targeting strategies includes the following:

- promotion of enterprises responsive to women's livelihoods such as production, processing and marketing of vegetables, fish, poultry, and honey, for income, household food security and nutrition;
- time, venue and environment friendly events for women's participation;
- self-targeting of women's only groups;
- provision of at least 50 percent of leadership positions for women in commodity associations, and 30 percent of women in the project management team;
- promotion of the use of Gender Action Learning System (GALS).

f. FGN/IFAD-assisted Value Chain Development Programme (VCDP): The FGN/IFAD-assisted Value-Chain Development Programme (VCDP) seeks to enhance the productivity and profitability of smallholder farmers and small/medium-scale agro-processors by improving their access to markets, and capacity to increase yield as well as add value to locally produced raw materials through improved processing and packaging. The coverage of its implementation, which started in March 2015 across six States - Anambra, Benue, Ebonyi, Niger, Ogun and Taraba, was raised to nine (9) in 2019, by including three new States of Enugu, Nasarawa and Kogi, covering five (5) LGAs in each, while the original five (5) LGAs in each of the earlier six States were increased to eight. The Programme Development Objective (PDO) is to sustainably increase the incomes and enhance food security for an estimated 100,000 rural poor households engaged in production, processing and marketing of rice and cassava in the targeted 63 LGAs across the nine (9) States.

1. **Success Stories from Beneficiaries of Agricultural Interventions – the Case of IFAD-VCDP**

The Nasarawa state IFAD-VCDP's Knowledge Management and Communication (KMC) unit shared some success stories from program beneficiaries, including the following:

i. **Woman made 2.5 million Naira- Thanks to intervention and adoption of good agronomic practices.**

Mrs. Dinatu Ishaya of Alagye community in Doma LGA is profoundly an example to all women that every success is possible for women if only they take agriculture as serious as expected. In just a single year, she made a whooping sum of ₦2.5 million from her 3 hectares farmland where she harvested 100 bags of rice (100 kg sized bag) and sold each for 25,000 Naira. The 50-year-old mother of 8 who is the Treasurer of Salama Okolo Multipurpose Society, Alagye, Doma LGA registered as a beneficiary of VCDP in 2020 and enjoyed interventions including inputs such as seeds, fertilizer, herbicides, as well as series of trainings on best agronomic practices, business management, gender, etc.

After a careful adoption of good agronomic practices, she harvested a record 100 bags, according to her in the same place where she used to harvest an average of 55 bags. "I was so surprised when we harvested it because I was not expecting the gap to be so much like that." So, what did Mrs. Dinatu do with the money? According to her, "I used about ₦1.5 million to build a house at Ube in Akwanga LGA. I also used ₦200,000 to buy a motorcycle (Bajaj) to assist me in going to farm always. Then I spent about ₦600,000 on the education of my children while about ₦400,000 was reinvested in my rice farm (Nasarawa IFAD-VCDP, 2022).

ii. **From Grass to Grace: The Amazing Story of ₦25 Million Worth All-Female Cassava Group in Wamba, Nasarawa State.**

Michelle Obama was proved right by the United Sisters Multipurpose Cooperative Society, Wamba, Nasarawa State when she said "there is no limit to what we, as women can accomplish." All they needed was a helping hand and they got this helping hand from FGN/IFAD–Value Chain Development Programme (VCDP), Nasarawa State. The VCDP donated market stores and stalls to these women which provided a massive boost to their activities in many ways. According to Mrs. Rachael Kpemishi Samuel, the group's secretary, "Before now, we used to hawk cassava round Wamba market every market day which was very stressful and less profiting. But now, we have our modern market stalls located at the heart of the market where people come to buy cassava from us without us having to suffer. Apart from that, during rainy season, we usually lose a lot because rain usually wet our cassava flour. But today, we don't mind if the rain continues to fall every market day because we are very safe".

Apart from boosting sales and easing storage difficulties, the market stores and stalls provide additional source of income to the group. Out of 12 stores, the group retained 2 and rented out 10 at the rate of ₦25,000 per year. This means a total of ₦250,000 for all 10 market stores per year. Similarly, 10 out of 14 market stalls were rented out at the rate of ₦10,000 each per year which means a total of ₦100,000 per year. By implication, United Sisters benefit an additional ₦350,000 annual income from market stores and stalls rented out to other business owners.

iii. **We made over 5 million Naira through VCDP's Dry Season Intervention – Ozanawa MPCS**

Formed in 2002, the Ozanawa Multipurpose Cooperative Society in Doma LGA of Nasarawa State which comprises of men, women and youths have been surviving on monthly contributions from members to invest and generate profits for the betterment of the lives of every member. "When we met FGN/IFAD – Value Chain Development Programme (VCDP) in 2020, our story started changing almost immediately. The coming of VCDP was indeed the beginning of our turn around" says the Chairman, Chief Ongburu Ari Ogiri.

The Ozanawa Multipurpose Cooperative Society is one of the nine FOs that benefitted from the dry season intervention of VCDP and for the first time in their history ventured into dry season rice farming. "We cultivated 5 hectares" says the Chairman, Chief Ongburu "and achieved 5.4 metric tons per hectare. At the end of the harvest, we got 202 bags of paddy rice (120 kg per bag)." He narrated further that the entire members of the group were overwhelmed by the massive result achieved within a very short period and how they have grown in less than one year encounter with VCDP. "We concluded that VCDP is that messiah we have been waiting for. Our group has become a talk of the whole town. Since we started in 2002, we have never seen anything close to this. VCDP is so wonderful and we are grateful to them."

2. **Climate Smart Agriculture and Good Agricultural Practices (GAP)**

According to World Bank (2022), Climate-smart agriculture (CSA) is an integrated approach to managing landscapes—cropland, livestock, forests and fisheries—that addresses the interlinked challenges of food security and accelerating climate change (ACC). Good Agricultural Practices (GAP) are voluntary audits that verify that fruits and vegetables are produced, packed, handled, and stored to minimize risks of microbial food safety hazards. CSA/GAP aims to simultaneously achieve three outcomes – a triple win:

a. **Increased productivity:** Produce more and better food to improve nutrition, security and boost incomes, especially of 75 percent of the world's poor who live in rural areas and mainly rely on agriculture for their livelihoods.

b. **Enhanced resilience:** Reduce vulnerability to drought, pests, diseases and other climate-related risks and shocks; and improve capacity to adapt and grow in the face of longer-term stresses like shortened seasons and erratic weather patterns.

c. **Reduced emissions:** Pursue lower emissions for each calorie or kilo of food produced, avoid deforestation from agriculture and identify ways to absorb carbon out of the atmosphere.

Climate-smart Agriculture involved practices, such as the locally practiced conservation in agriculture, aimed at conserving soil moisture, retaining crop residues for soil fertility, disturbing the soil as minimally as possible and diversifying through rotation or intercropping; while Good Agricultural Practice (GAP) is a certification system for agriculture, specifying procedures (and attendant documentation) that must be implemented to create food for consumers or further processing that is safe and wholesome, using sustainable methods.

3. **Escaping the Death Throat through Agricultural Insurance**

The need for a specialized Agricultural Insurance Company to provide insurance cover to farmers was informed by Government's concern over the vacuum created due to the unwillingness of conventional Insurers to accept Agricultural risks, which they considered too risky. This led to the establishment of the Nigerian Agricultural Insurance Scheme on 15th of November 1987. The implementation of the Scheme was initially vested in the Nigerian Agricultural Insurance Company Limited, which was later incorporated in June, 1988 but later turned into a corporation in 1993 by the enabling Act 37 of 1993. Nigerian Agricultural Insurance Corporation (NAIC) is therefore, a wholly-owned Federal Government of Nigeria insurance company set up specifically to provide Agricultural risks insurance cover to Nigerian farmers (NAIC, 1993). According to Industrial and General Insurance Plc. (IGI, 2022) an agricultural Insurance is a policy which involves the insured (farmer) paying a little sum (premium), usually in percentage to an insurance company (insurer) to guarantee against loss due to any of the perils of **death**, **flood**, **drought** etc.

The Agricultural policy covers the followings and protects the farmers from:

- ✓ Loss of and damage to the crops due to fire
- ✓ Flood
- ✓ Drought
- ✓ Windstorm
- ✓ Lightening
- ✓ Pests and Diseases.
- ✓ Death of Livestock/Birds/Fish due to accident or diseases.

According to Imah of Agrodomain Blog (2020) there are enormous benefits for farmers who take insurance policies to protect their crops, livestock, farming and harvesting practices from setbacks. From natural disaster to the risk involved in Agro business, to disruptions arising from Agric. technologies, benefits abound in Agricultural insurance. Timely insurance pay-outs after crop losses can help small holders' smooth consumption and prevent the sale of assets. Insurance can also be a catalyst, as lenders will be more likely to extend credit to farmers covered by insurance, allowing them to make productivity-enhancing investments."

A good agricultural practice ensures investment in new technology, machines, tools and applications. When

Agricultural insurance is taken against crops and livestock, this allows farm operators to open up for new technologies in the market. New technologies (GAP/Precision Agriculture) are invented each year to help farmers get more produce from their investments. Insurance companies allow farmers to get insurance covers for the new technologies such that, if they fail, farmers will not incur losses, as the insurance company would pay them their claims.

CONCLUSION

The economic situation, instability and effect of climate change has affected a lot of professions with farming inclusive. These effects sometimes seem discouraging to farmers and farming activities and yet the farmers are persistent and strive towards improving productivity. However, there is need for implementation of Government policies, suitable or favourable to farming system, financial assistance (funding/loans/grants), accessibility of improved inputs (seeds, fertilizers, pesticides etc.), equipment and modern facilities etc. to enable efficient and effective productivity in the farming sector.

Banditry or terrorism, as of today particularly in the country has negatively impacted food security. The implication of the impact means that there is reduction in the number of farmers due to their killings and also aggravating fear in the heart of farmers and also increasing the impoverishment of farmers due to kidnappings. Thus, Farmers are not willing to go to their farmlands as they will be chased out or killed; cattle rearing has become difficult, there is reduction in the quantity of crops stored in grain silos, there are risks of attacks when farmers visit local weekly markets and many farmers have become dependent on food provided either at internally displaced persons (IDP) camps or at the houses of friends and relatives. The negative impacts have also completely affected the farming schedules of both rainfed and irrigation farming in the states. The Federal, State and Local Governments have made efforts towards tackling the banditry/terrorism, but the situation still persists with reports that bandits are now imposing taxes on some farmers in some LGAs to allow them to cultivate their crops. Harsh weather leading to environmental degradation, drought, flood or pest and diseases can be devastating financially for agricultural producers (farmers) and have substantial adverse economic impacts on agribusinesses.

However, some solutions proffered to these negative effects of climate change on agricultural production should include: alliance to several government Agricultural Development and Pro-poor Interventions, adoption of Climate Smart Agriculture and Good Agricultural Practices (GAP), adequate preparation of farmers towards the upcoming season, adequate and accurate weather forecast, increase in availability of veterinary doctors, legislation of pesticide distribution and use, agricultural funding for research and technology development, Trade Liberalization and Market Development, Funding and infrastructure development and Consistency in government policy. Hitherto, our farmers are celebrated today due to their resilience and thrive against all odds and obstacles faced in the present-day farming, contributing immensely in terms of food security. The Agricultural sector will and still contributes to the Nation Gross Domestic Product (GDP) all as a result of farmers' efforts and persistence. As it said, "*Though the struggle exists but they the farmers keep pushing and making a difference*".

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Food security in Nigeria faces climate change risk with likely devastating outcomes on food production capacity. The study Assessed 'Climate-Smart Agricultural Practices and Food Security Situation among Farming Households in Southern Agricultural Zone of Nasarawa State, Nigeria'. A multistage sampling approach was used to select the farming households. Primary data were collected using a designed questionnaire. Data were analyzed using principal component analysis (PCA), household dietary diversity score (HDDS) and descriptive statistics. Under PCA, climate-smart agricultural practices have been grouped into 5 components: comprehensive field management (40.5%); on-farm risk reduction (15.3%); crop/livestock or mixed management (12.2%); agro-forestry (8.1%) and soil conservation practices (19.8%). Farming households with a confirmed average HDDS (2.7) were considered food insecure and the group with low dietary diversity score (75.7%) provides the percentage of food insecure households. Absence of information (33.6%) and capital (26.6%) were main factors constraining the use of climate-smart agricultural practices (CSAPs). It was revealed that CSAPs has the potential to improve food security. The research recommends encouraging farming households to adopt as many CSAPs as possible to improve their food security situation. Since absence of information is a key constraint, capacity building of extension agents to help design and formulate extension messages and agricultural policies that can hasten the spread of CSAPs is needed.
Keywords: *Climate-smart agricultural practices, farming households, food security.*

INTRODUCTION
Food security in Nigeria faces climate change risk with likely devastating outcomes on food production capacity. Increased temperatures and frequent variation in rainfall patterns have reduced yields, promoted the development of weed and pest infestation, and increased the probability of short-term crop failures and long-term productivity losses (World Bank, 2010). Efforts to improve global food security are most needed as the demand for food is increasing due to a rapid population growth.

Understanding the exact impact of climate change on food security is complex because vulnerabilities are unevenly distributed around the world, it ultimately hinges on the ability of communities and countries to address risks. In the context of food security, while some parts of the world may benefit from climate change, developing countries (such as Nigeria) may be negatively affected. Global warming and climate change have many negative consequences on agriculture, and all these consequences will increase as global temperature increases (Ayo *et al*., 2010).

According to Food and Agriculture Organization (2014), there will be a considerable crop yield loss that will be caused by climate change which will negatively affect farming households' livelihoods in Nigeria. As a result, the food security and income-generation opportunities of the farming households dependent on agriculture may be threatened. African crop yields estimated to decline by 10-20% by 2050 could even be up to 50% due to climate change (Nwaobiala and Nottidge, 2013). Given the severe food insecurity around the world, it was important to take measures to mitigate the negative outcomes of climate change on farm production. In response, the notion of climate-smart agricultural practices was created when the adoption of the Paris Agreement was introduced to strengthen global reaction to the threat of climate change by sustaining global temperature increase. (UNFCCC, 2015).

Climate-smart agriculture is not a new set of practices given the need to collectively discourse food security and climate change, it is a means to introduce the necessary changes in agricultural systems (FAO, 2013). Climate-smart agricultural practices share sustainability principles and guiding principles for food security, it emphasizes on production, farming households, increasing productivity, incomes and ensuring their stability. This package also focuses on four measurements of food security in times of accessibility, availability, usage and durability. Climate-smart agriculture measures include substantiated approaches such as use of mulch, intercropping, and incorporated pest innovations such as disease management, reduced/minimum/zero soil tillage, use of legumes in crop rotation, planting of trees on arable land/planting of crops on forest land, mixed farming, aquaculture, irrigation, detailed weather forecasting for farming households and timely notification strategies (FAO, 2010; World Bank, 2011). Furthermore, it includes adopting recent technologies such as modifying crop genetics to assist farming households cope with climate uncertainties and prepare the environment. Additionally, climate-smart agriculture has an interest in post-harvest management of agricultural outputs along the value chain to reduce losses and enable sustainable consumption patterns. Without climate-smart agriculture, surrounding areas could become uncultivable due to land degeneration through desertification, soil corrosion, continuous-cultivation and over grazing (World Bank, 2012). However, it stands that a commitment to climate-smart agriculture is needed by focusing on farming households in developing countries like Nigeria, the key to transforming the entire agricultural system. The objectives of the study include; identifying the climate-smart agricultural practices used, measuring the food security situation of the farming households and identifying the constraints to the use of climate-smart agricultural practices in the Southern Agricultural Zone of Nasarawa State, Nigeria.

METHODOLOGY

The study was carried out in Southern Agricultural Zone of Nasarawa State, Nigeria. The region is known for its long rainy season (May to October). The usual annual rainfall is about 839mm and the average annual temperature is 28.4°C. Products cultivated in the study area include; roots and tuber crops, grains, legumes, cocoyam. Furthermore, farming households in the study area put up domestic animals comprising: cattle, poultry, goats and sheep. Durable tree crops grown by farmers involve citrus, mangoes and cashews (NADP, 2017). Majority of the population are farmers.

A multi-stage sampling approach was employed to select respondents. During this stage, 3 Local Government Areas (LGAs) were randomly chosen from the 5 LGAs in the study area. Second, the three communities were purposively selected from each of the three LGAs, resulting in a total of nine (9) communities. Finally, due to the large population of farmers, 14% of the farmers were randomly selected from each of the nine communities giving an aggregate of 222 farming households sampled for the study.

Primary data were obtained using questionnaire. The questionnaire was administered with the help of trained enumerators. The data includes a collection of different climate-smart agricultural practices (CSAPs) farming households employ in response to climate change. This includes use of better varieties of crop, use of legumes in crop rotation, effective use of nitrogenous fertilizers, modification in dates of planting, planting trees on arable fields, use of terraces, use of living obstacles, use of cover crops, irrigation, etc., and the challenges associated with use of these practices. The questionnaire also provided a daily food intake schedule for respondents to complete.

Principal component analysis (PCA), household dietary diversity scores (HDDS) and descriptive statistics were utilized to analyze the data. The PCA criterion is exemplified as following:

$$Y_1 = a_{11}x_{12} + a_{12}x_2 + \dots\dots a_{1n}X_n$$
$$\cdot \qquad \cdot \qquad \cdot \qquad (1)$$
$$Y_j = a_{j1}x_{j2} + a_{j2}x_2 + \dots\dots, a_{jn}x_n$$

Where;

$Y_1 \dots Y_j$ = are unrelated principal components

$a_1 \dots a_n$ = correlation coefficients

$X_1 \dots X_j$, = specific strategic choices influenced by specific factors.

HDDS are obtained by adding the number of food group utilized by the farming household during the 24-hour recollection moment, from a maximum of 12 per day. This is illustrated below:

$$\text{Average} = \frac{\sum_{i=1}^{n} \text{HDDS}}{N}$$

where n= 1, 2, . . ., 12 per day

N= total number of farming households

RESULTS AND DISCUSSION

Climate-smart agricultural practices used by the farming households:

The principal component analysis made it feasible to reduce the largeness of the data without missing much communication. As indicated in Table 1, 16 climate-friendly farming practices are actively used by farming households in the study area. Using principal component analysis (PCA) the constructs were rotated using varimax technique (Chatterje *et al*., 2015), related practices were grouped into five (5) major components. This was then used for further analysis.

Table 1, illustrates the descriptive statistics of each individual components (climate-smart agricultural practices). The most generally employed component was that of comprehensive field management practices. 42% of farming households use at least 1 element of this component. This component includes use of cover crops, use of better varieties of crops, use of legumes in crop rotation, modification in times of planting, bound ridge system, diversifying varieties of livestock and crop, irrigation, use of organic manures and use of mulch. The second component was on-farm risk reduction practices used by 16% of farming households. This component included the use of terraces, reduced/minimum or no tillage and adoption of living obstacles. The third component relates to crop/livestock management practices used by 13% of the farming households which includes effective utilization of nitrogenous fertilizers, and utilization of better livestock breeds and crop varieties. The fourth component, which involves agro-forestry practices used by 9% of the farming households, includes planting crops on forest lands and planting trees on arable field. The fifth and second most frequently used component was of soil conservation practices used by 20% of farming households includes reduced/minimum or no tillage and utilization of mulching.

Table 1: List of climate-smart agricultural practices:

Component	Rate of Users (%)	Elements
Comprehensive field management practices (component 1)	42	use of organic fertilizers, modification in time of planting, use of mulch, diversifying livestock breeds and crop varieties, Irrigation, Utilization of enhanced crop varieties Bound/Tied ridge system.
On-farm risk reduction (component 2)	16	Reduced/minimum or no tillage, Adoption of living obstacles, Adoption of terraces.
Crop/livestock management practice (component 3)	13	Effective utilization of nitrogenous fertilizers, Utilization of better livestock breeds and crop varieties
Agro-forestry practice (component 4)	9	Planting crops on forest land Planting trees on arable field
Soil conservation practice (component 5)	20	Reduced/minimum or no tillage Utilization of mulching.

Measurement of food security situation of farming households using household dietary diversity score (HDDS).

To better understand the food groups consumed by farming households and their food security situation, household dietary diversity score (HDDS) was estimated. According to Cordero-Ahiman *et al.* (2017), there is no particular threshold value for classifying food groups. In this study, HDDS ≤ 3 was used as benchmark for classifying the low dietary diversity group. The range of ≥ 4 was classified as the moderate dietary diversity group, while HDDS ≥ 7 was classified as high dietary diversity group. The average HDDS was 2.7 (100%) for all the farming households. This explains that the food security situation of the farming households in the studied area is on the low. The findings shown in Table 2, shows a majority (about 75.7%) of the farming households belonged to the class with low dietary diversity score. Additionally, the finding also shows that some households (21.2%) consumed 4 to 6 food groups (classified as moderate dietary diversity group) while few of the households (3.2%) consumed about 7 or more food groups (high dietary diversity group). The justification for this could be that majority of the farming households are financially constrained as they do not participate in non-agricultural activity to generate additional income and also, lack information as a key constraint on the use of climate-friendly farming practices to improve their food security situation.

Table 2: Food security situation of farming households using HDDS

Food groups	Frequency	Percentage
Grains	176	29.3
Tubers/Roots	111	18.5
Vegetables	78	13.0
Fruits	32	5.3

Meats	12	2.0
Eggs	24	4.0
Fish and other sea foods	21	3.5
Legumes and seeds	36	6.0
Milk and dairy products	52	8.7
Fats and oil	15	2.5
Sugar/honey	25	4.2
Spices, condiments and Beverages	18	3.0
Average HDDS	2.7	100
Group/Classes	**Frequency**	**Percentage**
Low dietary diversity group (consume 3 or less food group)	168	75.7
Moderate dietary diversity group (consume 4 to 6 food group)	47	21.2
High dietary diversity class (consume 7 to 12 food group)	7	3.1
Total	**222**	**100**

Constraints to the use of climate-smart agricultural practices by the farming households

An attempt was made to identify the challenges faced by farming households using climate-smart agricultural practices to achieve food security. The result shown in Table 3, indicates that there are significant factors limiting the use of climate-smart agricultural practices by farming households in the study area. Absence of information is the most limiting factor (33.6%). A contemporary study by Sapkota *et al.* (2018), discovers that farming households who received information about their farms using modern information and communication technology had higher yields. The next limiting factor was scarcity of capital (26.8%), the availability of capital will boost farming households' financial resources, increase their cash base and enable households to buy significant contribution. Arguably, where capital is available, farming households are further inclined to utilize capital-intensive climate-smart agricultural practices, particularly irrigation, use of better livestock breeds and crop varieties or planting of trees on agricultural land, and also, competently paying for labor-intensive technologies. Adekemi *et al.* (2016), presumed that capital raises farming households' ability to purchase better seeds, fertilizers and other climate-friendly farming inputs. Nonetheless, this technology goes beyond other investment options accessible to farming households. Other opposing factors include labor shortages (21.6%) and in adequate access to water (11.2%).

Table 3: Constraints to the use of climate-smart agricultural practices.

Constraints	Frequency	Percentage
Scarcity of capital	67	28.8
Absence of information	84	36.0
Labor shortages	54	23.2
Inadequate access to water	28	12.0
Total	233	100

Source: Field survey, 2021

CONCLUSION AND RECOMMENDATIONS

Climate-smart agricultural practices have a significant association with farming households' food security situation. The rate at which CSAPs were encompassed into farming activity was still low, with comprehensive field management practice being the most commonly used practice to improve agricultural productivity. The result also shows that farming households are food insecure with a low dietary diversity score. Absence of information on climate-friendly farming practice and scarcity of capital were the main obstacles to adopting CSAPs in the study area. The study recommends farming households to employ CSAPs wherever possible judiciously, in order to have a greater impact on their food security status and an elixir to mitigate the negative consequences of climate change on agricultural activities. Considering the constraints, capacity building of extension agents is necessary to assist in creating agricultural policies that can hasten the design and development of improved messages and the spread of climate-friendly farming practice.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was conducted to examine the benefit and constraints associated with the production of horticultural crops among rural dwellers within Otukpa, Ogbadibo Local Government area of Benue state in 2023. Six communities (Efugo, Ede, Orido, Odoba,Olabigba, Olachagbaha) were surveyed. Both purposive and multistage random sampling techniques were adopted in selection of 60 farmers which made up the sample size. Primary data were collected using structured questionnaire from the sampled farmers. Data were analyzed with the use of statistical tools such as percentage, mean and four point Likert scale. The result of the study shows that majority (56.67%) of the farmers were females and 43.33% were males, majority (76.6%) were married while 100% of the farmers had one form of educational level or the other, however, secondary education was ranked highest with 50.00%. Olericulture production has the highest percentage of engagement followed by pomology, then floriculture production. It was observed from the study that majority of the respondents gained substantial income from horticultural activities (95.00%%), followed by ease in sourcing fresh food (93.33%), reduction in family budget (90.00%), better nutrition (66.67%), source of employment (33.33%), for environmental beautification (13.33%) and to ease emotional stress (5.00%). However, farmers are faced with challenges such as inadequate finance (X=3.45), lack of technical knowhow (X=3.42), pest and disease (X=3.40) and lack of storage and processing facilities (X=3.39), consequently, the study therefore recommends that the horticulturist in the study area should pool their resources together through forming cooperative society to enable them surmount some of the identified constraints to boost their production and generate more income.

INTRODUCTION

Horticulture is one of the fastest growing sectors of agriculture. Horticulture is a section of agricultural sciences that employs scientific understanding to produce vegetables, fruits and flowers and which is meant to enrich human diet. The growth of this sector was about 5.5 % during last two and half decades. Thus, horticulture can be defined as the science, technology, and business involved in intensive cultivation of plants for human use, including fruits, vegetables and ornamental plants (Alemayehu, 2016). Based on crop grouping and use the main division or branches of horticulture are Olericulture, a branch of horticulture which include the production of vegetable, processing and marketing. Floriculture is the cultivation and management of flowers, flowering plants and foliage plants. It also includes their uses in ornamental construction and floral arrangement (ISHS, 2011). Pomology, has to deal with the production of fruits and nuts that are basically perennials. Horticultural crops are utilized by both, individuals and industries to enhance the nutritional and economic standards. It is a basic requirement for human health and well-being. Horticultural crops are the primary source of poverty reduction in most agriculture-based economies (Anríquez and Stamoulis 2007). The expansion of smallholder farming can lead to a faster rate of poverty alleviation, by raising the incomes of rural cultivators and reducing food expenditure, and thus reduces income inequality (Resnick, 2004).
Notwithstanding the critical role that horticulture plays in modern communities, horticulture globally is undergoing some very significant challenges that are impacting on both the production of horticultural crops and also on the priorities for research and development. The horticultural sub-sector also reflects the problems in the agricultural sub-sector. These problems include inadequate knowledge and technology of production, insufficient planting materials, land tenure, poor extension services and insufficient post-harvest facilities (Babatola, 2004).

In light of this the study was conducted to examine the benefit and constraints associated with the production of horticultural crops among rural dwellers within Otukpa, Ogbadibo local government area of Benue state with the specific objectives to determine the benefits derived by the respondents and also to determine the constraints encountered in horticultural production in the study area.

MATERIAL AND METHODS

The study was conducted to examine the benefit and constraints associated with the production of horticultural crops among rural dwellers within Otukpa, Ogbadibo local government area of Benue state in 2023. Six communities (Efugo, Ede, Orido, Odoba,Olabigba, Olachagbaha) were surveyed. Otukpa is located on latitude 05^0 3^l N, Longitude 07^0 23^l E and 130m above sea level and rainfall average of 2300mm/annum. Multi-stage random sampling techniques were adopted in selection of 60 respondents which made up the sample size. Primary data were collected using structured questionnaire from the sampled respondents. Data were analyzed with the use of statistical tools such as frequency, percentage and four point Likert scale model and ranking using the mean score in SPSS.

RESULTS AND DISCUSSION

Result of data analysis in Table 1 shows that majority of the respondents were females (56.67%) than males (43.33%), with mean age of 40 years, which is in agreement with the findings of Tripathi *et al.* (2015) that majority of the vegetable respondents fall within the age bracket of 30-40 years indicating that there is a bright future for vegetable farming in the study area if, the potential of these youths are properly harnessed. Also it is an indication that most of the farmers are in their productive age, hence active participation in farming activities. Majority (76.67%) were married with average household size of 10 members indicating that they are responsible individuals, also, all (100%) of the farmers had one form of educational level or the other, however, secondary education was ranked highest with 50.00% which is an indication that most of the farmers are literate and thus enlightened and are aware of the importance's of horticultural production. More so, greater number (41.67%) had spent at most 10 years in production of horticultural crops which agrees with the findings of Mohammed and Afework (2016). They farmers cultivate a mean farm size of 0.5 hectare, a similar results were obtained by Mohammed and Afework (2016) which revealed that majority of fruit and vegetable farmers cultivate between 0.1- 5 hectare.

Data analyzed for horticultural practices in the study area is presented in Table 2. The result revealed that 78.33% of them are into Olericulture (vegetable production), 20.00% are into pomology (fruits and nuts production) while only 1.67% of the respondents are into floriculture production (flowers and Ornamental production). This could be due to market demand within the study area for vegetable as source of daily livelihood. This agrees with the findings of Kamei (2013) that all kinds of horticultural crops are viable and earn an additional income to every household.

Data analyzed for the benefits derived from horticultural practices in the study area is presented in Table 3. It was observed from the table that majority of the respondents gained substantial income from horticultural activities (95.00%%), followed by ease in sourcing fresh food (93.33%), reduction in family budget (90.00%), better nutrition (66.67%), source of employment (33.33%), for environmental beautification (13.33%) and to ease emotional stress (5.00%). The result indicates that majority of the respondents depend on horticulture for sustainability of their livelihood since majority of the horticulturist derived income from the practices, thus horticultural crop production should be encouraged to alleviate the rate of poverty. This is in agreement with the findings of Suleiman et al., (2020), that majority of the respondents in their study area generate a large amount of income from engaging in horticultural activities.

Data analyzed for the constraints to horticultural crop production in the study area is presented in Table 4 which shows that inadequate finance (x=3.45), lack of technical knowhow (x=3.42) and pest and disease were outstanding among the challenges facing the production of horticultural crops. This result indicates that financial insufficiency seriously impedes horticultural crops production in the area. Again, lack of storage and processing facilities(x=3.39) and insufficient planting materials (x=3.37) were among the strong constraints identified. Also, poor produce price (x=3.20), small available land (x=3.03) were observed as high militating factors. However, inadequate labour supply (x=2.70) was not known as strong factors hindering horticultural crops production in the area. The findings agress with the findings of Babatola (2004), some of the problems hampering the development of horticultural activities in Nigeria are inadequate knowledge and technology of production, insufficient planting materials, land tenure, poor extension services and insufficient post harvest facilities which has similarity with present result obtained in this study. Thus, horticulturist in the study area should be encouraged to pool their resources together through forming cooperative society to enable them surmount some of the identified constraints to boost their production and generate more income.

Table 1: Socioeconomic Characteristics of the respondents

Socioeconomic characteristics	Frequency	Percentages

CONCLUSION

The production of horticultural products play significant nutritional role in our everyday diet and likewise income generation to sustain livelihood, from this study it can be observed that majority of the respondents are in their working age class and majority are female. Olericulture production has the highest percentage of engagement followed by pomology, then floriculture production. Income generation, source of fresh food, reduction in family budget, better source of nutrition, source of employment and beautification of the environment are benefits derive from horticultural farming among others. However horticultural farming in the study area is faced with some problems such as inadequate finance, lack of technical knowhow, pests and diseases and lack of storage and processing facilities are the major constraints affecting horticultural farming in the study area. Also, insufficient planting materials, poor produce price, small available land for cultivation and inadequate labour supply. The study therefore recommends that the horticulturist in the study area should pool their resources together through forming cooperative society to enable them surmount some of the identified constraints to boost their production and generate more income.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analyzed agricultural extension services delivered and used among smallholder groundnut farming households in Rano local government area of Kano state, Nigeria. Purposive sampling procedure was used in selecting 2 communities based on their popularity in groundnut farming and a total of 81 respondents were randomly selected for the study. Data were collected with the aid of structured questionnaire. Descriptive statistics (frequency, percentage, mean and standard deviation) and regression analysis were used in analyzing the data. The results revealed the mean age of the respondents to be 37.7years, 100% of the respondents were male, with only 11.1% having no formal education and 88.9% engaged in other sources of income besides farming activities. Most (59.3%) respondents received information on groundnut farming activities very frequently from extension agents. Household size, educational level and contact with extension agents significantly influenced access and used of extension services. High cost of inputs, labor and GSM services were identified by 58%, 53.1% and 53.1% of the respondents respectively as constraints to information access and utilization. It was concluded that agricultural extension services on groundnut production were accessed and utilized by farmers as delivered by the service providers which was influenced by some socio-economic characteristics. However, it was recommended that training on record keeping should be strengthen by extension services providers to ensure adequate production data record by the farmers.
Keywords: *Extension services, Smallholder, Groundnut, Households*

INTRODUCTION
Groundnut *(Arachis hypogaea* L.*)* is the 6th most important oil seed crop in the world. It contains 48- 50% oil, 26-28% protein and 11-27 % carbohydrate, minerals and vitamin (Mukhtar, 2009). According to FAOSTAT (2011) and Girei *et al*. (2013), groundnut is grown in nearly 100 countries in the world with China, India, U.S.A, Indonesia, Nigeria, Myanmar and Sudan as major producers. A report by FAO in 2014 revealed that groundnut on an average is grown on 26.4 million hectares worldwide with a total production of 41.3 million metric tons and productivity of 1.676 kg ha^{-1} during 2012 (FAO, 2014). Moreover, Nigeria is one of the world's largest groundnut producers, accounting for 10%, 39% and 51% of the total worlds, Africa's and West Africa's groundnut production, respectively (ICRISAT, 2011). Before the fossil oil boom, groundnut was one of the major sources of revenue accounting for about 70% of total Nigeria's export earnings, making it the country's most valuable single export crop ahead of other cash crops like cotton, oil palm, cocoa and rubber (Harkness *et al.*, 1976). However, in the post-1967 period, the combined effects of drought, increasing prevalence of diseases such as rust, leaf spots and groundnut rosette disease (GRD) in addition to lack of crucial information on improved agricultural practices have caused a decline in groundnut production (ICS-Nigeria, 2005). This is exacerbated by the dearth of agricultural extension workers and the rate at which available research results were transferred to farmers due to limited resources available to the public extension agencies with which farmers are reached free of charge in developing countries (Budak *et al*., 2010). However, with the huge potential of this cash crop and in view of the above-mentioned problems, the findings from the study will serve as guide to government, development partners and researchers for improvement in groundnut production and bridging the gap of knowledge. In view of therefore, this study has been designed with the following objectives: identify the extension services accessed and utilized by groundnut farming households and sources of information used in accessing the extension services delivery; examine the relationship between socio-economic characteristics of respondents and their sources of information; and assessed the constraints militating against accessing extension services delivery in the area.

METHODOLOGY

The study was carried out in Rano Local Government Area (LGA) of Kano State. Kano State is located in North-Western Nigeria. The State is situated in a semi-arid region which lies between latitudes $10^{0}30'$ and $13^{0}02'$ north of the equator and longitude $7^{0}40'$ and $10^{0}39'$ east of the Greenwich meridian. It has a projected population of 10,067,208 people with an almost equal distribution of males (51%) and females (49%) (NPC, 2006) Agriculture is the mainstay of the economy involving at least 75% of the rural population. It is the major producer of groundnut before the oil boom of 1970s (producing at least 50% of the country total output).

Sampling Techniques

The communities, associations and respondents considered in the study were purposively selected due to implementation and participation in Tropical Legume 3 (TL3) Project in the area.

Table1: Sample Size

s/n	Community	Name of Associations	Total number of farmers	Sample size (100%)
1	Rano	1. Kofar kudu groundnut farmers association Rano	26	26
2	Rurum	1. Bayan kargo groundnut farmers association Rurum	26	26
		2. Bakin kasuwa multipurpose farmers association rurum	26	26
	Total		**81**	**81**

Data Collection Procedure and Analytical Tools

Data was collected using structured questionnaire, while descriptive and inferential (linear regression) statistics were used to analyze the data. The model of the linear regression was specified below:

$Y= \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + ei$……………………………. (1)

Where;

Y=Information source (number)

X_1= Age (years)

X_2= Gender (Female = 1, Male = 0)

X_3= Household size (numbers)

X_4= Years of farming experience (years)

X_5= Other sources of income

X_6= Extension contacts

X_7= Education level

β_1 - β_7 = Regression Coefficient

β_0= Intercept

RESULTS AND DISCUSSION

Socio-economic Characteristics of Groundnut Farmers

The results from table 2 shows case the minimum age of respondents to be 18 and maximum of 65. The mean age was 37.7 years. This implies that majority of the respondents are in their active age of life and farming requires adequate attention and a lot of sense of responsibilities. Their active age showcases the tendency and ability to access and utilize the necessary services that will improve their production activities. The mean of the household size was found to be 8 with minimum and maximum household size of 1 and 30 respectively. This implies that the respondents used the size of the household in obtaining necessary extension services. The average years spent in groundnut farming was found to be 14.4 with minimum and maximum years of 3 and 42, respectively. The years spent in groundnut production determined the experience obtained in the activity which resulted in seeking for necessary advices and information and adoption of improved technologies for improvement in the production processes that may lead to better output and improvement in livelihood.

The result from Table 3 shows that the entire groundnut farmers considered in the study were male implying that male dominated the production of groundnut in the area or else took advantage of the project without considering their female counter part. The male dominancy may be attributed to culture in Hausa communities where most farming activities were carried out my male which resulted in dominating the farming activities itself. In addition, it was found that most of the respondents (72.6 %) were married. This may lead to increase in their household size which invariably reduce cost of production if they employ family labor on their farms. The result further shows that most of the farmers had one level of formal education which may assist them making a wise decision to accesses and utilize extension services provided to them by the services providers. With respect to extension contact leading to access and utilization of services provided shows that most (88.9%) of the farmers had contact in one way or the other with extension personnel. This may be attributed to their belonging of cooperative group as most extension agents prefers reaching farmers in group rather than individual. This led to accessing required services that may lead to improvement of their farming activities. Most (88.9%) of the farmers have other source of income besides farming. This contributes to the sustainability of the farming activities and also help in sustaining the livelihood of the households.

Sources of Information on Groundnut Production

Table 2: Socio-economic characteristics of groundnut farmers

Source field survey, 2022

The results in table 4 depict the sources of extension services rendered by service providers with most of the services accessed from extension agents. This is attributed to the fact that the respondents participated in the project and the project ensured farmers worked in group for easy contact, accessing the necessary services required for the smooth running of the project. This is to ensure farmers adhered to the good agronomic practices that will help in attaining the expected maximum yield at the end of harvest.

Relationship between socio-economic characteristics of the farmers and sources of information used.

The findings in table 5 revealed that household size, education level and extension contact had significant relationship with sources of information on extension services rendered by services providers. The household size was negatively (B= -.363) significant at ($p<0.01$) explained the outcome. This indicated that as the household size decrease the more sources of information used. Similarly, education level was positively (B= 1.592) significant at ($p<0.01$) meaning that the higher the education level the more the sources of information used. Furthermore, extension contact was also negatively (B= -.363) significant at ($p<0.01$) meaning that the less contact with extension agents the more sources of information used for them to be able to acquire the necessary information.

Extension Services Accessed and Used

The findings in Table 6 shows the distribution of the extension services received and used by the farmers. Most of the farmers had access to and used the entire extension services provided on groundnut production. This resulted in more output that will also improve the livelihood of the farmers. Record keeping 23.4% (n=19) was the least extension service received by the farmers and Poor record keeping resulted in in appropriate data on their production.

Constraints to Information Access and Used

The results in table 7shows the problems militating against accessing and utilization of information on groundnut production through extension service delivery in the study area. The major constraints were cost of inputs such as seed and fertilizer (58%), followed by cost of labor (53.1%) and those accessing information using ICTs such as internets (53.1%) also found it difficult. Lack of adequate technical knowledge about the recommended farm practices and language barrier was also identified as factors militating against farmer`s access and utilization to information delivered to them. This may hinder the attainment of maximum yield per hectare not necessarily on the project but also beyond.

Table 6: Extension services accessed and used

Extension services	Frequencies	Percentage
Soil and climatic requirement	78	96.3
Site selection and land preparation	80	98.7
Sowing and sowing date	76	95.0

Lack of adequate technical knowledge on recommended farm practices.	11	13.6
Telephone/GSM services	43	53.1
Ineffective communication	6	7.4

Source**:** Field survey, 2021.

CONCLUSION

It is concluded that agricultural extension services were delivered to the groundnut farmers in the study area, with extension agents as the main source of delivering such services. However, socio-economic factors such as household size, educational level and contact with extension agents influence the accessibility and utilization of such information or services. It is therefore recommended that services on record keeping should be strengthen to ensure adequate record data on their production activities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study examined the level of ICT accessibility and utilization by farmers and extension workers in Makurdi, Benue State of Nigeria. Questionnaires were used to collect data from 120 respondents (60 extension workers and 60 farmers). The data were analyzed using descriptive and inferential statistics. The results show that majority (70%) of the extension workers and majority (60%) of the farmers were males within the age range of 40 – 53 years. Most (63.33%) of the extension workers were Diploma/NCE holders while 46.67% of the farmers had primary school education with farming experience within the range of 18-25 years. All (100%) extension workers and farmers had access to radio, while 96.67% and 46.67% of extension workers and farmers had access to television respectively. All (100%) of the extension workers had access to telephone with majority (83.33%) of the farmers also having access to telephone. Most (53.33%) of the extension workers complained of financial problem as the major factor militating against the use of ICTs while for the farmers 46.67% complained of inadequate awareness. Regression of some selected socio-economic characteristics of respondents on the level of utilization of ICTs shows R^2 value of 0.61. It further shows that there was a positive relationship between the levels of education of the respondents' utilization of ICTs which was significant at 5%. It was concluded that the use of ICTs among extension workers and farmers in Makurdi, Benue State as well as other states of the federation will help to promote participatory communication in the agricultural sector, and recommended adequate funding be provided to extension organizations to improve their ICT infrastructures, so as to enable staff utilize ICT facilities; and ICTs centers should be established in all parts of the State so as to create awareness among farmers.
***Keywords:** Accessibility, Utilization, Information Communication Technologies, Extension Workers, Farmers*

INTRODUCTION

Agriculture is one of the oldest industries and the origin can be traced to earliest human society. One of the major challenges to agricultural development in Nigeria and other African countries has been a low level of agricultural information exchanges among different stakeholders in the agricultural sector (Agwu, 2004).) Agricultural information is no doubt central in enhancing agricultural productivity and facilitating poverty alleviation among rural farmers (Adebayo 2006). There is a symbolic relationship between communication and development. The main purpose of agricultural extension is to assist farmers and their families to improve their living conditions. It involves dissemination of information on agricultural technologies and improved practices to farm families and ensuring farmers' capacity building through the use of communication and training methods. Accessibility of farmers to timely and relevant information will improve their agricultural production, processing and marketing. The improvements will translate into higher income and better living standards for the farmers (Ogunbameru, 2001). This can be feasible where there is adequate and accessible Information Communication Technologies (ICTs) for development.

A number of developments in recent times are shaping the future of extension services and are making way for the adoption of new and improved ICTs. A new paradigm of agricultural development is fast emerging, old ways of communication are being challenged and traditional societies are being transformed into knowledge societies all around the world. The use of ICTs is seen as means of achieving a great societal transformation. According to Shaik *et al*. (2004), when used as a broad tool for providing local farming communities with scientific knowledge, ICTs heralds the formation of knowledge societies in the rural areas of developing world. However, he advised that this can only be realized when knowledge and information are effectively harvested for agricultural and rural development. The use of ICT offers excellent possibilities for strengthening research-extension systems beyond the urban focus. Thus, for effectiveness and efficiency, extension service needs to be appropriately supported with the use of ICTs. A number of initiatives including the (CGNET), the USAID Leland initiative (1995 – 2002) and African highland initiative (1995 – 2000) have supported the establishment of communication networks in several countries of Africa. However, connectivity is still very much less than desired, and it could be argued that even for researchers in Nigeria, it is still less than the level at which significant impact can be expected (FARA, 2004). The study was conducted to examine the level of ICT accessibility and utilization among extension workers and farmers in Makurdi Metropolis, Benue State. Specifically, the study objectives were, to; describe the socio-economic characteristics; examine the level of accessibility and utilization of ICTs by the respondents; determine the effects of some selected socio-economic characteristics of the respondents on their level of utilization of ICTs; and identify constraints that hinder the effective use of ICTs in agriculture among respondents in the study area.

METHODOLOGY

The study was conducted in Makurdi, the headquarters of Benue state, located in the North central zone of Benue state, Nigeria. It lies between latitude 7º and longitude 8º north and east of the equator, and located in the guinea savannah of the Northern Nigeria. Makurdi is divided into two major blocks by River Benue hence the North and South Banks. It has a population of 2,261,990 million (NPC, 2006) with a land mass of 16km radius. Makurdi Local Government has a climate which falls within the humid tropical climate with wet season (March - October) and dry season (November – February). The average annual rainfall is about 1800mm and temperature range of 30ºCand 32ºC, which is high throughout the year (NPC, 2006).

The target population for this study included extension workers and farmers from Makurdi metropolis. A list of farmers was obtained from Benue state Agricultural Development Programme which was used to randomly select 15 respondents' farmers each from four wards within the metropolis. In addition, in the same vein, 15 extension workers from Benue State Agricultural Rural Development Authority (BNARDA) and 15 extension workers each from their three outlet Zones (Zone A, B and C) were randomly selected in the State giving an overall sample size of 120 respondents. (60 Extension Workers and 60 Farmers)

Data Analysis

Data were analyzed using descriptive statistics such as frequency counts, percentages, means and linear regression. The regression model is specified as follows

Regression model:

$Y_i= a+\beta_1X_1+\beta_2X_2+\beta_3X_3+\beta_4X_4+\beta_5X_5+U$

Where:

Y_i= Level of ICT utilization (in percentage)

X_1= Gender (male=1, female=0)

X_2= Age of respondents (in years)

X_3= Computer literacy (yes= 1, No= 0)

X_4= Educational status (Non formal = 0, adult education = 1, primary = 2, secondary =3, diploma = 4, HND = others = 6)

X_5= Working/farming experience (in years)

a= Constant

U= Error term.

RESULTS AND DISCUSSION

Socio – Economic Characteristics of Respondents

Gender: Table 1 shows that majority (70%) of the extension workers and most (60%) of the farmers were males.

Age: About (33.33%) of the extension workers and (40%) of the farmers were found to be within the age range of 47 – 53 years and 40 – 46 years respectively. This is an indication that they are in their active and vibrant age. This shows a significant implication for ICTs utilization among this age group within their Middle Ages as they will give serious consideration to what they are doing even when it comes to using hi – tech innovation.

Educational Level: This shows that most (63.33%) of the extension agents had National Diploma while majority (46.67%) of the farmers had secondary school education.

Working experience: About (36.67%) of the extension workers had between 26 – 33 years working experience while 40% of the farmers had between 18 – 25 years farming experience. This implies that both sets of respondents are well experienced in their various fields.

Computer literacy: among the extension workers, it was found out that most (60%) of the respondents had computer education. It implies that the extension workers are better able to use ICTs in extension service delivery.

Major Occupation: Majority (90%) of the farmers are fully engaged in farming business with only (10%) into trading. This implies that agricultural farming practice plays an important role among the rural population in the study area.

Table 1: Distribution of Respondents According to their Socio-economic Characteristics

Variables	Extension workers		Farmers	
	Frequency	%	Frequency	%
Gender				
Male	42	70.00	36	60.00
Female	18	30.00	24	40.00
Total	**60**	**100.00**	**60**	**100.00**
Age (years)				
33 – 39	14	23.33	10	16.67
40 – 46	12	20.00	24	40.00
47 – 53	20	33.33	14	23.33
54 – 60	14	23.33	12	20.00
Total	**60**	**100.00**	**60**	**100.00**
Mean age for extension workers = 47.00, for farmers = 46.27				
Educational level				
Non formal	0	0.00	28	13.33
Adult education	0	0.00	4	6.67
Primary	0	0.00	8	13.33
Secondary	0	0.00	20	46.67
Diploma/NCE	38	63.33	0	0.00
HND/B.sc	12	20.00	0	0.00
Others	10	16.67	0	0.00
Total	**60**	**100.00**	**60**	**100.00**
Working experience (years)				
10 – 17	8	13.33	4	6.67
18 – 25	18	30.00	24	40.00

Trading	-	-	6	10.00
Total			**60**	**100.00**

Accessibility to ICTs

Table 2 shows that all (100%) of both extension workers and farmers in the study area had access to radio, 96.67% of the extension workers had access to television while 46.70% of the farmers had access to television. All (100%) of extension workers had access to telephone while 83.30% of the farmers had access to telephone. This could be attributed to the advent of mobile telephone which makes it easier for more people to have access to telephone services. Most (70%) of the extension workers had no access to personal computer while majority 80% of the farmers had no access to personal computer. Majority (73.30%) of the extension workers had access to the internet services while very few (20%) of the farmers had access to the internet services.

Table 2: Distribution of respondent according to ICTs accessibility

ICTs accessibility	Extension workers		Farmers	
	*Frequency	%	*Frequency	%
Radio	60	100.00	50	100.00
Television	58	96.67	28	46.67
Telephone	60	100.00	50	83.33
Personal computer	18	30.00	12	20.00

Access to Internet service	44	73.33	12	20.00

*Multiple Responses

Utilization of ICTs by Respondents for Agricultural Information.

Table 3 shows that majority (96.67%) of both sets of respondents listen to agricultural programmes using their radio sets while 93.33% of extension workers watch such programmes from the televisions, for the farmers about 46.67% of the respondents' view agricultural programmes from television. 36.67% of extension workers utilize internet while few of the farmers use the internet. 16.67% of extension workers use telephone for agricultural information while 23.33% of farmers use telephone for agricultural information. Thus, the radio and television can be effectively used for transmitting agricultural programmes to both extension workers and farmers.

Table 3: Distribution of Respondent according to the level of ICTs used

ICT Utilization	**Extension workers**		**Farmers**	
	*Frequency	%	*Frequency	%
Listen to Agric programme on radio	58	96.67	58	96.67
Watch Agric programme on TV	56	93.33	28	46.67
Use Telephone for Agric information	10	16.67	14	23.33
Use Computer that links to the Internet	22	36.67	12	20.00

*Multiple Response

Constraints to the Effective use of ICTs

Table 4 shows that most (53.33%) of the extension workers indicated lack of finance as the main problem while for the farmers about 46.67% indicated lack/inadequate awareness about ICTs. The respondents also noted that inability to operate computer, irregular electric supply, poor network /inaccessibility, inadequate cybercafé, and non-cooperation of staff. All these have caused a setback to ICT utilization. These findings agree with Arokoyo (2005) who reported that despite the fact that developing countries have adopted a variety of ICT tools that could be effectively used by extension; there are still very serious limitations for their use particularly in the rural areas.

Table 4: Distribution of respondents according to constraints encountered

Constraints	**Extension workers**		**Farmers**	
	***Frequency**	**%**	***Frequency**	**%**
Irregular electric supply	30	33.33	20	22.22
Financial problem	48	53.33	22	24.44
Inability to operate computer	36	40.00	20	22.22
Non – cooperation of staff	22	24.44	6	6.67
Poor network/Inaccessibility	24	26.67	18	20.00
Inadequate awareness about ICTs	38	42.22	42	46.67
Inadequate Cyber cafes	22	26.67	18	20.00

***Multiple Responses**

Regression of some Socio-Economic Characteristics on the Level of Utilization of ICTs by Respondents

Table 5 showed the effect of some socio-economic characteristics on the level of utilization of ICTs in a regression analysis. It showed that the combined effect of independent variables (gender, age, educational status, farming/working experience, computer literacy, major occupation) with coefficient of determination R^2 of 0.61 on the level of ICT utilization (Y) explained about 61% of ICT utilization at 5% significant level. Educational status was positive and significant at 5%. While four of the independent variables namely gender, age, farming/working experience (years), computer literacy, and major occupation, had no significant effect on level of ICTs utilization. The result implies that educational level affects the use of ICT positively in the study area. Thus, the more educated a respondent is, the more the probability of using ICTs for agricultural information which will consequently result in higher productivity.

Table 5: Regression Analysis showing the Coefficients on the Level of Utilization by the Respondents

Model	**Beta**	**Standard Error**	**T – Value**
Constant	- 0.184	0.574	-0.321^{NS}
Gender	0.133	0.090	1.481^{NS}
Age (years)	0.009	0.018	0.495^{NS}
Educational Level	0.155	0.044	3.540**
Farming/working experience (years)	- 0.009	0.015	-0.648^{NS}
Major occupation	- 0.033	0.148	-0.220^{NS}

$R^2 = 0.61$, $R^{-2} = 0.526$

** = significant at 5% level
Ns = Not significant

CONCLUSION AND RECOMMENDATIONS

The use of ICTs among extension workers and farmers in Makurdi Benue State as well as other states of the federation will help to promote participatory communication in the agricultural sector especially when people are educated, to appreciate and use these ICTs especially the modern ones, this will go a long way to improve the people's lives in the area of food security exposing more farmers to the importance of ICT for agricultural development. The study recommends adequate funding should be provided to extension organizations to improve their ICT infrastructures, so as to enable staff utilize these ICT facilities. Similar ICTs centers should be established in all parts of the state so as to create awareness among farmers. There is a need to organize frequent training for both extension workers and farmers in the use of ICTs facilities.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study conducted in Abia State, Nigeria aimed to assess the awareness and utilization practices of orange-fleshed sweet potatoes (OFSP) among food vendors. A total of sixty food vendors were randomly selected from Abia State's three agricultural zones, and data were collected through structured interviews. The data were analyzed using descriptive statistics such as frequency counts, percentages, and mean score. The findings revealed that a majority (70%) of the respondents were aware of OFSP, indicating a significant level of knowledge about the crop among food vendors in Abia State. However, challenges such as scarcity/unavailability of the crop and poor awareness/acceptance hindered its utilization. Boiling was the preferred method of preparing OFSP (45%), followed by frying (35%). The study recommends increasing knowledge about OFSP among food vendors through awareness campaigns, training programs, and dissemination of information on its nutritional benefits. Including OFSP in menus can enhance consumer acceptance and utilization, potentially addressing micronutrient deficiencies and improving food security and nutrition in Nigeria.
Keywords: *Awareness, Utilization, Sweet potato, Food vendors.*

INTRODUCTION
Sweet potato (*Ipomoea batatas* L.) is a crucial food security crop for millions of people in Sub-Saharan Africa and Asia. The crop is among the world's most important crops, ranking fifth and seventh in production in Africa and the World, respectively (Ashs, 2007, J. Low, 2007, CIP, 2007). It is mainly grown for human food and animal feed. It produces carbohydrate-rich storage roots with a substantial amount of vitamins A, B complex, C, and E, as well as minerals including calcium, potassium, and iron. According to Chowdhury *et al*. (2011), orange-fleshed sweet potato (OFSP) is particularly promising because its levels of provitamin A and carotenoids are high and can easily be absorbed by the body. Orange-fleshed sweet potato has emerged as one of the most promising plant sources of β-carotene, the pro-vitamin A (Hagenimana and Low, 2000). A 100- 150 g serving of boiled tubers of orange-fleshed sweet 3 potato can supply the daily requirement of vitamin A for young children which can protect them from blindness (Tsou and Hong, 1992).

Utilization of OFSP presents numerous advantages for Nigeria. Firstly, the high nutritional content of OFSP helps combat vitamins A deficiency, particularly in vulnerable populations such as pregnant women and young children. This can contribute to reducing the prevalence of associated health issues, including blindness and compromised immune systems. Foods high in vitamin A that are simple to make may consequently play a significant part in enhancing human health in these circumstances. The potential of "bio fortified" staple crops—varieties cultivated for higher vitamin or mineral content—has come to light over the past 15 years. Orange-fleshed sweet potatoes (OFSP) are particularly promising (Chowdhury et al. 2011), because they contain significant levels of provitamin A and carotenoids that are simple to absorb by the body. The crop presents a workable substitute that can promote economic expansion, poverty alleviation, and rural development. The purpose of this study is to ascertain the level of knowledge and OFSP usage among food vendors in Abia State, Nigeria.

METHODOLOGY
The research was conducted in Abia State, Nigeria. The three (3) Agricultural zones were purposively selected for the study. From each of these Agricultural zones, one local government area was chosen. The selected local government areas for the study were Aba South (in the Aba agricultural zone), Bende (in the Bende agricultural zone), and Umuahia North (in the Umuahia agricultural zone). A total of 60 food vendors were randomly selected and interviewed. Twenty food vendors were chosen from each of the three selected local government areas. The selection of food vendors was based on their active involvement in the food vending industry. Both qualitative

and quantitative information was elicited from the food vendors using a well-structured questionnaire and the data collected were analysed with descriptive statistics like mean, frequency, percentage and rating scale methods.

RESULTS AND DISCUSSION

Demographic characteristics of Respondents: (n=*60)*

Table 1 provides a frequency distribution of the respondents based on various characteristics. The results show that majority (80%) of the sampled food vendors were female while men (20%) implying that women were more in the food vending business than men.

The mean age of the respondents in the study area was 35 years implying that the food vending business is dominated by young energetic people. Age is typically seen as a primary latent trait in adoption decisions, according to Agbamu (2006). The result further shows that the majority (56.7%) of the respondents were married, 18.3% single, and 16.7% widowed, and 8.3% were divorced indicating that married people dominated in food vending business in the study area. The result also indicates that more than half (55%) of the respondents had a household size of less than 5 members, 25% had between 6-10 household size, 20% were respondents with household size that ranges from 11 and above in the study area. In terms of education, about (41.7%) of the respondents attained secondary, tertiary (30%), 23.3% had primary educational while 5 percent had no educational qualification. This is consistent with the findings of Adedoyin et al. (1999), who identified education as a foundation for farmers' use of agricultural products. It is generally accepted that education encourages a positive mental attitude toward innovative ideas and procedures. Only 36.7% had less than 5 years food vending experience, 28.3% had between 6-10years of experience, 23.3% had between 11-15 years' experience, while 11.7 percent had above 16 years of experience in the business.

Table 1: Demographic characteristics of the Farmers: (n=60)

Variables	Frequency	Percentage
Sex:		
Male	12	20
Female	48	80
Age:

Awareness and Sources of OFSP Information.

The results in table 2 revealed that majority of respondents (70%) reported being aware of OFSP while (30%) of the respondents reported not being aware of OFSP. This indicates a relatively high level of awareness in the area. The most common source of OFSP information among the respondents was ADP (30%), Media sources (23.3%), Farmers (8.3%), and NRCRI/MOUAU (16.7%).

Table 2: Awareness and Sources of OFSP Information (n=60)

Variables	Frequency	Percentage
OFSP Awareness:		
Yes	42	70
No	18	30
Sources of OFSP Information:		
ADP	18	30
Media (Internet, print, radio, tv etc)	14	23.3
Farmer	5	8.3
NRCRI/MOUAU	10	16.7

Utilization of Orange Fleshed Sweet Potato in the study area.

The table 3 shows percentages for different food forms in terms of their utilization levels, ranging from "Very high" to "Very low." The result for raw form shows that (16.7%) respondents reported using it at a very low level, while only 5% used it at a very high level. The results show that boiling was the most popular way of utilizing OFSP among the respondents at (45%), while 1.7% used it at a very low level. The result shows that a significant proportion of respondents (20%) used OFSP leaves at a very low level. The results suggest that the utilization of OFSP in porridge form varied among the respondents, with 16.7% using it at a low level and 13.2% at a very high level. The table indicates that a significant proportion of respondents (30.2%) reported using OFSP in fried form at a very high level. However, 3.3% used it at a very low level. 20.7% used OFSP in juice form at a moderate level, while no respondents indicated using them flour, confectionaries, puree etc.

Table 3: Levels of Utilization of OFSP by the respondents (n=60)

Food form	Very high (%)	High (%)	Moderate (%)	Low (%)	Very low (%)
Raw/uncooked	5	13.3	11.7	8.3	16.7
Boiled	23.3	45	28.3	11.7	1.7
Leaves (as vegetables)	0	1.7	8.3	13.3	20
Porridge	13.2	5	6.7	16.7	11.7
Fried	30.2	6.7	15	15	3.3
Juice	0	3.3	20.7	3.3	10
Flour	0	0	0	5	0

Constraints Militating against the Utilization of OFSP

Table 5 shows the factors militating against the utilization of Orange Fleshed Sweet Potato (OFSP) in the study area. The result reveals that 63.9% of the respondents indicated scarcity/unavailability as the major challenge they are facing, followed by poor awareness/acceptability (41.1%). Similarly, 22.5% and 20.8% of the respondents noted low demand and high cost of OFSP as another prevailing problem confronting them in the study area. Furthermore, 18% and 9.7% of the respondents indicated sensory attributes and post-harvest challenges as their minor challenges facing the utilization of OFSP in the study area.

Table 4: Constraints Militating against the Utilization of OFSP

Constraints	Frequency ((n-60) Percentage
Scarcity/unavailability	63.9
Post harvest challenges	9.7
Poor awareness/acceptability	41.1
Sensory attributes (texture, colour, taste etc)	18
Low demand	22.5
High cost of OFSP	20.8

***Multiple responses**

CONCLUSION AND RECOMMENDATIONS

The study findings revealed a high-level awareness of OFSP among the food vendors; they also indicated ADP and media as their major sources of OFSP information. The result also revealed that OFSP is utilized more as boiled and fried while scarcity/unavailability and poor awareness/acceptability were the major constraints militating against the use of OFSP in the study area The results also revealed percentages for different food forms

in terms of their utilization levels, ranging from "Very high" to "Very low." Majority reported Utilizing OFSP in boiled and fried form at high level, OFSP is utilized in low forms in raw and juice.
This study therefore recommends that there is need for increased awareness and sensitization of OFSP among the food vendors in Abia State and the need to include OFSP in their menu to encourage consumer's acceptance and utilization.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study analyzed the effect of socioeconomic characteristics on value addition among rice farmers in Imo State. Nigeria. Data used for the study were collected with the aid of structured questionnaire administered to 150 randomly selected rice farmers. Data were analyzed using descriptive statistics and logit model. Result of the analysis showed that 44.7%, 30.6%, and 24.7% of the respondents have secondary, tertiary and primary education respectively. The result also reviewed that 56%, 36%, and 8% of the respondents had 6 – 10, 1 – 5, and 11 – 15 household members respectively. The results also indicated that the respondents that had 1–25, 26-50 extension contacts per year constituted 50% and 21%, respectively of the respondents; while 19% of the respondents had no contact with extension agents in the study area. Male rice farmers constitute 70% while 30% are female rice farmers. The result of age distribution shows that 50% of the rice farmers are between the age brackets of 51 to 60 years. This is followed by 30.6% of rice farmers in the study area who are between the age bracket of 41 to 50 years. The analysis noted that 14% and 4% are between 61 to 70 years and 31 to 40 years of age bracket respectively. The result also suggests that majority (64.7%) of the rice farmers have between 0.1 to 0.9 ha of rice farm. This is followed by 21.3% who had between 1 to 1.9 ha of rice farm. Rice farmers who had between 2 to 2.9ha and 3 to 3.9ha constitute 6% and 2% respectively. The result of the logistic analysis on the effect of socio-economic characteristics on value addition, showed that Household size, Gender, Age, Farm size and cooperative membership affected rice value addition. Hence socio-economic characteristics of rice farmers in the study area have significant effect on rice value addition. Value addition among rice farmers should be encouraged via good polices that would enhance gender participation and support large farm size.
Keywords: *Socio-economic characteristics, value addition, rice farmers.*

INTRODUCTION

The agricultural sector despite its significant decline in the share of Nigeria's GDP; from 63.8% in 1960 to about average of 24% during 2013 – 2019 (Fowowe, 2020; Oyaniran, 2020), and 22.35% between January and march 2021 (Sasu, 2023), is still the second-largest contributor to GDP growth (Varella, 2021), contributes significantly to rural development, food security and poverty alleviation (John et al., 2014.) and remains an important source of livelihood, economic development and creating employment for about 60% to 70% of the country's labour force (World Bank, 2014; Nigeria, FMARD 2016), an achievement which ranks the sector as the largest employer of labour in the country, Oyaniran,(2020). Nigeria, with a population of roughly 200 million, Africa's most populous country (Benson et al., 2020), is still largely characterized by production and direct sale of agricultural outputs in its raw form with very little capacity for transformation of produce from its raw form to other value-added products. This is attributed to inadequate capacity of primary producers to add value to their produce due to socio economic, technological and other constraints. According to FAO (2023), Nigeria's rice production rose from 3.7 million metric tons in 2017 to 4.0 million metric tons in 2018. In 2019, rice accounted for more than 14 percent of the crops cultivated by households in Nigeria, same year, the Government banned importation of rice in order to stimulate local production. In 2022, the quantity of milled rice produced in Nigeria was estimated at 5.4 million metric tons. Over the past few years, Nigeria has demonstrated a capacity to significantly increase paddy production. However, despite the annual increases in production, self-sufficiency in milled rice is yet to be attained due to mainly population growth which keeps increasing by 2.5-3.0% per annum and changes in consumers preferences influenced largely by growth in urbanization, NRDS II, (2020).

However, one important means of income generation that rural farmers have not paid much attention to is value addition (Obasi and Enyia, 2016). The poverty reducing potential of value addition is not only in generating rural income and employment but also by improvement in processing that reduce traditional food preparation times (Obasi and Enyia, 2016). value addition in the production of rice implies all the activities, processes or strategies and distribution of rice which in one way or the other contribute to benefit/utility maximization (Ugwu et al., 2014). This study considered value addition to be any improvement made to rice paddy to bring it to a form in which the consumer wants it. It ensures that the small-scale household does not suffer the biophysical losses, economic loss and nutrient losses and also minimizes the causes of total food loss during harvesting, food storage, processing, packaging, marketing and consumption losses. Despite the numerous benefits of value addition, majority of the rice farmers have continued to trade their produce in raw form. This could be linked to lack of capacity as well as processing equipment and socio-economic characteristics of rice farmers. The study is therefore, intended to; i. ascertain the socio-economic characteristics of the rice farmers in the study area, ii. determine the effects of socio-economic characteristics on rice value addition and also test if the socio-economic characteristics of rice farmers have any significant influence on rice value addition.

MATERIALS AND METHOD.

This study was conducted in Imo state, Nigeria. Imo State lies between Latitude $5^0 10'$ and $6^0 35'$ North of the equator and between Longitude $6^0 35'$ and $7^0 31'$ East of the Greenwich meridian. The State has a population of about 3,934 million people disaggregated into 2,032 males and 1,903 million females (NPC, 2006). It is bounded on the East by Abia state, on the North by Anambra and Abia State, and on the West by Rivers State. The State is divided into 27 administrative units called Local Government Areas which are grouped into 3 agricultural zones viz Owerri, Okigwe and Orlu. The population for our study comprised of rice farmers in Imo State. This study adopted multistage random and purposive sampling techniques. In the first stage, two of the major rice producing-agricultural zone in Imo state, were purposively selected. This is to ensure that the zones that are predominantly rice farmers are selected. Based on this, Okigwe and Orlu agricultural zones were chosen. From the two agricultural zone, two LGAs (Ihitte Uboma and Okigwe for Okigwe Zone), and (Ideato Noth and Ideato South for Orlu Zone) were purposively selected to give a total of four (4) LGAs. This was based on the concentration of rice farmers in the LGAs. The third stage involved the random sampling of 150 respondents from the list of rice farmers obtained from Imo State RIFAN. The selection of the respondents was done proportionately to ensure that LGA with more rice farmers had more respondents. Data were sourced principally through primary source. Data were obtained with the aid of structured questionnaire that was administered in-person to the sampled respondents. Data were analyzed using simple descriptive statistical tools and Logit model which is expressed as; $Li\ Y = Ln\ (P/1\text{-}P)$ (1).

$Ln\ (P/I\text{-}P) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_7 x_7$ (2).

Detailed description of the variables is as shown below.

Y = value addition (dummy variable, 1 for adding value, 0 for not adding value)

X_1 = household size (number of persons)

X_2 = gender (dummy variable, 1 for male, 0 for female)

X_3 = Age of the household head (years)

X_4 = Educational level (number of years spent in school)

X_5 = Extension visit (number of visits)

X_6 = Cooperative membership (dummy variable, 1 for member, 0 for non-member)

X_7 = farm size (hactare)

RESULTS AND DISCUSSION

The results in Table 1 showed that 44.7% of the respondents in the study area have secondary education, followed by 30.6% of the respondents who have tertiary education. The finding also showed that 24.7% have primary education. The finding suggests that there is high level of literacy among rice farmers in the study area. The result disclosed that majority (56%) had 6 – 10 persons, followed by 36% who had 1 – 5 persons. Only 8% had 11 – 15 persons. This may indicate that respondents in the study area have large household sizes. The result also showed that 50% of the rice farmers had between 1 – 25 contacts per year, 21% of the rice farmers had between 26 – 50 extension contact while 19% had no contact with extension agents in the study area. Male rice farmers constitute 70% while 30% are female rice farmers. The result of age distribution shows that 50% of the rice farmers are between the age bracket of 51 to 60 years. This is followed by 30.6% of rice farmers in the study area who are between the age bracket of 41 to 50 years. The data showed that 14% and 4% are between 61 to 70 years and 31 to 40 years of age respectively. The result also suggests that majority (64.7%) of the rice farmers have between 0.1 to 0.9 ha of rice farm. This is followed by 21.3% who had between 1 to 1.9 ha of rice farm. Rice farmers who had between 2 to 2.9ha and 3 to 3.9ha constitute 6% and 2% respectively. This result indicates that majority of the rice farmers in the study area are small scale rice farmers.

Table 1. Socio-economic characteristics of the respondents in the study Area.

Education level (years)	Frequency	Percentage	Mean
1 – 6	37	24.7	
7 – 12	67	44.7	
13 - 16	46	30.6	
Total	**150**	**100**	**9.6**
Household Size (person)			
1 – 5	54	36	
6 – 10	84	56	
11-20	12	8	
Total	**150**	**100**	**7**
Extension Visit (no/year)			
None	28	19

Female	45	30	
Total	**150**	**100**	
Age (years)			
≤ 30	1	0.7	
31 – 40	6	4	
41 – 50	46	30.6	
51 – 60	75	50	
61 – 70	21	14	
≥ 71	1	0.7	
Total	**150**	**100**	**53**
Farm Size (Ha)			
0.1 - 0.9	97	64.7	
1 - 1.9	32	21.3	
2 – 2.9	9	6	
3 – 3.9	3	2	
Total	**150**	**100**	**0.85**

Source: Survey data 2022.

The result in Table 2 showed that household size was statistically significant at 1% level and positively related to value addition. This implies that household size influences value addition that is households with more members participate more in value addition. The result also showed that gender was negative and statistically significant at 1% level. This suggests that value addition is gender biased. Age was found to be statistically significant at 1% level and positively related to value addition. This indicates that age influences value addition. Hence, older farmers participate more in value addition. Education was negative and statistically non-significant with value addition. This implies that the knowledge/skill required to participate in value addition could be acquired informally. Extension contact was found to be positive and statistically non-significant. This shows that Extension contact has no influence on value addition, and could be attributed to the fact that extension agents dwell more on production activities than post-harvest activities. Cooperative membership was found to be statistically significant at 5% level and negatively related to value addition. This implies that value addition is not dependent on cooperative membership. Farm size was found to be statistically significant at 1% level and positively related to value addition. This direct relationship implies that farm size influences participation in value addition.

Table 2: Result of logit regression on the effect of socio-economic characteristics on rice value addition

Variables	Coeff.	Std.Err.	Z	P>|Z |	Marginal effects

Hypothesis on the significant effect of socio-economic characteristics on rice value addition.

H_O: Socio-economic characteristics (X_1, X_2, X_3, X_4, X_5, X_5 & X_7) of the rice farmers have no significant influence on their value addition.

H_A: Socio-economic characteristics (X_1, X_2, X_3, X_4, X_5, X_5 & X_7) of the rice farmers have significant influence on their value addition.

To test this hypothesis, the logistic analysis already performed to achieve objective (ii) was re-employed. The result is presented in Table 3.2. The table showed that the chi-squared calculated was significant at 5% level of probability and concluded that the factors indicated actually affected rice farmers value addition. Therefore, the null hypothesis which stated that socio-economic characteristics of rice farmers have no significant effect on rice value addition was rejected.

CONCLUSION AND RECOMMENDATION

Based on the finding of this study, it could be concluded that value addition among rice farmers in the study area is influenced by socio-economic characteristic namely, Household size, Gender, Age, Farm size and Cooperative membership. Besides, rice farmers in the study area are small scale farmers of large household size, whose active and productive age falls within 41 to 60 years of age bracket with relatively high literacy level and poor extension contact. Value addition among rice farmers should be encouraged via good polices that would enhance gender participation and support large farm size among rice farmers. Government should create enabling environment to enable rice farmers queue into value addition which increases the shelf life of rice and in turn enhances rice farmers income generation and food security.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined the impact of socio-economic factors on profitability of cassava production in Ehime Mbano LGA Imo state. Specifically, it described the socio-economic characteristics of cassava farmers, determined the profitability of cassava farming, and determined the impact of socio-economic factors of cassava farmers on profitability of cassava production. Study area was in Ehime Mbano LGA of Imo state. Data were collected with a structured questionnaire from 80 randomly selected cassava farmers. Data were analysed using descriptive (frequency, percentage and means) and inferential statistics (regression analysis). The result showed that 51.3% of the respondents were males, the mean age of respondents is recorded at 33 years, most of the respondents (72.5%) were married, 46.3% of respondents had only secondary school qualification and the average household size of the respondents is made up 6 people. Cassava farming was profitable in the study area with a Net Rate of Return of 97%. The multiple regression with R^2 of 0.593 indicates that the model explains 59.3% of the variation in cassava production. Household size had a positive significance on cassava profitability while education had a negative significance on cassava profitability in the study area. To strengthen agriculture for food and nutrition security and export in a climate change environment, government and agencies should carry out sustainable cassava production programmes and policies to encourage and sustain cassava production.
Keywords: *Impact, Cassava, Profitability*

INTRODUCTION
Cassava is one of the most important crops grown in Nigeria with an annual production of over 60 million tonnes making it the world's largest cassava producer and it is crucial to the development of Nigeria's agro economy as it is consumed both locally and used as a raw material (Ikuemonisan *et al*., 2020). Cassava products are generally accepted by all classes of Nigerians, which makes it attractive to farmers (Itam *et al.*, 2014). Cassava tends to thrive where other crops fail even on marginal soils and a moderate climate (Omodara *et al*., 2023). Despite its leading position in cassava production, Nigeria remains an importer of cassava products (Olukunle, 2016). Cassava is an agricultural produce with the potential to generate foreign exchange for Nigeria through the exportation of the crop. However, the nature of its production which is moistly in the rural areas faces plethora of challenges which has affected its productivity (Inegbedion *et al.*, 2020). Majority of cassava in Nigeria is produced by farmers in the rural areas and forms a vitally important role in the survival of the rural dwellers, there challenges facing cassava production and if these challenges persist it could lead to a potential setback in cassava production (Oyekola *et al.*, 2021). There is a great potential both for export and domestic consumption for cassava. Its usefulness as a wide spectrum, range from the leaves to the roots which are mostly used for animal feeds and food processing (Itam *et al.,* 2014).
In Nigeria, the consumption of cassava varied from 35.6 million tonnes in 2002 to 52.4 million tonnes in 2011 while a major proportion of cassava produced in Nigeria goes to human consumption while a very low proportion goes to industry and foreign trade. According to Faborode (2016), the Nigerian economy is indeed mono-cultural with the dominance of oil overshadowing sectors such as agriculture and manufacturing. The impact on development has been low welfare capacity, low employment, high inequality and hence high multidimensional poverty or the paradox of poverty during plenty (Olukunle, 2016). While cassava plays a significant role in the survival of rural dwellers, the farmers still face challenges in producing cassava in substantial quantity (Shakleton, 2020). Thus, if these challenges remain unchecked, it can cause serious drawback to both social and economic development. Hence this study aims to describe the socio-economic characteristics of cassava farmers, determine

the profitability of cassava farming, and determine the impact of socio-economic characteristics of cassava farmers on profitability.

MATERIALS AND METHODS

Study Area

Ehime Mbano is a Local Government Area of Imo state Nigeria. It is located at Latitude 5^0 40' 54 North and Longitude 7^0 18' 11 East and is bounded in the East by Isiala Mbano L.G.A, in the West by Ahiazu Mbaise L.G.A, in the North by Okigwe L.G.A and in the South by Ihitte Uboma LGA. It has an area 169 Square km and a population of 130,931 (NPC, 2006).

Sampling procedure

A multistage ppurposive and random sampling technique was used for the selection of respondents for this study. Purposive sampling technique was used to select four (4) towns (Nsu, Ehim, Umue-Zeala and Umun-Akanu) due to their high involvement in cassava farming. Secondly from the four towns selected, two (2) villages were randomly selected. Thirdly, ten (10) cassava farmers were randomly chosen each from the villages selected. Hence the sample size of cassava farmers used for this study was eighty (80) respondents inclusive of both Male and Female.

Data Analysiss

Descriptive statistical tools involving percentages, means, and frequency distribution tables were used to analyze data generated on socio- economic characteristics. The variables were fitted with functional forms of multiple regression, results were based on the significant parameters and overall significance of the estimated model. Gross margin was estimated, and this is indicative of farmers' productive capacity while the net profit gives an indication of the actual returns profile after deducting the fixed cost components from the gross revenue. Gross margin and net profits were estimated to assess the level of profitability of cassava enterprise.

Profitability of the enterprise is mathematically expressed as:

GM=TR-TVC

NPI=GM-TFC=TR-TC

GRR=GM/TVC)

NRR = NPI/TC

Where,

GM = Gross Margin.

TR = Total revenue

TVC = Total Variable Cost.

TFC = Total Fixed Cost

TC = Total Cost

NPI = Net Production Income= Net Profit

GRR= Gross Rate of return on Investment.

NRR = Net Rate of Return on Investment.

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents

The socio-economic characteristic under consideration includes gender, age, marital status, educational qualification, and household size of the respondents.

Figures in table1 shows that most of the respondents used for this study were males accounting for 51.3% while 48.8% of the respondents were females. This could be because the male gender is more involved in farm level production while the female gender tends towards processing. This is in line with a study by Suleiman *et al.* (2017) which stated that males are labour efficient which leads to higher productivity. The results also shows that the mean age of the respondents is recorded at 33 years. This indicates that majority of the respondents for this study are young and active. This is in line with a study by Aminu and Okeowo (2016) which stated that younger people are the most dominant in crop farming.

The results also shows that most of the respondents are married, which constituted 72.5% of the respondents. the respondents that are single and have never been married constitutes 27.5% of the respondents. The preponderance of married people can be an incentive for more farm labour supply which can directly lead to a higher cassava production. This is in line with a study by Olukunle (2016) which states that most rural farm dwellers are married and contributes positively to labour for cassava production. Results also shows that most respondents had only secondary school qualification as represented by 46.3% of the respondents, those with tertiary level education qualification are represented by 27.5% of the respondents, those without any form of formal education are represented by 15.0% of the respondents and farmers with only primary school qualification are comprised of 11.3% of the respondents. This indicates that majority of the sample used for this study had one form or another of formal education. This is in line with a study by Dauda *et al.* (2015) which stated that farmers in the rural areas have a form of formal education. Findings also shows that the average household size of the respondents is 6 people. This implies that most of the respondents have a household size of more than 4 people living under the same roof. This is in line with a study by Suleiman *et al*. (2017) which stated that that most of farmers had large household size of 4-6 members which will enhance family labour availability.

Table 1 Socioeconomic characteristics of the respondents

Variable	Frequency	Percentage	Mean
Gender			
Male	41	51.3	
Female	39	48.8	
Age distribution (years)			
16-25	25	31.3	33 years
26-35	30	37.5	
36-45	16	20.0	
46-55	9	11.3	
Marital status			
Married	58	72.5	
Single	22	27.5	
Educational qualification			
No formal education	12	15.0	
Primary qualification	9	11.3	
Secondary qualification	37	46.3	
Tertiary education qual	22	27.5	
Household size (people)			
1-3	13	16.3	6 people
4-6	37	46.3	
7-9	20	25.0	
10-12	10	12.5	

Average profitability of cassava production/ hectare

The results in Table 2 shows that on the average profitability per hectare of cassava farming, the total cost consists of ₦9,905.48 as variable cost and ₦18,391.28 as fixed cost component. Based on the gross revenue realized per metric tonne of output, profitability indicator was ₦43,740. Gross margin and net profit per metric tonne of cassava output at the farm level were positive. The gross margin at the farm level was ₦33,835 while the net profit was ₦15,443. In terms of rates of returns, the net rate of return was 97% based on net profit. The net rate of return of 97% implies that for every one Naira (100 kobo) invested in cassava production by an average cassava farmer at the small-scale level, there is a net profit of 97 kobo.

Table 2 Indicators of profitability of cassava production per hectare

Category	**Amount NGN/ Ha**
Variable Cost Components:	
Cost of manure	10000
Planting material cost	12500
Cost of herbicides/pesticides	15000
Total labour cost	75000
Transportation cost	40000
Total Variable Cost (TVC)	152,500
Fixed Cost Components:	
Land	55,000
Farming tools	16,700
Interest paid	10,000

Total Fixed Cost (TFC)	81,700
Total Cost (TC) = TVC + TFC	234,200
Profitability Indicators:	
Gross Revenue (Quantity of output multiplied by price of output)	460,300
Gross Margin = GR-TVC	307,800
Net Profit= GR-TC	226,100
Gross Rate of Return= GM/TVC	2.01
Net Rate of Return=NP/TC	0.97

Impact of the socio-economic characteristics of farmers on cassava profitability.

Table 3 shows that the overall regression model was significant, which indicates that the variables measured have a significant impact on profitability of cassava production. F (4,41) = 14.93, p <.001, R^2=.593). Also, R^2 =0.593 which depicts the model explains 59.3% of the variation in cassava production. Coefficients were further assessed to ascertain the influence of each of the socio-economic factors on profitability of cassava production and the results revealed that Household size has a positive significance on cassava profitability while education has a negative significance on cassava production. The positive significance of household size is against the findings of Suleiman *et al.* (2017).

Table 3 Socio-economic characteristics impacting profitability of cassava production.

Variables	B	T-value	p-value
Constant	11.809	1.682	0.100
Gender	-2.630	-1.654	0.106
Age	2.369	1.139	0.261
Educational qualification	-0.280	-2.163	0.036*
Household size	4.701	3.867	0.000*
R^2	0.593		
F (4,41)	14.93		

*Note. *p < 0.05*

CONCLUSION AND RECOMMENDATIONS

Based on the findings from this study, it was concluded that cassava farming was profitable in the study area. Household size and educational qualifications are the factors affecting profitability of cassava production. To strengthen agriculture for food and nutrition security and export in a climate change environment through cassava production, government and private agencies should carry out sustainable cassava production programmes and policies to encourage cassava production.

Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study evaluated the socio-economic importance of Bamboo among residents of Alamala Barracks and Soyoye area of Ogun state. Structured questionnaire was used to collected data from randomly selected 100 respondents. Data were analysed using percentage and correlation. Findings revealed that modal ages were 33 years and 23 years in Soyoye and Alamala Barracks respectively. The majority (74.3%) of the respondents in Alamala Barracks were males as well as 57.5% in Soyoye. Furthermore, 51.4% had a tertiary form of education in Alamala barracks as against 38% in Soyoye. Bamboo usage among the community residents revealed that 82% use it for construction in Soyoye as against same percentage for decoration in Alamala barracks. Spearman's Rank Correlation value of 0.0857 implied a low correlation between bamboo usage rates across the two communities in spite of their closeness. Bamboo was largely used for recreational and aesthetic activities in Alamala Barracks as against economic benefits for most Soyoye residents. Therefore, increased cultivation of Bamboo through awareness and support programs is recommended because of the enormous benefits of the plant in the two communities. Also profitable investment can be made from Bamboo in Soyee and Alamala Barracks.
Keywords: *Benefits, Bamboo, Correlation, Soyeye, Alama Barracks, Ogun State*

INTRODUCTION

Bamboo (*Bambusa*) is a drought-resistant perennial woody grass belonging to the group angiosperm and the order monocotyledon. They are in the sub-family of *bambusoideae* and family *poacae*. Forest composition was assessed in the last century in terms of the commercial value of timber in Nigeria, Bamboo was found in a number of states particularly in the southern part of the country (Nwaihu, *et. al*, 2015). According to a report by Raw Materials Research and Development Council in 2004, the most endowed states in terms of bamboo occurrence were observed to be Ogun, Oyo, Osun, Ondo, Edo, Delta, Rivers, Akwa Ibom, Cross River, Abia, Ebonyi, Enugu, Anambra and Imo States and at least 10% of the natural vegetation in these states is dominated by bamboo, with existing bamboo clumps showing appreciable gregarious growth that is contiguous over large areas. The report also indicated availability of bamboo in Niger, Taraba, and Plateau states as well as within the Federal Capital Territory (Asiru, *et al*, 2017).

Bamboo is an important renewable resource that when managed properly can bring people out of poverty, thereby improving the economy of the country (Satish, *et al*., 2020). This is why it is of utmost importance to identify the various uses of Bamboo trees and the benefits that can be derived from its parts to the people of Alamala Barracks and Soyeye areas of Ogun state.

The lack of information on the socioeconomic importance of Bamboo species has been linked to the non-sustainable utilization of many of these species in some parts of Nigeria. Recently in Nigeria, the prospects for multi-functional utilization were on the increase due to increased dependence on the importation of raw materials and the obvious ecological and land degradation taking place in most parts of the country (Ogunwusi, *et al*., 2013). This study aims to describe the socio-economic importance of Bamboo in Alamala Barracks and Soyeye areas of Ogun state, Nigeria.

METHODOLOGY

Alamala Barracks was built as a military barrack, where troops of various sizes and complexity in the Nigerian Military and their families are quartered. It is situated in Abeokuta North, Ogun state, Nigeria, its geographical coordinates are 7° 11' 0" North, 3° 14' 0" East. Zip Code: 110101 with Latitude: 7.17239 Longitude: 3.27902 and Soyoye, is located at Abeokuta, Nigeria with coordinates of Latitude: 7.16987 and Longitude: 3.273982. The study areas; Alamala barracks and Soyoye community were selected purposively based on their prominence for bamboo cultivation and utilization. A set of structured questionnaires were randomly distributed to 100 respondents but only 75 questionnaires were retrieved. Data collected were analysed using percentage and Spearman's Rank Correlation.

RESULTS AND DISCUSSION

Table 1: Socio-economic characteristics of the Respondents (N=75)

Variable		Soyoye (%) N=40	Mode	Alamala (%) N=35	Barracks	Mode

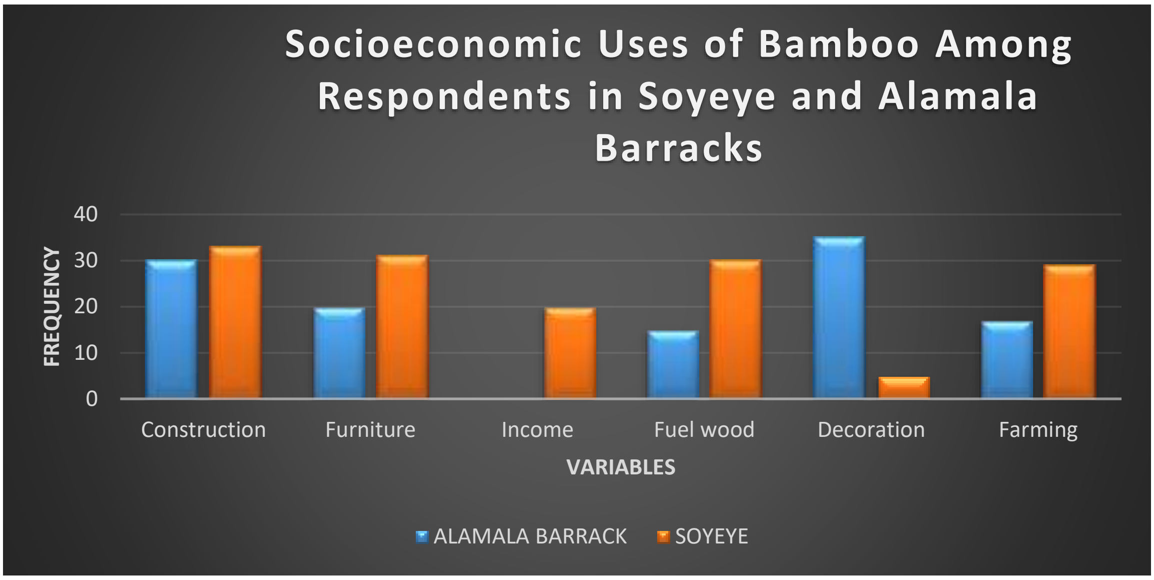

Figure 1: Socioeconomic uses of Bamboo in the study areas

Socio-economic uses of Bamboo

The result highlights the socio-economic uses of bamboo in Alamala barracks by the respondents. Majority of the respondents said bamboo tree is mainly used for decoration, it is also used for construction, some said it is used in furniture making while less than half said the tree is used in farming and fuel wood respectively. These findings showed that Bamboo is highly good for decorations and also agreed with the report of (Ijeomah, 2007). While in Soyoye, a majority said bamboo is used for construction, some said it is used in furniture making, construction of houses, huts, fences, walking sticks, chairs, baskets, beds, and various artifacts. The use of Bamboo as a main construction material is in agreement with (Akoto *et al.*, 2018; Okokpujie *et al.*, 2020) as it is considered a cheaper and viable alternative for housing due to its strength, flexibility, and versatility.

Correlation between the Study Areas

Correlation revealed that X and Y variables represent the frequency of responses from Soyoye and Alamala Barracks respectively on the economic uses of Bamboo plants. Spearman's rank correlation value equals 0.0857, this showed that the correlation value is low (close to zero) and so no significant relationship or association between the two study areas despite their closeness and similarity in the use of the plant. The two areas are said to be independent of one another. Technically, the response from on locality cannot be used to predict the other quantitatively.

Table 2: Relationship between the uses of Bamboo in Soyoye and Alamala Barracks

X	Y	Rx	Ry	d = Rx – Ry	d²
33	30	1	2	-1	1
31	20	2	3	-1	1
20	0	4	6	-2	4
10	15	5	5	0	0
5	35	6	1	5	25
29	17	3	4	-1	1

$\sum d^2 = 32$ $\quad n = 6$

$\rho = 1 - (6 \sum d_i^2 / n (n^2 - 1))$

$= 1 - (6 \times 32/6 \times (36 - 1))$

$= 1 - (192/210)$

$= 1 - 0.9143$

$= 0.0857$

Analysis of the socioeconomic characteristics of the respondents showed that the majority of the respondents in both study areas were males and in their youthful and active period with ages ranging from 20-30 years and 31–40 years in Alamala Barracks and Soyoye respectively which means they are expected to be cognizance of the happenings in their community and is in agreement with (Ogunjinmi *et al.*, 2009) who reported that the respondents should be knowledgeable and able to give reliable information as matured males were involved in harvesting of bamboo. The marital status of the respondent in Soyoye and Alamala Barracks revealed that the proportion of married outweighed that of single which is also in agreement with (Nwaihu *et al.*, 2015) that had more married respondents in their research on Bamboo utilization in Imo State. The majority of the respondents in Alamala Barracks had tertiary education, as against that of Soyoye who had only a few but more with no formal education. This implied that Alamala Barracks residents were majorly working class with higher education qualifications while Soyoye had more artisans because of the educational level. This may have a negative impact on bamboo resource management as reported by (Shiferaw *et al.*, 2021) that resources can be more conserved and maintained appropriately if the community acquires education and has good knowledge resources and vice versa.

CONCLUSION

This study described Bamboo as a non-timber forest product that finds its enormous use in recreational and aesthetic activities for the people of Alamala Barracks may be because the respondents of the study areas do not really engage in farming, but were dominantly civil servants while in Soyoye, bamboo use ranges from construction, traditional medicine, furniture and to main source of income as majority of the respondents were traders. However, there was no significant relationship or association between Alamala Barracks and Soyoye regarding the various uses of Bamboo in the two localities. This fact is evident in the correlation coefficient of 0.0857 as estimated from the variables.

RECOMMENDATION

Based on the enormous benefits derived from the use of Bamboo in the study areas, the government or private sector should encourage more cultivation through various awareness and supports programmes. Also profitable investment can be made from Bamboo in Soyee and Alamala Barracks of Ogun state, Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was carried out to determine rural amenity-based as a veritable to enhance extension agents' effectiveness in delivering information on cassava production to rural farmers for food security in Delta State. Two purposes and two research questions guided the study. The work specifically adopted a survey research design. The population of the study was 200 which consisted of 120 extension agents and 80 agricultural education lecturers in tertiary institutions of Delta State. There was no sampling because the whole population was of the manageable size. The questionnaire was face validated by three experts from agricultural Education Department, Federal College of Education (Technical) Asaba, Delta State. The instrument used for data collection was questionnaire tagged ''veritable tool to enhance extension agents in delivering information on cassava production to rural farmers questionnaire'' (VTEEAEDICPRFQ) consisting of 27 items was developed from the literature and used as the instrument for data collection. The scale for questionnaire was: Strongly Agreed (SA)-4, Agreed (A)-3, Disagreed (D)-2, Strongly Disagreed (SD)-1. 200 copies of the questionnaire were distributed to respondents but 193 copies were returned which was at 97% return rate. The data collected were analyzed using mean and standard deviations to answer the research questions. The result of analysis showed that provision of electricity, and construction of good road network can enhance extension agent in delivering information to rural farmers on cassava production for food security in Delta State. Based on the result of the study, it is recommended that Delta State government through the ministry of agriculture should provide amenities in the rural areas such as good road network and electricity to the rural areas to enhance extension agents in delivering information to farmers.

Keywords: *Rural Amenity, information, extension agents, rural farmers, cassava, and food security.*

INTRODUCTION

Cassava (*Manihot esculenta*) is a major food and industrial crop in the tropical and sub-tropical Africa. It is a major food in Nigeria particularly, Delta State. According to Okeme *et al.* (2020), cassava is a drought tolerant, famine reserve crop and can withstand extended period of drought and some varieties can survive on annual rainfall of only 200mm if suitably distributed. Cassava production as used in this study entails all processes geared towards making sure that farmers obtain innovative information on cassava production to ensure food security.

Food security simply means an assurance and an access to sufficient quantities and quality of food in the right proportion for all, including the poor (Ayansina and Adeogun, 2017). Food security is achieved when the people in all States of Nigeria have access to sufficient safe and nutritious food to meet the dietary needs and food preference for an active and healthy life (Egbe *et al*., 2022). According to (Agholor, 2016), the reason why the farmers are still using traditional based approach is lack of knowledge on innovative ideas to apply modern techniques in commercial agriculture. In submission of (Adesiji *et al*., 2010), farmers need timely agricultural information from the extension agents.

Agricultural extension agents are the trained persons in extension education who are made to spread agricultural information to rural farmers (Okeowo, 2015). Okeowo, stated further that extension agents train farmers, provide advisory services and information to farmers, also help them form organization for sustainable food production and marketing, as well as teaching rural farmers on improved cultivation, rearing of animals and processing of crops. Extension agents work under the ministry of agriculture either at the state or federal level and Agricultural Development Program (ADP). Mgbenka and Mbah (2018) also described extension agent as a trained employee who develops and delivers educational programs to assist rural farmers in economic and community development, leadership, agriculture and environment. The rural farmers in this study are small holder farmers who carry out agricultural activities in the villages and are in need of agricultural information from extension agents.

The Nigerian agricultural extension service is bedeviled by several problems as identified by Imoloame and Olarewuju (2014) such as inadequate funding, poor logistic support, and poorly trained personnel at local level, ineffective agricultural research extension linkages, and insufficient agricultural technologies for farmers and disproportionate number of extension agents to farm family ratio. Other observed problems stated by Asikadi, (2010) are poor input supply, lack of clientele participation in program development, irregular policy and program instability. Asikadi, (2010) further attested that to address the above problems, some veritable tools have to be employed such as provision of rural amenity-based infrastructures should be provided to keep the rural areas comfortable for the rural farmers.

Rural amenity-based are facilities provided that focused on developing the rural areas where the extension agents are sent to work with the farmers. In submission of Ndem *et al*. (2020), rural amenities are desirable facilities that are provided in the rural areas to make life comfortable and lively. They identified some of the rural amenities-based infrastructures as; recreational centers, health care services, portable water, civic centers, reliable security network, good road network, sound vehicles, modern markets, standard schools at affordable prices for the children, rural electrification, WIFI for internet connections, computers/laptops, electricity, good road network among other

As it stands, most rural farmers in Delta State still operate at subsistence level with low input and low return from their farms because of dearth in information (Egbe *et al.,* 2022). This signifies that there is a gap between government research stations and rural farmers. This gap could be filled by extension agents, who are the go-between the farmers and the research information institutes. It is against this background that this work was carried out to determine rural amenity-based; a veritable tool to enhance extension agents' effectiveness for food security in Delta State. Specifically, the study determines the provision of electricity in the rural areas to enhance extension agents in delivering information on cassava production to rural farmers and the provision of good road network to enhance extension agents in assisting the rural farmers in marketing of cassava products.

METHODOLOGY

The study was conducted in Delta State. Delta was chosen for the study because it is an agrarian State, dominated with rural farmers who are in need of agricultural information. Survey research design was adopted for the study. Two research questions guided the study. The study was carried out in three senatorial zones in Delta State. The population of the study was 200 comprised of 120 extension agents and 80 agricultural education lecturers in Delta State. The entire population was studied since the population was manageable. Hence, there was no need for any sampling technique.

A questionnaire tagged 'veritable tool to enhance extension agents in delivering information on cassava production to rural farmers questionnaire'' (VTEEADICPRFQ) consisting of 27 items was developed from the literature and used as the instrument for data collection. The scale for questionnaire was: Strongly Agreed (SA)-4, Agreed (A)-3, Disagreed (D)-2, Strongly Disagreed (SD)-1. The questionnaire was face validated by three experts from agricultural Education Department, Federal College of Education (Technical) Asaba, Delta State. The questionnaire was administered to 200 respondents and collected with the help of three research assistants. There was 97% return rate which equated to 193 respondents. Cronbach alpha was used to determine the internal consistency of the questionnaire which yielded a coefficient of 0.77. Mean and Standard deviation was used to answer research questions. The cutoff point of 2.50 was applied in decision making for the research questions thus; any item with a mean value of 2.50 and above was agreed as a veritable tool for enhancing extension agents in delivering information while any item value less than 2.50 was rejected as a veritable tool for enhancing extension agents in delivering information to farmers.

RESULTS

Result in table below revealed that the mean responses range from 2.10 for item 9 to 3.81 for item 7. The respondents agreed to items 1 to 8 but disagreed with item 9. This implies that mean responses in the way provision of electricity listed except electronics using mobile app can enhance extension agents in delivering information on cassava production to farmers for food security in Delta State. The findings of this study showed that extension agents and agricultural education lecturers in Delta State rated all the items in research question 1 above the cut-off point of 2.50. This is an indication that the respondents agreed that charging phones and laptops, using desktop to connect to internet, Ipad/Tablets for getting handy information and making some designs, Electricity helps the extension agents to use power point in making presentations to the rural farmers. Electricity helps the extension agents in using television to show some agricultural activities that can facilitate the learning of the rural farmers, radio for organizing programmes that can reach out to large number of farmers at a time, use electronics to monitor and evaluate farmers using mobile apps. The result agrees with Mgbenka and Mbah, (2018) who identified that rural electrification enhances the extension agents in delivering timely information on cassava production to rural farmers.

Table 1: Mean responses of extension agents and lectures on the ways provision of electricity in the rural areas can enhance extension agents in delivering cassava production information to farmers for food security in Delta State.

S/N	ITEM STATEMENT	MEAN	S.D	RANK
1	Charging phones to stay connected in delivering information information to rural farmers	3.50	0.44	Agreed
2	Charging of Laptops computer in making graphic work with the production of images in educating the rural farmers	3.55	0.67	Agreed
3	Desktop for connecting to internet in searching relevant agricultural information	3.67	0.68	Agreed
4	Ipad/Tablets for getting handy information and making some designs	3.56	0.65	Agreed
5	Electricity helps the extension agents to use power point in making presentations to the rural farmers.	3.64	0.54	Agreed
6	Electricity helps the extension agents in using television to show some agricultural activities that can facilitate the learning of the rural farmers.	3.68	0.59	Agreed
7	Radio for organizing programmes that can reach out to large number of farmers at a time	3.81	0.43	Agreed
8	Electricity helps the extension agents to plug the digital camera to show pictures and videos that can enhance the understanding of the rural farmers during training	3.65	0.47	Agreed
9	Use electronics to monitor and evaluate farmers using mobile apps	2.10	0.49	Disagreed
	Grand mean	**3.46**	**Agreed**	

SD = Standard deviation

Result in Table 2 below revealed that the mean responses range from 2.40 for item 7 to 3.81 for item 4. The respondents agreed to items 1 to 6 and 8 but disagreed with item 7. The grand mean of 3.50 indicates that construction of good road network in the rural areas can enhance extension agents in delivering information on cassava production to the rural farmers.The implication is that the respondents agreed that Quick access to farm inputs, Increase in the total area cultivated by the cassava farmers, Creating an enabling environment to promote agricultural production and alleviates poverty, Facilitation of technology transfer and adoption of best practices in planting cassava, Increasing the quick access to demonstration farms scattered around the community, Increase in the number of demonstration plots that where they teach the rural farmers new innovations, and increase in the number of extension services which facilitate the introduction of more efficient cassava farming system. The result is in agreement with Ndem *et al*., (2020), who reported that construction of good road network in the rural areas is one of the rural amenities lead to quick delivery of agricultural information and multiple demonstration plots by extension agents.

Table 2: Mean responses of respondents on the ways on the ways construction of good road network in the rural areas enhances extension agents in delivering information on cassava production to the rural farmers.

S/N	ITEM STATEMENT	Mean	SD	Rank
1	Quick access to farm inputs	3.54	0.59	Agreed
2	Increase in the total area cultivated by the cassava farmers	3.56	0.53	Agreed
3	Creating an enabling environment to promote agricultural production and alleviates poverty	3.67	0.65	Agreed
4	Facilitation of technology transfer and adoption of best practices in planting cassava.	3.81	0.57	Agreed
5	Increasing the quick access to demonstration farms scattered around the community.	3.65	0.78	Agreed
6	Increase in the number of demonstration plots that where they teach the rural farmers new innovations.	3.68	0.81	Agreed
7	Facilitating the mobilization of the community to address common problems regarding the outbreak of pests and diseases.	2,40	0.79	Disagreed
8	Increase in the number of extension services which facilitate the introduction of more efficient cassava farming system.	3.66	0.76	Agreed
	Grand mean	**3.50**	**0.08**	**Agreed**

S.D = Standard deviation

CONCLUSION

There is dearth of agricultural information to rural farmers in Delta State. It was discovered in this study that all the veritable tools if provided could enhance extension agents' effectiveness in closing the gap in information delivery to rural farmers. From the findings it was concluded that charging phones to stay connected in delivering information to rural farmers, radio for organizing programmes that can reach out to large number of farmers at a time, facilitating the mobilization of the community to address common problems regarding the outbreak of pests and diseases and increase in the number of extension services which facilitate the introduction of more efficient cassava farming system and creating an enabling environment to promote agricultural production and alleviates poverty. Certainly, the effectiveness of extension agents in information delivery to rural farmers, will lead to substantial increase in cassava production and ensure food security.

RECOMMENDATIONS

Based on the findings and conclusion of this study, the following recommendations were made:

1. Delta State government through the ministry agriculture should provide electricity to all rural areas to make the place lively.
2. The local government through the town unions and elites should among other projects construct good road network at the rural areas to enhance extension agents in delivering quick innovative information to rural farmers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This paper attempted to look at the approach to enhancing food security in Nigeria. Food security is an issue that needs the attention of stakeholders who are the leaders of this great Country Nigeria at various levels. From the Federal down to the local government rural farmers need support to boost and increase food production as well as the security and the safety of their lives. This is necessary because many rural farmers especially in the Northern parts of Nigeria are migrating to urban areas for safety due to the crisis going on in the country, which has left many homeless and jobless due to constant attacks. Crisis of any kind affect food supply, which may eventually lead to food insecurity. Insecurity of any kind could hinder or slow down growth and development of an individual or nation. Having enough food for all is what is needed for growth development in Sub- Sahara Africa and indeed Nigeria.

Keywords: *Food security, enhancing approach, Insecurity.*

INTRODUCTION

The relevance and significance of food to human existence cannot be overemphasized, thus steady food supply gives stability to individuals, families, societies, nations and the world at large. Iweoha *et al*. (2015) opined that food is the most basic need of man. Its adequacy affordability and security have been the pursuit of every community. One of the indices of a Nations development is the level of food and nutrition that is available to its citizenry. The disparity in national development between developed, developing and underdeveloped nations has been linked to the issue of food and security. Food security has to do with having at all times an adequate level of food and food products to meet the increasing consumption demand to mitigate fluctuation in output and price (Idrisa, 2008). In the same vein the World Bank Policy Study (2006) defined food security as access to enough food for active healthy living by all people at all times. On the other hand, food insecurity according to Food and Agricultural Organization (2010) refers to the consequences of inadequate consumption of nutritious food, considering the psychological use of food by the body as being within the domain of nutrition and health. Furthermore, malnourishment also leads to poor health, hence individuals fail to provide for their families. If left unaddressed, hunger will set in motion, and an array of outcomes that perpetuate malnutrition which reduce the ability of adults to work and give birth to healthy children this also will erode children's ability to learn and lead productive healthy and happy lives. This truncation of human development undermines a country's, potentials for economic development for generations to come (Otaha, 2013).

Despite all effort to meet up with food security in Nigeria, this effort has being abused due to the frequent crisis and unrest that has cause setback to agricultural activity, this has contributed negatively in enhancing food security in the states as people run away from homes to save their lives, this is the problem that need to be readdress to enhance food security, hence this study.

RESULTS AND DISCUSSION.

Results for this study were collected from previously established studies published in journals, conferences, textbooks and workshops. This was done to gather related information as a means of enhancing food security in Nigeria and the Sub-Saharan Africa at large.

Causes of Food Insecurity in Nigeria

In recent years, however, most farm lands have been deserted due to some illegal activities in Nigeria such as kidnapping, banditry, robbery and herder's clashes, which have created fear to farmers. If this menace is unchecked, farmers will prefer to stay at home in fear, while hunger and poverty have its way into homes of helpless farmers. Any country that fails to prepare or plan for its future, by making provision for the needed resources, food inclusive for development, that country is bound to remain in perpetual conflict in particular social, emotional as well as economic conflict. The survival and development of any nation in any aspect of life is associated with the strength and ability of that nation to handle issues and challenges with much ease, and this can only be achieved when food is available and accessible not on how much weapons of destruction available. The greatest weapon that has kept and built nations is sufficient food supply. The challenges in Nigeria have affected farm produce as many farmers are chased out of their farm lands; some are forced to relocate to urban areas where they depend on what people can offer them. According to Eme, Onyish Anthony Uche and Uche (2014). From Benue to Taraba, Nasarawa and Plateau in the North Central region and Zamfara and Kaduna States in the North West, clashes between farmers and herdsmen have left in its trail heavy loses of lives and property. These loses of lives have adversely affected farming activities and other related businesses. This has resulted in drastic reduction in farm outputs, a development that has heightened the fear of hunger.

Already most farmers in the affected States have abandoned farms for fear of being attacked by the herdsmen. For the predominantly farming communities of Nasarawa and Taraba States, farming is no longer business as usual. Several farmers have been displaced and dispossessed of their farms by armed men believed to be Fulani herdsmen. In the North West, Katsina, Sokoto and Zamfara States have been experiencing such activities of bandits, which have crippled farming activities in some parts of these states (FEWS NET, 2019).

Effects of Food Insecurity

Without food, lives will be wasted that is why many developing countries (Nigeria inclusive) face malnutrition problems such as Protein Energy Malnutrition (PEM). Apart from banditry, farmers also face challenges of drought, flood and even political instability. The growth and development of any country is tied to steady food supply. Food security remains an elementary and basic requisite for national development and as such, has been used by different people to convey different thoughts. The duo further reiterated that the rapid annual population growth in Nigeria, particularly in the last decades has seen food insecurity spiraling to become the norm in many homes, a trend which has escalated the intensity of poverty and lack of access to food. They also submitted that there is interplay of population growth, bad policies of government, lack of infrastructural development, rural-urban drift, and lack of incentives, poverty of peasants as well as undercapitalization to fuel the fangs of food insecurity in Nigeria (Igbinedion and Aihie, 2015). On the Nigeria food security outlook of famine, Early Warning system Network (2013) reported that Nigeria witnessed an unprecedented flooding cases between July and October, 2012 as a result of persistent heavy rainfall coupled with the release of water from several dams. These incidences caused the displacements of about 2.8 million people. Several months later, the affected households could still not fully recover their livelihoods. High level of food insecurity soon ensured in the regions due to low food stocks and high food prices. However, most households have started returning to their homes to rebuild their livelihoods (FEWSNET, 2013). The paper therefore examined an approach to enhancing food security in Nigeria.

Sustainability Development in Ensuring Food Security

In rethinking the approach for sustainable development in ensuring food security in Nigeria, the potentials of agriculture can be enhanced through institutional frameworks, governance and accountability. From the empirical study of Osabohien *et al.* (2018a) employing the Auto-regressive Distributed Lag (ARDL) technique in examining the role of institutional framework on food security, pointed out that institutional framework in Nigeria exerts a negative effect on food security, due to weak institutional quality in Nigeria. According to Osabohien *et al*. (2018b) the Nigerian agricultural sector remains an important sector of the economy, owning to the fact that the sector employs approximately 75% of the total work force, especially in the rural communities where most of the farmers earn their livelihood.

A study by Munene *et al.* (2018) employed the adaptive governance approach and noted the need to redirect strategies to achieve sustainable development. This would be more effective through the implementation of the framework requiring non-traditional management and governance approaches for substantial reduction of food waste. It was noted that Adaptive governance (AG) has been known to be the medium to drastically change the link between development and disaster risk, with potentially far-reaching implications for policy and practice to ensure food security. Osabuohien *et al.* (2018) used qualitative method with focus group discussion to examine how local institutions contribute to food (rice) production in Ogun State, Nigeria where they pointed out that local institutions play a key role in food production. In the study by Herbel *et al.* (2012), it was shown that achieving food security and the enhancement of dietary level is at the heart of the Sustainable Development Goals (SDGs). In line with that, Sidibé *et al.* (2018) noted that achieving food security can be done through the enforcement of rules and laws designed at the national level which remains one of the central institutional mechanisms for efficient multi-scale governance in most countries.

Enlightenment to Stakeholders by Policy Makers to Improved Food Security

According to Osabohien *et al.* (2019) policymakers are increasingly enlightened on the food security perspective, which has over the years reflected poorly in institutional terms. This study fills this gap by addressing the question as to what forms of accountability and governance is more appropriate to govern food systems in a more holistic way to achieve sustainable development goals (SDGs) by year 2030. In Africa, food security in relatively is high on the policy agenda of governmental authorities all over the globe (Candel, 2014). 'Food security governance' relates to the 'formal and informal' rules and processes through which interests are expressed, and decisions which are germane to food security in a country are prepared, implemented and enforced on behalf of members of society.Studies by Rodrik (2010), Osabuohien *et al.* (2018) to achieve food security reveal the need for equal opportunity in resource allocation and the delivery of services; coherent and coordinated policies, institutions, and actions. This means that the challenge for policymakers interested in addressing the key policy issues are to redesign strategies that allow countries to have a stable and affordable food supply that is equitably distributed as household food insecurity continues to be widespread with strong inequities across and within countries governance and strategies. Given the pathetic economic situation in some critical parts of the country, for example; the north east (Scribner, 2017; Ajayi and Adenegan, 2018), where starvation has been prevalent due to insurgency, the use of the right approach to addressing the national challenge of food insecurity, based on a platform of accountability, have remained a maximum requirement for achieving the right results of this subject area.

CONCLUSION

The study revealed that food security Can only be enhanced if government allocate equal resources and delivery of services and enforcement of rules and laws designed at the national level.Food security can also be enhanced by sustainable development and the strategies to reduce food waste.

RECOMMENDATIONS

Food security can be improved in the following ways:

1. Reducing food waste and food loss. ...
2. Improving infrastructure. ...
3. Promoting fair trading practices. ...
4. Paying attention to diversification. ...
5. Reducing the yield gap. ...
6. Combating climate change. ...
7. Addressing the indirect causes of food insecurity

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted in Ebonyi and Nasarawa States with the aim to identify preferred traits and market segments for the end users and for future Breeding programme activities. A multistage sampling was used to select 40 actors from each state for the group discussion. Data collected with the use of ODK (Open Data Kit) includes: current sweetpotato varieties being cultivated, sweetpotato preferred traits, preferred traits in future variety and sweetpotato market segment and were analyzed descriptively. Results indicated that the most important traits for future adoption of sweetpotato variety were high yield, big storage roots, early maturity, pest-free, white fleshed storage roots and white skin for market demand due to external appearance. Considering end users preferences and constraints, breeding programmes should involve the farmers, marketers, food processors and consumers to meet their need for easy adoption of new released varieties.
Keywords: *Adoption, Preferred traits, Stakeholders, Value chain and Breeding*

INTRODUCTION
It has been suggested that before commencing a breeding programme, there is need to find out what are farmers' priority needs in a variety, the farmers' preferences and practices (Chambers, 1997). The only effective way to get information and the opinion of stakeholders on the sweetpotato production and constraints to increase the crops utilization is by Participatory Rural Appraisal (PRA) (Gasura *et al*., 2008; Gibson *et al*., 2007). This is a research tool that involves community members. The methods include interviewing farmers with the use of matrix scoring and listed traits are paired and ranked (traits compared pair by pair). It also involved focused group discussions (FGD) which may involve the use of pictures and cards, questionnaire surveys and review of relevant articles (Fuglie, 2007; Mmasa *et al*. 2012). This was the case for selecting for traits for breeding including sweetpotato breeding.

The sweetpotato crop feeds over 100 million people in the poor communities in Africa, and therefore plays a significant role in human nutrition and livelihood. The crop is a cheap source of protein (2-8%), carbohydrate (32%), fibre (56%) and micronutrients, especially iron (70 mg/kg), zinc (33 mg/kg), and vitamin A that enhance normal body and mental growth and development. The mineral iron, provide 127% and 80% of daily estimated average requirements of children and women respectively. The roots can also be processed into flour for bread making, starch for noodles and as raw material for industrial starch and alcohol (Ukom *et al*., 2009). Tewe *et al*. (2000), reported that sweetpotato flour is utilized in sweetening local beverages like Kunu-zaki, burukutu, and for fortifying baby foods and fufu/pounded yam in Nigeria. The leaves are used as vegetables in yam and cocoyam porridge and are rich in proteins, vitamins and various minerals. Sweetpotato has varieties of varying colours including white, yellow orange and purple fleshed.

However, these existing varieties are degenerating as a result of pests and diseases, climatic changes and customer's demand. The natural way of developing new varieties is by hybridization. Hybridization is one of the ways to generate variability in sweetpotatoes and as noted by Nwankwo *et al*., (2011), it is one of the revolutionary tools which tend to create genetic novelty for selection. Considering end users preferences and constraints, breeding programmes should involve the client to meet their need for easy adoption of new released varieties. This paper was to provide a baseline for the development of traits preferred by end users with the following objectives: to identify what varieties the end users are currently using, to identify preferred traits by end users and constraints hindering sweetpotato production, to identify market segments for end users in order to increase sweetpotato production and utilization and to establish a database of preferred traits by sweetpotato end users for consideration in future Breeding program activities.

MATERIALS AND METHODS

The study area: The study was conducted in Nasarawa (North Central) and Ebonyi (Southeastern part of the country) States.

Nature of respondents: Participants were selected from sweetpotato stakeholders, who were made up of male and female farmers, marketers, consumers and food processors. These made up the Focus Discussion Group (FDG) in each State. The discussion was conducted using questionnaire, participatory methods and data were collected on variety dissemination, market segments and preferred traits of the sweetpotato.

Sampling procedure: A multistage purposive and random sampling was used. Firstly, the study purposively selected one agricultural zone with high intensive production of sweetpotato. Secondly, the study purposively selected one LGA with intensive production. In the third stage, two communities were selected randomly from the Local Government Area giving a sample of 4 communities – 2 from each State. In the last stage, 20 (10 males and 10 females) sweetpotato stakeholders were systematically selected giving a total of 80 respondents for the study – 40 from each state.

Data collection for SSQ: Data was collected using ODK, established during Participatory Rural Appraisal (PRA). Administration of a Semi-Structured Questionnaire was addressed through PRA (Gibson *et al*., 2007; Gasura *et al*., 2008).

FOCUS GROUP DISCUSSION (FGD)

Nature of respondents: FGD was established in each State. A total of 40 persons attended the meeting at the Ministry of Agriculture of each State. (Total of 80 participants from the two States) made up of: farmers, marketers, consumers and agricultural extension agents were the nature of the participants that made up the FGD in the two States. The 20 males and 20 females in each State regardless of heads of household and discussion were not based on sexes.

Data analysis: The data collected were analyzed descriptively using percentage, mean, standard deviation and frequency.

RESULTS AND DISCUSSION

Rank and trait preference of sweetpotato

The results in Table 1 showed the participants rank of sweetpotato among roots and tuber crops in the states, and preferred traits. The FGD in Ebonyi State ranked sweetpotato among the roots and tuber crops as third preferred crop after yam, cassava and after cocoyam; whereas in Nasarawa State sweetpotato was ranked 2nd after yam and after cassava and cocoyam.

Table 1: Participants Rank of sweetpotato among roots and tuber crops in the states, an preferred Traits

Responses	Ebonyi	Position	Nassarawa	Position
The rank of sweetpotato among roots and tuber crops in the states	Yam, Cassava, Sweetpotato, Cocoyam	3rd	Yam Sweetpotato, Cassava, Cocoyam	2nd
6 traits preferred in descending order	**High yield**, White fleshed, Big storage root, white skin, Extra-early maturity, High dry matter		**High yield**, Big storage root, White fleshed, No pests, Moderate sugar, White skin	

Source: Sweetpotato field survey in Ebonyi and Nasarawa States, 2022-2023

The study also highlighted the mention six traits preferred in a future variety in descending order as; high yield, white fleshed, big storage root, white skin, extra-early maturity and high dry matter while the group in Nasarawa State mentioned high yield, big storage root, white fleshed, no pests, moderate sugar and white skin. This showed common traits of high yield and big storage roots. Generally, every farmer requires high yielding varieties that would enhance his/her income generation. Big storage roots are a function of high yield. The mention of white skin, and white flesh colour in both States indicated that the market. Interestingly, Orange fleshed sweetpotato colour was not mentioned in the study areas – calling for new area of research and promotion.

Number of participants, Varietal status and Most preferred varieties

The number of participants, varietal status and most preferred varieties are presented in Table 2. he results in Table 1 indicated that 90% of the participants in the FGD cultivated landraces in Ebonyi State while 10% of the participants cultivated improved varieties. In Nasarawa State, the 95% of the participants in the FGD cultivated landraces while 5% cultivated improved varieties. This indicated the availability and possibly affordability and choice of landraces over improved varieties in both study areas.

Table 2: Number of participants, Varietal status and Most preferred varieties (FGD)

Responses	Ebonyi State		Nasarawa State	
	Freq. (40)	%	Freq. (40)	%
planted landraces	36	90.0	38	95.0
plant improved varieties	4	10.0	2	5.0
Do you regard sweetpotato as food and cash crop	40	100.0	40	100.0
Do you regard sweetpotato as food crop only	0	0.0	0	0.0
Do you regard sweetpotato as cash crop only	0	0.0	0	0.0
preferred Landraces	34	85	35	87.5
preferred improved varieties	6	15	5	12.5
Received varieties from Agric Extension Agents	3	7.5	6	15
Not received varieties from Research Institute	37	92.5	34	85.0
Not received training from research Institute	40	100.0	40	100.0

Source: Sweetpotato field survey in Ebonyi and Nasarawa States, 2022-2023

This was clearer as about 85% and 87.5% of the respondents in Ebonyi and Nasarawa State respectively reported that the landraces were their most preferred varieties than 15% and 12.5% who preferred improved varieties. The landraces being cultivated and preferred possess white skin and white fleshed storage roots. However, this may be that the traits appeal to the eyes and command high market price. However, the 7.5% and 15% from Ebonyi and Nasarawa States that cultivate improved varieties claimed that they obtained their seeds (planting material) it from the research Institute and Agricultural Extension Officers within their State. The reason behind the low adoption of some of these varieties as observed during the FGD was low dry matter as t complained that they could not pound the improved varieties as *fufu* because it of its softness. Hence, this call for breeding for end-users preferred varieties for ease of adoption and usage. The study also showed that all (100% each) the respondents in both States agreed that sweetpotato is both food and cash crop. This may be the reason why almost all the farmers cultivate sweetpotato for food since it is their staple food and as well cash crop for income generation. About 92.5% of the participants in Ebonyi State and 85% in Nasarawa State reported that they have not received any improved varieties from the Research Institute in the country, while 7.5% and 15% respectively do received. The high percentage of those who do not received improved varieties through Agricultural extension Agents was an indication of poor communication gap of Agricultural Extension Agents and Research Institute. This was also in the case of percentage (100% each for both states) that never received training from Research Institute indicating very poor circulation of information on sweetpotato technologies and as well confirmed the findings of poor use of improved varieties.

Marketing of sweetpotato roots and foliage

The results in Table 3 presented the respondents view on the marketing of sweetpotato root and foliage in both States under study. The results showed that about 37.5% and 50% (Ebonyi) and 25.0% and 60% (Nasarawa) of participants do not sale storage roots and fodder to livestock farmers respectively.

Table 3: Marketing of sweetpotato roots and foliage

	Ebonyi state		**Nasarawa State**	
Responses	**Freq(40)**	**%**	**Freq(40)**	**%**
Not marketing storage roots to livestock farmers	15	37.5	10	25.0
Sold fodder to livestock farmers	5	12..5	6	15.0
Not selling roots and fodder to livestock farmers	20	50	24	60.0
Not selling leaves as vegetable for human consumption	0	0	0	0

Source: Sweetpotato field survey in Ebonyi and Nasarawa States, 2022-2023

However, the discussion revealed that the livestock farmers such as pigs, sheep and goats purchase storage root (especially un-marketable roots) of sweetpotato for fattening their animals. Also 12.5% and 15 % of the participant in Ebonyi State and Nasarawa State respectively sold sweetpotato leaves as fodder to livestock farmers. This shows that even the leaves of sweetpotato could be used for income generation although many do not concept the idea (sweetpotato livestock fodder business) as a business. However despite the fact that the leaves of sweetpotato are rich in protein and vitamins, there was no business as to commercialize it as vegetable for human consumption. This was against a prior expectation as none (0.0% each) of the participants reported selling sweetpotato leaves as vegetable for human consumption probably due to the unawareness of sweetpotato leave diet, hence calling for exploitation and awareness.

Preference for Local Varieties

The reasons why the Focus Group preferred the local varieties are presented in Table 4.

Table 4: Preference for local Varieties

Responses	Ebonyi State Frequency(40)	%	Nasarawa State Frequency(40)	%
Variety known for long time	18	45	17	42.5
Possess white flesh and white skin colour	7	17.5	9	22.5
Local varieties can be harvested any time	6	15.0	4	10.0
Good cooking quality	2	5.0	3	7.5
Can be pounded for fufu	4	10.0	3	7.5
Yield	3	7.5	4	10.0

Source: Field survey, 2022-2023

The study showed that the stakeholder preferred their local varieties because of it is known for a long time (45% and 42.5%); possess white flesh and skin colour (17.50% and 22.50%), harvested any tie (15.0% and 10.0%), can be pounded as *fufu* (10.00% and 7.50%) and yield (7.5% and 10.0%). From the discussion, it was observed that some of them have seen the improved varieties but to change to new variety or varieties not known to their forefathers had been difficult, it seems as if they were betraying their forefathers' crop. Other reasons given for clinging to the local varieties was artistic. By this assertion, they acknowledged that local varieties were low yielding. Low yield is a bad trait in any crop. Farmers do not want any low yielding variety for food and income generation.

Traits preferred in future sweetpotato varieties

The traits the focus group would prefer in future sweetpotato variety are presented in the Table 5.

Table 5: Traits preferred in future sweetpotato varieties

Traits	Ebonyi state Frequency	%	Nasarawa State Frequency	%
High yield	9	22.5	8	20.0
White skin colour	6	15.0	5	12.5
white fleshed storage root colour	2	5.0	3	7.5
Big storage root	3	7.5	6	15.0
erect varieties	0	0	0	0
high dry matter	5	12.5	6	15.0
resistant to pests	4	10.0	1	2.5
moderate sugar	0	0	4	10.0
low sugar	5	12.5	0	0
drought tolerant	6	15.0	5	12.5
low fibre	0	0	2	5.0

Source: Sweetpotato field survey in Ebonyi and Nasarawa States, 2022-2023

The study showed that about 22.5% and 20% of the participants in Ebonyi and Nasarawa States reported that they would like their future sweetpotato varieties to be high yielding. This was followed by white skin colour and drought tolerant (15.5% and 12.5% each), high dry matter and (12.5% and 15%), low sugar (12.5% for Ebonyi), and resistant to pest (10.0% and 2.5%) for Ebonyi and Nasarawa States respectively. However, as rainfall is becoming irregular and unpredictable, farmers tend to go for future varieties to be drought tolerant. Dry matter content is a component of yield of a variety, they would prefer their future varieties to possess high dry matter in the storage roots. Fibre content in the storage roots reduces flour yield, however, 5% of those that participated in Nasarawa State will prefer future sweetpotato varieties to contain low fibre in the storage roots. In the next generation sweetpotato varieties, 12.5% of the focus group participants in Ebonyi State and 10% that participated in Nasarawa State want their new varieties to be of low sugar and moderate sugar respectively in their storage roots. No future sweetpotato varieties would contain all these traits in one variety only a combination of traits for a variety for various end–users.

CONCLUSION

The most important traits for adoption of sweetpotato variety are high yield, big storage roots, early maturity, pest-free, white fleshed storage roots and white skin for market demand due to external appearance. Others include: taste, nutritive value and multipurpose utilization, considering end users preferences and constraints, breeding programmes should involve the farmers, Marketers, food processors and consumers to meet their need for easy adoption of new released variety. Based on the focus group discussion, there is need for training of the sweetpotato stakeholders on sweetpotato production in some related areas. As most of the farmers cultivate landraces indicating that the very few released varieties were not in the hands of the stakeholders. The study therefore call for urgent need for awareness and sensitization of the farmers, Marketers, food processors and consumers of the importance and benefits of these sweetpotato varieties released by the NRCRI for easy adoption.

Many of the traits mentioned as constraints to all the stakeholders need to be addressed by breeding team while others were of agronomy and post-harvest handling.

ACKNOWLEDGEMENT

The Authors wish to thank CIP (International Potato Center, Lima Peru, South America) for funding this Survey under **Sweet GAINS PROJECT** in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined factors influencing biodiversity losses among rural households in Kogi State. A multistage sampling technique was adopted and a sample size of 200 respondents drawn from six Local Government Areas spread across the three agricultural zones of the state. Data were collected with the aid of structured questionnaire and were analysed using percentages, means and Varimax rotated factor matrix. The results elucidated that majority of the households were headed by males. The average age of the respondents was 51 years with average education attainment of 6 years with an annual income of 252,000 naira. The household and farm sizes were 14 persons and 2.7 hectares respectively. The results also elucidate that cutting down of trees (0.931), bush burning (0.878), increase in population (0.745), grazing (0.760), erecting of buildings (0.552) hunting activities (0.530), destruction of habitats (0.520), mining (0.511) were variables loaded high under factor 1 (Socio-economic constraints). Furthermore climate change (0.896), erosion (0.867), over flowing of streams (0.762), natural disaster (0.752), pollution (0.531) and drying up of water bodies (0.412) were significant under factor 2 (geographical constraints). The study recommended policy measures that would help improve and integrate the livelihood of rural communities and reduce their overdependence on the natural environment in order to promote sustainable environment.
***Keywords:** Biodiversity Losses, Rural Households, Kogi state*

INTRODUCTION
Biodiversity has been and will continue to be an important part of agricultural practices worldwide. Biodiversity is important because it provides man with many resources. It plays a crucial role in maintaining ecosystem functions and services such as pollination, pest control, and soil formation (Abere and Opara, 2018). Biodiversity in Nigeria is seriously under the threat of extinction from human activities, climate change, economic development, land use changes from agriculture, invasive species and pollution, crude oil exploration and exploitation, canalization that has threatened mainly the mangroves, deforestation, desert encroachment, over hunting, land use, road and residential buildings construction (Anwadike, 2020). The growing concerns over the increasing rate of biodiversity loss globally have sparked extensive research into various ways by which biodiversity composition can be preserved (Bellard *et al.*, 2012). Loss in biodiversity due to human activities have been rapid recently than at any time in human history and the factors responsible for biodiversity loss are either steady, show no evidence of declining over time or increasing in intensity (Millennium Ecosystem Assessment (MEA), 2005; David (2011)). Oribhabor (2016) stated that species are becoming extinct at the fastest rate known in geological history due to human and industrial activities which continue to result in the discharge of various pollutants into the environment threatening the health of the population and damaging the quality of the environment. Consequently, biodiversity losses alter ecosystem processes, undermine ecosystem functioning and weakens the resilience of ecosystems to environmental change and compromise their ability to continuously supply ecosystem services, loss of livelihoods, increased contact with diseases and reduced food security. In spite of the dare consequences of biodiversity loss on human existence, there are inadequate empirical evidences on knowledge about factors that influence biodiversity loss in the study area. Thus, there is urgent need to undertake a study of this nature to provide empirical evidence for policy direction.

METHODOLOGY

The study was conducted in Kogi State, Nigeria. The population of this study consisted of all heads of rural households in the four agricultural zones in Kogi State namely: namely Aiyetoro-Gbede (Zone A), Anyigba (Zone B), Koton karfe (Zone C) and Aloma (Zone D). A Multi-stage sampling procedure was used for data collection. In the first stage, three out of the four agricultural zones in the state were randomly selected namely: The selected zones were Anyigba, Aloma and Koton karfe. Two (2) Local Government Areas (LGAs) were purposively selected from each of the three agricultural zones due to abundant agricultural activities carried out in the zones resulting in a total of six (6) LGAs in the second stage. The selected LGAs are Ajaokuta, Ankpa, Dekina, Ofu, Olamaboro, and Lokoja. In the third stage, two rural communities were randomly selected from each of the LGAs using simple random sampling techniques to get six communities. Finally, a sampling frame was developed from the population of households from the selected communities which was used to obtain the total sample size of 200 respondents for the study, using 10% proportional allocations. Data were collected with the aid of structured questionnaire. Descriptive statistics was used to achieve objective one while factor analysis was used to achieve objective two. Variables for this study were measured as follows: age (Years), Sex (Male=1, otherwise =0), Marital status: (married = 1, otherwise = 0), Household size (number), Income (naira), level of education (years spent in school), Farm size (hectares), primary occupation (farming=1, otherwise=0). A Four (4) point Likert-type scale of: strongly agree (4), agree (3), disagree (2) and strongly disagree (1) was used to determine the perception of the respondents on the factors influencing biodiversity losses in the study area.

RESULTS AND DISCUSSION

The result in Table 1 shows the distribution of the respondents according to socio-economic characteristics. The result indicates that one hundred and fifty nine (159) representing 79.5 were male headed.

Table 1: Distribution of respondents according to socio-economic characteristics (n=200)

Parameters	Frequency	Percentage	Mean
Sex			
Male	159	79.5	
Female	41	20.5	
Age (Years)			
31-40	21	10.5	
41-50	73	36.5	
51-60	73	36.5	51
≥61	33	16.5	
Marital status			
Married	180	90.5	
Others	20	9.5	
Level of education			
Non-formal	48	24	
Primary education	65	32.5	6
Secondary education	63	31.5	
Tertiary education	24	12	
Household size			
1-5	15	7.5	
6-10	102	51.0	
11-15	67	33.5	14
16-20	16	8	
Farming Experience (Years)			
1-10	19	9.5	
11-20	91	45.5	18
≥21	90	45.0	
Farm size (Hectare)			
1-2	88	44	
3-4	86	43	2.7
≥5	23	13	
Farming Occupation			
Farming	196	98.0	
Others	4	2.0	
Annual income (Naira)			
≤100,000	18	9.0	
100,001-200,000	66	33.0	
200,001-300,000	73	36.5	252,000

300,001-400,000	35	17.5
≥400,001	8	4.0

Source: computed from field data (2023)

The average age of respondent in the study area is 51 years with average education of 6 years. This suggests that the average household head in the study area barely completed primary education. The average household size in the study is 14 persons. Large family members are considered important asset as source of farm labour.

The average farming experience of respondents is 18 years with average farm size of 2.7 hectares with an average annual income of 252,000 naira. This indicates that an average respondent is a peasant barely earning to survive. This situation is worrisome and could lead to more dependency on nature. The result in Table 2 shows varimax rotated factors constraining biodiversity in the study area as perceived by the respondents. Based on scree plot and total variance explained, two (2) factors were extracted and retained for naming and interpretation of constraints to biodiversity. In this wise, clustered variables in the rotated factor matrix, factor 1 and 2 were named socio-economic constraints and geographical constraints respectively. The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy result was 0.806 above the cut-off of 0.50 and above (Yong and Pearce, 2013). The variables that loaded high under factor 1 (Socio-economic constraints) were cutting down of trees (0.931), bush burning (0.878), increase in population (0.745), grazing (0.760), erecting og buildings (0.552), hunting activities (0.530), destruction of habitats (0.520), mining (0.511). The high factor loadings illustrate how closely the variables are to the factor (socio-economic). This result collaborates in part with the findings of Asthana and Asthana (2012), Aguoru and Audu (2012).

Table 2: Varimax rotated factor matrix for factors constraining Biodiversity in the study area (n=200)

Variable	Factor	
	1	2
Bush burning	.878**	.302
Erosion	.316	.867**
Increase in population	.745**	.351
Cutting of trees	.931**	-.262
Grazing	.760**	-.326
Hunting activities	.530**	.321
Erecting buildings	.552**	.254
Over flowing streams	.073	.762**
Poor income	.502**	.279
Climate change	-.310	.896**
Extraction of herds	.325	.221
Natural disaster	-.204	.752**
Destruction of habitats	.520**	.319
Pollution	.382	.531**
Bandits/militant activities	.500**	.023
Mining	.511**	.032
Drying of water bodies	.034	.512**

Source: Computed from field data (2023)
** factor loadings of 0.50 and above are significant

The variables which loaded high in the factor (geographical constraints) included: climate change (0.896), erosion (0.867), over flowing of streams (0.762), natural disaster (0.752), pollution (0.531) and drying up of water bodies (0.412). This result collaborates with finding of Muluneh (2021). The geographical constraints have both direct and indirect effects on biodiversity. The direct effects can be seen in terms high temperatures increasing the frequency and intensity of fire outbreaks and droughts. The indirect effect can be seen as how it can alter the cultural, social and economic landscape of human activities that affect biodiversity. The cumulative effects are extinction of some species, migration, disease outbreak and low agricultural yield. For instance, air pollution is harmful to humans and other living things. Climate change is known to be responsible global warming resulting in rising earth's average temperature causing large scale wildfire outbreaks seen in Turkey, Greece, Italy, Portugal, Cyprus, Algeria and Tunisia.

CONCLUSION AND RECOMMENDATIONS

The study concludes that the major factors influencing biodiversity losses in the study area are cutting down of trees, bush burning, increase in population, grazing, erecting of buildings, hunting activities, destruction of habitats, mining. Other factors that have significant effects on biodiversity include climate change, erosion, over flowing of streams, natural disaster, pollution, drying up of water bodies. The average rural households are largely peasants and their livelihoods depend largely on exploitation of the natural resources which in turns depleting the biodiversity. Based on these findings, the following recommendations are made:

i. Designing integrated crop-livestock-fisheries systems for the recycling of nutrients among the farm components;
ii. Setting up agro-forestry system to deliver soil retention, water and air purification services;
iii. Provision of social amenities in the rural communities in order to improve the livelihood of the rural communities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study assessed the growth rate of cassava production and the doubling time of cassava production between 1961 and 2014 in relation to Structural Adjustment Programme (S.A.P.) and Agricultural Transformation Agenda (A.T.A.) policies during the period under study. Pre-SAP period and post-SAP periods were also assessed. The data were sourced from the Food and Agricultural Organisation (1961-2014). Exponential functions as well as the quadratic function in trend variables were used. The result shows that the mean growth rate of cassava in hectares was 8.3%, negative yield of -2.4% and a 7.6% growth rate of cassava output translating into a doubling time of 8 years for cassava hectarage, -23years for yield and 7 years for output. The increase in output might be a result of the expansion of hectarage under cultivation. It was observed that before the introduction of the Structural Adjustment Programme (SAP), the hectarage under cultivation increased by 1.8%, eventually leading to an increase in yield by 0.2% and output by 2.0%. The result under the SAP period shows the growth rate of hectarage, yield, and output to be 16%, -1.0%, and 0.0% respectively. However, there was an improvement in the growth rate of the hectarage, yield, and output after the SAP period, the growth rate of cassava hectarage increased by 2.0%, yield increased by 0.1%, and output increased by 27.2%. The result of the study under the ATA period shows a progressive growth rate of hectarage and output but with a declining rate of growth of yield. Hectarage grew by 18.4%, while yield decreased by -12.0% and output increased by 5%. The declining yield may be due to the non-adoption of modern technology and the conservative nature of the farmers. The study also observed that the introduction of S.A.P and A.T.A. does not appreciably improve the acceleration of the growth rate of cassava production as the doubling time is more of stagnation and deceleration. It was recommended that only technologically driven agricultural policies that will increase production and sustainability be introduced.

INTRODUCTION
Nigeria is the largest producer of cassava in the World with an annual estimate of 60.001 million metric tons, 7.737 million hectares cultivated, and a yield of 77,543 kg/ha, (Food and Agricultural Organization Statistical Database (FAOSTAT, 2021). The country has consistently been ranked as the world's largest producer of cassava since 2005, (FAO, 2012). Global production of cassava amounted to about 278 million metric tons in 2018 out of which Africa's share was put at about 61% (FAOSTAT, 2020). In the same period, Nigeria's production alone increased from 18% (about 42.5 million metric tons) in 2010 to 21.5% (about 59.8 million metric tons) in 2018. FAO projects that by the year 2025, about 62% of global cassava production will be from sub-Saharan Africa (FAOSTAT, 2020).
This development has been attributed to the significant advances made in cassava variety improvement in Nigeria by the International Institutes for Tropical Agriculture (IITA), National Root Crops Research Institutes (NRCRI), Umudike in collaboration with the National Co-ordinated Research Programme (NCRP) on cassava Eke-okoro, and Njoku, (2012). Nigeria Presidential Initiative on Cassava launched in 2003 brought cassava and its potential to the national limelight. The Initiative has a goal of promoting cassava as a viable foreign exchange earner for Nigeria, and also developing the cassava production system in order to sustain the national demand. Another way to increase production is to plant improved varieties that are proven to be disease-tolerant and higher yielding (Ogunyinka and Adebayo, 2020). Another recent government action on cassava production was the federal government's Agricultural Transformation Agenda (ATA). The transformation focuses on the cassava value chain with the production of High Quality of Cassava Flour (HQCF) and making it mandatory for the replacement of

up to 10% wheat flour in bread with cassava, (Asanke-pok, 2013). As part of its effort to develop a vibrant cassava market locally and internationally, the government designed a cassava master plan in 2005 thereby encouraging large production of cassava in the country.

In Africa, cassava is an important staple crop particularly in the tropical countries as the crop has a high potential of feeding rapidly increasing population and is generally more affordable if compared to other staples. In Nigeria, it is the third most consumed crop in the country (FAOSTAT, 2012) after Sorghum and millet, followed by rice, yam and maize. Akinpelu *et al.* (2011) mentioned that the consumption of cassava for poor household in urban areas has double that of non-poor households while in rural areas, the consumption of cassava by poor households has triple that of non-poor households. In Nigeria, cassava is consumed in all regions of the country. Although cassava is rich in carbohydrates, it is very poor in protein and vitamins and as such, several projects are underway to improve the nutrition potential of cassava (via the introduction of Vitamins A) so as to make the crop more suitable for combating hunger and food security issues. The majority (88%) of cassava produced in Africa is used for human food, with over 50% used in the form of processed products (Oyewole and Eforuoku, 2019). Although the crop is considered a staple in many countries, this situation is changing in some countries where cassava is now an industrial and cash crop (Reincke *et al*., 2018).

In Nigeria, cassava products can be grouped into five categories. These are fresh roots, dried roots, pasty products, granulated products, and cassava leaves. A wide array of products can also be processed from cassava. Firstly, the freshly peeled tubers can be either boiled or roasted for food. Boiled tubers can also be further pounded or added to soup and stews. To prevent rapid deterioration, non-food products such as starch and chips (animal feed) can also be produced from the tubers. Chips can also be further grounded into flour for human consumption (for baking pastries, pasta production, etc.). Fermented cassava can also be used for alcohol production or further processed into biogas (Kenyon and Ochieng, 2006). Most advanced processing forms can transform cassava into biodegradable packaging, starch sweeteners, etc.

METHODOLOGY

This section assessed the growth rate of cassava production and the doubling time of cassava production between 1961 and 2014 in relation to Structural Adjustment Programme (S.A.P.) and Agricultural Transformation Agenda (A.T.A.) policies during the period under study. Pre-SAP period and post-SAP periods were also assessed. The data were sourced from FAO (1961-2014) Exponential function as well as the quadratic function in trend variables were used.

The exponential function is given as:

$$Q_t = ae^{bt} \quad (1)$$

Implicit of the model was linearized to give the following equation

$$\ln Q_t = a + bt + u \quad (2)$$

where: Q_t = crop variable: production (tonnes), hectarage (ha) and yield (kg/ha), t = trend variable 1961-2014, u = error term, b = estimated coefficient, a = constant. To determine the effect of macroeconomic policies on the cassava by measuring the acceleration and deceleration in the cassava crop economy during the period under study, the log quadratic trend equation was estimated as follows:

$$\ln Q_t = a + bt + ct^2 + u \quad (3)$$

According to Ghosh, (2010), Ammani, (2015), and Nmadu *et al.*(2015), the positive significant value of 'c' indicates acceleration while a negative implies a deceleration and insignificant values imply stagnation in the growth process. The doubling time is the number of years it will take to double the rate of growth of a time series. The doubling function is presented as follows.

$$n = {}^{ln2}\!\Big/_{ln\left[1+\left(\frac{r}{100}\right)\right]} \quad (4)$$

Where n = doubling time (in years)

r = growth rate in (percent per year) obtained from the growth equation.

According to Barlett, (2011), the approximate life span of an American is 69.7, the researcher indicated that when r = 1% per year, n = 69.7.

The formula therefore can be approximated by equation (5a)

$$DT = 69/r \quad (5a)$$

(Barlett, 2011 and Nmadu, 2015) where DT = doubling time. In this study, the doubling time was determined using 55 as the approximate life span of a Nigerian. United Nations Population Fund, (UNFPA, 2019). Thus equation (5a) is transformed into:

$$DT = 55/r \quad (5b)$$

The compound growth rate was computed for each variable as follows:

$$R = (e^{b-1}) \times 100 \quad (6)$$

Where r = compound rate of growth, b = estimated coefficient from equation (1) and (3) were applied to the entire period variable and the sub-periods in the study, that is, pre-SAP, 1961-1985 SAP, SAP- 1986-1993, Post-SAP-1986-2010 and ATA- 2011-2014.

Trend of cassava hectarage, yield and output in Nigeria from 1961 to 2014

Table 1 presents the compound growth rate computed from the exponential growth equation of cassava production in Nigeria. The result shows that the mean growth rate of cassava hectarage was 8.3% which translated to negative yield of -2.4% and 7.6% growth rate of cassava output. The increase in output might be as a result of expansion of hectarage under cultivation. The entire periods under study shows an encouraging result on the hectare, yield, and output with growth rates of 4.1%, 0.1%, and 4.2% respectively. It was observed that before the introduction of the Structural Adjustment Programme (SAP), the hectares under cultivation increased by 1.8%, eventually leading to an increase in yield by 0.2% and output by 2.0%. This result is in agreement with Nmadu *et al.* (2015) that the expansion in area planted to yam and cassava was the main component of increased production. Although cassava was not a traded commodity during the Agricultural Marketing Board (pre-SAP) period, there was a positive increase in the growth rate of cassava production in Nigeria. This development was due to the establishment of the national and international collaborative cassava development programme in 1970 which made national and international research institutions become actively involved in cassava improvement and development in Nigeria and eventually led to the development of new improved varieties of cassava. It was observed that the yield of cassava during the SAP period declined and output was stagnant despite large expansion of cassava hectarage under cultivation, most likely due to outdated production technology as well as low management skills. The result under the SAP period shows the growth rate of hectarage, yield, and output to be 16%, -1.0%, and 0.0% respectively. However, there was an improvement in the growth rate of the hectarage, yield, and output after the SAP period.

Table 1 Compound Growth rate of cassava production computed using the exponential coefficients

Variable	Hectarage	Yield	Output
Entire periods	4.0713	0.1181	4.1941
Pre-SAP	1.8019	0.2222	2.0270
SAP	15.9031	-0.9645	0.0030
Post SAP	1.6068	0.0816	27.2476
ATA	18.3533	-11.6856	4.5229
Mean	8.34658	-2.44380	7.59892

Source: Computer result output, 2019

The growth rate of cassava hectarage increased by 2.0%, yield increased by 0.1%, and output increased by 27.2%. The improvement recorded in cassava production was due to presidential initiative policies introduced after SAP which led to the establishment of the Cassava Multiplication Programme (CMP) and Root and Tuber Expansion Programme (RTEP) with the objective of enhancing national food self-sufficiency, improving rural households' food security and income for poor farmers within the cassava producing States of Nigeria, (Iyagba and Anyanwu, 2012). The Agricultural Transformation Agenda (ATA) was another policy established in 2011. The result of this study under the ATA period shows a progressive growth rate of hectarage and output but with a declining rate of growth of yield. Hectarage grew by 18.4%, while yield decreased by -12.0% and output increased by 5%. The declining yield may be due to the non-adoption of modern technology and the conservative nature of the farmers. The increase in hectarage and output under ATA was probably due to farmers' accessibility to agro-inputs through a voucher system of distribution.

Table 2 shows the number of years it will take to double the rate of growth of cassava time series (Doubling time). The result shows that it will take the mean of 8 years (that is by the year 2022 from 2014) to double the rate of growth of cassava hectarage based on the current trend. This translated to high cassava output which will take 7 years to double the growth rate (that is by the year 2021) and the doubling time for yield indicated that cassava production technology is as old as 1992. This confirms the assertion that most policy reforms in the past were translated to '’hectarage expansion‟, meaning that more land is put under cultivation which leads to over-utilization of labour and low efficiency of the other inputs (Nmadu, *et al.*, 2015). The result also shows that pre-SAP and post-SAP periods will take a very long time to double the growth rate of cassava hectarage and yield.

Table 2 Doubling time for cassava production in Nigeria

variables	hectarage	yield	output
Entire period	13.5092	465.7070	13.1136
Pre-SAP	30.5233	247.5247	27.1336
SAP	3.4584	-57.0243	18,3333.333
Post-SAP	34.2295	674.0196	2.0185
ATA	2.9967	-4.7066	12.1603
Mean	8.3466	-22.5059	7.3110

Source: Computer result output, 2019

Table 3 shows that the hectarage, output, and yield exhibited significant and positive trends in the entire period for both hectarage and output except for the cassava yield. During this period the coefficient of the trend variable was significantly different from zero at 1% for hectarage and output and yield non-significant. Table 3 also presents the acceleration (A), deceleration (D), and stagnation (S) of the cassava growth rate. The results show that over the entire period, the output and hectarage accelerated with the exception of cassava yield which was decelerated. The pre-SAP period shows that hectarage was stagnant which led to a deceleration of yield and output while during the SAP period, there was an acceleration of cassava hectarage but yield declined and output remained stagnant. The post-SAP period shows an accelerated growth rate for cassava yield and output but there was a decline in the growth rate of hectarage, probably due to better farming methods and adoption of technology. The ATA period was not different from other sub-periods; the result under the ATA period indicated accelerated output with a stagnant growth rate of hectarage and yield. During all the sub-periods acceleration was observed to be highest compared to deceleration and stagnation for cassava hectarage. The implication of this is that, the policy presentation for cassava translated to a sustained increase in growth rate.

RECOMMENDATION AND CONCLUSION

Following the introduction of policies that affect cassava production in Nigeria, the research analyzed the cassava production in Nigeria for the periods of 1961 to 2014, it was observed that it is very important to give cassava production the desired attention with an aim of improving the production in the future. The reintroduction of the Agricultural Transformation Agenda that seeks to distribute inputs through the voucher system will enable the inputs to reach the target farmers at the right time and this will encourage commercial agriculture in Nigeria. Adequate funding of research institutes and universities of Agriculture will go a long way in providing the desired high-yielding seeds to the farmers hence only technologically driven agricultural policies that will increase production and sustainability be introduced. Even though the result shows that there was more acceleration in output there was deceleration and stagnation in yield and hectarage in PRE-SAP, SAP, POST-SAP, and ATA periods. The result shows that the mean growth rate of cassava hectarage was 8.3%, negative yield of -2.4% and a 7.6% growth rate of cassava output translating into a doubling time of 8 years for cassava hectarage, -23years for yield and 7 years for output.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Cocoa, a significant cash crop with a historical economic role, has been impeded by climate change, more especially the production aspect. The aspects of climate change that are actually detrimental to cocoa production by way of increase in plant diseases are a prolonged dry season and too much rainfall. Resurrecting cocoa production requires analyzing how cocoa farmers perceive and respond to climate change. This study therefore examined the adaptation strategies for the control of diseases caused by climate change among Cocoa Farmers in Ondo State, Nigeria. The study was carried out in Ondo state. Information was collected from the respondents with the aid of structured questionnaire. One hundred and forty four cocoa farmers' information was used for analysis. Data was analyzed using descriptive statistics such as frequencies and percentages. Majority (83.3%) of the cocoa farmers were male. Eighty seven percent of the farmers were married. About 79% of cocoa farmers in the study area are educated. Fifty two percent of the farmers have between 5 and 10 years of farming experience and 42% have greater than 10years of farming experience. Majority (95.8%) of the farmers have knowledge on weather. Twenty five percent of cocoa farmers in the study area are of the opinion that excessive rainfall is as a result of climate change. Six percent understand that increased incidence of drought is as a result of climate change and 16.6% affirmed that the pest and disease infestation on their farms is as a result of climate change. The strategies that were used are processing of crop to minimize postharvest losses (91.7%), crop varieties that are well acclimated (87.5%) and shade crops (87.5%). Fifteen percent reported that they experienced low effect of black pod disease on their farm after excessive rainfall, more so when fungicide is not properly or regularly sprayed, 52.1% experienced medium effect while 29.2% had high effect of the disease on their farm. Cocoa farmers in the study area have accepted the fact that climate change is a major issue in the area and they have come up with some adaptation strategies to adjust to the situation.
Keywords: *Climate change, Cocoa production, Diseases, Ondo state*

INTRODUCTION

Climate change has noticeably impacted agricultural production, particularly in the case of cocoa beans (Asante *et al*., 2017). Every stage of cocoa bean production relies heavily on favorable climatic conditions (Nabuurns *et al*., 2007). Among various climatic factors, rainfall variations exert a more substantial influence on cocoa yield than any other (Akrofi-Atitianti *et al*., 2018). The crop's sensitivity to soil water deficiency is pronounced, necessitating well-distributed rainfall throughout the growing season (Parmesan *et al*. 2022). Optimal cocoa development thrives in a hot and humid atmosphere (Adegbenro *et al*., 2023). Acidic soils are tolerable for cocoa, as long as their nutrient content remains high. The development and ripening of cocoa pods are susceptible to black pod disease, which closely correlates with weather patterns and climate (Fowler and Coutel, 2017). This disease thrives in damp environments, particularly impacting the period between July and August when the short dry spell turns wet, especially in West Africa.Oluyole and Lawal (2008) indicated that a possible loss in yields of between 50% and 70% in cocoa production as a result of climate change is imminent if no chemical measures were applied. Sucking insects like mirids pose a threat, especially when moisture deficits are severe from September to March (Okoffo *et al*., 2016). Intense light enhances insect proliferation. Notably, climate change could alter the pace and phases of cocoa pests' and pathogens' development. Hence, understanding climate change among cocoa farmers becomes paramount.

Perception, defined as an accurate grasp of reality, is key to climate change adaptation. It involves using senses to comprehend the environment. Farmers' experience is invaluable in gauging climate change. Consequently, adaptation hinges on recognizing change. Farmers who discern climate shifts are more likely to consider adaptation. Adaptation encompasses adjustments made to leverage new opportunities or mitigate losses due to external changes (Peterson *et al.*, 2011). It's a means of enhancing society's resilience to various temporal scales of change. In farming, adapting to climate change involves farm households taking action to harness positive impacts or alleviate negatives. Adaptive capacity, as per IPCC (2001), refers to a system's ability to adjust to, cope with, or exploit changes. Cocoa, a significant cash crop with a historical economic role in West Africa, has been impeded by climate change. Boosting its production requires a study on how these farmers view and adapt to climate change. This study seeks to understand climate Change and adaptation strategies for the control of diseases among cocoa farmers in Ondo State.

Objectives

The-objectives of the study-were to;

- determine the adaptation strategies for the control of diseases caused by climate change in the study area

-assess the effect of climate change on pests and diseases

METHODOLOGY

The study was carried out in Ondo state in the year 2022. Three Local Government Areas (LGAs) were purposively selected known for cocoa production. The LGAs selected were Idanre, Ondo East and Akure South. These LGAs were selected based on the fact that they are high cocoa producing LGAs in the State. Apart from this, the infestations of pests and diseases for cocoa are high in the area. Fifty farmers were randomly selected in each LGA. A total of one hundred and fifty cocoa farmers were selected in the state in year 2022, after sorting out for missing data one hundred and forty four cocoa farmers' information were used for analysis. Information was collected from the respondents with the aid of structured questionnaire. The data retrieved from the information collected were analyzed using descriptive statistics such as frequencies and percentages. The statistical package used for the analysis is STATA.

RESULTS AND DISCUSSION

Socio economic characteristics of Cocoa Farmers in Ondo state

Table 1 revealed the Socio economic characteristics of cocoa farmers in Ondo state. Majority (83.3%) of the cocoa farmers were male. Oluyole *et al*. (2023) affirmed that men are mostly involved in tree crop production while women are more involved in processing. Eighty seven percent of the farmers were married, 6.3% were single, 4.2% were divorced while 2.1% were widowed. The marital status of farmers can play a great role in labour availability on the farm. For farmers that are married they might use more of family labour as compared to hired labour (Pierotti *et al*., 2022). Their wives and children can assist in harvesting, breaking pods, fermentation and drying of cocoa beans. About 79% of cocoa farmers in the study area are educated. They either have a primary, secondary or tertiary level of education. Education plays a great role in the adoption of new techniques. Fifty two percent of the farmers have between 5 and 10 years of farming experience and 42% have greater than 10years of farming experience. Wongnaa and Babu (2020) affirmed that farmers' years of experience in cocoa farming could assist them in adapting to climate change by using local methods in cocoa farming.

Table 2 presented the Concept of Climate change and cocoa cultivation among farmers in the study area. Majority (95.8%) of the farmers are aware of weather changes. This would enable them to know ways to mitigate and adapt to climate change. Twenty five percent of cocoa farmers in the study area are of the opinion that excessive rainfall might as a result of climate change. Six percent understand that increased incidence of drought is as a result of climate change. Nineteen percent understands that the crop failure they encounter on their farm is as a result of climate change, 10.4% of the farmers ascribe the decline in cocoa yield to climate change, 16.6% affirmed that the pest and disease infestation on their farms is as a result of climate change while 22.9% ascertained that high wind and heat waves they experience is as a result of climate change. Sixty three percent of cocoa farmers got information on climate change from radio/television while the others got information from friends, extension workers and farmers' cooperatives. Nine out of ten farmers in the study area have knowledge on the effect of climate change either positive/negative. Thirty one percent of the farmers reported that their cocoa yield was low compared to the previous years. Twenty seven percent reported that their yield was moderate, 16.7% reported that it was high while 25% reported that it was normal. Their responses above affirmed that most of the cocoa farmers experienced climate change. Eighty eight percent of cocoa farmers in the study reported that they have been experiencing climate change for between 1 and 10years.

Adaptation Strategies to Climate Change

Table 3 revealed the strategies that cocoa farmers in the study area used to adapt to climate change. Some of the strategies that were used are processing of crop to minimize postharvest losses (91.7%), crop varieties that are well acclimated (87.5%), shade crops (87.5%), recommended planting distance (87.5%), planting of early maturing cocoa variety (83.3%), organic matter (81.3%), use of chemicals such as fungicide, insecticide and herbicide (81.3%), reclamation of wet land/river valley (81.3%). The other strategies used by the farmers are conservation of soil and water, making of contour bund around farm land, planting under existing trees, increase in number of weeding of crop land and protection of water shed and mulching. Kosoe and Ahmed (2022) also confirmed the use of strategies mentioned above in Ghana.

Table 3: Adaptation Strategies to Climate Change

Variable	Frequency	%
Conservation of soil and water	114	79.2
Use of organic matter	117	81.3
Use of inorganic fertilizer	99	68.8
Planting pest and disease resistant crop	90	62.5

Effect of Climate Change on Pests and Diseases

In table 4 cocoa farmers reported the effect of climate change on pests and diseases. Fifteen percent reported that they experienced low effect (that is, little effect) of black pod disease on their farm, 52.1% experienced medium effect while 29.2% had high effect of the disease on their farm. In general, 95.9% of the farmers (Figure 1) affirmed that they experience black pod disease on their farms showing that black pod disease is a major issue among cocoa farmers in the study area. Also in figure 2, 8% of cocoa farmers in the study area do not experience cocoa swollen shoot on their farm while 18.8% had low effect, 52.1% had medium effect and 20.8% had high effect. Furthermore 12.5% of the farmers did not experience vascular wilt disease on their farm while 16.7% had low effect, 50.0% moderate effect and 20.8% had high effect. Other diseases that cocoa farmers in the study area highly experienced are leaf defoliation (41.7%), cherelle wilt (41.7%). Okeniyi *et al*. (2021) affirmed that as a result of climate change there is the occurrence of pests and diseases on cocoa such as cherrele wilt, mirid, termite infestation and cocoa swollen shoot.

Source: Field Survey, 2022

CONCLUSION AND RECOMMENDATION

Cocoa farmers in the study area affirmed that climate change is a major issue ~~and~~ have come up with strategies to adapt to the climate change. Specifically, some of the adaptation strategies that are majorly implemented by the farmers are conservation of soil and water, use of organic matter, use of shade crop, use of chemicals such as fungicide, insecticide, herbicide, use of recommended planting distance and timely processing of crop to minimize postharvest losses. It is hereby recommended that scientists at the Cocoa Research Institute of Nigeria should come up with new varieties of cocoa that are resistant to pests and diseases brought about as a result of climate change incidence.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Climate change and its impact on agriculture are major concerns for a food secured economy especially for developing countries like Nigeria. The carbon footprint of agriculture is also a concern for future climate. Nutrition Sensitive Agriculture seek to ensure the production of a variety of affordable, nutritious, culturally acceptable and safe food to meet the dietary requirement of populations in a sustainable manner. Food security is a situation by which all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life. Agriculture provides the foods that can improve nutrition, and nutrition supports agricultural labour requirement by providing the energy and good health farmers need to maximize productivity. These make sustainable agricultural practices a prerequisite for National Food Security today. This study reviewed the impact of climate smart and nutritional sensitive agriculture on national food security in Nigeria. The objectives of the study are to: identify climate smart and nutrition-sensitive agricultural practices used by small and medium scale farmers; identify the factors influencing the adoption of climate smart and nutrition-sensitive agriculture by small and medium scale farmers and to ascertain the impact of climate smart and nutrition-sensitive agriculture on National Food Security in Nigeria. The study adopted systematic review of literature in which accessible research results of adequate quality were identified, critically reviewed and integrated with the aim of generating fresh synthetic ideas. Secondary data were used in this study. Relevant scientific published documents were retrieved using the Web of Science (WoS) and Scopus core collection databases. The literature search was conducted on various databases, including Google Scholar, Scopus (Elsevier) and Springer (Nature) and, FAOSTAT using the Search Technique. Articles considered for inclusion contained essential vital words from the topic. A random google search recognizing the appropriate keywords was used and results gotten from the search were used for the systematic review of twenty-five (25) articles. The result showed that, crop and livestock diversification, planting of cover crops to increase soil fertility, use of drought resistant varieties and use of organic manure were the major climate smart and nutrition sensitive agricultural practices used by small scale farmers in Nigeria. The adoption of various climate smart and nutrition-sensitive agricultural strategies was significantly influenced by socioeconomic, institutional and climate related factors. The study concluded that the adoption of climate smart and nutrition-sensitive agriculture is low among the farmers. Also, impact of climate smart and nutrition-sensitive agriculture include enhancing achievement of national food security, enhancing soil quality, increases food productivity, reduces greenhouse gas emission and restoring degraded lands. Nonetheless, policy factors such as extension service delivery can be triggered to enhance the adoption of Climate Smart and Nutrition Sensitive Agriculture among the small and medium scale farmers and ensure National Food Security in Nigeria.
Keywords: *Climate change, Climate Smart Agriculture, Nutrition Sensitive Agriculture*

INTRODUCTION

Climate Smart Agriculture (CSA) has been presented as an alternative form of agriculture for conserving the environment while addressing the food needs of the world's population (FAO, 2014). The concept was originally put forth in 2010 by FAO after the Hague Conference on Agriculture, Food Security and Climate Change in 2009

(FAO, 2010; World Bank, 2010). According to FAO (2010), the main aim of CSA is to repackage agriculture in the context of a changing climate, to assure a 'triple win', thus, adaptation, mitigation and development. Climate Smart Agriculture is thus defined as a form of agriculture that sustainably increases agricultural productivity and incomes; enhances adaptation and building resilience to climate change, reducing or removing Greenhouse Gases (GHGs) where possible, and enhancing the achievement of national food security and the sustainable development goals (FAO, 2014). In a related view, Shea (2014) suggests that CSA is a focus-based concept that involves developing new technologies that can help farmers transition from current strategies to more climate-aware practices and encourage farmers to abandon or lessen reliance on methods that increase GHGs. It adopts some form of sustainable land management practices that engage farmers in sustainable intensification measures such as agroforestry, conservation tillage, residue management, green manuring and improved water management to improve agricultural performance (Palombi and Sessa, 2013; DeLonge *et al*., 2016). It also enables farmers to use their knowledge and skills more effectively, share information, opt for more efficient pro-environmental technologies and build stronger associations to facilitate effective negotiation of better market prices (Branca *et al*., 2011).

Agriculture is fundamental to food production. Traditional agricultural development tends to focus on productivity, production and income rather than nutrition. Agriculture, including CSA, must transform to become nutrition-sensitive in order to deliver on healthy diet to ensure national food security (FAO, 2017). Nutrition-Sensitive Agriculture (NSA) is an approach that addresses potential disconnect between agriculture and nutrition. It seeks to ensure the production of a variety of affordable, nutritious, culturally acceptable and safe food to meet the dietary requirement of populations in a sustainable manner (GIZ, 2016). It has a goal of improving human nutrition (UNICEF, 2010). It is a solution that recognizes the interconnections with agriculture and nutrition. Unlike conventional agriculture interventions whose focus is on increased agricultural production and income, the primary objective of NSA interventions is to use food-based approaches to improve nutrition (GIZ, 2016).

Although, the government and other stakeholders have promoted a number of Climate Smart and Nutrition-Sensitive Agricultural practices, some small and medium scale farmers have adopted these practices on their farms voluntarily. However, there is a dearth of knowledge on the drivers of the choice and use of the Climate Smart and Nutrition-Sensitive Agricultural practices and their implication on household food security. Therefore the objectives of this study are to identify Climate Smart and Nutrition Sensitive Agricultural practices used by small and medium scale farmers in Nigeria, identify the factors influencing the adoption of Climate Smart and Nutritional Sensitive Agriculture by small and medium scale farmers in Nigeria, and ascertain the impacts of Climate Smart and Nutritional Sensitive Agriculture on National Food Security in Nigeria.

RESEARCH METHODOLOGY

Study Area

The study was conducted in Nigeria, which comprises of 36 States and the Federal Capital Territory (FCT) under the Six (6) Geo-Political Zones. Nigeria is located in West Africa along the western coast of Africa.

Research Design

The study adopted systematic review of literatures in which accessible research results of adequate quality were identified, critically reviewed and integrated to generate fresh synthetic ideas.

Types and Sources of Data

Secondary data were used in this study. Relevant scientific published documents were retrieved using the Web of Science (WoS) and Scopus core collection databases. These databases are widely used in most review studies. They provide a wide range of peer-reviewed research documents, including scientific articles, books/book chapters, and conference proceedings, among others, in almost all scientific disciplines.

Method of Data Collection

The literature search was conducted on various databases, including Google Scholar, Scopus (Elsevier) and Springer (Nature) and, FAOSTAT using the Search Technique. Articles considered for inclusion contained key words from the topic. A random google search recognizing the appropriate keywords was used and results gotten from the search were used for the systematic review of twenty-five (25) articles.

Method of Data Analysis

Data were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

Climate Smart and Nutrition Sensitive Agricultural Practices used by Small Scale Farmers

The type of Climate Smart and Nutrition Sensitive Agricultural practice used by small scale farmers in Nigeria is presented in Figure 1.

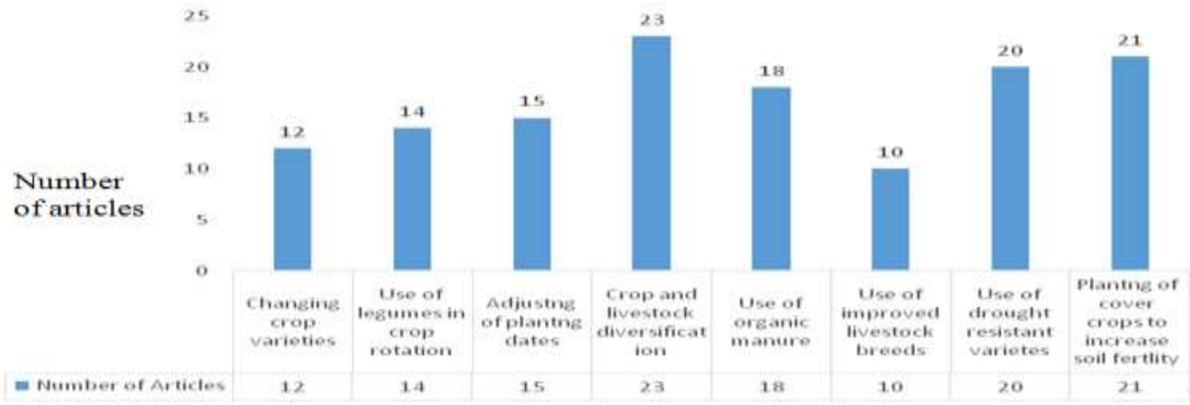

Figure 1. Climate smart and nutrition sensitive agricultural practices

Crop and livestock diversification, planting of cover crops to increase soil fertility, use of drought resistant varieties and use of organic manure were the major climate smart and nutrition sensitive agricultural practices used by small scale farmers in Nigeria. The reason for high adoption of planting of cover crops to increase soil fertility and drought tolerant varieties was traced to the need to provide adaptive measures against short rainfall duration in the Nigeria. Nevertheless, the cover crops which are mostly legumes also provide some essential dietary needs to the household and ensure national food security. The high adoption of agronomic practices in general was based on the realization of its yield enhancing potential which has made dissemination of the practice widespread. As fertilization is expected to enhance the capacity of improved seed varieties to express yield potential optimally, farmers are expected to use fertilizers. To be climate smart, the blend of both organic manure and inorganic fertilizers is recommended (FAO, 2013).

Factors influencing the Adoption of Climate Smart and Nutrition-Sensitive Agriculture by Small and Medium Scale Farmers
Socio-economic factors

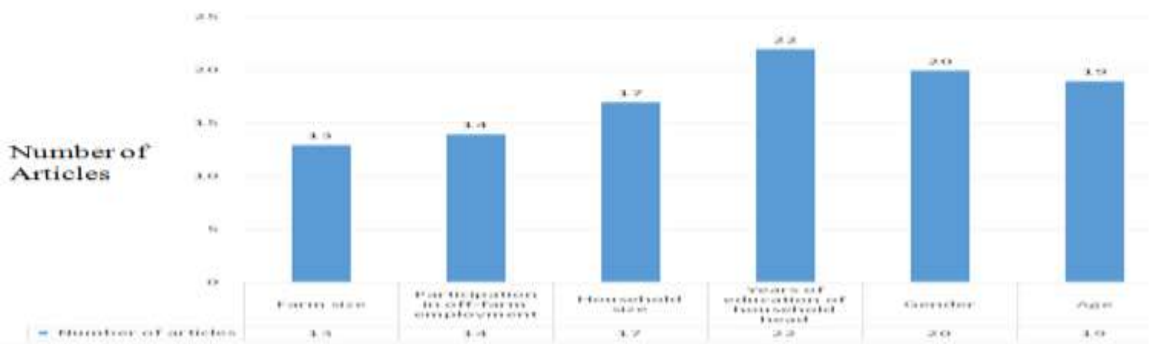

Figure 2. Socio-economic factors influencing the adoption of climate smart and nutrition-sensitive agriculture by small and medium scale farmers
The socio-economic factors influencing the adoption of Climate Smart and Nutrition-Sensitive Agriculture by smallholder farmers is presented in Figure 2. The factors include age, sex, years of education of household head, household size, farm size and participation in off-farm employment. The result shows that a number of these factors had substantial influence on the adoption of climate smart and nutrition-sensitive agricultural practices. The sex of the household head had a positive effect on the adoption of climate smart and nutrition-sensitive agricultural practices. Male heads were noted to have a higher probability of adopting climate smart and nutrition-sensitive agricultural practices vis-à-vis their female counterparts. The estimated positive effect of sex on climate smart and nutrition sensitive agricultural practices is consistent with the findings of Abu *et al.* (2018). Contrary to this finding, Adedeji *et al.* (2017) estimated that female farmers have a higher probability of adopting row planting of rice. The number of households is used as a proxy for labour availability for farm activities. The result

shows that higher household size substantially affects the adopting climate smart and nutrition-sensitive agricultural practices. This finding is supported by studies such as Idrisa *et al.* (2014) and Adedotun *et al.* (2020). Education plays a crucial role in improving the human capital and the understanding of climate smart and nutrition-sensitive agriculture and the need for adoption. The result shows that education highly influenced the adoption of the practices. This implies that higher education leads to the adoption of more climate smart and nutrition-sensitive agricultural technologies. This is consistent with the findings of Ayorinde *et al.* (2022) which that education enhances the adoption of climate smart and nutrition-sensitive agricultural practices.
Climate related shocks

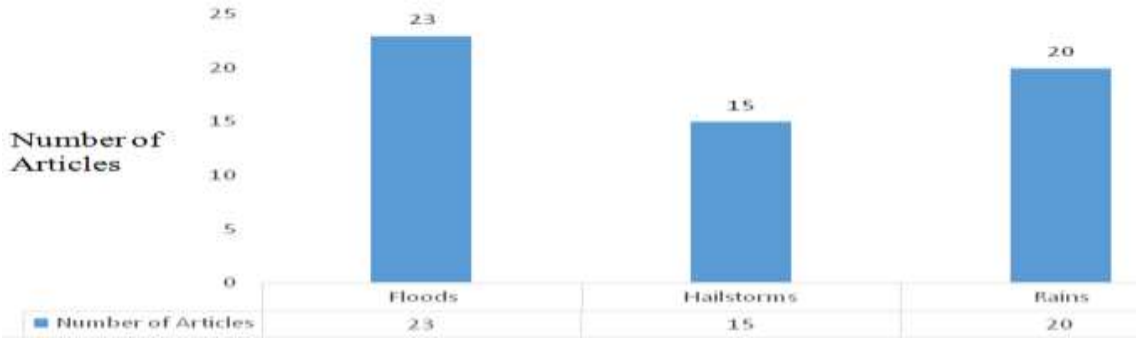

Figure 3. Climate related factors influencing the adoption of climate smart and nutrition-sensitive agriculture by small and medium scale farmers
The climate related factors include floods, hailstorms and rains. These factors affect the adoption of Climate Smart and Nutrition-Sensitive Agricultural practices (Figure 3). These farmers could be implementing a responsive strategy that included farm risk reduction through diversified production means. Previous study by Funminiyi *et al.* (2020) had a contrary result where frequent hailstorms were the main sources of production risks related to climate change that discouraged farmers adoption of production techniques for yield stability.
Institutional characteristics

Figure 4. Institutional factors influencing the adoption of climate smart and nutrition-sensitive agriculture by small and medium scale farmers
Institutional factors affecting adoption of climate smart and nutrition-sensitive agriculture were highlighted from the articles. This includes distance to the market, group membership, extension agents and credit access (Figure 4). Access to extension services greatly informed the adoption of climate smart and nutrition sensitive-agriculture by the farmers. Thus, farmers who had access to extension services had higher probability of adopting the technologies than those who did not. Extension officers are generally responsible for transferring technologies to the farmers. Therefore, it is expected that the farmers become more aware of these technologies and their importance. This justified the need for enhancing the provision of extension service to farmers, especially, in the era of climate change and the rapid technological advancement. Adebayo and Ojogu (2019) also estimated a positive effect of extension access on technologies adoption.

Impact of Climate Smart and Nutrition Sensitive Agriculture on National Food Security

The impact of climate smart and nutritional sensitive-agriculture on national food security in Nigeria is presented in Figure 5.

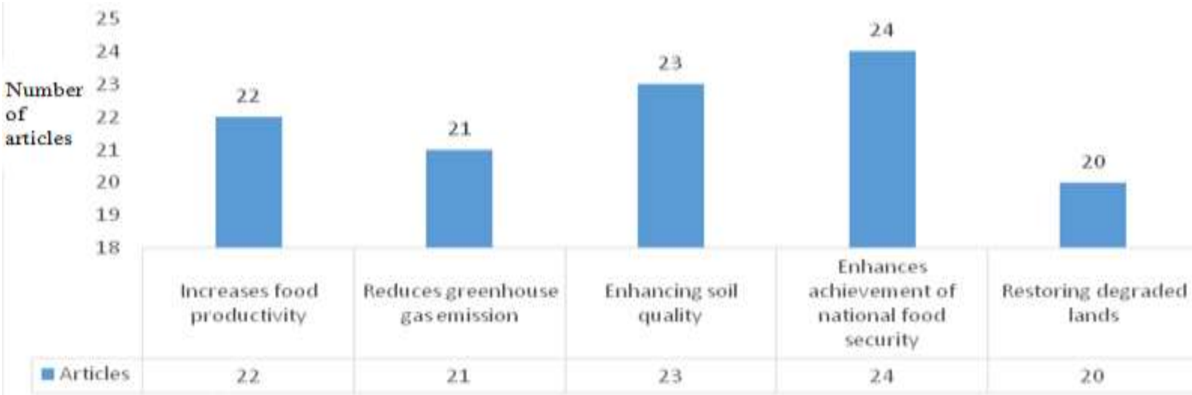

Figure 5. Impact of climate smart and nutrition-sensitive agriculture

From the results in Figure 5, impact of climate smart and nutrition-sensitive agriculture has great effect in enhancing achievement of national food security, enhancing soil quality, increases food productivity, reduces greenhouse gas emission and restoring degraded lands. This is in line with Igberi *et al.* (2022) findings which showed that adoption of climate smart and nutrition-sensitive agriculture sustainably increases productivity and resilience (adaptation), reduces/removes GHGs (mitigation), and enhances the achievement of national food security and the sustainable development goals. Similarly, Halliru *et al.* (2021) reported that practicing of climate smart and nutrition-sensitive agriculture are relevant as they enhance soil quality, brings about adaptation and mitigation benefits by regulating carbon, oxygen, and plant nutrient cycles, leading to enhanced resilience to drought and flooding, and to carbon sequestration. In terms of child stunting, wasting, low birth-weight, Nigeria is at or slightly below the Sub-Saharan Africa's average, and from the global perspective; far from ideal. Anemia in women of reproductive age, though the data is outdated, is considerably higher than the average of the Central and Western Africa and also ranked very close to the bottom in the world. While the situation requires continuous attention, what is noteworthy about Nigeria's nutrition situation is that the country is seemingly making good progress in tackling under-nutrition in the past few years. To realize the country's desire to achieve these global targets, there appear to be two important dimensions that need attention: improving major underlying drivers of nutrition through multi-sectoral approaches; and adoption of climate smart and nutrition-sensitive agriculture.

CONCLUSION AND RECOMMENDATIONS

Agronomic practices in term of cultivation of high yielding, drought tolerant, disease and pest resistant varieties were the most adopted climate smart and nutrition-sensitive agricultural practices. It can be concluded from the review that, climate smart and nutrition-sensitive agriculture has a positive impact on food security. It further allows for more efficient resource use of agricultural production systems which offered considerable potential for increasing agricultural productivity, income, food security and the resilience of rural livelihoods while reducing the intensity of agricultural emissions. It is therefore recommended that government policy and supportive programmes towards climate change mitigation and adaptation should focus on adoption of climate smart and nutrition-sensitive agricultural practices especially those ones that were not highly adopted by the small and medium scale farmers. Also, efforts should be made by Universities and Research Institutes and to adequately train the Agricultural Extension Agents on all the components of climate smart and nutrition-sensitive agricultural practices.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study assessed Agricultural extension training programmes among smallholder farmers in Ningi local government area of Bauchi State, Nigeria. A multi-stage sampling method that includes purposive and random sampling was used to select 120 respondents for the study. Data were collected with aid of questionnaires and analyzed using descriptive statistics (mean, standard deviation, frequency and percentage) and inferential statistics (logistic regression analysis). The result reveal that, majority of the respondents (71.7%) were male with 35.8% of the respondent having mean age of 44.1. Almost half of the farmers (49.2%) having mean farm size of 3.7 land. The mean score of farmers' perception regarding extension agent performance shows that, the extension agents provide good ideas that help in improving farmers' production with the highest mean score of 2.2 and that the extension agent provide continuous support to help the application and implementation of the information taught, having the lowest mean score of 1.7.The result of the logistic regression analysis shows that the training need of farmers were significantly (P<0.05) influenced by marital status (2.350), farming experience (3.444), and number attending the extension training (2.020).The study recommends that emphasis should be place on the creation of small farmer groups in which training can be easily conducted.
Key words: *Assessment, Agricultural, Extension, Training, programmers*

INTRODUCTION
Almost all countries in the world deliver some type of extension services to help rural people advance their agricultural productivity and improve their living standard (Ijeoma and Adesope, 2015). Extension is responsible for serving about one billion small-scale farmers in the world (Davis, Nkonya, kato and Nkuba, 2010). The improvement of agricultural sciences and technology has brought about dramatic changes in the agricultural sector (Nagel, 1997). This has led to the increased need and opportunity for investigating the effectiveness of agricultural extension services in various parts of the world. Also, this situation stimulates the need for new approaches to promote the transition of new innovations into concrete benefits to poor farmers in developing countries (Hellin, 2012).
Over the years, agricultural extension has been at the fore-front in the delivery of adequate information to farmers for increased productivity. According to Apantaku and Oyegunle (2016) and Agbamu (2007), agricultural extension service delivery all over the world has been concerned with communicating research findings and improved agricultural practices to farmers. The roles of extension today go beyond technology transfer and training of farmers but include assisting farmer to form groups, dealing with marketing issues, addressing public interest issues in rural areas such as resource conservation, health, monitoring of food security and agricultural production, food safety, nutrition, family education, and youth development and partnering with a broad range of service providers and other agencies (Ijeoma and Adesope, 2015).
Agricultural extension aims to disseminate relevant information for effectiveness and efficiency of agricultural activities but is confronted with certain constraints. Iwena (2008) identified absence of credit facilities, insufficient motivation of the personnel, inadequate resources, poor transportation network, high level of farmers' illiteracy and language barriers as some of the constraints faced by farmers in Nigeria. According to Munyua (2000), lack of access to basic agricultural knowledge and information by rural farmers can be assumed to be as a result of some constraints to effectiveness of agricultural extension activities which have made these farmers to stick to

their old traditional methods of farming system and animal husbandry practice, hence resulting in poor crop and livestock productivity.

The current poor performance of the agricultural extension system is as a result of inadequate resources to enable it to perform its role effectively. But perhaps a more important factor is its bureaucratic organization, which tends to contradict its very mission of working closely with farmers and with other service agencies to stimulate agricultural modernization. Mattee (1994), and Boone, Gartin, Wright, Lawrence, and Odell (2002) insisted on the importance of improved agricultural extension in the 21st century given that the agricultural sector is facing many technological advances, new agricultural laws, and innovative marketing strategies, all of which need to be communicated to farmers through well-established extension programs. This calls for the need to study all aspects related to extension, including the main stakeholders (farmers), in looking for better means of improving the extension programs.

Thus, the study to identified farmers' perceptions in order to find better means of helping them effectively to participate in the extension training programmes by developing programs and use of methods that meet their needs.

The broad objective of the study was to assess the agricultural extension training programs among smallholder farmers in Ningi Local Government Area of Bauchi State, Nigeria. However, the specific objectives were to: identify the socio-economic characteristic; examine the perceived attitude of farmers toward agricultural extension training programs; determine the influence of socio-economic characteristic of farmers on training needs of agricultural extension program in respondents in the study area.

METHODOLOGY

The study area was Ningi Local Government Area is among the 20 Local Government Areas in Bauchi state. It is divided in to eleven (11) wards and has a total land area of 4,625km square and located on 11° 4, 9° 34 E /11°.67 N 9.5°-67 E and has a total population of 387,192 (NPC 2006). The headquarters of the Local Government Area (Ningi) is 102 km away from the state capital (Bauchi) along Bauchi-Kano federal highway.

The population for this study consisted of farmers growing cash and food crops in Ningi local government area of Bauchi state. A multi-stage sampling technique was employed for the study. In the first stage, purposive sampling was used to select five (5) wards (Balma, Kudu- yamma, Tiffi-guda, Nasaru and Dingis ward), this is because of the presence of extension activities in the areas. In the second stage, two (2) villages were randomly selected from each ward resulting in a total of ten (10) villages. In the third stage, 120 farmers were randomly selected from the sample frame of 2415 farmers' base on the data collected from Agric department Ningi LGA (2018). This forms the sample size of the study and it represent 5% of the sample frame. Both Primary and secondary information were used for the study, structured questionnaire was used to obtain primary information. While secondary information was obtained through literature review and record from Agric Department Ningi LGA. The questionnaires used were both closed and open ended.

Data analysis was conducted using the Statistical Package for the Social Sciences (SPSS) computer program. Descriptive and inferential statistics consisting of mean, standard deviation, frequency table, percentages, and regression analysis were used to analyze the data. The analysis also involved the identification of the characteristics of the respondents and how they relate to various aspects of the study. Frequencies and percentages were used to describe farmers' socio-economic characteristics.

In order to determine the influence of selected socio-economic characteristic on farmers training needs, the Binary Logistic Regression model that was used and is specified below:

$$\text{LOG } \frac{P}{1-P} = \text{LOG } Y = \alpha + \beta 1X1 + \beta 2X2 + \beta 3X3 + \beta 4X4 + \beta 5X5 + \beta 6X6 + \beta 7X7 + \beta 8X8 + \mu$$

Where;

LOG $\frac{P}{1-P}$ = Log of the probability (P) of needed training relative to no need training

Needed training = 1; No need training = 0

X1 = Age (in years)

X2 = Sex (male =1; female = 0)

X3= Marital status (married=1; otherwise=0)

X4 = Level of education (in years)

X5 = Household size (in number of persons)

X6 = Farm size (in number of hectares)

X7 = Farming experience (in years)

X8 = Number of attending the extension training in a mouth (once=1; otherwise=0)

μ = error term

RESULT AND DISCUSSION

Distribution of Respondents by Sex: The study revealed that most of the respondents (71.7%) were male only 28.3% were female. This finding is consistent with the study by Okwusi and Aboh (2007) in which 95% of the sample of 20 respondents interviewed were male. This disparity was also reflected in the number of women taking part in extension training as well, as in this study.

Distribution of Respondents by Age: As indicated in Table 1, the distribution of respondents based on ages, revealed that the mean age is 44 years. This showed that most of the farmers were middle age farmers. The findings regarding the distribution of respondents based on age in this study is consistent with the study by Modibo *et al*., (2010).

Farm Size Distribution of Respondents (Ha): According to the result obtained almost half of the farmers (49.2%) owned about two to four hectares on which different crops were grown. Only 0.8% of the respondents owned more than 10 hectares, but indicated that they did not cultivate all of it. Instead, they leased some of it to other farmers in need. In addition, 24.2% of the respondents had farms with less than 2 hectares, 18.3% owned 5-7 hectares and 7.5% of the respondent owned 8-10 hectares. Most of the farms were not located at one site. The result also revealed that the mean farm size is 3.7 hectares this implies that a greater proportion of the respondent were small-scale farmers.

This result is in line with the study by Olatunji (2005). Ijeoma and Adesope (2015), as pointed out by Ibitoye and Onimisi (2013), total farm output is higher if bigger farms have higher productivity as compared to small ones. This may justify the reason for food insecurity in most rural families despite the fact that they are busy with farming activities each and every season.

Table 1: Socioeconomic characteristics of respondents

Variable		Frequency	Percentage	Mean
Age				
Male		86	71.7	
Female		34	28.3	
		120	**100**

Distribution of Respondents According to Farmers' Perceptions Regarding Extension Agents' Performance

The mean score of farmers' perceptions and views about the performance of the extension agent in providing useful ideas to help farmers improve production was 2.17, (Table 2), whereas the mean score of their perception of the availability of the extension agent in helping farmers when they are in need was 2.1. Furthermore, the mean scores of the farmers perceptions of the extension agents' preparedness for the training programs was 1.2; extension agents having all training facilities was rated 1.8; extension agents being friendly and easily approachable was rated 2.1; the efficiency of the extension agents in helping farmers was rated 1.8 and extension agents providing continuous support to help farmers implement technologies was rated 1.7 (Table 3).

Table 2: Respondents' Perceptions of Extension Agents' Efficiency in Training and Helping Farmers

Perception	N	Min	Max	M	SD
Extension agent provide good ideas that help in improving my production	120	1	5	2.1750	1.25591
Availability of extension agents to help farmers	120	1	5	2.1333	1.24979
Extension agents are well prepared during training session	120	2	5	1.1750	1.01801
Extension agent has all training Facilities	120	2	5	1.8083	0.99828
The extension agent has the efficiency in helping farmers	120	1	4	1.7833	1.05467
Extension agents are friendly and easily approachable for advice	120	1	5	2.0500	1.31993
Extension agent provides continuous support to help the application and implementation of the information taught	120	2	5	1.666	0.99015

Source: Field survey, 2018

Note. Perception statements were rated on a Likert- scale on which 1 = strongly agree, 2 = agree, 3 = I don't know, 4 = disagree, and 5 = strongly disagree.

Binary Logistic Regression

Table 3: Influence of Socio-economic characteristics of Farmers on their Training Needs

Variable	B	S.E	Wald	Sig.	Exp(B)
Age	0.054	0.057	0.922	0.337	1.056
Sex	0.587	0.614	0.915	0.339	1.799

Educational level	-0.063	0.081	0.607	0.436	0.939
House hold size	-0.073	0.069	1.131	0.288	0.930
Farm size	0.050	0.097	0.259	0.611	1.051
Farming experience	0.147	0.079	3.444*	0.063	1.159
Number of attending The Extension training	-.0631	0.444	2.020*	1.55	0.532
Constant	-3.646	1.725	4.468*	0.35	0.26
-2 Log likelihood				127.382	
Cox & Snell R square				0.160	
Nagel kerke R Square				0.225	

Source: Field survey, 2018

The result of the binary logistic regression in Table 4.17 shows that the training need of farmers were significantly ($p<0.05$) influenced by marital status, farming experience, and number of attendances to extension training.

CONCLUSIONS AND RECOMMENDATIONS

It was concluded that most farmers understand the usefulness of extension training programs in improving their agricultural production, there is a great need to improve the way services are offered as well as the dissemination of information about training to capture the attention of many farmers regarding the training to be conducted.
The study recommends that the extension program planners should focus on current problems facing farmers and provide technology and knowledge that are of interest to farmers. This can best be done by employing a participatory approach to extension as well as by strengthening collaboration between extension and research so as to be able to update farmers on any new innovations.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An experiment was conducted during the rainy season of 2021in botanical garden of federal university of Lafia, Nasarawa state to evaluate the flowering seed setting potential of sweet potato (Ipomea batatas (L) Lam). Vine and seed of five different accessions ,namely;TIS8164,TIS87/0087,UMUSPO3,UMUSPO4,EX-IGBARIAN were used and these were laid out in a Randomized complete block design (RCBD)with three(3)replications. Flowering parameters such as mean number of days to onset of flowering and mean number of flower produced per plant were observed in the field while pollen viability test was conducted in the laboratory. The analysis of variance (ANOVA) result for mean number of days to onset of flowering showed that significant difference existed between the different sweet potato accessions at 5% level of probability across both seed and vine. Highest mean number of days to onset of flowering for seed accessions was recorded in EX-IGBARIAN with 58.00 days, and least mean number of days to onset of flowering for seed accessions was recorded in TIS8164 with 54.33days.While the highest mean number of days to onset of flowering for vine accessions was recorded in EX-IGBARIAN with 63.33days and the least mean number of days to onset of flowering for vine accessions was recorded in UMUSPO4 with 32.67 days. The result for mean number of flowers produced per plant also showed that significant difference existed between the different sweet potato accessions at 5% level of probability across both seed and vine .The highest mean number of flowers produced per plant for seed was observed in TIS8164 with 18.33 and the least mean number of flower per plant for seed was observed TIS87/0087 with 4.60.While the highest mean number of flower per plant for vine accessions was observed in UMUSPO4 with 10.17 and the least mean number of flower produced per plant for vine accessions was observed in TIS87/0087 with 2.40.The result for pollen viability showed that ,the highest pollen viability for seed was recorded in TIS87/0087 with 4.90 and the least pollen viability for seed accessions was recorded in EX-IGBARIAN with 4.43.While the highest pollen viability for vine accessions was recorded in UMUSPO3 with 5.00 and the least pollen viability for vine accessions was recorded in UMUSPO4/TIS87/0087 with 4.67.The result of this study showed that even though flowering potentials in sweet potato Ipomea batatas.(L) Lam was observed to be low, some of the accessions used showed some potentials that could be used in improving seed set, thereby increasing the availability and varieties of planting materials of sweet potato.

Keywords: *Pollen viability, Flowering, seed settings, sweet potato Ipomea batatas. (L) Lam.*

INTRODUCTION
Sweet potatoes *(Ipomoea batatas* (L) Lam) belongs to the family Convolvulaceae (morning glory) family, the crop is originated in the central or south American low land with subsequent dispersed to North America, Europe, Africa and Pacific between 15th and 20th century (Carperna, 2009). The crop is a dicotyledonous, perennial vine, cultivated as an annual, crop, sweet potatoes is a crop that is very well suited to local growing conditions especially during our prolonged dry season. When growing with irrigation, high yields are obtainable and root quality is good, poor yield and quality associated with low ambient and soil temperatures are problems for southern growers, which can provide a market opportunity for okay grown crops (Gruneberg *et al.,* 2004). Sweet potatoes is an important food security crop grown in many of the poorest regions of the world mainly by women for food and as a source of family cash income (Peter, 2004) (Anginyah *et al*., 2001). The tuberous roots and leaves of sweet potatoes is an excellent source of carbohydrate, protein, iron, vitamin A, C and fibre. Sweet potato vine has crude protein content ranging from 16 to 29% on dry matter basis which is comparable to leguminous forages increased milk yield (Estes, 2009). The fresh tuberous root contains 80 to 90 % carbohydrate of dry matter (Elston, 1963).

The sweet potato is mainly propagated by vine cuttings, planted on mounds or ridges and in single or double rows (Siddigue *et al.*, 1988). It is one of the world's most important food crops due to its high yield and nutritive value. Its importance in starch, alcohol, livestock, pharmaceutical and textile industries cannot be over emphasized (Tewe *et al.*, 2003). The orange-fleshed varieties with high β-carotene content have become very important in combating vitamin A deficiency especially in children. The cultivation and production of sweet potato is on the increase in Nigeria. The crop has moved up from a minor crop status to an enviable position of being the fourth most important root and tuber crop after cassava, yam and cocoyam (Tewe *et al*., 2003). Survey reports placed Nigeria, as the number two producer of sweet potato in Africa with an annual production output of 2.5 million Mt in 2004 from 149,000 Mt in 1961 (FAO, 2004). The ravaging effect of diseases and pests have also been noted, even as emphasis is also shifting to include such important traits like dry matter and starch content (Tewe *et al*., 2003). Clones adapted to tropical environments have been reported to flower more readily than those adapted to temperate environments, where flowering is mostly artificially induced (Onwueme, 1978). This study was carried out to evaluate the seed setting pattern of sweet potato (*Ipomoea batatas* (L) Lam) propagated by vine and seed in Lafia, Nasarawa State.

MATERIAL AND METHODS

The experiment was carried out at the research and experimental plot of the botanical garden of Federal University of Lafia, Nasarawa State, Nigeria, located on latitude 8°28N and longitude 8°23E.(NIMET,2010). Land preparation was done manually planting will be done using the standard potatoes planting method. Weeding was carried out manually once at two weeks interval after planting using hoe. The vine and seed of potato were collected from the National root crops Research Institute (NRCRI) Umudike, Abia State, Nigeria.

The experiment was laid out in a Randomized complete block design (RCBD) with three (3) replications. Plots measuring 3m x 3m with each plot consisting of three (3) rows each measuring 3m x 0.7m with inter row spacing of 0.5m and intra row spacing of 1m will be used giving a total plot size of 399m^2**.** Data was collected in the field from randomly selected and tagged plant from each plot. The following parameter will be observed:-Number of Days to Onset of Flowering, Number of Flowers Per Plant, Pollen Viability.

Data collected were subjected to ANOVA (Analysis of Variance) and LSD method at 5% level of probability to compare difference among treatment using Genstant discovery version 3 statistical software.

RESULTS

Analysis of variance (ANOVA) result for the mean number of days to onset of flowering showed that significant difference exist between the different accession of *Ipomea batatas* (L) Lam at 5% level of probability as shown in Table 1.The earliest number of days to onset of flowering was observed in Tis8164 with 54.33 days followed by Tis87/0087 with 55.67days, Umuspo4 with 57.00days, Ex-igbarian with 58.00days while Umuspo3 accession did not flower as shown in Table 1.

Analysis of variance (ANOVA) for number of flower produced per plant showed that significant different exist between the different accession of *Ipomea batatas* (L) Lam at 5%level of probability. TIS 8164 recorded the height number of flowers produced per plant with 18.33, followed by Umuspo4 with 12.53, Ex-igbarian with 7.47,TIS87/0087 with 4.60 while Umuspo3 accessions did not produced any flower with 0.00 as shown in Table1 Pollen viability ranges from 0.00 in Umuspo3 to 4.90 in Tis87/0087 and the difference was significant. Highest pollen viability was observed in Tis87/0087 with 4.90, followed by Tis8164 with 4.77, Umuspo4 with 4.77, Ex-igbarian with 4.43, pollen viability test was not conducted on Umuspo3 due to the lack of flowering as shown in Table 1. Analysis of variance (ANOVA) result for the mean number of days to onset of flowering showed that significant difference exist between the different accession of *Ipomea batatas* (L) Lam at 5% level of probability as shown in Table 1.

TABLE 1: Pollen Viability Parameters of Sweet Potato *(Ipomea batatas* (L) Lam) as Propagated by Seed

Accessions	No Days To Onset Of Flowering	Number Of Flowers Per Plant	Pollen Viability
TIS8164	54.33 ± 0.58^{a}	18.33 ± 7.37^{a}	4.77 ± 0.40^{a}
TIS87/0087	55.67 ± 7.64^{a}	4.60 ± 0.69^{a}	4.90 ± 0.17^{a}
UMUSPO3	0.00 ± 0.00^{b}	0.00 ± 0.00^{c}	0.00 ± 0.00^{b}
UMUSPO4	57.00 ± 6.08^{a}	12.53 ± 2.33^{acb}	4.77 ± 0.40^{a}
EX-IGBARIAN	58.00 ± 0.00^{a}	7.47 ± 0.5^{b}	4.43 ± 0.23^{a}
LSDS	7.96	6.32	0.52

Analysis of variance (ANOVA) for number of flower produced per plant showed that significant different exist between the different accession of *Ipomea batatas* (L) Lam at 5%level of probability. Umuspo4 recorded the height number of flowers produced per plant with 10.17, followed by Tis8164 with 5.97, Umuspo3 with 5.33, Ex-igbarian with 3.87 while Tis87/0087 with 2.40 as shown in Table 2. Pollen viability ranges from 4.67 in Tis87/0087 and Umuspo4 to 5.00 in Umuspo3 and the difference was significant. Highest pollen viability was observed in Umuspo3 with 5.00, followed by Tis8164 with 4.80,Umuspo4 ,Ex-igbarian with 4.77, Umuspo4 with 4.67,Tis87/0087 with 4.67 as shown in Table 2. The earliest number of days to onset of flowering was observed in Umuspo4 with 32.67days followed by Tis8164 with 42.33days, Umuspo3 with 59.00days, Tis87/0087 with 61.00days while Ex-igbarian flowered late with 63.33 as shown in Table 2.

TABLE: 2 Pollen Viability Parameters of Sweet Potato *(Ipomea batatas* (L) Lam) as Propagated by Vine

Accessions	Number Of Days To Onset Of Flowering	Number Of Flower Per Plant	Pollen Viability
TIS8164	42.33±4.16[a]	5.97±2.40[a]	4.80±0.17[a]
TIS897/0087	61.00±5.20[b]	2.40±1.06[b]	4.67±0.35[a]
UMUSPO3	59.00±8.66[c]	5.33±6.1[a]	5.00±0.00[b]
UMUSPO4	32.67±2.31[d]	10.17±2.39[c]	4.67±0.35[a]

DISCUSSION

Variation in the number of days to onset of flowering amongst accessions could be attributed to both genotypic and environmental factors and influence. Robert *et al*., (1996) reported that when the critical photoperiod is exceeded, flowering is delayed, and the delay increase with photoperiod, until ceiling photoperiod to attained.in photoperiod longer than the ceiling, there is no response to either the number of days to onset of flowering or the number of flower per plant. In this study of the accession propagated by seeds it showed that Ex-igbarian took longest time to flower at 58days while Umuspo3 of the seed accession did not flower all through the replications in the studies. While for the accessions propagated by vine showed that Ex-igbarian took the longest time to flower at 63.33days. This can be describe as having poor sensitivity to photoperiod, (Chung and Myeong, 1996). Accessions that flowered late took a longer time to transit from the vegetative to reproductive phase.

Variations in the mean number of flowers per plant and rate of flowering depend on the length of time in which new flower are produced as well as length of life of individual flower (Reiger and Sedgley, 1996). For the accessions propagated by seedTis8164 with 18.33 produced the highest number of flower per plant. While for the accession propagated by vine Umuspo4 with 10.17 produced the highest number of flower per plant.

Pollen viability accession propagated by seed ranges from 0.00 in Umuspo3 and 4.90 in Tis87/0087 while pollen viability for accession propagated by vine ranges from 4.67 in Tis87/0087/Umuspo4 and 5.00 in Umuspo3.this study indicate that pollen viability is low. The high temperature condition in Lafia Nasarawa state might have contributed to low pollen viability of the different sweet potato accessions across vine and seed. Mes and Menge (1954), also reported that extreme temperature conditions of the environment effect pollen viability of crop plants.

CONCLUSION

Result of this study showed that flowering potentials of sweet potato *(Ipomea batatas* (L) Lam)in Lafia is extremely low, thus resulting in negligible or no seed set during cropping season, thereby making it difficult to propagate sweet potato by using seedws.it is therefore recommended that more work be carried out on the improvement of sweet potato *(Ipomea batatas* (L) Lam) through seed in Lafia, Nasarawa State.

RECOMMENDATIONS

i- Based on findings of this research, the vine accession was seen to have performed more than the seed accession in this research, so it is therefore recommended that the vine accession should be adopted for crop improvement in *Ipomea batatas* (L) Lam in Lafia Nasarawa State.

ii - It is also recommended that more advanced research be carried out to explore the potentials for seed production on *Ipomea batatas* (L) Lam in Lafia Nasarawa State.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

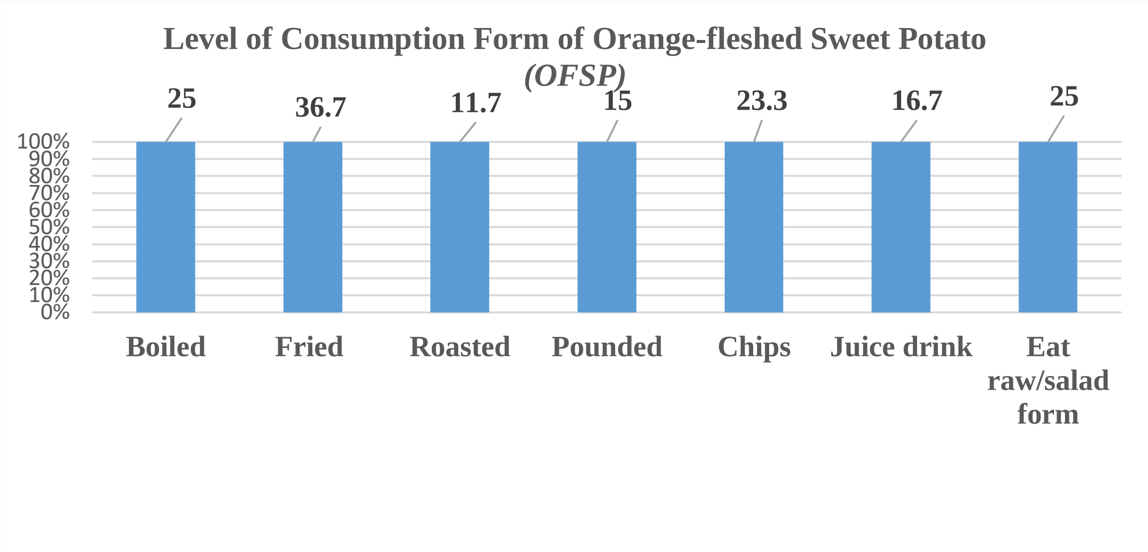
ABSTRACT
The study assessed the level of consumption of Orange Fleshed Sweet Potato (OFSP) products among rural households in Abia state. Using random and purposive sampling methods, a sample size of 60 respondents who had received the OFSP in the study area was chosen. Data were gathered by questionnaires, interviews, and Focus Group Discussions (FGDs) and analyzed using descriptive statistics. Results show that consumption level of OFSP was higher in fried, boiled and eating it raw and in salad forms while majority consume the products because of its colour, crispness, and taste. Absence/scarcity of the products in local markets, dearth of information on OFSP and scarcity of vines were the most serious constraining factors to consumption of the products in the study area. Therefore, promotional activities such as awareness campaigns and nutritional information showcasing the potentials of OFSP products is highly recommended. This would increase intake and help to attain the goal of eliminating vitamin A deficiency (VAD) in Nigerian.
Keywords: *Consumption, OFSP, Rural Households*

INTRODUCTION
Orange-fleshed sweet potato (OFSP) is an improved breed of sweet potato (*Ipomea batatas*) that is cultivated in tropical and semi-tropical regions of the world for food and source of income especially among the rural dwellers. Orange-fleshed sweet potato varieties are rich in beta carotene, (a precursor of vitamin A) and with proven high content of this nutrient, it is considered a key crop to combat vitamin A deficiency (VAD) problem in the Sub-Saharan Africa (Afuape *et al*., 2015). As reported, millions of Nigerians, irrespective of age, sex or geographical location consume less vitamin A than the body needs while women and children remain the most vulnerable, resulting in reduced immunity, impaired vision, and, in some cases, even blindness and death (Egesi *et al*., 2014; Njoku*etal*,2013). Vitamin A deficiency retards growth increases risk of disease, and can cause reproductive disorders (NRCRI, 2014 and Onyeneke *et al*., 2018). Since the presence of β-carotene in the new sweet potato could improve the nutritional status of the consumers, there is therefore a need to evaluate the consumption level of these newly bred crops. Obviously, the consumption of this β-carotene can help in combating vitamin A deficiency, which is a serious public health problem in many parts of the World today and formulation of different food products from the crops will also help to enhance its consumption (Ayinde *et al*., 2016 and Ilona *et al*., 2017). This study, therefore, specifically assessed the level of consumption form of orange sweet potato *(OFSP)*; assessed the consumer preference and acceptability of OFSP products; determined the factors influencing consumption of OFSP products and identified constraining factors to consumption of OFSP in the study area.

METHODOLOGY
The study was carried out in Abia State located in south-east Nigeria. A multi-stage sampling technique was used to select respondents for the study. Ohafia and Umuahia agricultural zones were purposively selected for the study. The reason for purposive selection is because OFSP vine has been introduced in those locations through suitable training. The second stage involved random selection of two (2) blocks from the chosen agricultural zones making a total of four (4) blocks. The third stage involved random selection of three (3) circles from each of the chosen blocks to give a total of twelve (12) circles. In the fourth and last stage five (5) respondents were randomly selected from each circle to give a total of sixty (60) respondents. A structured questionnaire and FGD were used to interview the respondents, in all sixty (60) respondents made up the sample size for the survey. Data collected were analysed by means of descriptive statistics and mean count.

RESULTS AND DISCUSSION
Level of consumption form of orange fleshed sweet potato *(OFSP)*

The result in Figure 1 showed that 36.7% of the households consume in fried form, 25.0% boiled while 25.0% eat it raw/slice as salad and consume. Furthermore, 23.3% of the households consume OFSP in form of chips, 16.7% as juice, 15.0% in pounded form while 11.7% in roasted form. This result implies that consumers mainly and frequently consume OFSP in fried, boiled and chew it raw. It is very important to note that processing the OFSP into value added products such as chops, bread, chin-chin, cake, drinks, etc. is likely to boost frequency of consumption in Nigeria, particularly among children. This study agrees with the report of Amadi *et al*., (2019).



*Source: field survey, 2021 *Multiple responses recorded*

Consumers' Preference and Acceptability of OFSP Products

The result in Table 1 showed that majority of consumers in Abia state prefer and extremely liked consuming OFSP because of its orange colour, crispness and taste of the raw/salad, boiled and fried OFSP. This implies that the consumers' preference and acceptability of OFSP products was moderate. This study conforms to the findings of Oparinde, *et al*, (2017), who said that the yellow color of the root and its processed products is seen as evidence of the presence of vitamin A and is liked by consumers. Amadi *et al*., (2019) reported that to aid in acceptance, public relations tools need to be implemented to increase consumer demand and inspire positive attitudes surrounding new products made from bio-fortified crops.

Table 1: Distribution of respondents based on consumption preference and acceptability of OFSP.

Consumption Preference of Orange-fleshed Sweet Potato	Frequency (n=60)	Percentage (%)
Boiled OFSP		
Colour	31	51.7
Taste	15	25.0
Mouth feel	12	20.0
Fried OFSP		
Crispness	28	46.7
Colour	29	48.3
Taste	18	30.0
Roasted OFSP		
Colour	21	35.0
Taste	13	21.7
Mouth feel	13	21.7
Bounded OFSP		
Texture	13	21.7
Colour	21	35.0
Mouldability	11	18.3
Raw/Salad OFSP		
Crispness	24	40.0
Taste	16	26.7
Colour	21	35.0
Drinks/Chips OFSP		

Palatability	17	28.3
Colour	26	43.3
Taste	20	33.3

Source: Field survey, 2021 *Multiple responses recorded

Factors influencing consumption of OFSP Products

The overall factors influencing respondents' consumption of OFSP products in Abia state was high with a grand mean score of ($\bar{x}$ = 2.3) which is higher than the decision mean cut-off of 2.0 (Table 2). The result shows that the factors influencing respondents' consumption of the products showed that they affirm that the products have health/nutrition value/information ($\bar{x}$ = 2.4), vitamin A content ($\bar{x}$ = 2.3), high quality products ($\bar{x}$ = 2.1), palatability of the products ($\bar{x}$ = 2.2) and simple to process ($\bar{x}$ = 2.4). The result further showed that OFSP products is not always available and accessible in some of the study area. This finding is in line with Bouis *et al.*, (2017), HarvestPlus (2016), and Ilona *et al*., 2016) that information of the nutrition and health benefits content remains an important factor and its instrumentality in the integration of bio-fortified food to people's diet, thus increasing adoption and consumption for good vision and strong immune system.

Table 2: Mean responses of the respondents on factors influencing their consumption of OFSP products.

Variables	HI	LI	NI	Total	Mean
Health/nutritional value	33(99)	18(36)	9(9)	144	2.4
Vitamin A content	29(87)	21(42)	10(10)	139	2.3
The products are of high qualities	25(75)	18(36)	17(17)	128	2.1
The products are palatable	21(63)	27(54)	12(12)	129	2.2
The products are simple to process	27(81)	29(58)	4(4)	143	2.4
The products are available and accessible	11(33)	32(64)	17(17)	82	1.4
Grand mean					**2.3**

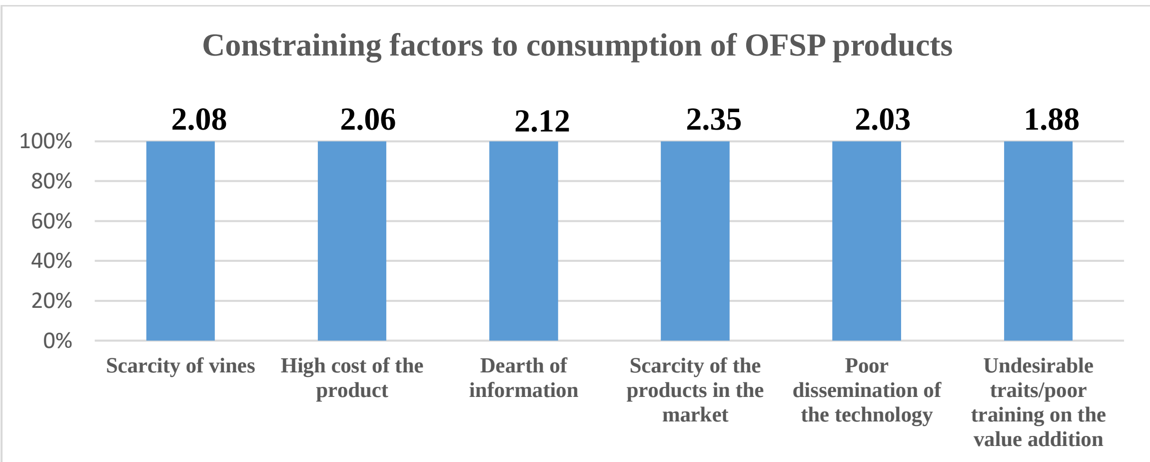
Constraining factors to consumption of OFSP products

Figure 2 shows the mean scores of constraining factors to consumption of OFSP and the result shows that the overall grand mean score ($\bar{x}$ = 2.03) which is greater than the decision mean cut-off of 2.0 was below the decision mean cut-off. The result shows that absence/scarcity of the products in the local market, dearth of information on updates on the technology from the developers in rural areas, scarcity of vines, high cost of the products and poor dissemination of the technology were the most serious constraints to the consumption. This implies that the extension programme needs to intensify efforts in technology deliveries and updating in the rural areas. These factors are retrogressive to the total utilization goal of the vitamin A variety. Some factors militating against adoption of biofortified crops and products, according to (HarvestPlus, 2016 and Onyeneke *et al*., 2018) include: marketability, price fluctuation, costs related to the distribution of new vitamin A varieties in places, cropping patterns and the multi-cultural nature of the targeted populations in Nigeria whereby some people still mix the cropping of these improved varieties with the local ones, thus reducing its multiplicity ability.



Source: ***Filed survey 2021***

CONCLUSION

The study concluded that consumption of OFSP in fried, boiled and eating raw/ salad forms were the most consumed forms among the households. The consumers preferred and accepted the products mainly because of the orange colour, crispness and taste. It was also revealed that health/nutrition value, vitamin A content, simple to process and high quality of OFSP were the major factors that influenced consumers while absence/scarcity of the products in local markets, dearth of information on OFSP and scarcity of vines were the most serious constraining factors to consumption of the products in the study area. Therefore, promotional activities such as awareness campaigns and nutritional information showcasing the potentials of OFSP products as well as disseminating more vines to users are highly recommended. This will boost consumption level and achieve the focus on eradicating vitamin A deficiency (VAD) among rural households in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
National Root Crops Research Institute (NRCRI) Umudike in collaboration with International Institute for Tropical Agriculture (IITA) Ibadan and Catholic Relief Services (CRS) midwifed the cassava seed entrepreneurship model with the aim of commercializing cassava seed in Nigeria. NRCRI is involved in three project States namely Abia, Akwa Ibom and Imo. A paradigm shift from the informal seed distribution system that is characterized by low adoption, absence of varietal traceability, seed sharing and low incomes to a formal seed system where seed sourcing is organized, seed quality is assured and certified. The farmers have access to land with more than one hectare, willingness to extend cassava seeds to other farmers and abiding by National Agricultural Seed Council (NASC) regulations, major source of foundation seed was *from NRCRI. Commercialization of cassava seed offer disease free planting materials to farmers, improved income of the Cassava Seed Entrepreneurs (CSEs), create employment opportunities, supply of high-quality improved cassava varieties, provide substantial new income-generating opportunities and increased adoption level of improved certified cassava varieties. Among the challenges to cassava seed commercialization were bottle necks in seed certification that led to introduction of licensed seed inspectors. It is therefore recommended that the project should popularize and upscale the released varieties through market day promotions, demonstration farms and product lunch for greater achievements.*
Keywords: *Commercialization, Improved Cassava Seed, NRCRI and BASICS-II Project.*

INTRODUCTION
Cassava (*Manihot esculenta*) is a staple food for many people in large parts of Tropical Africa, South America and Asia and over 700 million people in western and central Africa with an average consumption of approximately 500 calories per day (Ogbuokiri *et al.*, 2015). It is considered the most important tropical root crops providing food and income to over 30 million farmers, processors and traders (Apata, 2019). Cassava is cultivated in almost all agro-ecological zones in Nigeria. Over 90% of cassava produced in the country is consumed locally with less than 10% utilized for industrial purpose. Cassava represents the largest crop by area and production volume in Nigeria. Cassava has received the greatest attention in terms research leading to great improvement in yield and nutritional quality (Eke-Okoro, 2011). Achieving increased yields starts with the selection of high quality planting materials and adopting proper planting procedures. It is propagated by stem cuttings which must behandled properly for good sprouting and establishment. The importance of cassava to resource-poor farmers in Nigeria cannot be overemphasized. Cassava has played and continues to play a remarkable role on the agricultural sector of Nigeria, it can survive droughts, inexpensive, resistant to pests and easy to grow. Cassava has a special capacity to bridge the gap in food security, poverty alleviation, and environmental protection (Clair and Etukudo, 2000).
Seed systems are governed by both formal and informal rules that impact on the level of influence and participation for both men and women and their ability to benefit from the system (Galie, 2013). In Nigeria, the seed industry is still developing especially for crops like cassava whose botanical seeds are not consumed or popularly used for planting. Although production of cassava is dominated by over 6 million families, typically smallholders with an average farm size of 0.5ha, over 90% of these farmers use the informal seed system by recycling stems from the previous harvest (Sahel, 2016). This informal seed system describes the process where farmers acquire seeds from traditional sources based on seed exchange or gift or purchase from other farmers and local markets. Comparatively, the informal seed system is not characterized, regulated and supervised by any private or public institution but dominated by smallholder farmers. Within this informal system, seed varieties are

selected, multiplied and distributed at the local level based on traditional knowledge. In most cases, smallholder farmers combine different crops and manage to maintain the genetic diversity usually consisting of the traditional landraces. In contrast to the informal seed distribution system, the formal seed system notably ensures the development and distribution of improved seed varieties through a series of interdependent activities (Ewuziem and Asumugha, 2018). The existing seed systems have operated at a local scale, based on diverse farmer practices for selection, multiplication and exchange of planting material.

Building an economically sustainable, integrated cassava seed system (BASICS) is a project that seek to help Nigerian cassava producers reach the potentials of 45MT/ha by involving the development of a commercially sustainable cassava seed value chain based on the purchase of quality seed by farmers. To further ensure the sustainability of the project, vibrant and profitable cassava seed entrepreneurs are encouraged to venture into the seed business. These seed businesses will provide healthy seed of more productive varieties leading to adoption of new varieties to improve productivity and food security, increase incomes of cassava growers and seed entrepreneurs, and enhance gender equity. The Cassava seed entrepreneurs (CSEs) model is a distinctive pathway of seed delivery in, Abia, Imo and AkwaIbom States, to help develop a network of community based seed enterprises. These CSEs source breeders' seed of improved varieties of cassava from Umudike Seed Company, NRCRI Go, Seed Company IITA and the Foundation Seed Producer (FSPs) to multiply and sell to farmers in their vicinity. The strategy is to carefully select grass root entrepreneurial seed producers in the project target areas as CSEs using laid down criteria to ensure compliance requirements for certification by the National Agricultural Seed Council of Nigeria. Commercialization of cassava seed is the process by which cassava seed entrepreneurs produce surpluses which can be sold in the market and thus increase their market participation (Adamu, 2021). In line with policy thrusts, the Federal Government of Nigeria in recent times has consistently promoted the increasing commercialization of agricultural production through its different schemes, policies and programmes. The commercial seed production model based on cassava seed entrepreneurs (CSEs) distributed in a hub-and-spoke model with quality control oversight is a profitable and sustainable model to reach cassava seed farmers (Legg *et al.*, 2022). Commercially sustainable seed systems for cassava, which deliver certified seed of improved varieties, offer great potential benefits to farmers, including:

i. increased productivity resulting from low disease and pest levels.
ii. provides an assurance that what they pay for is what they get.
iii. commercial seed systems that supply high quality products also provide substantial new income-generating opportunities for farmers.

Furthermore, structured commercial cassava seed systems that provide quality assurance may enhance dissemination of improved varieties to smallholder farmers and inform breeding programs on varietal demand and trait preferences, which in turn will result in a more dynamic and productive cassava economy (Legg *et al.*, 2022)

NRCRIs Experience in Commercialization of Cassava Seed in BASICS Project

i. NRCRI is involved in three project States namely Abia, AkwaIbom and Imo.
ii. Capacity building given to CSEs on good agronomic practices, Techniques and handling of SAH (Semi-Autotrophic Hydroponics) materials - Modern Technique in producing clean planting materials through Biotechnology, Business & Enterprise development/strategies for stems & roots, and Integrated Pest and Disease Management. Pest Control-Types & control measures Disease and Record Keeping & Management, cost of production for cassava stems per hectare.
iii. A paradigm shift from the informal seed distribution system that is characterized by low adoption, no varietal traceability, seed sharing and low incomes to a formal seed system where seed sourcing is organized, seed quality is assured and certified.
iv. Stakeholder synergy consolidating.
v. Farmers organization and cooperatives encouraged.
vi. The farmers have access to land with more than one hectare.
vii. Major source of cassava seed from NRCRI Umudike.
viii. Commercialization of cassava seed increased and offer great benefits to Cassava Seed Entrepreneurs (CSEs), including: increased productivity resulting from supply of high-quality improved cassava varieties.
ix. Registration of CSEs on the Cassava Seed Tracker.
x. Willingness to extend disease free cassava seeds to other farmers and abide by National Agricultural Seed Council (NASC) regulations.
xi. Certification intensified, Licensed Seed Inspectors (LSIs) came on board.
xii. Willingness to pay for cassava seed increased.
xiii. Provide substantial new income-generating.
xiv. Create employment opportunities.
xv. Demand for preferred varieties increased.
xvi. Adoption level of improved certified cassava varieties increased.
xvii. Business opportunities of the seed entrepreneurs expanded.

xviii. Seed companies in cassava emerged.
xix. Association of cassava seed entrepreneurs at Zonal, State and National levels are existing.

Challenges Faced by the CSEs from NRCRI Experience

The challenges faced by the cassava seed entrepreneurs are high cost of transportation, low mechanization and use of tractor, theft of certified cassava seeds from the farm, menace of cassava seed farm by cattle, bottle necks in seed certification that led to introduction of licensed seed inspectors. This finding is in line with the report of Anyaegbunam *et al.* (2022), that constraints faced by the seed entrepreneurs were cattle menace, inadequate finance, low level of mechanization, high cost of inputs, poor road network and low patronage.

CONCLUSION AND RECOMMENDATION

NRCRI experience in commercialization of cassava seed of BASICS Project spread through informal and formal stages of seed system in the Zones. Commercialization of improved cassava seed suppled high quality products, increased production, and provided substantial new income-generating opportunities for farmers and business potentials of the CSEs. Among the challenges to cassava seed commercialization were bottle necks in seed certification that led to introduction of licensed seed inspectors, high cost of transportation, low mechanization, theft of certified cassava seed from the farm, and menace of cassava seed farm by cattle. It is therefore recommended that the project should popularize and upscale the released varieties through market day promos, demonstration farms and product lunch for greater achievements.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Livestock production plays a significant role in rural livelihoods and the economies of developing countries like Nigeria. They are providers of income and employment for producers and others working in, sometimes complex, value chains. They are a crucial asset and safety net for the poor, especially for women, and they provide an important source of nourishment for billions of rural and urban households worldwide. These socio-economic roles and others are increasing in importance as the sector grows because of increasing human populations, incomes and urbanization rates. To provide these benefits, the sector uses a significant amount of land, water, biomass and other resources and emits a considerable quantity of greenhouse gases. Managing the required intensification, food insecurity and the shifts to new value chains is also essential to avoid a potential increase in food-borne and other diseases. Food security and growth in agricultural output depends on technological usages, which enhances the productive capacity of the agricultural sector. The study explored the challenges of animal production and food security in Nigeria with an attempt to explore the current trends in food production as it relates to food security in Nigeria.
Keywords: *Livestock production, sustainable path, economic recovery, food security*

INTRODUCTION
The relationship between agriculture and development, especially in Sub-Saharan Africa, cannot be overemphasized. We are at a moment in time where our actions could be decisive for the resilience of the world food system, the environment and a billion poor people in the developing world, let alone for the fate of our planet (Olaoye, 2014). The society has realised that there are major pressures on the world's food and ecological systems, where changes to the biogeochemical cycles on a global scale may be irreversible and where new drivers, such as climate change, are likely to exert additional pressures for feeding 9 billion people in the future in a sustainable manner. The demand for animal products is rising concurrently, particularly in developing nations, which puts further strain on the world's natural resources. In West Africa, Nigeria is a key centre for the consumption of animal products. It is also one of the major producers of livestock in the region (Zougmoré *et al.*, 2016). For Nigeria and the livestock-producing neighbouring Sahel nations, meeting the rising domestic demand and gaining access to these booming markets are crucial economic issues. The majority of countries in the globe are currently dealing with enormous population growth and environmental problems, which have put their respective countries' food security in danger (Huang and Ukpong, 2019). There needs to be a proportional increase in food production to feed this expanding population.
Food is a vital requirement for human survival since it provides the essential nutrients required for the body's general function. According to the Food and Agriculture Organisation (FAO), food comprises grains, oils, and

products from animals (Tubiello *et al*., 2013). However, this definition now includes other goods including sugar, fruits, vegetables, legumes, roots, and tubers (Crentsil and Ukpong, 2014).
According to Inyeinyang *et al*. (2019), one of the aspects of poverty is food insecurity, which includes both the availability and access to food (supply and entitlement). The inability to buy enough food that may be regarded adequate to give the necessary amount of protein and energy needed by the human body within a specific time can be characterised as food poverty, and livestock production is a contributing component to these needs for high-quality food. Depending on the degree of income, the contribution of livestock varies from home to household. The consumption of livestock protein and other animal products like milk, meat, and eggs also varies from household to household because some livestock keepers sell their stocks for money in order to buy food grains, cereals, and vegetables, while others keep the smaller mammals for food (Inyeinyang *et al.*, 2019). This provides some proof of how crucial agriculture is to economic growth. However, without economic growth, continuous economic progress is impossible. According to the World Bank (2006), high levels of poverty will result in slow economic growth, and low levels of poverty would result in fast economic growth. As a result, sustained economic development requires economic growth (Akanbi and Du Toit, 2011). This essay examines the benefits and drawbacks of animal production as a long-term strategy for Nigeria's economic growth and food security. Additionally, it covers important aspects that will probably determine how much the industry contributes in the future to economic development, environmental preservation, and food security. Our investigation on the contributions of agriculture to economic growth, as measured by Gross Domestic Product (GDP), in Nigeria is motivated by the knowledge that economic growth is essential for sustained development.

The current state of the livestock sector in Nigeria

The animal husbandry sector in Nigeria in its current state is unable to ensure the self-sufficiency of the population in animal products. The nation possesses abundant animal resources, including cattle, sheep, goats, and poultry, as well as beaches and fishing and aquaculture reservoirs, but these resources are insufficient to support the population's needs, Dixon *et al.*, 2001). The population of Nigeria is growing faster than the population of farm animals, according to research, and despite positive dynamics in the production of meat and fish, Nigeria's external dependence on imports, whose share in livestock production is roughly 20%, has not yet been overcome. In addition, Nigeria is the most densely populated country in Africa, with over 200 million inhabitants in 2022, and it is predicted that by 2050, that figure will have nearly doubled to 402 million (Adegbeye *et al.*, 2020). As a result, there will be a greater demand for food products with an animal origin. Given the situation, it is crucial to pay attention to the issues preventing the full development of animal husbandry, as this is the most significant step towards enhancing the nation's food security, enhancing the diet of the populace, and modernising the agricultural sector of the economy. The conflicts between farmers and pastoralists, which not only result in human and animal losses, disrupt population peace, and jeopardise the nation's food security, should receive special attention as the principal barrier to the expansion of animal husbandry (Abdulyakeen, 2022).

The Livestock Sector and its Contributions to Nigerian Economic Development

Livestock is a significant component of Nigerian agriculture and plays a significant role in the country's economy. In small-scale farming systems throughout the developing world, animals play a significant role in sustaining livelihoods. In these systems, livestock and crops frequently surround a dynamic interface. Animals are crucial to human welfare everywhere in the world.

• The provision of food and animal products used for food by people in many parts of the world is the most significant use of livestock. Meat and milk are two examples of animal products that are utilised as human food; they may also be found in livestock feed. Blood meal and bone meal are sources of protein and minerals, respectively. All types of families, both in rural and urban regions, can obtain nutritious food from livestock. For a very long time to come, bullock power will probably continue to be the primary source of draught power for agricultural operations and the transportation of agricultural products to local markets.

Socio-economic Nigeria's macro livestock industry is important.

Gross domestic product (GDP) growth and income generation are both a result of the high demand for livestock food and goods, which has aided farmers in growing their businesses. Farmworkers are given employment options, and a wide range of livestock industry knowledge and services are provided. Research and development efforts are strengthened in the areas of antimicrobial resistance, food safety, and drug toxicology. Cattle, donkeys, camels, and horses are used as draught animals by local farmers for land preparation (tilling, ploughing) in agricultural crop production. This supports public health and offers pertinent information for economic planning and policymaking in the areas of financing, health, and agriculture. Additionally, this guarantees ongoing breed line improvements for higher meat and milk yields to fulfil the rising food demands of Nigeria's population (Shi *et al.*, 2022).

Enhancing livelihoods and eliminating poverty among farmers and herders. These represent a number of additional payments to the households engaged in agriculture (Kemp *et al.*, 2013). Livestock are significant sources of investment and boost the value of many assets that the agricultural households could not otherwise employ. For instance, the transformation of feed biomass, such as weeds, straw, cultivated forages, public grazing areas, and surplus grains, into valuable goods like meat, milk, and eggs for consumption and/or the sale of, as well as the provision of services, such as the draught power pack (Holzworth *et al.*, 2014). These allow family members to increase the value of the work they already do on the farm.

Nigeria's Livestock Sub-Sector: Challenges and Way Forward

Nigeria animal production is facing numerous challenges with certain factors militating against successful animal production (Mgbenka *et al.,* 2016). In spite of the contribution it has made socioeconomically to the growth of the Nigerian state, the industry however, is challenged with some issues that are begging for attention which include:

1. Capital is one of the most important production elements that man is aware of. A farm that produces and processes animals needs capital to get started, and it needs capital to maintain productivity. Capital is one of the main obstacles facing the livestock business, particularly in emerging nations like Nigeria. Financial shortcomings have caused animal businesses to grow slowly, go dormant, or even be destroyed. Low-wage workers, who predominate in the animal business, are unable to meet the needs of the sector, particularly when productivity is subpar.

2. Exorbitant price of animal feeds: Animals need nutrient-rich feeds in order to fully develop and be productive. Farmers do not frequently use animal feeds, and even when they are, they are often out of reach financially. Since farmers raise animals for profit, they need to buy feed at a price that will allow them to break even as well as generate a respectable profit.

3. Animal illnesses: The livestock business continues to face a real danger from animal diseases. Animal illnesses that damage animals and consequently lower productivity pose a persistent threat to animal products. Despite numerous attempts at vaccination, viral infections like Newcastle disease and other infectious diseases are much more devastating to the chicken business.

4. Access to veterinary services (vaccines and drugs). Since the majority of animal production activities take place in rural or remote areas that are inaccessible to proper veterinary services and many of those that find the high cost of veterinary services prohibitive, then turn to readily available quacks who wreak havoc on the animal industry by using outdated vaccines, phoney medications, and incorrect prescriptions for treating diseases. Vaccines and medications of all kinds of low quality are readily available on the market nowadays and can be taken by virtually everyone.

5. Education levels of farmers: It is a well-known truth that the majority of farmers have low education levels or are even illiterate, making it challenging to use contemporary animal production techniques where traditional systems have failed or produced less profit. More graduates should be encouraged to pursue careers in animal production in order to grow the industry, which will be a wonderful idea. These graduates will introduce cutting-edge techniques for animal production that ensure the nation's food security and the growth of the industry.

6. The Government's Function: The government's unsuccessful policies are frequently detrimental to the development of the livestock sector. Politicians may impose import restrictions in an effort to support domestic sectors, but they rarely offer workable substitutes. There aren't enough good loans to maximise animal productivity, and access roads aren't built in a way that makes it easy to transport animal goods from the farm to the table. The government can assist by collecting eggs to minimise egg glut, a problem that the poultry business occasionally faces.

8. Market and storage facilities: The animal products market is essential to the industry's viability. Because most animal products are perishable and expire quickly, the market for animal production is poorly organised, and farmers frequently suffer losses rather than gains.

9. Inadequate Extension services: Extension services are essential in encouraging ethical farming and agricultural practises among our stakeholders in the livestock business. If farmers are knowledgeable about some areas of production, the cattle business can produce more than it is now doing. In order for farmers to succeed in their chosen profession and make a meaningful contribution to the economy of the country, extension specialists offer technical assistance to farmers on ways for maximising productivity as well as market-related problems.

10. Insufficient work force: The animal production business in Nigeria is suffering from a lack of labour, particularly skilled labour. In some places, one man is doing the work of several, which reduces productivity. Because of the possibility for a nation with over 200 million citizens, this is a serious worry. Nigeria will have enough individuals employed in animal production if more people are encouraged to do so.

Way forward for Livestock Industry in Nigeria

Food security and the development of any country depend heavily on animal production. It offers the following benefits to the economy:

(a) foreign exchange; (b) employment for the populace; (c) a rich source of protein, which is necessary for human nutrition; (d) prestige; (e) income for the populace; (f) draught power; (g) transportation; (h) raw materials for the clothing and shoe industry; and (i) by-products that can be used in a variety of other industries, such as the cosmetic industry.

Through commercial farming using modern techniques, livestock production has undoubtedly made a significant contribution to meeting the world's need for protein. It is also claimed to have contributed to the socioeconomic development of Nigerian state in particular, and it is anticipated to further boost development in a way that will ensure food sufficiency.

The following are the steps that Nigeria's agriculture will take to increase animal production for food security, and to strengthen the basis for decision-making, a thorough mapping of agricultural potentials is required, considering the following elements:

1. Without being able to feed and maintain the health of its population, a nation cannot be prosperous. If the government would allocate adequate funds to this subsector and promote commercial or large-scale production in order to meet the nation's food need, animal production would be a potential industry. The government should create attractive incentives to encourage young people to work in agriculture, including teaching them how to engage in commercial farming.
2. Provisions for the storage of animal products in deep freezers and other storage facilities, which are now employed with technical improvement, should be made in order to promote optimum animal productivity. Nigeria will increase its animal production with the aid of contemporary meat preservation techniques, enabling the country to engage in worldwide trade and strengthen its economy.
3. Disease prevention must be a concern for animal farmers since if one is sick, everyone is at risk. The government needs to treat this seriously and make sure that farmers have access to and can afford all of the vaccines required to help manage animal sickness. The government needs to provide subsidies for veterinary services to farmers in order for the nation to have a solid and sustainable system for raising animals.
4. They should be trained in current and sustainable business practices, and if necessary, they should be having periodic experience sharing with related counterpart both within and outside Nigeria on good practices. Moreover, considering the country's current economic situation, I think technology transfer is necessary because agriculture is the only industry that has a chance of improving the economy.
5. The federal government should introduce a programme that allows states to start animal production that is unique to each state because different states cannot produce the same livestock due to climate variability and geography.
6. To help enhance the quality and accessibility of feed materials, there is a need for further investment in the livestock sector; this requires sustained funding and support from the government and other economic partners.
7. Appropriate policies are also required to help livestock farmers, especially small-scale farmers, by offering incentives, subsidies, high-quality veterinary care, and effective breeding programmes with adequate capacity upgrading and upscaling of the existing and acceptable technologies.

CONCLUSION

Animal production has remained an important aspect of any economy. Viable agricultural programmes/policies and activities in any nation are capable of sustaining the food supply and reserves needed for the welfare of the citizens. However, in Nigeria, agriculture is despised by able bodied young men and women who do not have interest in animal production. Both the educated and non-educated roam the nooks and crannies of the cities in the urban areas looking for non-existent white-collar jobs. Because of poor attitude to animal production, there is also this disequilibrium in the production, demand and supply of food. Government must cultivate local initiatives by promoting grassroots awareness on the importance of cooperative animal husbandry and farming, which will result to greater gain of animal production, and government, should provide a platform for interaction with the local farmers in order to discover their problem and provide the needed solution.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study evaluated the sweet potato supply chain performance with evidence from National Root Crops Research Institute, Umudike, Abia State, Nigeria. The data were collected from a total of 206 sweetpotato supply chain actors who patronized the Institute during 2020 planting season using a semi-structured questionnaire. The study examined the level of customer satisfaction, vulnerability and resilience of supply chain using rating scale analysis. The results showed an average total level of satisfaction (2.12), resilience (3.05), and vulnerability (3.17) with performance evaluation of 59.20% above average indicated an efficient system of supply. The study therefore recommends effective monitoring, evaluation, and follow-up of chain actors to ensure effective performance and supply at a sustainable manner.
Keywords: *Quality, Resilience, Satisfaction, Sustainability and Vulnerability*

INTRODUCTION
One of the major obstacles to Nigeria's sweetpotato production system is the lack of a sustainable seed system, which includes a demand and supply mismatch (Namada, 2012). Understanding the current seed supply chain structure and developing it or making improvements to it becomes essential for seed entrepreneurs. According to Simchi-Levi *et al.* (2008), a supply chain (SC) is a group of individuals connected by the exchange of goods, information, and money with the aim of lowering system costs. Depending on the quantity and placement of intermediary facilities in the supply chain, the supply structure may change. The supply chain to produce sweetpotato seeds typically consists of the following facilities: supplier (from the Tissue Culture (TC) lab), manufacturer (screen house), distributor **[Decentralized Vine Multipliers** (DVMs)], and root producers (wholesaler and retailer). Each facility in the supply chain processes orders based on the information at their disposal and places order to the immediate upstream facility. The upstream facility supplies the downstream crops demand from available material. Upstream facilities point in the direction of the end provider, whereas downstream facilities point in the direction of the final consumer. Customers pick up the product from the final supply chain site in the end.

The National Root Crops Research Institute (NRCRI), Umudike at the upstream of sweetpotato supply chain has taken scientific steps to ensure continuous availability of different classes of sweetpotato seed (of all released varieties) all year long on a revenue basis. With the Institute facilities **(tissue culture laboratory, screen houses, and net tunnels), sweetpotato seeds are produced, multiplied, maintained, and sold to the downstream farmers. NRCRI supplies its seeds to categories of chain actors ranging to DVMs, seed entrepreneurs and farmers in various states of the country. However, the Institute in the past had developed the capacity of a cluster DVMs– empowered to sell commercial seeds to root producers in various communities of the states. T**hese groups of farmers and others get quality seed (certified) from NRCRI for subsequent and continuous production. This study, hence, examined the Institute's performance in the sweetpotato supply chain among its actors to primarily achieve system sustainability, with objective to ascertain the level of customers satisfaction in the supply chain; and to examine the level of vulnerability and resilience of the supply chain among the actors.

METHODOLOGY

The study was carried out from the upstream (NRCRI, Umudike) to the downstream (customers) across Nigeria who patronized the NRCRI sweetpotato seed business unit in the year 2022. Semi-structured questionnaire was used as a tool for data collection. Data was collected through face-face interaction and on-line (Google docs. survey) for those that transacted by proxy. The level of customer satisfaction was measured using a 3-point scale of Very Satisfied (VS), Satisfied (S), and Not Satisfied (NS). The study also used 6-point rating scale of Very High (VH), High (H), Moderately High (MH), Low (L), Very Low (VL), and None (N) with acceptable mean score of 3.50 for level of vulnerability and resilience of the seed supply chain. Respondents with mean score of 2.0 and above (level of customer satisfaction) and 3.50 and above (level of vulnerability and resilience) implied that they are in confirmation with the statement while respondents with mean score of less than 2.0 (level of customer satisfaction) and 3.50 (level of vulnerability and resilience) are not in use. This was calculated with equation below.

$$Xs = \Sigma fn/N \text{ ------------- } (1)$$

Where Xs =mean score, Σ = summation, f= frequency, n = likert nominal value, N= number of the respondents.
Xs=1+2+3/3 = 6/3=2. 00 (level of customer satisfaction)
Xs=1+2+3+4+5+6/6 = 21/6=3.50 (level of vulnerability and resilience)

RESULTS AND DISCUSSION

Socio-Demographic Features of the Respondents

The results in Table 1 presented the socio-demographic characteristics of the respondents. The results showed that the respondents (customers) had a mean age of about 46.00 years, educational level of 19 years, 0.75 hectare cultivated with sweetpotato and farming experience of about 2.5 years. This implied that the sweetpotato seed actors were still young and agile, had formal education; still grow sweetpotatoes for sustenance with little experience. Majority of farmers (70.9%) belonged to one or more cooperative societies, and more than half of them (53.4% and 52.4%) were female.

Table 1: Socio-demographic Variables of the Sweetpotato Seed Buyers

Variables	Mean	Std. dev.	Min	Max
Age	46.0182	9.6212	29	74
Educational level	15.8019	4.6873	5.50	16.00
Area with sweetpotato (ha.)	0.42	0.8569	0.01	4.00
Sweetpotato Farming experience	2.544	2.7078	1.00	12.00
Dummy (%)				
Sex(female)	53.40			
Membership of cooperation	70.90			

Source: Field Survey, 2022

Quantity of Sweet potato supplied

The study also measured the performance of the sweet potato seed supply system using percentage performance evaluation as showed in Table 2. The results showed that the system have an average performance of 59.2%, indicating an average performance of the system, heading toward efficient system of 100%.

Table 2: Percentage Performance Evaluation of Sweet potato Seed Chain

Quantitative measures	Number (Bundle)
Quantity of seed produced yearly	3500
Quantity of seed sold (Quantity Given to other Chain)	2075
Performance Evaluation (%)	59.20

Source: Field Survey, 2022
The system is efficient if quantity produced/sold = 1 or 100%

Level of customer satisfaction

The results in Table 3 showed the level of satisfaction by sweetpotato seed supply chain actors. The result showed that among the parameters examined, the customers were satisfied by the variety given (2.49), customer's service (2.04), production information accessed (2.28), NRCRI production environment (2.16), quality (2.50), appearance of the vines (2.50), color of the leaves (2.38), vigor of the vines (2.17), number of nodes (2.28), and packaging (2.20). The highest score from quality and appearance confirmed the study of Okoye *et al*, (2021) on the use of quality seed vines (cuttings) in any crop production as a critical factor influencing yield of that crop. Nevertheless, the actors were not satisfied with the quantity given (1.54), yield (1.95), proximity to the seed source (1.83), price (1.99), purity of the vine (1.99), and labeling (1.71) having a below mean of 2.00, the acceptable mean benchmark. This indicated that they were poor satisfaction of customers in the quality of vine at certain price, even the yield and labeling.

Table 3: Level of Satisfaction by Sweetpotato Seed Supply Chain Actors (Pooled)

Parameters	Very Satisfied	Satisfied	Never satisfied	Mean
Variety given	116(348)	74(148)	16(16)	**2.49**
Quantity	20(60)	72(144)	114(114)	1.54
Yield	54(162)	88(176)	64(64)	1.95
Customer service	68,6(222)	66(132)	66(66)	**2.04**
Production Information	80(240)	104(208)	22(22)	**2.28**
Proximity	48(144)	76(152)	82(82)	1.83
Environment	76(228)	86(172)	44(44)	**2.16**
Price	42(126)	120(240)	44(44)	1.99
Purity	42(126)	(240)	4444)	1.99
Quality	110(330)	90(180)	6(6)	**2.50**
Appearance (neatness)	128(384)	60(120)	12(12)	**2.50**
Color of the leaves	96(288)	92(184)	18(18)	**2.38**
Vigor of the vines	54(162)	134(268)	18(18)	**2.17**
Cuttings (Number of nodes)	64(192)	136(272)	6(6)	**2.28**
Packaging	58(174)	132(264)	16(16)	**2.20**
Grand mean				**2.12**

Seed chain Vulnerability

The results in Table 4 presented the Likert analysis of sweetpotato seed (SPS) chain vulnerability among sweetpotato seed chain actors. The results of the study showed that the system was vulnerable to disease (3.64) and pest (4.13) with mean score of 3.50 and above. This implied that the sweetpotato seed have the quality or state of being exposed to the possibility of being attacked by pest and disease. The study also showed that the seed chain is not vulnerable to adverse environmental condition (3.10), unfavorable weather (3.23), weeds (2.68), drought (2.41), and others (3.01) with mean scores below 3.50, the acceptable cut-off mean.

Table 4: Likert Analysis of Seed chain Vulnerability among SPS Chain Actors (Pooled)

Vulnerability	VH	H	MH	L	VL	N	Mean
Disease	66(396)	22(110)	16(64)	34(102)	10(20)	58(118)	**3.64**
Pest	22(132)	76(380)	34(136)	64(192)	0(0)	10(10)	**4.13**
Adverse environmental condition	16(96)	36(180)	38(152)	34(102)	26(52)	56(56)	3.10
Unfavorable weather	6(36)	42(210)	26(104)	76(228)	32(64)	24(24)	3.23
Weed	0(0)	40(200)	26(104)	40(120)	28(56)	72(72)	2.68
Drought	0(0)	22(110)	16(64)	64(192)	26(52)	78()78	2.41
Others	32(360)	6(30)	0(0)	22(66)	16(32)	92(92)	3.01
Grand mean							**3.17**

VH= Very High, H= High, MH= Moderately High, L= Low, VL = Very Low, N= None
Acceptable mean score = 3.50, Figures in Parentheses are the weighted Likert frequencies

Sweetpotato Seed Supply chain Resilience

The results in Table 5 showed the Likert analysis of sweetpotato seed chain resilience among sweetpotato seed chain actors. The results of the study showed that the sweetpotato seeds were resilient to environmentally friendly (3.63), climate conduciveness (3.59), price of the seed (3.94) and demand/supply (4.50). This was an indication that the seed chain system had the capacity to withstand or to recover quickly from shock either from increase or decrease in any of the environmental and climate conditions, price, and demand of sweetpotato seeds. This result may possibly be explained by the time of planting -raining seasons and their level of education which exposed them to knowledge of handling seed even at dry and adverse weather conditions. More so, with increase in sweetpotato seed demand, the system will still be able to supply and produce due to the quality of the production. The study also showed that the system was not resilient to disease/pest (2.28), customer in-responsiveness (2.33), Poor monitoring scheme (2.22), and government intervention (1.94), implying that system will be unable to withstand shock or to recover quickly from these parameter measurements.

Table 5: Likert Analysis of Sweetpotato Seed chain Resilience

Resilience	VH	H	MH	L	VL	N	Mean
Environmental condition	66(396)	36(180)	12(48)	10(30)	12(24)	70(70)	**3.63**
Disease/pest	12(72)	28(140)	16(64)	6(18)	32(64)	112(112)	2.28

CONCLUSION AND RECOMMENDATIONS

The study evaluated the performance of sweetpotato seed supply chain using evidence of NRCRI and proffered policy recommendations as implications for seed business sustainability. The study showed that the customers were generally satisfied especially in the areas of customer services, access to production information, production environment, quality, appearance, and vigor of the seed among others. The supply chain system generally showed a moderate efficient performance system of supply. The study therefore calls on the NRCRI and other seed companies on sweetpotato to work and hold tight the strengths and opportunities in the seed supply chain to sustain and mitigate the threats and weaknesses. Effective monitoring, follow-up mechanism and periodic evaluation are recommended to ensure quality maintenance, customer satisfaction, reduced chain actor’s vulnerability and increases resilience.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Labour is one of the production factors. It is anticipated that as adoption increases, farmer's output will increase and there will be corresponding increases in the amounts of production inputs, one of which being labour. Therefore, the purpose of this study was to determine how adoption affected the labour that resource-poor farmers in Imo State utilized to produce cassava. One hundred and eighty (180) resource-poor farmers were randomly chosen for the study using the simple random sampling technique. Regression analysis and linear correlation were used to analyse the data at a 5% level. The findings showed that adoption has no significant effect on labour. The hypothesis that there is no significant effect of adoption on labour for cassava production was accepted, while the alternative hypothesis was rejected, on the basis of the findings. Therefore, it was recommended that rural farmers should organize themselves into cooperatives to be able to meet up with the challenges of hiring farm labour.
Keywords: *Labour, Effect, Recommendations, Adoption and Cassava*

INTRODUCTION
The main goal of agricultural extension recommendations for farmers to embrace is to increase farmers' yield. Findings have demonstrated that adopting improved crop production technologies packaged by the Agricultural Extension Department increased farmers' income, allowing them to increase the purchase of production inputs while also significantly improving their crop yield (Agbarevo, 2011; Ifenkwe, 2018 and Obinne, 2020). As a result, there is a positive relationship between adoption on the one hand and yield, income and the capacity to employ more production inputs, such as agrochemicals, equipment and financing on the other. Therefore, it is anticipated that increased implementation of extension recommendations will also boost agricultural labour demand. Indeed, farm labour is typically mostly provided by the family in Africa (Dauda, 2019). Hired labour is utilized to supplement household labour. In this regard, Adegeye and Dittoh (2020) noted that although three categories of labour: family labour, hired labour and exchange labour—can be distinguished in Nigeria (Africa), family labour is the primary source of farm labour.

They added that family labour was primarily employed in Nigeria. In addition, as everyone in the family or household contributes to the development of the home lands, it includes the labour of all men, women, and children. For resource-poor farmers (small-scale farmers), who make up around 95% of the farming population, family is the primary and occasionally the only source of labour. Given that the strength of labour availability is positively connected with the area under cultivation (khan, 2019), it is well known that labour availability increases the size of the land that is put under cultivation. In a study on labour mobility for agricultural productivity, Osabo (2021) discovered that the amount of family labour greatly influenced the amount of family land needed and the intensity of agricultural activities throughout the year. He also noted that, more often than not, the availability of workers during the growing season is a bigger barrier to raising agricultural output than the availability of land. Furthermore, there is ample proof that a manpower shortage exists even when a farmer with limited resources extends the area under cultivation. As farmers adopt new agricultural technologies, this problem gets worse. Therefore, labour serves as a productivity barrier for farmers who lack access to resources. It is made worse by the fact that farmers with limited resources might want to recruit more workers to expand the area under cultivation and, as a result, boost productivity, but they might not be able to do so due to the high cost of hiring workers (Rahman, 2020). Therefore, hired labour is only used in the direst situations where family labour is severely reduced as a result of rural-urban migration (Nwankwo, 2020). It is against this background that this study was conceived to examine the effect of adoption on quantity of farm labour used by resource-poor farmers in Imo State, Nigeria.

MATERIALS AND METHODS

The study was conducted in Imo State, Nigeria. It is one of the states in South East, Nigeria. Agriculture is the major occupation of the people and the major arable crops cultivated in the area include cassava, yam, sweet potato, cocoyam and vegetables (NAERLS, 2021). The state has three agricultural zones, namely, Orlu, Okigwe and Owerri. Two blocks were randomly selected from each zone, and three circles were randomly selected from each block, making a total of eighteen circles. A total of 180 farmers were included in the sample, ten from each circle of cassava growers. Primary data were collected through the use of structured questionnaire. Utilizing linear correlation and regression analysis, data on the adoption of recommendations and labour were collected and analyzed. To obtain an adoption index for each farmer, Farmers' responses were categorized into (a) rarely adopted (b) adopted and stopped using innovation, and (c) adopted and still using innovation. To each of these categories, numerical values 1, 2, and 3 were assigned, accordingly. The subject index was calculated using the average response. With a 95% level of confidence, regression analysis and linear correlation were used to test the null hypothesis that adoption does not influence labour.

The regression equation is given by the formula: $y = a + bx$

Where:

y = labour (dependent variable)
a = intercept
b = slope
x = adoption (independent variable)

RESULTS AND DISCUSSION

The findings demonstrated that adoption had no significant effect on farm labour needed to produce cassava. This is as a result of the F-value of 1.727 being determined to be non-significant.

Table 1: The Effect of Adoption on Labour for Cassava Production

Variables	Co-efficient	Standard Error	t-value
Constant	3.645	2.532	1.439
Adoption	1.597	1.214	1.315
R	0.09706		
R-Square	0.00963		
F-Value	1.72768^{NS}		
Sampling size	180		

NS = Not significant

Therefore, the alternative hypothesis was not accepted; the null hypothesis, that adoption has no significant effect on farm labour for cassava production, was accepted. This indicated that resource-poor farmers do not require more manpower to produce cassava as a result of the use of improved cassava production technology. This is so because the family mostly supplies the labour employed in the farm. The number of farm workers needed depends on the size of the family, therefore even when adoption increases the size of the farm, labour is more or less constant. This is so because adoption does not increase the size of the family. Additionally, rural farmers organize themselves into labour unions and alternate working on one other's fields. Therefore, it was not surprising to see that adoption did not necessarily result in more people working in agriculture, even if more cultivable land would require more man-hours and man-days. In support of the aforementioned, Olayide (2020) noted that although three categories of labour: family work, hired labour, and exchange labour—can be identified in Nigeria (Africa), family labour is the most significant component of employment for small-scale (resource-poor) farmers, who make up roughly 95% of the farming population. Similarly, Mabro (2021) found that the amount of family labour available to be employed during periods of high demand for labour substantially influences the amount of family land required and the level of agricultural production. As new agricultural technology (innovation for adoption) is developed, this problem gets worse, he said. This suggests that a barrier to the adoption of such new technology or technologies is the difficulty of boosting farm manpower as required by the deployment of new technology. This is due to the positive correlation between family size and agricultural labour for farmers with limited resources, which cannot be altered by using new technologies. Furthermore, Ojidoh (2021) noted that hired labour is utilized in exceptional cases where family labour is dramatically reduced as a result of rural-urban migration, schooling, or an increase in the average age of farmers. Therefore, lack of workforce is a barrier to agricultural productivity because family labour and even child labour are still challenges (IFAD, 2020).

CONCLUSION

The study has demonstrated that adoption of improved cassava production technologies does not increase labour significantly. This suggests that even while the need for manpower may rise as a result of adoption, the number of farm labourers engaged is mostly constant. Since farming is arranged on a farm-family basis, resource-poor farmers are not prevented from increasing labour on farms when necessary; rather, they are constrained by the lack of labour or by the high cost of labour, or even both. Instead of hiring more farm labours, the additional labour requirements might be supplied by farm family members working more hours on farms. The rural-urban migration, which deprives agricultural families of labour, makes the situation worse. Government must build agro-cottage industries in order to provide basic social amenities in rural areas in order to stop the flood of rural-urban migration. The fact that the current generation of farmers is ageing out without being replaced by younger people serves as more evidence of this. However, if rural farmers can come together as cooperatives, they will be able to overcome the difficulties of employing farm labour, in order to boost farm output, this would help to alleviate some of the manpower availability obstacles.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined the perceived effects of use of ICT on cassava value chain actor (consumers) in Anambra State. A structured questionnaire was utilized to collect relevant information from 100 randomly selected respondents. The study revealed that 68% of respondents were between the ages of 21 and 40, with the majority (65%) being female, and having at least, a primary education (78%). The study also found that the major perceived effects of ICT use were providing consumers with fast access to information on produce/products (x=4.11), providing information on availability of produce/products (x=4.10), and providing information on quality and condition of goods (x=4.09). Major constraints to the utilization of ICT by the respondents were inadequate durable ICT equipment/facilities with mean of $\bar{x}$= 2.20 and high cost of ICT facilities and low literacy ($\bar{x}$= 2.17). It is therefore recommended that consumers should be trained on the usage of ICT, and they should be made to understand the relevance of ICT tools in cassava value chain.
Keywords: *ICT, Perceived effects, Value Chain, Consumers*

INTRODUCTION
Cassava (*Manihot esculenta*) is a staple crop of choice across cultures and social divides in Nigerian households, widely eaten by all though processed differently. Most of the roots produced is consumed locally as traditional meals while small fraction of cassava output in the country is produced for commercial use in the livestock feed, ethanol, textile, confectionery, and food industries (Droppelmann, 2018). It is the most important crop by production, the second most important crop by consumption and it is largely cultivated by small-scaled farmers that depend on seasonal rainfall ((Sahel, 2016). Value chain is a set of activities that a firm performs in order to deliver a valuable product or service for the market (De Marchi *et al.*, 2018). Along the chain a value is added which give such product a competitive advantage in terms of quality and attracting a higher price at the market (Gereffi, 2018). In other words, a value chain is a series of activities or processes that aims at creating and adding value to an article (product) within it analyzing the opportunity cost of the new sequence along the product worth. According to Mukherjee and Maity (2015), ICT is an umbrella term that includes any communication device or application, encircling radio, television, cellular phones, computer and network hardware and software, satellite systems and so on, with the various services and applications connected with them, such as videoconferencing and distance learning. It also consists of a wide range of technologies starting from radio, television, and telephone to modern technologies like mobile phone, multimedia, internet, and satellite-based communication systems. They "old" ICT consist of the radio, television and telephone, and the "new" ICT consist of computers applications, satellite and wireless technology and the Internet.

METHODOLOGY
The study was carried out in Awka Agricultural Zone of Anambra State. A multi-stage sampling technique was adopted in selecting the respondents. Two local government areas (Awka South and Awka North) were randomly selected from the zone; two communities were selected from each of the local government areas (Nibo, Nise, Ugbenu and Achalla); twenty-five (25) cassava consumers were randomly selected from each of the communities. A total of 100 responses were returned and formed the sample size. The data for this study were obtained from primary source. Questionnaire was used for data collection and complimented with interview schedule. The questionnaire comprises of demographic characteristics, the perceived effects of use of ICT on consumers and major constraints to use of ICT. Data generated for this study were analyzed using descriptive statistics such as frequency distribution, percentage, and mean score.

RESULTS AND DISCUSSION

Socioeconomic status of the respondents

The result in Table 1 shows that greater proportions of the consumers (37.0%) were on the age bracket of 21-30. It implies that the consumers are predominantly within the productive and economically viable age, Majority (65.0%) of the consumers are female. This implies that female play a significant role in food processing for household. Majority (73.0%) of the consumers were married. It may imply that economic imperatives of family responsibility may be the driving force behind married person participating in the cassava value chain production for food security. It revealed that majority of the consumers (78%) had at least a primary education with 12% and 16% having secondary and tertiary education respectively. This implies that majority of the consumer households have basic literacy but may not be said to be adequately educated. Response on household size revealed that majority (73.0%) of the consumers had household size of between 4-6 persons. It implied that cassava is an important root crop for household food security.

Table 1: Distribution of the respondents according to their socio-economic status

Perceived effects of the use of ICT on cassava value chain actor (consumers)

Table 2 shows the perceived effects of use of ICT on the consumers. Results in Table 2 reveal that all consumers in the cassava value chain had been affected positively using ICT. The following were the major effects on consumers by the use of ICT: provides information on the unit of measurement ($\bar{x}$ = 4.24), it provide consumers with fast access to information on product ($\bar{x}$= 4.11), provide information on availability of product ($\bar{x}$= 4.10), information on quality and condition of goods ($\bar{x}$= 4.09), information on how to use a product ($\bar{x}$= 4.08), provides information on stock and supplies ($\bar{x}$= 4.07), provides information on market trends and price ($\bar{x}$= 3.91) and provides information on types of packaging ($\bar{x}$= 3.90). The implication of this finding is that consumers have real time and make value for their money. This result agrees with Baumuller (2017) who states that ICT services can facilitate the dissemination of information about availability of produce and prices as well as provide platforms for produce trading and bargaining.

Table 2: Perceived effects of the use of ICT on cassava value chain actor (consumers)

Perceived effects of use of ICT on cassava value chain actors (consumers)	Strongly agreed	Agreed	Uncertain	Disagreed	Strongly Disagree	Total	Mean
It provides consumers with fast access to information on product	250	120	24	10	7	411	4.11
Provide information on availability of product	225	140	30	10	5	410	4.10
Provides information on types of packaging	200	124	45	14	7	390	3.90
Provides information on stock and supplies	255	100	30	16	6	407	4.07
Enhance fast payment of products	230	108	45	10	7	400	4.00
Provides information on the unit of measurement	235	116	45	20	8	424	4.24
Information on how to use a product	215	140	39	10	4	408	4.08
Information on quality and condition of goods	220	144	30	10	5	409	4.09
Provides information on market trends and price	205	120	45	14	7	391	3.91
						Grand Mean	**3.65**

Source: Field survey, 2021. Cut off mean=3.00

Table 3 reveals the major constraints to the use of ICT by cassava value chain actors (consumers). The highest constraints was inadequate durable ICT equipment/facilities with mean of $\bar{x}$= 2.20, followed by high cost of ICT facilities and low literacy ($\bar{x}$= 2.17), inadequate ICT training centre ($\bar{x}$= 2.15), high cost of internet subscription ($\bar{x}$= 2.14), high cost of maintenance service ($\bar{x}$= 2.13), general lack of awareness of the important of ICTs in agriculture ($\bar{x}$= 2.12), poor network coverage ($\bar{x}$= 1.93) and erratic power supply ($\bar{x}$= 1.79). These findings agree with Godson-Ibeji (2016) who identified challenges on use of ICT as erratic power supply, poor network coverage, inadequate ICT training centre, high cost of ICT facilities, high cost of internet subscription, high cost of maintenance service and poor infrastructure.

Table 3: Constraints on the use of ICT by cassava value chain actor (consumers)

Variables	Infrastructure	Financial	Technological	Total	Mean Score
Erratic power supply	90	70	35	195	1.79
Poor network coverage	120	60	30	210	1.93
Lack of durable ICT equipment/facilities	150	80	10	240	2.20
Inadequate ICT training Centre	135	90	9	234	2.15
High cost of ICT facilities	147	76	13	236	2.17
High cost of internet subscription	156	68	9	233	2.14
High cost of maintenance service	126	96	10	232	2.13

Low literacy level among actors	153	70	14	237	2.17
				Grand mean	**1.88**

Source: **Field survey, 2021Cut off point = 2.0**

CONCLUSION

Based on the findings of this study, it is possible to conclude that consumers had a positive perception of the use of ICT in their cassava value chain activities, as ICT is one of the driving forces that bring about development and positive change in the livelihoods of people all over the world, and particularly in Nigeria. Due to constraints such as inadequate facilities and low literacy level, ICT is still underutilized in rural regions. It is therefore recommended that consumers should be sensitized and trained on the relevance and usage of ICT, and they should be made to understand the relevance of ICT tools in cassava value chain. Coordination of efforts by government, researchers, telecoms, ICT specialists, and consumers will result in full utilization of ICT in Nigeria's cassava value chain.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study analyzed sesame production in Donga Local Area of Taraba State, Nigeria. The specific objectives of the study were to estimate the costs and returns in sesame production; estimate the profitability of sesame production among the farmers; determine the effect of socio-economic variables on the income of sesame farmers; and identify the constraints to sesame production. Multi-stage sampling procedure was employed to select respondents for this study. A well-structured questionnaire was administered to 60 randomly selected sesame farmers. The primary data collected were analyzed using descriptive statistics, farm budgeting technique, and multiple linear regression. The study revealed that sesame production in the study area was profitable with a net farm income of ₦143, 007.63/ha and the return on Naira invested estimated at 1.60 (implying a 60 Kobo return per each Naira invested). Sesame production in the study area was faced with the problem of high cost of input, inadequate access to credit, inadequate extension services, pest and disease, continuous farmers/herders' clashes, and poor market facilities. It was recommended that sesame farmers should be encouraged to use herbicides /pesticides during their production as this aid in boasting their level of output. Sesame farmers are also encouraged to form cooperative groups to enable them to have access to loan and production inputs.

INTRODUCTION
Sesame (*Sesamum indicum L.*) is one of the important cash crops that can boost incomes of its producers and marketers which could in turn help in improving their livelihoods. It is one of the ancient oil seed crops known and use by mankind, which original area of domestication was not clear, but it is considered to have its origin in Africa and spread through West Asia, China and Japan (Rukwe *et al*., 2020). It is the eighth edible oil seeds in terms of production in the world and has higher oil content than other oil seed crops. The world over, there are about 4.8 million tons of sesame seed produced with Myanmar the largest producer while India and China are the largest exporters (Junaidu *et al.*, 2022). Similarly, sesame has been one of the cash crops produce in most part of northern Nigeria, mostly by small scale farmers which help them to acquire more income for taking care of their families as well as improving their livelihood assets. It has remained popular cash crop among farmers due to its good local and international markets potentials (Ikwuakam *et al.,* 2016).
Production of sesame seed in Nigeria has been increasing steadily because of favourable prices and demand of the commodity. Consequently, earnings of the producers and marketers are enhanced (Tahir *et al.*, 2021). Sesame seed has over 15% margin in terms of value added compared to other cash crop such as shea nuts and palm kernel.Sesame is used for various purposes such as raw materials in agro-allied industries, food, feed as well as means of generating revenue for its producers, marketers and governments. For instance, its seeds are used in confectioneries, biscuits, breads, etc., and may be baked into crackers, often in the form of sticks (Ikwuakam and Lawal, 2015). The demand for Sesame and its products is growing both at national and international levels. Therefore, there is a huge market demand for the crop. The previous status as a minor crop makes it received very little attention in aspects of research, production, processing, and marketing of the produce in the Country. Determining the benefits, and socio-economic variables and constraints influencing production of this important produce will be of great importance looking teeming population youth without job in our community. Sesame oil is of high quality free from undesirable flavour and contained antioxidant (Musa *et al.*, 2020). It is the sterling qualities that stimulate interest in the production of the crop. There are very high potentials for Sesame production

in Nigeria, but the average yield of 300kg/ha is considered too low and unattractive, hence knowing the limiting factors to boost production is imperative.

Sesame ranks the eight in the world production of edible oil seed, with higher oil content than other oil seeds. It is grown mainly for its seeds that contain approximately 50% oil and 25% protein (Gwandi *et al*., 2021). The presence of some antioxidants (sesamum, sesamolin and sesamol) makes the oil one of the most stable vegetable oils in the world, it also content nutritional and medicinal qualities, the seeds contain essential amino acid and fatty acids and a good source of vitamins. Production must be increased to take advantage of huge market potential of this crop (Madina, 2020).

Despite the benefits of sesame, less attention is directed towards its production and processing in Donga Local Government Area (LGA) for optimum benefits. Thus, improvement in the production and process of the crop could greatly help in increasing farm incomes as well as enhancing the livelihoods of the farmers and marketers of the crop in the LGA. Therefore, it is important to assess the economic analysis of sesame production to the livelihood of the farmers in the Donga LGA of Taraba State.

Objectives of the study

The broad objective was to analyze the economics of sesame production in Donga LGA of Taraba State. The specific objectives were to:

i. estimate the costs and returns in sesame production in Donga Local Government Area.
ii. estimate the effect of socio-economic variables on the output of sesame in the study area; and
iii. identify the constraints to sesame production in Donga Local Government Area

METHODOLOGY

The study area

Donga Local Government Area is one of the 16 LGAs in Taraba State, Nigeria. It is in the Southern part of the State having boundaries with Kurmi LGA at the East, Wukari LGA at the West, Bali LGA at the North and Takum LGA at the South. The LGA has 10 wards namely: Gyattaaure, Kumbo, Assibiti, Suntai, Nyita, Fada, Gayama, Mararraba, Akate and Kadarko wards. The study area occupies a total landmass of 3120km^2 with the total population of 87,021 people (NPC, 2006). The temperature of the area ranges between 28^0-38^{0}C with an annual rainfall of about 1,200 – 1,800mm per annum. The major occupations are inclined on agricultural activities such as cultivation of crops like cowpea, groundnut, maize, rice, sorghum, cassava, millet and yam and others.

Sampling technique and data collection

Multi-stage sampling procedures were adopted to select respondents for the study. The first stage involved a purposive selection of Donga LGA because of the predominant role in production and marketing activities of sesame in the area (Rukwe *et al.,* 2022). Stage two involved the random selection of five wards out of ten wards of Donga local government area. At the last stage, random sampling technique was also used to select 12 sesame farmers in the selected ward, thus, 60 respondents were selected for this study. Primary data was used and were collected through well-structured questionnaire. The data were collected in the 2022 cropping season.

Method of data analysis

Data were analyzed using Descriptive Statistics, Farm budgeting technique and inferential statistic. Farm budgeting technique was used to achieve objective (i), inferential statistic (multiple regressions) used to achieve objective (ii) and descriptive statistics such mean, frequency and percentages as may be required were used to achieve objective (iii). In analyzing the Gross margin (GM) = Gross income -Total variable costs. In this analysis, since data on fixed variables are difficult to be isolated from the variable inputs, all are variable inputs due to small nature of the farm size hence, the determined gross margin is taken to be the profit of the venture. Where: NFI = Net farm income (profit).

In determining the effect of socio-economic variables on output in sesame production, the multiple regression equation is given by $y = \alpha + \beta_1X_1 + + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \varepsilon$. Where y = dependent variable (output of sesame in kg); X_1- Age of Respondent in years; X_2 – Sex (dummy); X_3 – Marital Status (dummy); X_4 – Household size in numbers; X_5 – Experience in years; X_5 – Educational Level (dummy); X_6 – farm size in hectares; $\beta_1 - \beta_{16}$ = coefficients; α = constant term; and ε =error term

RESULTS AND DISCUSSION

Costs and returns analysis

The costs and returns associated with sesame production in the study area are as presented in Table 1. The average variable cost was ₦72, 422.37 per hectare out of which labour constituted the largest component. The result revealed that labour is the most used input among the respondents because it has the highest variable cost (₦ 25,126.50). This is in line with findings of Rukwe *et al.* (2020) in their study on Economics of Sesame Production among Small scale farmers in Southern Part of Taraba State, Nigeria, where labour constituted the highest variable cost of ₦35,000.00/ha. Therefore, sesame production is labour intensive in the study area. The average quantity of inorganic fertilizer used by the farmers was 61.3kg per hectare which is less than the recommended rate of 100kg per hectare. The low rate of fertilizer usage could be attributed to lack of fund. The average quantity of seed planted per hectare was 5.39kg. The seeding rate is higher than the recommended seedling rate of 5kg/ha (NAERLS, 2010). This means that the farmers are overusing seeds.

Seed are important factor influencing yield potentials in terms of optimum return of the crop in the study area. Herbicide had average cost of ₦ 17, 955/ha. This may be attributed to the market price is higher, and it is not often combined with manual weeding in the study area. The average quantity of herbicide used by sesame farmers was 9.45 litres per hectare which is not consistent with the recommended rate of 2-2.5 litres per hectare. The average cost of pesticides / insecticides used by sesame farmers for control of pests during flowering was ₦ 7,920.00/ha. Transportation costs of the output to house and markets was ₦ 1,200 and cost of bags was ₦ 1,964.2. The average fixed cost was estimated to be ₦ 16,450 per hectare. The total cost of cultivating a hectare of sesame farm was ₦ 88, 872.37.

The average quantity of yield per hectare in the study area was 421.6 kg. The average yield obtained 421.6 kg/ha is lower than the average yield of 1000kg when grown under improved management practices as reported by Essien *et al.* (2020). Low yield experienced in the study area was because of pests' and disease infestation and used of local varieties. The unit price was ₦ 550/kg on the average. The unit price was at its lowest amount of ₦400 during harvesting period and rose steadily to its peak at ₦ 550 at planting season. Average gross farm income of ₦ 231,880.00 per hectare was estimated. The net farm income of ₦143, 007.63 per hectare was estimated. The profitability index (ratio of total revenue to total cost minus 1) was 1.6, implying that for every ₦1 invested in Sesame farming there was a return of 60 Kobo. This finding implies that sesame production is highly profitable in the study area and thus any effort at expanding its production would be a good decision because a significant difference was observed in terms of cost of inputs incurred and returns realized. This is in line with the findings of Rukwe *et al.* (2021) who found profitability index 2.3 indicating that for each Naira invested, there is a return of 1.30 kobo.

The gross ratio which measures the overall financial success of a farm was 0.4. This ratio shows that the total farm costs was about 40% of the gross income. The lower the ratio, the higher the return per Naira invested. This indicates that sesame enterprise in the study area can survive in the long run.

Table 1: Costs and returns of sesame production in the area

Variables	Average quantity/ha	Unit price (₦)	Value (₦)
1. Gross Returns			
a) Average yield (kg)	421.6	550	231,880
2. Inputs			
i. Variable costs			
a) Seeds (kg)	5.39	620.00	3,341.8
b) Fertilizer (kg)	61.3	10,780.67	14,014.87
c) Herbicides (ltr)	9.45	1,900	17,955
d) pesticides (ltr)	3.60	2,200.00	7,920
e) Labour (man/day)	23.93	1,050	25,126.5
f) Transportation (₦)		300	2,100
g) Bags (₦)	7	280.6	1,964.2
Total Variable Cost			**72,422.37**
ii. Fixed inputs			
a) Cutlass			2,000
b) Hoe			1,600
c) Sprayer			12,500
d) Sickle			350
Total Fixed Cost			16,450
3. Total Costs (i)+(ii)			**88,872.37**
4. Net Farm Income NFI			**143,007.63**
5. Rate of Return			**1.6**
6. Gross Ratio (TC/GR)			**0.4**

Effect of socioeconomic variables on the output of sesame farmers

The regression model analyzed of the factors that affect the output of sesame revealed that age, household size, farm size significantly affected the output. The p-value was highly significant at 1% level ($p = 0.000$). From the regression results in table 2, the regression model explains about 73% of all the variability in the data set ($R^2 = 0.73$). This means that independent variables introduced in the model greatly explain the dependent variable. Age had a positive and significant ($p < 0.10$) effect on the output (net farm income) of sesame farmers in the study area. The older the farmer, the more experienced he/she is in the production of sesame in the study area. These farmers are willing to adopt new technologies that can enhance the productivity of the farm. The household size of the respondents had positive significant ($p < 0.05$) influence on the sesame farmers' net farm income due to the labor intensiveness of production. Hence, a large household size could provide a larger labour force for production. Findings revealed that farm size also have strong and significant effect (at 1% probability level) on the net farm income of the producer. In the study area, access to land is becoming more and more difficult. Most farmers rent the land they use for cultivation. Other variables like experience, age and educational level insignificantly influenced the net farm income.

Table 2: Effect of socio-economic variables on the output of sesame production

Variables	Coef.	Std.err	T	P>(t)
Constant	2.9643	0.68034	4.36***	0.000
Age	0.2612	0.13644	1.91*	0.058
Year of experience	-0.009	0.02767	-0.33ns	0.743

Constraints associated with sesame production

Table 3 shows the constraints faced by farmers in the study area. The result revealed that high cost of farm input is the commonest constraints affecting sesame production, as reported by 71.6% of the sampled farmers. Inadequate access to credit was second among the problems faced by farmers in the study area, as 65% of the sesame farmers considered it to be a problem, thereby indicating that inadequate access to credit was limiting sesame production. Farmers still have the chance to improve on production of sesame in the study area if they have access to credit facilities. About 61.7% of the sesame farmers agreed that inadequate extension services were one of the constraints in sesame production. This implies poor adoption to innovation and techniques that could have been used to promote sesame production, hence limiting the production potential of the crop. The findings also revealed that 60% of the farmers are confronted with the problem of Pest and disease. Farmers can cope with pests and diseases by sowing disease resistant varieties and the use of agrochemicals recommended for applications. The results further revealed that incessant farmer/herder clashes account for 48.3% of the constraint militating against sesame production. This implies where there is no peace, production activities will be affected, hence limiting the production potential of the crop. Inadequate market information ranked 6th constituting 45% of the sesame farmers that it is a constraint militating against sesame production. This implies that most farmers are unable to maximize their profit from sesame production due to poor market information. This result agrees with the findings of Essien *et al.* (2020) and Tahir *et al.,* (2021) that identified high cost of inputs, poor access to credit, poor extension and pest and disease to be major constraint faced by sesame farmers in Nasarawa and Adamawa States respectively.

Table 3: Constraints to sesame production in the study area

Constraint	Frequency (n=60)	Percentage
High cost of farm input	43	71.6*
Inadequate access to credit	39	65*
Inadequate extension	37	61.7*
Pest and disease	32	60*
Incessant farmer/herder clashes	29	48.3*
Inadequate market information	27	45*

CONCLUSION AND RECOMMENDATIONS

Conclusion

Sesame production is a profitable venture in the study area. The regression model results revealed that age, household size, farm size significantly affected the output of sesame in the study area. Noticeable gaps in sesame production could be drastically improved upon if perceived constraints such as high cost of input, poor access to credit, pest and disease and inadequate extension services are addressed would increase the output of yield hence raise the disposable income of the farmer and earn the country more foreign exchange.

RECOMMENDATIONS

Based on the findings of the study, the following recommendations were made:

i. Sesame farmers are therefore encouraged to form a cooperative group so that it can enable them to have access to loan by such doing they can assess credit to improve in their productivity.

ii. The farmers should be encouraged to use improved seeds to increases their farm output.
iii. The government and private sectors should encourage sesame farmers by improving extension services to acquire more innovations.
iv. Government and NGOs should subsidize farm input for sesame farmers to encourage them cultivate more since the venture was found to be a profitable venture in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The transfer of root crop technology plays a pivotal role in poverty alleviation and food security, particularly in regions where root crops are dietary staples. The contributions of the National Root Crops Research Institute (NRCRI) in Umudike, Abia State, Nigeria, to the dissemination of innovative root crop technologies and agricultural knowledge through a multifaceted approach involving research, development, and technology transfer, NRCRI has made significant strides in empowering smallholder farmers and communities. NRCRI's efforts in developing improved root crop varieties, managing pests and diseases, promoting value addition, and capacity building. NRCRI's methods, including Farmer Field Schools, demonstration plots, and extension services, have facilitated the adoption of sustainable agricultural practices, leading to increased agricultural productivity and improved livelihoods. The institute's contributions underscore the critical role of technology transfer in addressing poverty and food security challenges and offer valuable insights for similar initiatives worldwide.

INTRODUCTION
Root crops, including potatoes, sweet potatoes, cassava, yams, carrots, and beets, represent a diverse and vital group of agricultural commodities cultivated for their underground edible parts, such as roots, tubers, and rhizomes. These crops hold immense significance in global agriculture, addressing critical issues related to food security, income generation, and agricultural resilience. Root crops are fundamental to food security, particularly in regions where they serve as dietary staples. For example, cassava, a drought-tolerant root crop, plays a pivotal role in providing a consistent source of calories for over 800 million people in sub-Saharan Africa (FAO, 2013). Likewise, sweet potatoes, rich in complex carbohydrates and beta-carotene, contribute significantly to nutrition and food security in many developing countries (Low *et al.*, 2017).
Beyond their nutritional value, root crops serve as sources of income for millions of small-scale farmers. The sale of root crops, whether in local markets or for export, offers economic opportunities to rural communities. This income generation supports livelihoods and contributes to poverty reduction (Nweke *et al.*, 2002). Root crops also exhibit resilience to various environmental stressors, making them valuable assets in the face of climate change. Potatoes, for instance, can be grown at different altitudes and are adaptable to a range of climatic conditions, allowing farmers to diversify their income sources (Hijmans *et al.*, 2009). This resilience contributes to the sustainability of agriculture and helps mitigate the risks associated with changing weather patterns.

The Role of Technology in Poverty Alleviation
Technology plays a pivotal role in poverty alleviation by offering innovative solutions to longstanding challenges faced by impoverished communities. It provides pathways to economic empowerment, improved healthcare, education, and access to essential services. Technology can be instrumental in addressing poverty by fostering economic growth and enhancing the overall quality of life for marginalized populations.
One of the key ways technology contributes to poverty alleviation is through economic empowerment. Digital platforms and mobile banking systems, for example, enable individuals in remote and underserved areas to access financial services, save money, and engage in small-scale entrepreneurship (Jack & Suri, 2014). Moreover, the rise of e-commerce and online marketplaces creates opportunities for micro-entrepreneurs to reach broader customer bases, generating income and reducing poverty (World Bank, 2019).

In the context of healthcare, technology facilitates better access to medical services and health information, particularly in rural or underserved regions. Telemedicine, wearable health devices, and mobile health apps enable remote diagnosis and monitoring, improving healthcare outcomes for vulnerable populations (Free *et al.*, 2013). Educational technology also plays a critical role in poverty reduction by expanding access to quality education. Online learning platforms, Massive Open Online Courses (MOOCs), and digital libraries enable individuals to acquire new skills and knowledge, enhancing employability and income potential (Chuang & Chen, 2018).

Furthermore, technology-driven solutions can enhance agriculture, another critical sector in poverty alleviation. Tools such as precision agriculture, weather forecasting apps, and crop monitoring systems empower smallholder farmers to increase crop yields and income (FAO, 2019).

Role of NRCRI in Developing Root Crop Technologies

The National Root Crops Research Institute (NRCRI) in Umudike, Abia State, Nigeria, plays a pivotal role in the development of root crop technologies, contributing significantly to agricultural innovation and food security in Nigeria and beyond. NRCRI serves as a research hub, focusing on the improvement of root crops such as cassava, yams, and sweet potatoes. Its contributions span several key areas:

1. **Variety Development:** NRCRI conducts extensive research and breeding programs to develop improved varieties of root crops. These efforts aim to enhance crop yields, disease resistance, nutritional content, and other desirable traits. For instance, NRCRI has developed high-yielding cassava varieties that are resistant to pests and diseases, increasing the productivity of smallholder farmers (Akpan *et al.,* 2017).
2. **Pest and Disease Management:** The institute conducts research on the management of pests and diseases that affect root crops, providing farmers with innovative solutions to protect their crops. This research is crucial in ensuring stable root crop production, especially in regions where these crops are dietary staples (Nweke *et al.,* 2002).
3. **Technology Transfer:** NRCRI actively engages in technology transfer by disseminating improved varieties, best agricultural practices, and post-harvest handling techniques to farmers and extension services. Through workshops, training programs, and extension services, NRCRI ensures that farmers can effectively adopt and apply the developed technologies in their fields (Low *et al.,* 2017).
4. **Value Addition:** NRCRI also focuses on adding value to root crops by promoting their utilization in processed products. This not only creates income-generating opportunities for farmers but also reduces post-harvest losses. For example, NRCRI has been instrumental in promoting the processing of cassava into various products, including flour and chips (Banjo *et al.,* 2017).

Contribution of NRCRI in Alleviating Poverty

The National Root Crops Research Institute (NRCRI) in Umudike, Abia State, Nigeria, has made substantial contributions to poverty alleviation through its research, development, and technology transfer efforts related to root crops. These contributions are multifaceted and have had a profound impact on the livelihoods of smallholder farmers and communities:

1. **Improved Varieties:** NRCRI’s research programs have led to the development of improved root crop varieties with characteristics such as higher yields, disease resistance, and enhanced nutritional content. These varieties, when adopted by farmers, not only increase food production but also provide opportunities for surplus production and income generation (Akpan *et al.*, 2017).
2. **Pest and Disease Management:** NRCRI’s research on pest and disease management strategies has equipped farmers with knowledge and tools to protect their root crop yields. By reducing crop losses due to pests and diseases, farmers can secure their food supply and generate surplus for sale (Nweke *et al.*, 2002).
3. **Value Addition and Agribusiness:** NRCRI has played a pivotal role in promoting value addition to root crops. The processing of root crops into products like flour, chips, and snacks has created income-generating opportunities along the value chain, benefiting both farmers and entrepreneurs (Banjo *et al.*, 2017).
4. **Technology Transfer:** Through farmer field schools, demonstration plots, workshops, and extension services, NRCRI has actively transferred agricultural technologies and best practices to farmers. This knowledge transfer empowers farmers to make informed decisions, improve their agricultural practices, and increase their income (Low *et al.,* 2017).
5. **Climate Resilience:** NRCRI’s research on drought-resistant and climate-smart root crop varieties enhances farmers’ resilience to climate change. By providing options that thrive under challenging conditions, NRCRI helps protect farmers’ incomes and food security in the face of environmental uncertainties (Lipper *et al.,* 2014).
6. **Capacity Building:** The institute’s efforts to build the capacity of local farmers and extension workers contribute to improved agricultural productivity. Farmers equipped with knowledge and skills are better prepared to manage their resources effectively and lift themselves out of poverty (Van den Berg *et al.,* 2013).

CONCLUSION

In conclusion, root crops hold immense significance in addressing global challenges related to food security and poverty alleviation. These crops, including cassava, yams, and sweet potatoes, serve as dietary staples, provide resilience to challenging environmental conditions, and offer nutritional diversity, making them crucial for ensuring a stable food supply. Moreover, root crops contribute significantly to income generation, especially for smallholder farmers in impoverished regions, by offering economic opportunities along the agricultural value chain.

Technology transfer plays a vital role in harnessing the potential of root crops for poverty alleviation. Organizations like the National Root Crops Research Institute (NRCRI) in Umudike, Abia State, Nigeria, actively engage in research, development, and technology transfer efforts related to root crops. These institutions develop improved crop varieties, disseminate knowledge and best practices, and promote value addition, ultimately empowering farmers and communities to improve their livelihoods.

STRATEGIES FOR ENHANCING THE AVAILABILITY OF ROOT CROPS PLANTING MATERIAL TO SMALLHOLDER FARMERS IN IKWUANO LOCAL GOVERNMENT AREA, ABIA STATE

F. N. Aboajah
National Root Crops Research Institute, Umudike, Abia State.
***Correspondence author email address**: aboajahfriday@yahoo.com

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The paper provides a concise overview of the strategies designed to address the critical issue of enhancing the availability of root crops planting materials for smallholder farmers in Ikwuano Local Government Area, Abia State. Farmers in Ikwuano LGA face several challenges related to limited access, high costs, and inadequate knowledge among farmers regarding planting materials. To tackle these issues and promote sustainable agriculture, a multifaceted approach is proposed. The strategies outlined encompass the establishment of community seed banks, promotion of local seed production, and strengthening of farmer cooperatives. These initiatives aim to ensure a consistent supply of quality planting materials while reducing financial burdens on smallholder farmers. Additionally, the plan emphasizes the importance of educational programs and awareness campaigns to empower farmers with knowledge about improved varieties and modern agricultural practices. Infrastructure development and access to credit are critical components of the plan, addressing issues related to transportation, storage, and financial support. The collaborative efforts of government agencies, non-governmental organizations, research institutions, and community leaders are instrumental in the successful execution of these strategies. By implementing these comprehensive strategies, we aim to improve food security, enhance rural livelihoods, and promote sustainable root crop cultivation in Ikwuano Local Government Area, ultimately contributing to the broader goals of agricultural development and economic empowerment.

INTRODUCTION

Root crops play a crucial role in local agriculture, particularly in areas like Ikwuano Local Government Area, Abia State. Root crops encompass a diverse range of plants, including cassava, yam, sweet potatoes, and taro, among others, which thrive in various climates and soil conditions. The importance of root crops in local agriculture can be underscored by their contributions to food security, income generation, and overall agricultural sustainability.

Firstly, root crops are vital for ensuring food security in many areas. They are often staple foods that form the basis of daily diets for millions of people. For example, in sub-Saharan Africa, cassava and yam are primary sources of carbohydrates, providing a significant portion of the daily caloric intake for millions of individuals (Egesi *et al.*, 2012; Howeler, 2002). The reliable production of root crops is essential for addressing hunger and malnutrition, particularly in rural areas where access to diverse food sources may be limited.

Moreover, root crops serve as a source of income for smallholder farmers in local agriculture. They are relatively low-cost crops to cultivate and are well-suited to small-scale farming operations. Farmers can generate income by selling surplus root crops in local markets or processing them into value-added products like flour, starch, or snacks. This economic aspect is vital for rural livelihoods, poverty reduction, and the empowerment of smallholder farmers (Alamu *et al.*, 2019). Furthermore, root crops contribute to agricultural sustainability. They are often resilient to adverse weather conditions, such as droughts, making them suitable for cultivation in areas with variable climates (FAO, 2008). Additionally, they can be intercropped with other crops, promoting biodiversity and reducing the risk of pest and disease outbreaks (Ngailo *et al.*, 2013). The incorporation of root crops into local agricultural systems can enhance overall resilience and reduce the environmental impact of farming practices.

Significance of enhancing planting material availability for smallholder farmers

Enhancing the availability of planting materials is of paramount significance for smallholder farmers. Smallholder farmers, who typically cultivate small plots of land with limited resources, constitute a substantial portion of the world's agricultural workforce, particularly in developing countries (Hazell & Wood, 2008). Ensuring access to high-quality planting materials holds several crucial implications for their livelihoods and agricultural productivity.

First and foremost, improved access to planting materials directly impacts food security. Smallholder farmers often rely on their own seed stocks, which may be of variable quality and susceptible to diseases or pests. By providing them with access to certify and disease-free planting materials, the risk of crop failure due to poor-quality seeds is reduced, thereby enhancing food production and availability (FAO, 2010). This is particularly important in areas where smallholder farmers play a critical role in supplying food to local communities.

Secondly, enhancing planting material availability contributes to increased agricultural productivity and income for smallholders. High-quality planting materials are typically associated with higher crop yields, as they are often bred for traits like disease resistance, improved yield potential, and adaptability to local conditions (Almekinders *et al.*, 2018). Increased productivity not only ensures an adequate food supply but also allows farmers to generate surplus produce for sale in local markets, thereby boosting their income and economic well-being.

Furthermore, the availability of quality planting materials is essential for crop diversification and resilience. Smallholder farmers are vulnerable to climate change and market fluctuations, and having access to a variety of planting materials allows them to adapt to changing conditions (Lipper *et al.*, 2014). Diversification can also reduce the risk of crop failures and enhance the sustainability of farming systems.

Current Challenges in Availability of Root Crops Planting Material

The availability of root crops planting materials faces several significant challenges, particularly in areas like Ikwuano Local Government Area, Abia State. These challenges can hamper agricultural productivity and food security, and they demand attention to ensure the sustainability of root crop cultivation by smallholder farmers.

One major challenge is the limited access to quality planting materials. Smallholder farmers often rely on saved seeds or cuttings from previous harvests, which may carry diseases, have low genetic diversity, or suffer from degeneration over time (Alamu *et al.*, 2019; Grubben & Denton, 2004). Ensuring a consistent supply of disease-free, high-yielding planting materials is critical to overcoming this limitation.

Another challenge is the high cost associated with acquiring planting materials. Improved and certified varieties are often more expensive, making them less accessible to resource-constrained smallholder farmers (Ezeh *et al.*, 2018). This cost barrier can discourage farmers from adopting improved varieties and hinder the adoption of modern agricultural practices.

Inadequate knowledge and awareness among smallholder farmers regarding the importance of using quality planting materials and the availability of improved varieties represent another significant challenge (Hossain *et al.*, 2019). Without proper training and extension services, farmers may continue to use traditional materials, limiting their agricultural potential and yield.

Strategies for Enhancing Availability of Root Crops Planting Material

Enhancing the availability of root crops planting materials is crucial for improving agricultural productivity and food security, especially for smallholder farmers in areas like Ikwuano Local Government Area, Abia State. Several strategies can be employed to address the current challenges and boost the accessibility of quality planting materials.

One effective strategy is to promote local seed production (Almekinders *et al.* 2018). This involves establishing community seed banks, providing training on seed production techniques, and supporting farmers in seed multiplication. By decentralizing seed production and empowering local communities, this strategy ensures a consistent supply of planting materials that are well-adapted to local conditions.

- Strengthening farmer cooperatives and associations is another key strategy (Harris *et al.*, 2017). These organizations can facilitate collective procurement of planting materials, enabling bulk purchases that reduce costs for individual farmers. Capacity building for cooperative leaders and members can also enhance their ability to negotiate favorable terms with seed suppliers.
- Research and extension services play a vital role in improving planting material availability. Collaborating with agricultural research institutions can lead to the development of improved root crop varieties (Ezeh *et al.*, 2018). Additionally, conducting trials for these varieties and disseminating the findings through extension programs helps educate farmers on best practices for selecting and using quality planting materials.

- Access to credit and financial support is essential to address the high cost of planting materials (FAO, 2010). Establishing microcredit schemes for farmers and subsidizing the cost of planting materials can alleviate the financial burden on smallholders. Linking farmers with financial institutions enables them to access loans and resources for investing in quality planting materials.
- Information and awareness campaigns are pivotal in increasing knowledge among smallholder farmers (Hossain *et al.*, 2019). Creating educational materials, organizing workshops, and utilizing local media can help disseminate information about the benefits of root crops and improved planting materials. Raising awareness empowers farmers to make informed choices about their agricultural practices.
- Finally, infrastructure development is essential for the distribution and preservation of planting materials (FAO, 2010). Improving transportation networks ensures that planting materials can reach remote areas, while building storage facilities helps prolong the shelf life of seeds and cuttings. Access to clean water for irrigation is also critical to support root crop cultivation.

Implementing these strategies for enhancing the availability of root crops planting materials is essential to boost agricultural productivity and food security for smallholder farmers in Ikwuano Local Government Area, Abia State. By addressing the current challenges and promoting sustainable practices, these strategies can contribute to improved livelihoods and agricultural sustainability.

Challenges and Mitigation

Addressing the challenges faced in enhancing the availability of root crops planting materials for smallholder farmers in areas like Ikwuano Local Government Area, Abia State, requires careful consideration of potential obstacles and the development of effective mitigation strategies.

1. **Limited Access to Quality Planting Materials:** To mitigate this challenge, it is crucial to establish and maintain community seed banks, ensuring a consistent supply of high-quality planting materials. Additionally, partnerships with agricultural research institutions can facilitate the development of disease-resistant and high-yielding varieties, addressing the issue at its root (Almekinders *et al.,* 2018).
2. **High Cost of Planting Materials:** To alleviate the financial burden on smallholder farmers, subsidies can be introduced, making improved planting materials more affordable. Microcredit schemes can also be established to provide farmers with access to funding for purchasing quality planting materials (FAO, 2010).
3. **Inadequate Knowledge and Awareness:** Education and awareness campaigns should be intensified to inform farmers about the benefits of using quality planting materials. Extension services play a crucial role in training farmers on best practices and disseminating information about improved varieties (Hossain *et al.,* 2019).
4. **Infrastructure Limitations:** To overcome infrastructure challenges like poor transportation networks or lack of storage facilities, partnerships with government agencies and NGOs can be established to fund and implement infrastructure development projects. This includes improving road networks for easier transportation of planting materials and constructing storage facilities to prolong seed shelf life (FAO, 2010).
5. **Climate Change and Environmental Factors:** Climate-smart agricultural practices, such as diversifying crops and implementing sustainable farming techniques, can help mitigate the effects of climate change on planting material availability (Lipper *et al.*, 2014). Research into climate-resilient crop varieties can also be prioritized.

In summary, addressing the challenges related to the availability of root crops planting materials requires a multifaceted approach that combines policy changes, financial support, education, and infrastructure development. Mitigation strategies should be tailored to the specific needs and constraints of the local context to ensure the sustainability of root crop cultivation and improve the livelihoods of smallholder farmers.

CONCLUSION

In conclusion, the challenges surrounding the availability of root crops planting materials in areas like Ikwuano Local Government Area, Abia State, present significant barriers to agricultural productivity and food security. However, by implementing a well-structured plan that encompasses strategies such as promoting local seed production, strengthening farmer cooperatives, enhancing knowledge and awareness, and investing in infrastructure, there is great potential for improvement. These strategies not only address the immediate challenges but also pave the way for a more sustainable and resilient agricultural sector. Through collaboration among stakeholders and a commitment to mitigating challenges, we can empower smallholder farmers, enhance food security, and contribute to the economic development of rural communities. The importance of root crops in local agriculture cannot be overstated, and by focusing on availability, we can make meaningful strides towards improving the livelihoods and well-being of those who rely on them.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was carried out to determine the level of adoption of orange-fleshed sweet potato (OFSP) varieties among farmers in Ebonyi State, Southeastern Nigeria. A multistage sampling technique was used to select 128 OFSP farmers from two agricultural zones in the state. Data were obtained using well-structured questionnaire and analyzed using descriptive statistics, such as means, percentages, tables and frequency distribution tables and adoption score index of 7 point Likert scale. Result indicated that the mean age of sweet potato farmers in Ebonyi State was 49.86 years, mean farm size was 1.71ha and mean years of farming experience was 9.65. The levels of adoption of OFSP by farmers were: UMUS-PO/I (X=3.78) and UMUS-PO/3 (X=3.63), showing a high level of OFSP adoption in the Study Area. The result further indicated that the major determinant of OFSP low adoption were; inadequate credit facilities (74.21%), poor government support (68.75%) and low extension coverage (66.41%). It was recommended that government should provide support through the provision of credit facilities and adequate extension personnel to the farmers in Ebonyi State.
***Keywords**: adoption, OFSP, farmers, determinant and Ebonyi*

INTRODUCTION
Orange fleshed sweet potato (OFSP) was developed to enhance food security status of farmers and improve their livelihood.The adoption of OFSP should be an important route to improve the livelihood of poor sweet potato farmers by enhancing sweet potato productivity, food security status, income level and poverty alleviate among the farmers and generality of Nigerians (Solomon *et al*, 2010; Solomon *et al*, 2011). Sweet potato is a very important food crop and ranked fourth in terms of consumption as the world's most important food crop. However, the orange fleshed sweet potato varieties are rich in beta carotene, (a precursor of Vitamin A.) a micronutrient that combat vitamin A deficiency [VAD] problem in sub-Saharan Africa (Solomon *et al*., 2011).
The adoption rate of OFSP is subject to its profitability, degree of risk associated with it, capital requirements, agricultural policies and socio-economic characteristics of farmers (Shideed and Mohammed, 2005; Solomon, 2010; Solomon et al., 2011). Vitamin A and Iron deficiencies have several negative health and economic consequences, including earlier mortality rate of pre-school age children and reduced productivity of adults. It has been observed that there has been a problem of low adoption of orange-fleshed sweet potato in Nigeria (Nwosu, 2005). The essence of this study was to find out the determinant of low adoption of OFS in the study area.

METHODOLOGY
The study was conducted in Ebonyi State, Nigeria. Multi-stage sampling techniques were adopted for the study. Two out of the three agricultural zones were purposively selected. The zones were Ikwo and Ezza South. These zones were selected because of farmers' involvement in Orange- fleshed sweet potato production. The second stage involved a random selection of two blocks from the chosen agricultural zones making it four [4] blocks. The third stage involved random selection of two circles from each of the chosen blocks to give a total of eight [8] circles. Finally, sixteen OFSP farmers were randomly selected from each of the eight [8] circles given a total of one hundred and twenty- eight [128] respondents selected for the study.

Adoption score index
The level of adoption of OFSP was determined using adoption score index. This was achieved with the aid of a Likert scale graded thus: Unaware = 0, Aware = 1, Interest = 2, Evaluation = 3, Trial = 4, Acceptance = 5 and Satisfaction = 6. In accordance with Okoye *et al* (2009). The mean adoption level was determined as follows:
Mean score was computed by multiplying the frequency of each response pattern with its appropriate nominal value and dividing the same with the number of respondents to the terms.

This is summarized with the equation below:
Decision Rule
Less than 1.0 = Unaware stage of OFSP
1.0 - 1.49 = Awareness stage of OFSP
1.5 - 1.99 = Interest stage of OFSP
2.0 - 2.49 = Evaluation stage of OFSP
2.5 - 2.99 = Trial stage of OFSP
3.0 - 3.49 = Adoption stage of OFSP
3.5 above = Satisfaction stage of OFSP

RESULTS AND DISCUSSIONS

Table 1: shows that 92.19% of sweet potato farmers in Ebonyi State had one form of formal education or the other as against 7.81 that had no formal education. The results indicated that the respondents in the study area had more literate farmers. The high proportion of the literate people among the OFSP farmers implied that they are in a better position to be aware, understand and adopt the crop. Education has always been known to play a positive role in the adoption of innovation among farmers. Also, 50.78% of OFSP farmers had household sizes of between 4 and 6 persons; 41.41% of them had household size of between 7 and 9 persons and only 7.81% had a household size of between 1 and 3 persons. The mean household size was 6 persons. The results collaborated with the study of Ekwe and Onunka (2006) which indicated that most farmers in Ebonyi State had large households that readily provided labor for on and off- farm activities. The farm size result shows that the majority [59.38%] of the OFSP farmers had farm sizes of between 1 and 2 hectares. This finding is in agreement with the work of Emodi (2009) who observed that small-scale farmers predominate in the Southeast agro-ecological zone of Nigeria. The result also showed that 68.75% of orange-fleshed sweet potato farmers had farming experience of between 1 and 9 years. In addition, 47.66% of orange- fleshed sweet potato farmers in Ebonyi State belong to cooperation societies. Group membership in a Cooperative Society enables farmers to access loans to purchase additional equipment (Shiferaw et al, 2006). The result also shows that only 42.97 % of orange- fleshed sweet potato farmers had access to Extension Agents. The results of the level of OFSP adoption by farmers are presented in Table 2.

Table 1: Selected Socio-economic Characteristics of Sweet Potato Farmers in Abia State

Variables	Frequencies	Percentages
Educational Status		
No of formal education	10	7.81
Primary education	45	35.16
Secondary education	43	33.59
Tertiary education	30	23.44
Household size		
1-3	10	7.81
4-6	65	50.78
7-9	53	41.41
Farm Size		
<90	22	17.19
1.0 -3.0	61	47.65
3.1 -5.0	27	27.09
5.1 and above	18	18.06

0-9	88	68.75
10-19	38	24.22
20 above	2	1.56
Membership of cooperative		
Yes	61	47.66
No	67	52.34
Access to extension agent		
Yes	64	50.0
No	64	50.0
Total	**128**	**100**

Source; Field Survey, 2021

Table 2: Distribution of OFSP Farmers According to their levels of Adoption

OFSP	Unaware	Aware	Interest	Evaluation	Trial	Accept	Reject	Total	Mean adoption score
UMUSPO/3	4	9	20	16	39	29	11	464	3.63
	(0)	(9)	(40)	(48)	(156)	(145)	(66)		
UMUSPO/1	1	5	19	15	49	34	5	484	3.68
	(0)	(5)	(38)	(45)	(196)	(170)	(30)		**3.71**

Source; Field Survey, 2021

The level of Adoption of Orange - fleshed sweet potato among farmers in Ebonyi State showed that farmers adopted UMUSPO/3 (X=3.63) and UMUSPO/1(X=3.78) and the level of Adoption was high. The grand mean adoption score for Orange- fleshed sweet potato varieties was (X=3.71). This finding is in agreement with Nwakor *(*2021) which reported a high level of women participation in Orange -Fleshed Sweet potato production among small- scale farmers in Abia State.

CONCLUSION

The study showed a high level of adoption of orange fleshed sweet-potato among farmers with formal education. Majority of the educated farmers who cultivate the orange fleshed sweet potato (UMUSPO/1 and UMUSPO/3) know of its health benefits. OFSP boost immunity, it is good for pregnant women and lactating mothers. Orange fleshed sweet potato is good Vitamin A micro-nutrient food for pre-school age children. The study also indicated that most farmers in Ebonyi State had large household sizes that readily provided labour for on and off-farm activities. OFSP farmers needed strategic support to boost OFSP adoption and productivity across the country.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Cassava has replaced a number of traditional staples since its introduction to Africa in the sixteenth centuries. It has been successfully integrated into many agricultural and food systems across the continent. Today, cassava can be produced primarily for food purposes, particularly in the forms of gari or fufu particularly for small-scale farming families. It has traditionally been a crop that provides food security in Nigeria, due to its characteristics and its ability to thrive in even the most difficult conditions. Nigeria has been identified as a country with a high rate of food insecurity and vulnerable to climate change effect with history of environmental catastrophes that have had a significant impact on people's lives. By increasing cassava production, food security will be improved, as the longer the cassava remains in the farm, the more likely these groups of people are to have access to food.
Keywords: *Cassava, food security, farmers, small scale, production.*

INTRODUCTION

The world production of cassava amounted to 302.66m tons in 2020 (Onyediako and Adiele, 2022) and Africa is the largest region of cassava growing with 193.62m tons in 2020. Nigeria is the largest producer in the world, with 60m tons with others countries like South-East Asian countries, Brazil, Indonesia, Thailand, and Vietnam following FAO (2022). The total area of cassava harvested in the world has increased significantly in recent years, with the total area harvested in 2020 being 7.7m ha, according to (FAOSTAT, 2022). Nigeria is the world's biggest cassava producer but more than 90% of cassava production is locally consumed being one of the Nigeria's most important staple foods. More than 90% of the country's rural families consume cassava daily, whether it is in the forms of gari, fufu, starch, tapioca, chips, or in the supported forms such as bread, chin-chin, doughnut, cake, and chips.

According to the Food and Agriculture Organization of the United Nations (FAO), cassava is Africa's third most important source of calories (after rice and maize) in Africa's tropics and subtropics (FAO, 2020). Cassava is widely cultivated in several sub-Saharan African countries. Currently, more than 50% of the global consumption of cassava is in Africa. Cassava has replaced a number of traditional staples since its introduction to Africa in the sixteenth and has been successfully integrated into many agricultural and food systems across the continent. Today, cassava can be produced primarily for food purposes, particularly in the forms of gari or fufu. The root and stem of cassava are gradually integrated into the agri-business sector (Ezeibe, 2015). Initially, cassava was used as a famine reserve crop, as it offered a more dependable food source during drought and famine periods. In recent years, it has become a staple food as well as a profitable cash crop with industrial importance in the global economy. Currently it is considered as a cash crop generating huge cash income for most households, compared to other staples, which has a positive impact on poverty alleviation (Obisesan, 2012; Ezeibe, 2015). Cassava is considered a crop for food security in many underdeveloped countries, as it can be a source of calories even during the dry season. Originating in South America's tropical rain forests, cassava has become a staple crop in many African countries. In recent years, many countries have begun to explore new methods in their agricultural systems to sustainably increase production to support food security and to produce non-food items from cassava.

According to the International Fund for Agriculture in Development (IFAD) (2012) that Africa, is home to 600 million people who rely on cassava for dietary food energy. Nigeria continues to be the largest producer of cassava in the world, and for the entire population living in lowland and subtropical areas of West and Central Africa, it is a major source of dietary energy. However, Nigeria has not been able to produce enough cassava to export due to the small size of many cassava farms and several factors that lead to low productivity on most of the farms in Nigeria, such as manual labor, the use of little or no agro-chemicals, the lack of experience in using high-yield roots, the lack of resistant varieties to major disease and pest, and other environmental issues, the worst of which are climate changes and insecurity.

According to the International Monetary Fund (IMF) (2022), food security is the availability of sufficient food to meet the calorie requirements of an adult female at a daily caloric rate of 2200 to 3200 calories per day and an adult male at a caloric rate of 2900 to 3000 calories per day. Furthermore, the report further stated that the cost associated with meeting the caloric rate of 2251 per day (agricultural weight requirement for food security) is approximately ₦ 82,000.00 per capita per year. As a result, approximately 40% of the population in Nigeria is classified as food insecure, as supported by the research of Mekonnen *et al*. (2021) and Okou *et al*. (2022). The prices of staple foods in sub-Saharan Africa have increased by an average 23.9% in the period of 2020-22. This has made it difficult for those with an average income to access food.

Otaha (2013) defined food insecurity as a situation in which individuals are not adequately nourished due to a lack of physical access to food, as well as a lack of economic or social support. Those who experience food insecurity include those whose food intake is lower than their minimum energy requirements, as well as individuals who experience physical symptoms due to nutritional deficiencies or an inadequate diet, or due to the body's inability to utilize food effectively due to an infection or disease while FAO/CFS (2010) defined food insecurity as the consequences of inadequate intake of nutritious food, taking into account the physiological utilization of food as part of nutrition and health.

Nigeria has been identified as a country with a high rate of food insecurity, a vulnerability to climate change, and a history of environmental catastrophes that have had a significant impact on people's lives. Despite its declining economy, the country still has an estimated 96 million people living in extreme poverty, representing 48% of the population. As the population continues to expand and poverty rates remain relatively stable, this has resulted in an increase in absolute poverty, which in turn leads to an increase in food insecurity. This paper examines the role and potential of cassava as a rescue crop in Nigeria's efforts to reduce food insecurity. The novel varieties of cassava developed by NRCRI Umudike in partnership with IITA Ibadan, with the assistance of local and foreign donor agencies, possess the characteristics of high yield, resistance to disease, early maturing, and high food quality, which will enable Nigeria to capitalize on the opportunities presented by their availability.

Roles and potentials of Cassava to rescue food insecure people in Nigeria

Certain varieties of cassava are resistant to drought and can be cultivated on inhospitable soils, with the ability to remain in the soil for a period of two years. This makes cassava a major source of food security, particularly for small-scale farming families. These families are essentially subsistence farmers who use cassava as a food source. They harvest pieces of food when there is a food shortage in the home or when they need to provide for family members, including children, siblings, and husbands and wives, who may be out of the home or in urban areas. By increasing cassava production, food security will be improved, as the longer the cassava remains in the farm, the more likely these groups of people are to have access to food.

The long value chain of cassava has enabled it to be locally processed into a variety of food products, providing an alternative source of sustenance, particularly for poor households. In Nigeria, cassava is a dietary staple food, with products such as cassava flakes (Gari), flour (Pupuru and Lafun), paste (akpu and Fufu), and sliced roots (abacha) all derived from the storage roots. According to Montagnac *et al*. (2009), in cases of food shortage, many people turn to Elibo, a combination of cassava and maize flour. To maximize the potential of the cassava sector in areas such as export, industrial use, food security, and economic development, it is essential to harness the latest technologies and innovations in production, processing, and packaging.

Leaves of cassava varieties that are low or free from cyanide are used as vegetable in the diets of many rural populations in Nigeria. Cassava leave has been identified as a source of vitamins and proteins. Also cassava leave can easily be converted to protein by small ruminant animals reared by the resource poor farmers in Nigeria. It is a common practice that rural farmers use cassava leaves to feed their livestock which in turn are used to boost food security in the area. Also cassava stem is currently commercialized in Nigeria, as a result of the robust cassava seed system that is transforming into a formal system from the hitherto informal system that has been in existence for a very long time in Nigeria. Cassava stem can generate up to ₦400,000 per ha of land, thereby increasing income to farmers. Such increased incomes are potential food security platforms for the rural cassava farming populations in Nigeria.

CONCLUSION

Cassava has been a crop of interest in Nigeria because of the numerous advantages the crop can offer to farmers. Most Nigerians rely on cassava as their food bank especially at this time of severe economic hardship. Cassava farm owners are less vulnerable to food stress because they are sure of at least one meal per day. In this circumstance the pains of food insecurity and its attendant consequences are felt in a lesser proportion than those that do not own cassava farms. At this period, the technological advancement deployed by the research centre with mandate on cassava and her collaborators to ensure high yielding, early maturing and disease free varieties are made available to farmers should be exploited to increase food security in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study focuses on the impact of internal displacement on household food security among farmers in Benue State, Nigeria. It investigates the relationship between internal displacement and food security. The study employed a social survey design, using a combination of cluster, random, and purposive sampling to select 429 respondents. Data was collected through semi-structured questionnaires and analyzed quantitatively and qualitatively. The study found that internal displacement resulted in reduced food production (mean score 3.54), acute food shortages, and increased food prices (mean score 3.55), as well as decreased access to safe food (mean score 3.38). There was a strong positive relationship (R=0.802) between rural crop farmers' displacement and household food insecurity. Internal displacement has devastating effects, leading to significant changes in family structure, gender roles, relations, and identities.
Keywords: *Displacement; Food security; rural farmers; Impact.*

INTRODUCTION
Internal displacement is a common consequence of Nigerian inter-communal, religious and political violence, flooding and forced evictions (Internal Displacement Monitoring Center -IDMC, 2013). In other words, internal displacement of persons could be triggered by natural disasters or human-induced conflict which leads to violent clashes. Irrespective of the cause of the displacement, the phenomenon always leaves negative socioeconomic footprints on millions of people worldwide. A serious source of concern however lies with internal displacement of persons arising from human-induced violent clashes and conflicts in recent times. Internally displaced persons (IDPs) arising from violent clashes are victims of various kind of injustices or violence confrontations, perpetrated against them by their own government or agents of communal clashes, riots, terrorism, natural disasters, religious conflicts, among others (Hamzat, 2013). In recent times, the issue of herders' invasion and occupation of farm land across the regions in Nigeria has become a major threat to food security (Olobakole &omowumi 2017). Displacement around the world has been a main cause of a rise in global hunger in recent years. More recent figures as indicated by The UNHCR (2016) and World Bank (2017) show that the number of displaced persons rise from about 40 million people in 2011 to almost 66 million in 2016 (World Bank, 2017).
In Benue State, these clashes reinforce circles of extreme poverty and hunger, and destroy social status, food security and affect mostly the most marginalized groups that include women and children of a teaming population (FAO 2017). In the host communities, nomadic herdsmen relocate as a result of conflict and host farmers, especially women and children, who remain behind, stop going to the distant farms for fear of attack by the nomads in the bush. Such displaced farmers have become a source of liability to other farmers whom they have to beg for food for themselves and their families (Bukari, Sow, & Scheffran, 2018). This has created a vicious cycle of poverty in such communities and affected the education of children leading to obstacles in their development and mass displacement. These conflicts have demonstrated high potential to exacerbate insecurity and food crisis particularly in rural communities where most of the conflicts are localized, with reverberating consequences nationwide. The inversion and pre-occupation of farm lands in Nigeria by Fulani herders have persisted and stand out a threat to national food security, livestock production and eradication of poverty with farmers often regarded as the most vulnerable (Dimelu *et al*., 2017). The invasion of north-central states by herdsmen have forced farmers to abandon their fertile farmlands, rendering several communities deserted and reduced farmers to tenants in internally displaced persons (IDPs) camps (Dimelu, Salifu, Enwelu & Igbokwe,

2017). It is against this background that this study examined the impact of internal displacement on household food security among farmers in Benue State.

MATERIALS AND METHODS

This study employed social survey design. A combination of Cluster sampling, random sampling and purposive sampling was used in selecting the respondents for the study and data collected with the use of a well semi-structured questionnaire. Benue State is divided into three senatorial districts, namely, North East senatorial district (Zone A) North West Senatorial District (Zone B) and Benue South Senatorial district Zone (C). These three Senatorial Districts make up the three clusters selected for this study.

One (1) L.G.A was purposively selected from each of the three senatorial districts. These are L.G.As that has the greater number of displaced persons. Logo Local Government area was selected from Zone A. Makurdi Local Government Area was selected from zone B. Agatu local government area was selected from zone C. Furthermore, two (2) internally displaced persons (IDPs) camps and two (2) communities were randomly selected from Logo and Makurdi L.G.As while only two communities were randomly selected from Agatu L.G.A. This is because there is no IDP camp in zone C, as displaced persons are living within the host community.The total number of registered displaced households in the six (6) selected communities (11,353) and four (4) IDP Camps (4,886) is sixteen thousand, two hundred and thirty nine (16,239). This figure therefore represents the sample frame (Benue State Emergency Management Agency 2018) from where a total number to 429 respondents were drawn using a mathematical formula given by Miller and Brewer (2003). Data were analyzed using descriptive statistics such as percentages and mean and inferential statistics such as correlation.

RESULTS AND DISCUSSION

The results point out that that internal displacement lowered the sufficient production of food with a mean score of 3.54.(Table 1). It also identified acute food shortage and increase in food prices ($\bar{x}$=3.55) as one of the impacts of internal displacement in the area. There is lack of access to safe food ($\bar{x}$=3.38); drastic reduction of production of nutritious food ($\bar{x}$=3.47); shortage of labour ($\bar{x}$=3.47); hunger ($\bar{x}$=3.53); degraded nutritional status on IDPs ($\bar{x}$=3.58); food lost in the farm ($\bar{x}$=3.88); limited or no access to farm lands ($\bar{x}$=3.78); fear of uncertainties in cultivating new farm lands ($\bar{x}$=3.8); and Continuing internal displacement would finally result to total damage of national food staple ($\bar{x}$=4).

The above is an indication of food insecurity in the area due to outflow of large numbers of physically active and economically productive as well as educated and non-educated population from the affected areas due to violence and incessant attacks. It is a known fact that the problem of food insecurity is usually associated with rural households and the urban poor who are more vulnerable to high food prices and limited access to food as a result of low income by implication, internal displacements causes economic recessions, and employment disruption and erode finances for social protection, and thus cause food insecurity through these channels.

This results Shows lack of access to necessities of life such as food, water and shelter. The findings are in line with the assertions of IDMC (2019) that internal displacement impacts the lives of affected people in many ways: It can influence their health, education, livelihoods, housing conditions, social life, security and environment positively, but most often does so negatively. Some of these impacts can have further repercussions and create vulnerability loops that are difficult to get out of. For instance, when a family loses its income as a result of displacement, young family members may be forced to drop out of school to support their parents, sacrificing their chance to get a degree and eventually making it harder for them to find decent work.

The findings are indications that internal displacement affects food security in terms of degradation of Agro-ecosystem area, limited or lack of access to land. This agrees with the assertions of Terminiski (2013) that people might be evacuated from their habitual homeland without adequate compensation, guarantees or mechanisms of social support, or to the initial phase of a process of resettlement which is associated with physical relocation of people from their homes. Internal displacement of persons also provides fertile ground for human rights abuses including torture, rape, killings, as well as forced evictions, loss of food and loss of heritage. The finding support Ellen *et al.*, (*1999*),who stated that conflicts also tend to affect food and commodity prices; such prices influence the levels of farmers' income and their vulnerability to food insecurity. The findings imply that irrespective of the cause of the displacement, the phenomenon always leaves negative socioeconomic footprints on millions of people worldwide.

Table1: Impact of displacement on food security

Impacts	Strongly Agree	Agree	Disagree	Strongly Disagree	Mean
Availability					
Internal displacement lowers the sufficient production of food	250(69.4)	60(16.6)	45(12.5)	5(1.38)	3.54
Food lost in the farm	344 (95.5)	16(2.5)	-	-	3.88
Limited or no access to farm lands	311(86)	39(8.6)	10 (2.7)	-	3.78
Affordability					

Increase in food prices	210 (58.3)	140(38.9)	7(14)	3(1.94)	3.55
Access					
Internal displacement causes lack of access to safe food.	213(59.16)	98 (24.7)	32 (8.8)	17(4.7)	3.38
Continuing internal displacement would finally result to total damage of national food staple	360 (100)	-	-	-	4
Utilization					
As a result of internal displacement, production of nutritious food is drastically reduced	198(55)	142(39.4)	11(3.0)	9(2.5)	3.47
Hunger	230(63.8)	100(27.7)	20(5.5)	10(2.7)	3.53
Internal displacement has negative impact on nutritional status on IDPs	250(69.4)	80(22.2)	20(5.5)	10(2.7)	3.58
Shortage of labour	198(55)	142(39.4)	11(3.0)	9(2.5)	3.47
Fear of uncertainties in cultivating new farm lands	300(83.3)	60(16.7)	-	-	3.8
Poverty					

Field survey, 2021: Decision rule: ≥ 2.5 = accepted < 2.5 = rejected
Figures in parenthesis are percentages

Table 2: Relationship between Rural Crop Farmers Displacement and Household Food Insecurity in Benue State

Correlations

		Rural crop farmers displacement	Household food insecurity
	Pearson Correlation	1	.713
	Sig. (2-tailed)		.802
	N	360	360
	Pearson Correlation	.713	1
	Sig. (2-tailed)	.802	
	N	360	360

Source: Field data 2022

The result reveals that there is strong positive relationship (R=0.802) between rural crop farmers' displacement and household food insecurity. This implies that if displacement of farmers continues to increase, household food insecurity in the study area will also increase. Its malevolent effects on individuals, families, and communities are wide-ranging and include 'impoverishment, social isolation, exclusion from health, welfare and education provision, the breakdown of social relationships and support structures, and the undermining of authority structures and social roles.

CONCLUSION

The findings thus conclude that the impacts of internal displacement on IDPs are devastating. It leads the people to dramatic changes in family structure and gender roles, relations, and identities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT:

Agricultural extension services have long been recognized as crucial to enhancing agricultural productivity and food security in Nigeria. This paper provides a comprehensive review of the willingness of Nigerian farmers to pay for these services, shedding light on historical developments, policy frameworks, and factors influencing farmers' decisions to invest in extension services. Historically, agricultural extension services in Nigeria have evolved from government-led initiatives to a more pluralistic approach involving private and international organizations. The transition has been marked by changing strategies and challenges, with efforts to improve the effectiveness of extension services. Through an examination of various studies, this review explores the factors influencing farmers' willingness to pay for extension services across different regions of Nigeria. Factors such as age, income, farm size, education, and experience in agriculture play significant roles in shaping farmers' decisions to invest in extension services. The findings reveal varying levels of willingness to pay among farmers, influenced by economic conditions, government policies, and the perceived benefits of extension services. The paper also discusses the policy landscape in Nigeria, highlighting the progression of agricultural extension policies over the years and their impact on the extension system. From the early Agricultural Development Projects (ADPs) to the more recent Agricultural Extension Transformation Agenda (AETA), these policies have aimed to redefine roles, responsibilities, and approaches in extension services. However, challenges in implementation, particularly at the state level, have posed obstacles to their success.

Keywords: *Agricultural Extension Services, Willingness, Pay, Nigeria, Review*

INTRODUCTION

The improvement of farm production and food security in Nigeria has historically been greatly aided by agricultural extension programs. These services, which included technology transfer, rural development, managerial skills, and non-formal education, were first designed as a way to bring research-based information and knowledge to rural sectors. According to the traditional African perspective of extension, the main goals were to train farmers, transfer technology, increase production, and improve yields (Christoplos, 2010). As a holistic system, extension seeks to open up access to knowledge, information, and technologies for farmers, their organizations, and other market participants. Additionally, it encourages cooperation with research, education, agriculture, and relevant institutions, allowing them to advance their management, organizational, and technological capabilities (Christoplos, 2010).
In the context of agricultural extension services, the idea of "willingness to pay" (WTP) is relevant. According to Birner et al. (2006), agricultural extension is a system made up of many organizations that helps people involved in agriculture solve problems and acquire knowledge, skills, and technology to improve their quality of life. Governmental bodies, producer groups, agricultural associations, and private sector actors are all involved in this. WTP is an indicator of farmers' willingness and readiness to invest in agricultural extension services. Farmers are willing to pay for these services when they recognize their value in meeting their specific needs and improving agricultural practices.

The ability of extension services to narrow the knowledge gap between farmers and researchers is a critical component of agricultural development in many developing countries. According to Van den Ban and Hawkins (1998), these services help people become more aware of ways to increase farm yields, which in turn raises their income and standard of living. According to Picciotto and Anderson (1997), effective agricultural extension systems constantly update and improve their strategies in response to new research knowledge that is in line with farmers' requirements. Public extension services have, however, frequently come under fire for failing to adapt to the various demands of farmers, failing to inspire beneficiaries to take an active role in their programs, and having limited quality of field employees (Idachaba, 2005).

Considering the difficulties involved with public extension systems, there has been an increase in interest in enlisting the private sector to provide extension services as a solution to these limitations (Okoro et al., 2006). It is unclear if the implementation of a fee-paying extension system will increase efficiency, equity, and efficacy in assisting both commercial and subsistence farmers. Farmers' willingness to pay for extension services is influenced by a number of variables, including the severity of the issues that these services can address and their financial benefits (Singh and Narain, 2016).

Exploring several paradigms and models, such as the innovation-diffusion model, the economic constraints model, and the adopter's perception model, is crucial to understanding the dynamics of farmers' willingness to pay for agricultural extension services. These paradigms consider factors such as the efficacy and relevance of extension services, how benefits are perceived, the size of farms, and farmers' educational backgrounds. According to Adesina and Baidu-Forson (1995), efficient extension services should be tailored to farmers' requirements and give them the information they need to make informed decisions. This would help to reduce poverty and enhance farmers' standard of living.

Many developing countries, including Nigeria, have recently reviewed and strengthened their extension systems in response to the realization of the critical importance of agricultural extension in ensuring food security and rural development. The effectiveness of these redesigned systems depends on farmers' readiness to pay for these services, making the assessment of farmers' willingness to pay a critical aspect of extension planning and implementation

Against this backdrop, this paper undertakes a comprehensive review of research conducted on the willingness of Nigerian farmers to pay for extension services, aiming to provide valuable insights and suggest a path forward for agricultural extension programs in the country. The study encompasses several key objectives: examine the historical trends in agricultural extension services in Nigeria; evaluate extension policies and programs in Nigeria; ascertain farmers willingness to pay and the factors that influence farmers' WTP for agricultural extension services in different regions of Nigeria; identify the common challenges and barriers faced by farmers that hinder their willingness to pay for extension services and; identify gaps in the existing literature on WTP for extension services in Nigeria and suggest areas for future research.

Historical Development of Agricultural Extension in Nigeria

Agricultural extension services have long played a pivotal role in engaging rural farming households, both within Nigeria and on a global scale. Nevertheless, the terrain of agricultural extension in Nigeria has undergone dynamic transformations, necessitating heightened participation and financial support from the private sector (Oladoja, 2004). Historically, the Nigerian government has been a central contributor to the funding and administration of extension services, with origins dating back to the pre-independence era. In response to the challenges faced by the agricultural sector, various government programs and initiatives have been introduced to revitalize this essential sector (Alabi and Mafimisebi, 2004).

Pre-Colonial and Colonial Periods:

In the period before colonial rule, farmers independently selected and introduced improved crop varieties and animal breeds, often through interactions with neighboring communities and trans-Saharan traders (Williams, 1978). Traditional agricultural practices relied heavily on apprenticeships, with knowledge being passed down through generations. During the colonial era, agricultural development initiatives were launched to boost production. In 1893, the Department of Botanical Research was established, and in 1905, the British Cotton Growers Association initiated cotton cultivation at Moor Plantation, Ibadan. By 1921, a unified Department of Agriculture was formed after the amalgamation of Northern and Southern Nigeria, with a primary focus on increasing the production of export crops for the British market (Williams, 1978).

Post-Colonial Agricultural Extension:

The post-colonial period in Nigeria can be categorized into two main groups: government-organized agricultural programs and those organized and sponsored by private entities. Government-led initiatives encompass the National Accelerated Food Production Project (NAFPP), Agricultural Development Projects (ADP), Operation Feed the Nation Programme (OFN), River Basin Development Authority (RBDA), and various other programs designed to enhance agricultural productivity (Omotayo, 2004). Additionally, private organizations such as the Nigerian Tobacco Company (now British American Tobacco Nigeria), oil companies like Shell Petroleum Development Company, religious institutions like the Catholic and Anglican churches, and non-governmental organizations (NGOs) like the Leventis Foundation have contributed to offering extension services. International organizations including the World Bank, International Fund for Agricultural Development (IFAD), United States Agency for International Development (USAID), Technical Centre for Agricultural and Rural Cooperation (CTA), and Food and Agriculture Organization (FAO) of the United Nations have also actively participated in agricultural extension and rural development in Nigeria. Private processing and marketing companies have also been integral to the extension framework, providing farmers with credit, inputs, and advisory services (Alam et al., 2013).

The evolution of agricultural extension in Nigeria witnessed a transition from the conventional Ministry of Agriculture extension system during the post-colonial national government era to the Agricultural Development Project Extension System (ADPs) in the 1970s. The ADP system introduced the Training and Visit (T and V) extension approach, characterized by professionalism, time-bound schedules, concentrated efforts, regular training, and manageable agent-to-farmer ratios. In 1990, the Unified Agricultural Extension System (UAES) emerged as a modification of the T and V system, allowing for a single Village Extension Agent (VEA) to provide extension services across various agricultural sectors (Okwu and Ejembi, 2001).

Government Institutions Supporting Agricultural Extension:

The Federal Government of Nigeria actively supports agricultural extension through several institutions, including the Project Coordination Unit (PCU), Agricultural Projects Monitoring and Evaluation Unit (APMEU), National Agricultural Extension and Liaison Services (NAERLS), and the Agricultural and Rural Management Training Institute (ARMTI). These entities provide coordination, monitoring, multimedia materials development, and management training for agricultural personnel (Ladele *et al*., 2002, and Adegbola and Bamishaiye, 2013).

Extension Policies and Programs in Nigeria:

Extension activities in Nigeria have historically lacked clear plans and coordination. They have often been treated as secondary to agriculture, lacking a dedicated policy framework. For instance, the Training and Visit (T&V) system, while initially promising, faltered once World Bank sponsorship was withdrawn due to its lack of government ownership and legal backing. This inconsistency has hindered the effectiveness of extension services (Osuntogun and Olufokunbi, 1986).

Agricultural extension policies play a crucial role in guiding decisions and investments in this field. In Nigeria, several policies have been implemented over the years to promote agricultural extension. One of the earliest initiatives was the Agricultural Development Projects (ADPs), established in 1975 to address declining agricultural productivity. However, a comprehensive agricultural extension policy was not in place until the Unified Agricultural Extension Services (UAES) policy in 1991. While it aimed to improve extension services, it fell short in addressing coordination, institutional arrangements, collaboration, and funding (USAID, 2010).

A significant step came with the 2001 Agricultural (Extension) Policy, which was a marked improvement over previous policies. It expanded beyond self-sufficiency to encompass national food security, allocating roles and responsibilities to various stakeholders, including state governments. The state governments were tasked with enhancing primary agricultural production and providing effective extension services, among other responsibilities. However, implementation challenges at the state level persisted (FMARD, 2012).

A more recent development is the Agricultural Extension Transformation Agenda (AETA), introduced as part of the Agricultural Transformation Agenda (ATA) in 2012. AETA aimed to modernize agriculture and transform the extension system into a demand-responsive, market-oriented, and technology-driven service. It emphasized the roles of different stakeholders and built on the 2001 Agricultural Policy, bringing a more pluralistic approach to extension services (FMARD, 2011).

Nigeria has seen a series of agricultural extension policies and programs over the years, with each attempting to address the challenges and needs of the agricultural sector. The 2001 Agricultural Policy and the subsequent AETA have marked significant milestones in defining roles and responsibilities and moving towards more effective extension services. However, challenges in implementation at the state level continue to impact the overall success of these policies (Issa & Issa, 2013; Naswem & Ejembi, 2017; Oyelami et al., 2018

A Review of Farmers' Willingness to pay and Factors influencing Willingness to pay for Extension Services in Nigeria.

In their study, Paparrizos, Kumar, and Ludwig (2021) investigated the willingness of farmers in Bangladesh to pay for participatory climate information services (CIS). The findings revealed a substantial willingness to pay among farmers, with over 90% in the experiment group expressing their willingness to pay in co-developed CIS. This contrasts with the 75% willingness observed in the control group. The annual subscription fees farmers were willing to pay ranged from 970.92 taka ($11.45) to 1387.20 taka ($16.36). These results underscore the high potential for participatory CIS, emphasizing the need for government and private sector involvement to develop CIS tailored to smallholders' needs.

Similarly, Mwaura, Muwanika, and Okoboi (2010) conducted a study in Uganda to assess farmers' willingness to pay for extension services. Their findings revealed that approximately 35% and 40% of farmers engaged in crop and animal husbandry, respectively, were willing to pay an average of Ugandan shillings 3,400 ($1.8) and 3,700 ($2) per trip for extension services. Interestingly, the demand for extension services was found to be relatively low when considering private sector engagement.

In Benin and Togo, Agossou *et al*. (2023) explored the determinants of farmers' willingness to pay for improved cultivars of Macrotyloma geocarpum. Their study revealed that more than 90% of respondents expressed a strong willingness to pay for improved seeds of Macrotyloma geocarpum. Factors influencing the amount farmers were willing to pay included the low yield of current cultivars, the expected yield of the improved variety (set at over 1 ton per ha), socio-linguistic group affiliation, and the adoption of improved agricultural technologies.

In Nigeria, Akinnagbe and Adesina (2018) investigated the willingness of farmers in Ondo State to pay for Agricultural Extension Services. Their findings revealed that approximately 57% of respondents were not inclined to pay for specified extension services due to factors such as low income from farming and the inconsistency of government policies. However, about 43% were willing to pay for certain services like personal visits and information on funding sources. Conversely, Umar *et al.* (2012) assessed the willingness of farmers in Niger State to pay for demand-driven extension services. Their study showed that the majority of respondents (81.2%) were willing to pay for extension services and were prepared to make cash payments. The mean annual amount respondents were willing to pay for extension services was ₦14,991. Factors such as farm size, the degree of commercialization of crop enterprises, and farm income significantly influenced this willingness to pay.

Furthermore, Onuche et al. (2015) analyzed the willingness of small-scale fish and crop producers in Kogi State, Nigeria, to pay for Agricultural Extension Services. Their findings indicated that farmers were willing to pay an average of 1.8 USD per month for extension services. Various factors influenced this willingness, including education, income, farm size, confidence in the present extension system, and extension contacts.

The factors influencing the willingness to pay for extension service delivery was examined by Akinyemi *et al.* (2019) among crop farmers in Katsina State, Nigeria. They employed a probit model for data analysis, and the results revealed that farmers were willing to pay for extension services. The factors influencing willingness to pay for extension services as revealed by the study include age of the farmers, farmer's income, the proportion of commodities sold, land ownership and household size. As a recommendation, the study suggests the implementation of efficient marketing mechanisms for farmers' produce. This can potentially enhance the overall effectiveness of extension services and benefit both farmers and the agricultural sector. Okere *et al.* (2021) assessed the willingness of smallholder oil palm farmers in Edo State, Nigeria, to pay for extension services. The study found that factors such as age, marital status, household size, transportation cost, and distance from extension service points influenced the likelihood of paying for these services. Conversely, factors like education, farm size, farming experience, income, availability of extension services, and extension visits increased the likelihood of willingness to pay.

In Kwara State, Nigeria, Falola et al. (2012) investigated the willingness of fish farmers to pay for Agricultural Extension Services. Their study identified factors affecting willingness to pay, including stock size, nature of production, level of education, and age of the farmers. The study recommended improved extension services and the encouragement of fish production among young, educated individuals.

Lastly, in a study conducted by Onoh *et al.* (2014) in South-Eastern Nigeria, researchers aimed to understand the factors influencing farmers' willingness to pay for agricultural extension services. The study revealed that factors such as the level of education, farm size, income, and farming experience had a direct relationship with farmers' willingness to invest in extension services. Specifically, farmers with higher levels of education, larger farms, higher incomes, and more experience in agriculture were more inclined to pay for extension services.

Collectively, these studies provide valuable insights into farmers' willingness to pay for agricultural extension services, highlighting regional variations, influencing factors, and potential implications for policy and service development. Nevertheless, there exists a research gap regarding the specific types of extension services that farmers are willing to pay for and how the effectiveness of these services impacts their willingness to invest. Additionally, most of the studies are region-specific, suggesting the potential for future research to conduct comprehensive national-level studies in Nigeria and other countries to gain a more holistic understanding of farmers' preferences and willingness to pay for agricultural extension services.

Constraints to willingness to pay for Extension Services in Nigeria

The study by Onoh et al. (2014) identified several constraints affecting farmers' willingness to pay for extension services, including the prevalence of free government extension services, scarcity of farm inputs, prior agricultural training received by farmers, and financial incapability. Akinnagbe and Adesina (2018) highlighted additional constraints, such as low income from farming, inconsistency in government policies, the absence of a clearly defined institutional framework, corruption and nepotism, poor basic infrastructure like road networks, an unfavorable environment for farmer participation in extension funding, and the inadequacy of ready-made markets for increased farm outputs resulting from improved extension services.

Olajide and Oyebode (2020) discussed constraints related to the practicability of services offered by one-stop agricultural extension delivery support centers. These constraints include skepticism regarding government policies, concerns about policy stability, and past failures of similar programs, which pose potential threats to the success of extension services.

WAY FORWARD:

Moving forward, several critical considerations emerge for improving agricultural extension services in Nigeria:

Policy Implementation: There is a need for improved policy implementation, particularly at the state and local government levels. Efforts should be made to ensure that policies are translated into practical actions that benefit farmers on the ground.

Tailored Extension Services: Extension services should be tailored to meet the specific needs of different regions and farming communities. A one-size-fits-all approach may not be effective, given the diversity of Nigeria's agricultural landscape.
Technology Integration: Embracing modern technology, such as digital platforms and mobile applications, can enhance the delivery of extension services. These technologies can facilitate information dissemination and real-time support to farmers.
Public-Private Partnerships: Collaboration between the public sector, private organizations, NGOs, and international agencies should be encouraged. These partnerships can bring diverse resources and expertise to the extension system, expanding its reach and impact.
Research and Data: Continued research is essential to understand evolving farmer needs and preferences. More studies should be conducted to explore the specific types of extension services that farmers are willing to pay for and the impact of service effectiveness on willingness to pay.
Capacity Building: Training and capacity building for extension workers and agents should be prioritized to ensure they have the knowledge and skills required to effectively support farmers.
Market Linkages: Extension services should not only focus on production but also on marketing and value chain linkages. Helping farmers' access markets for their produce can significantly enhance their income.
Community Engagement: Involving farming communities in the design and implementation of extension programs can lead to a sense of ownership and improve program outcomes.
Monitoring and Evaluation: Robust monitoring and evaluation mechanisms should be established to assess the impact of extension services continually. This feedback loop can guide program improvements.

CONCLUSION

In conclusion, this comprehensive review highlights the intricate landscape of agricultural extension services in Nigeria, with a particular focus on farmers' willingness to pay for these critical services. Over the years, agricultural extension has evolved from a government-centric model to a more diverse and pluralistic approach involving private sector actors, NGOs, and international organizations. Despite this evolution, challenges persist, affecting the effectiveness and reach of extension services.
Several key findings emerge from the analysis of various studies. Firstly, the willingness of Nigerian farmers to pay for extension services varies across regions and is influenced by a myriad of factors, including age, income, farm size, education, and farming experience. These factors interact with economic conditions, government policies, and the perceived benefits of extension services, shaping farmers' decisions to invest in them.
Secondly, the policy landscape in Nigeria has seen several shifts, from the early Agricultural Development Projects (ADPs) to the more recent Agricultural Extension Transformation Agenda (AETA). While these policies have aimed to redefine roles, responsibilities, and approaches in extension services, challenges in implementation, particularly at the state level, have posed significant hurdles.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
*Gangrenous dermatitis is a bacterial disease seen in turkeys and chickens caused by Clostridium septicum, C perfringens type A, and Staphylococcus aureus , either singly or in combination. It presents increased mortality in the flock. Physical examination, presents ruffled feather, somnolence, droopy wings, lethargy, i n appetence while Post mortem examination revealed; Greenish discoloration of the shank, dark reddish purple to green, weepy areas of the skin of the abdomen, pectoral muscle and neck areas. Areas of affected dermis and subcutis were characterized by extensive blood-tinged edema with congestion of the entire pectoral and abdominal areas. There was a foul smelling odour. Birds that died in the morning hours were already putrid by 12 noon. This disease is primarily a disease of broilers of over 4 weeks of age which is typical of this case. The battery cage system being operated in this farm is rarely used in broiler production because of the fragile nature of the birds and the early age at which the birds were transferred is a risk factor. Although it has got its merits in effective utilization of the available space hence holding more birds than the deep litter system, it is not a common practice. This case of gangrenous dermatitis is linked to injuries sustained during transfer to the battery cages. Samples were collected aseptically and submitted for microbiologic culture and isolation of the organisms .Result showed heavy growth of Staphylococcal species. Clostridium could not be cultured because of its fastidious nature and special media requirement. Gangrenous dermatitis was confirmed. Treatment with Oxytetracycline inj. long acting 20mg/kg I/M given at the 4th week was effective.***

Keywords: *Gangrene, dermatitis, Clostridium and staphylococcus*

INTRODUCTION
Synonyms of Gangrenous dermatitis: Necrotic dermatitis, Clostridial dermatitis, Gangrenous cellulitis, Gangrenous dermatomyositis, Gas edema disease (Kahn, et al., 2010). Gangrenous dermatitis is a bacterial disease seen in turkeys and chickens caused by *Clostridium septicum*, *C perfringens* type A, and *Staphylococcus aureus*, either singly or in combination. Morbidity may be up to 50% and mortality is high. It occurs due to invasion of 'normal' wounds by 'normal' bacteria in immunosuppressed birds. Immunosuppression is therefore a predisposing factor, especially following congenital Chick Anaemia Virus infection or early Infectious Bursal Disease Virus infection (Gumboro Disease). The condition is characterized by rapid onset of acute mortality (McMullin, 2004; Kahn *et al.*, 2010)

METHODOLOGY
The clinical sign observed was death occurring in well-fleshed birds suddenly because the incubation period is relatively short (12–24 hours). Other clinical findings are general in nature and include depression, incoordination, in-appetence, leg weakness, ataxia, and high fever. Occasionally dejection, gangrenous skin, severe cellulitis especially of thighs, wings, and wattles. Gross lesions consist of dark reddish purple to green, weepy areas of the skin. Affected areas included abdomen, breast, wings, or legs.

Areas of affected dermis and subcutis are characterized by extensive blood-tinged edema, with or without gas (crepitus). Infection may extend into underlying musculature, which may be discolored and contain edema and gas.

Diagnosis was based on clinical signs and/or lesions which are almost pathognomonic (Jordan, and Pattison., 1996). Diagnostic confirmation is based on the presence of lesions and recovery of an abundant growth of causative agent(s) from affected tissue of recently dead birds (McMullin, 2004).

Gangrenous dermatitis has historically been treated effectively with administration of many broad-spectrum antibiotics. Water acidifiers have been used in cases to reduce, but not eliminate mortality where mortality rates are low or antibiotic efficacy has been poor (Kahn *et al*., 2010; Chauhan and Sushovan., 1996). Prevention and control involves good hygiene and management. Avoid skin trauma and immunosuppression (congenital Chicken Anaemia Virus infection, early Infectious Bursal Disease Virus infection). Total cleanout and disinfection of affected houses has reduced or eliminated gangrenous dermatitis infection on farms with historical problems. Salting of floors has also reduced bacterial challenge in subsequent flocks. Reducing excessive moisture and microbial levels in poultry house litter and minimizing trauma are useful adjuncts to other prevention and control measures. Where infection is secondary to predisposing viral infection, modification of vaccine programs directed at immunosuppressive agents may be used to control widespread gangrenous dermatitis (McMullin., 2004, and Kahn, *et al*., 2010,; Jordan and Pattison., 1996).

Species affected: Avian. Breed affected: Aborika. Farm population of birds: 10,000 AGE: 6 Weeks plus

Primary complaint: The farmer reported that birds in his farm started dying few weeks ago.

Case history: Birds were transferred through four pens before they arrive to the battery cage system at 5th week. The transfer was done weekly. The vaccination programme was up to date. Observation showed that the birds affected are the ones kept on battery cage system of poultry production. The ones kept on deep litter were not affected. The birds died soon after they showed signs of disease. Dead birds presented skin discoloration. They had been treated previously with Ciprofloxacin and EST MIX® at different occasions prior to our invitation.

On physical examination of the birds during the necropsy examination, the following were observed; Ruffled feather, somnolence, droopy wings, lethargy, Inappetence. Post mortem examination conducted revealed; greenish discoloration of the shank, dark reddish purple to green, weepy areas of the skin of the abdomen, pectoral muscle and neck areas. Areas of affected dermis and subcutis were characterized by extensive blood-tinged edema with congestion of the entire pectoral/ abdominal areas. There was a foul smelling odour. Birds that died in the morning hours were already putrid by 12 noon we arrived.

Sample for Diagnosis

The following samples were aseptically collected; liver, haemorrhagic/congested area of the pectoral and thigh muscle, fat sample at the perineal area and submitted for microbiologic culture and isolation of the organisms.

Differential Diagnosis was Chick anaemia virus and Alvian influenza virus.

Tentative Diagnosis was Gangrenous dermatitis based on clinical signs and post mortem lesion.

Laboratory Test Result showed heavy growth of Staphylococcal species. Clostridium could not be cultured because of its fastidious nature and special media requirement.

Confirmatory Diagnosis was Gangrenous dermatitis.

RESULTS

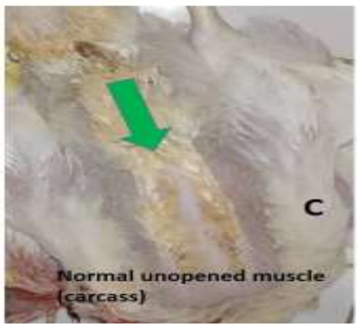
The case presented was a case of ganreneous dermatitis

Treatment: Oxytetracycline Inj. long acting 20mg/kg I/M given at the 4th week. Withdrawal period was strictly adhered to according to Aliu, (2007).

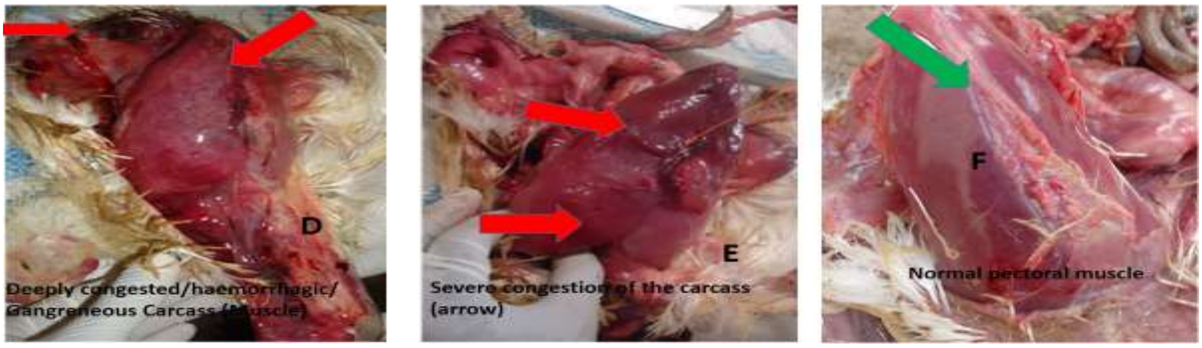
Rationale for therapy: Tetracycline is so effective in the treatment of clostridial diseases and most common bacterial disease of poultry (Aliu, 2007).

Severely gangrenous unopened Carcass (see arrow)

Gangrenous unopened pectoral muscle and lower abdomen (see arrow)



Normal unopened muscle (carcass)



DISCUSSION

Gangreneous dermatitis presents increased mortality in the flock. Clinical signs and post mortem lesions seen in this case agrees with that described by Jordan and Pattison (1996) and Chauhan and Sushovan (1996).(plate A, B,D AND E).

Both *Clostridia and Staphylococci* are ubiquitous in the poultry house environment and in (intestine) or on skin of the birds. Gangrenous dermatitis often is believed to occur as a sequela of other diseases that produce immunosuppressive effects such as Infectious bursal disease, Chicken infectious anemia, Reticuloendotheliosis, Reovirus, and Inclusion body hepatitis. Environmental conditions that promote poor litter conditions may also predispose flocks to gangrenous dermatitis, especially when present in conjunction with challenges from immunosuppressive viruses. Failure to remove moribund or dead birds as soon as it occurs may increase incidence of the disease, because such birds serve as reservoirs of the causative agent(s). Management practices that lead to wound, overcrowding, feed outages, irregular time of feeding may increase incidence of infection. Affected farms tend to have repeated outbreaks if the environment is not treated (McMullin, 2004, and Kahn *et al*., 2010)

Gangrenous dermatitis is primarily a disease of the broiler over 4 weeks of age which is typical of this case. Mortality can reach 8-9% in untreated cases (Jordan and Pattison, 2007). The battery cage system being operated in this farm is rarely used in broiler production because of the fragile nature of the birds and the early age at which the birds were transferred is a risk factor. Although it has got its merits in effective utilization of the available space hence holding more birds than the deep litter system, it is not a common practice. This case of gangrenous dermatitis is linked to injuries sustained during transfer to the battery cages.

RECOMMENDATION

There should be careful transfer of birds to reduce injuries especially in the battery cage system being operated in this case. Infectious bursal disease vaccination should be modified; removal of moribund or dead birds as soon as possible, avoidance of overcrowding, feed outages and inconsistent feeding time to avoid undue struggle for feed is highly recommended.

ASSESSMENT OF THE ADOPTION STAGES OF IMPROVED SWEET POTATO PRODUCTION TECHNOLOGY IN OTUKPO LOCAL GOVERNMENT AREA OF BENUE STATE, NIGERIA

I. I. Okonkwo* and G. U. Okonkwo
National Root Crops Research Institute, Umudike, Umuahia, Abia State, Nigeria.
***Corresponding author's email address**: okonkwoannainno@gmail.com

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study assessed the response of farmers to the adoption stages of improved sweet potato production in Otukpo LGA of Benue State, Nigeria. Otukpo was purposely chosen because of its nearness to National Root Crops Research Institute (NRCRI), Umudike which has its national mandate of researching on root and tuber crops. Well structured questionnaire was used to collect the samples at random. Two districts out of four were used. One hundred and eighty (180) farmers were randomly selected for the study. Frequency distribution table and line graph were used to analyze the data. The result showed that 40% of the farmers were aware of the technology, while 31%, 18%, 6% and 5% were interested, tried, adopted and unaware of the technology respectively. The study therefore called for policies that would increase the adoption level of the production in the area, thus, practical knowledge and sweet potato value addition like confectioneries and drinks are recommended.
Keywords: *Sweet potato adoption stage,*

INTRODUCTION
Sweet potato *(Ipomea batatas*) is dicotyledonous plant that belongs to the bindweed or morning glory family, Convolvulaceae. The plant is a herbaceous perennial vine, bearing alternate triangle-shaped or palmately lobed leaves and medium-sized sympetalous flower. It is a cover crop that is usually grown for its edible underground root, and leaf. Its large, starchy sweet-taste tuberous roots are used as a root vegetable while the young shoots and leaves are sometime eaten as leafy vegetable. However, many authors have referred sweet potato as an economic important crop due to its relevance in both home consumption and industrial uses.

The root is produced industrially for making flour, cake, chips, doughnut, and bread as well as starch for textile (Nwankwo *et al*., 2021). According to Truong *et al*., (2018), the beta-carotene in sweet potato (Orange fleshed sweet potato) is a nutritional content that is capable of defeating the war against vitamin A deficiency in our society. Furthermore, the studies of (Low *et al.*, 2007; Hotz *et al.*, 2012) indicated that increased consumption of orange-fleshed sweetpotatoes improved the vitamin A status of children, pregnant women, and lactating mothers. In the world food map, sweet potato ranks the fifth most important food crop in the tropics and the seventh in the world food production (FAO, 2016). El-Sheikha and Ray (2017) reported that Sweet potato has the capacity to fight hunger in our society by meeting up the family food requirements, reducing poverty, and increasing food security of a nation.

Sweet potato is highly productive crop in Southern and Northern part of Nigeria especially when all the agronomic practices accrue to it are adopted and applied. The crop according to Nwankwo and Bassey (2021) adapts to a wider range of climatic and soil conditions in both Northern and Southern part of the country. Sweet potato thrives well in the Southern part of the Nigeria despite of high amount of rain fed and acidity level in the region (Nwodo, 2008). Despite its relevance in combating the food insecurity and generation of income to farmers, many farmers are yet to adopt it as one of their major food crops. This study, therefore tend to address the level of adoption of the sweet potato technology in the study area.

METHODOLOGY
Study Area
The study was carried out in Otukpo Local Government Area (LGA) of Benue State. The Local Government Area is a tropical savanna climate with a longitude of 7` 11` 35 North and 8` 8` 47 East, Latitude of 1'19306-8'14639 and Altitude of 207m. it comprises of four district namely; Otukpo, Ugboju, Adoka and Akpa. The LGA bounds with some other LGAs; Apa LGA to the North, Obi, Ado and Okpokwu to the South, Gwer west and East to the

East and to the West is Ohimini LGA. The LGA is mainly known for rice, yam, cassava, quinea corn and maize productions as the major staple.

Sample Selection

Samples selection was based on the districts, communities and farmers. From the four district in Otukpo LGA, two (Otukpo and Akpa) were selected for the study because of their close vicinity to National Root Crops Research Institute, Otobi Sub-station. Nine (9) communities from each of the selected district were selected, hence, a total of 18 communities were selected. From each of the community, ten (10) farmers were selected and therefore a total of one hundred and eighty (180) farmers were selected for the study.

Data Analysis

A frequency table and graph chart was used to assess the responsiveness of farmers to adoption stage in the study area.

RESULTS AND DISCUSSION

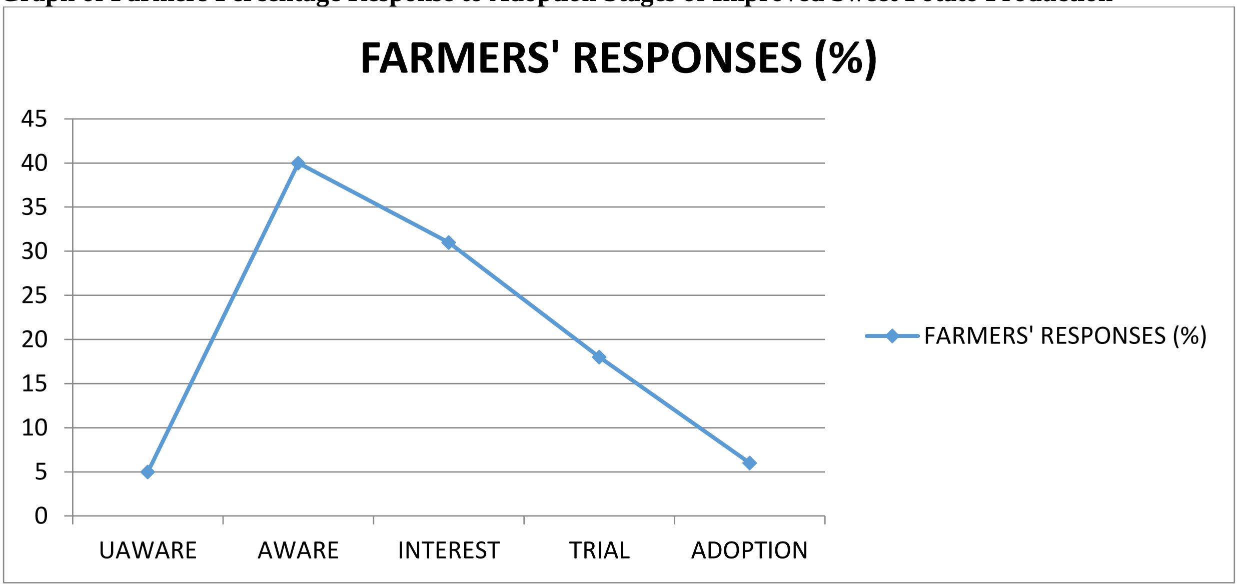
Table 1 shows the responses of farmers towards adoption stages in the study area are represented on the graph above. The result showed that 5% of the farmers were unaware of the technology while 40% of the farmers were aware and is an indication that the larger population of the farmers in the area was acquainted with the knowledge of the production of the improved sweet potato. The high level of awareness of the technology could also be attributed to the practical orientation gotten by the farmers from the Research Institute domiciled in the region. According to Madhu *et al.* (2020), management orientation through extension activities inspires farmers to be aware and know more about the scientific advantages of soil health card in Mandya District of Karnataka.

Table 1: Farmers Responses io Adoption Stage

S/N	ADOPTION STAGES	PERCENTAGE OF RESPONSE (%)
1	UAWARE	5
2	AWARE	40
3	INTEREST	31
4	TRIAL	18
5	ADOPTION	6

SOURCE: SURVEY 2021

Graph of Farmers Percentage Response to Adoption Stages of Improved Sweet Potato Production



However, there is a sharp decrease from 40% to 5% as shown on the graph above. Farmers lost interest on the technology which resulted to low level of trial and adoption by them. This therefore, could be attributed to the fact that the farmers have alternative staple foods which might have more relative economic advantage than the sweet potato. Research evidence indicates that if a potential user sees no relative advantage in using the innovation, it will not be adopted Greenhalgh *et al.* (2004).

SUMMARY AND RECOMMENDATION

The result showed that 40% of the farmers were aware of the technology, while 31%, 18%, 6% and 5% were interested, tried, adopted and unaware of the technology respectively. This therefore, implied that awareness creation is not enough parameter for technology adoption but additionally, practical demonstration that will enable the farmers to try what they learnt is recommended. Also the sweet potato value addition like confectioneries and drinks is recommended as policy that would boost up its production in the area and beyond.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cassava is a popular crop in tropical countries, providing a reliable source of food during the lag period between planting and harvest. It is drought-tolerant and can grow in marginal soils with low fertility and rainfall. Over 800 million people globally consume cassava and its products, especially in Sub-Saharan Africa. However, the seed industry in Nigeria is still nascent, especially in crops like cassava with low propagation and development cycles. Cassava can generate about 5-10 stem cuttings per plant, which is low compared to grains like rice, maize, and cowpea. The development cycle of cassava is one year, putting it at a disadvantage in seed yield compared to grains. The study aims to evaluate the seed yield of newly released cassava varieties under varied planting methods and the economic returns of planting materials obtained from two cassava varieties. The study aims to identify which varieties will yield more returns to farmers interested in commercial cassava seed enterprise. The study was conducted at the National Root Crops Research Institute Umudike's Western farm using a 2x2 factorial design and a Randomized Complete Block Design (RCBD). The experiment involved two newly released cassava varieties (Dixon and Poundable) and two planting lengths (L1=25cm, L2=12.5cm). Data was collected from sprout count, plant height at harvest, number of roots per plot, root weight per plot, number of stem per plot, stem weight per plot, biomass weight per plot, number of rots per plot, total root yield per plot, and total seed yield. The results showed that variety significantly influenced plant height, with Poundable having a mean height of 168.7cm and Dixon having an average height of 124cm. Fertilizer rates also influenced plant height, with higher rates leading to higher plant height and seed yield. The second length of cassava cuttings (L2=12.5cm) allowed seed entrepreneurs to plant larger areas of land with the same stem yield as the first length (L1=25cm).
Keywords: *Comparative analysis, root yield, newly released varieties, cassava*

INTRODUCTION
Cassava is a popular crop grown in almost every tropical country. Its agribusiness prospects places it over several traditional staples, hence its successful incorporation into many farming and food systems on the continent. Cassava was initially adopted as a popular food security crop; this is because it provides a more reliable source of food especially during the lag period between the planting season and harvest. It is also drought tolerant and has tenacity to grow in marginal soils with relatively low fertility and rainfall (Spencer and Ezedinma, 2017). Cassava is one staple crop that requires little or no external inputs for production (Udensi *et al.*, 2011). According to Boykin *et al.* (2019) over 800 million people globally; especially in the Sub-Saharan Africa, consume cassava and products made out of cassava. In recent times, it has emerged as both staple food and profitable cash crop of industrial significance in the world economy (Aerni, 2006). The seed industry in Nigeria is still nascent especially in crops like cassava with relatively low level of propagation. Its vegetative mode of propagation is also a strong limitation to cassava production (Onunka *et al.,* 2016). According to Nurul Nahar and Tan (2012) one cassava plant can generate about 5-10 stem cuttings and this is too low compared to that of the grains like rice, maize, cowpea to mention but a few which have high multiplication ratios. Furthermore, the development cycle of cassava is one year and it puts cassava to a disadvantage in quantity of seed yield, when compared to grains whose development cycle fall between 3-5 months (Onunka *et al.,* 2016). Extant literature is the fact that varied stake length i.e. the recommended 25cm length and 12.5cm do not show any significant difference in the quantity of stem yield generated by certain cassava varieties. It is therefore imperative that among other treatments, the effect of the stake lengths on newly released varieties be evaluated. Apart from these bottlenecks already identified in the production of substantial quantity of cassava seeds, handling of the planting materials is cost intensive due to

its bulkiness. These impediments indicates that more research is needed in the seed system of the cassava value chain to tap into the numerous opportunities it provides.

Cassava enterprises in Nigeria especially the commercialization of the planting materials (seed cuttings) has a great future and can significantly contribute to the reduction of hunger, unemployment and poverty now that these challenges are being addressed. Furthermore, the crashing of crude oil in the global oil market make it extremely difficult for Countries like Nigeria to solely depend on it in running their economy. There is lack of knowledge of the total output of stem cuttings and the economic returns per variety of cassava per hectare. Coupled with the fact that these cassava-planting materials come in diverse architectural build, some have two or three stems per stand, while others have initial and apical branches and these places varieties at advantage over others. The question therefore is which varieties will yield more returns to the farmer who wants to go into commercial cassava seed enterprise. This study therefore seeks to evaluate the seed yield of all the varieties, the economic returns of planting materials obtained from two cassava varieties by looking at the number of stem cuttings derivable from each selected cassava variety, the number of bundles that can be derived from a selected cassava variety and determine the total returns from the stem cuttings from each selected variety. Hence, there is need to evaluate the seed yield of some newly released cassava varieties under varied planting methods and the economic analysis of the seed yield.

MATERIALS AND METHODS

Study Area: The study was carried out in the Western farm of National Root Crops Research Institute Umudike. The experimental design is a 2x2 factorial design implemented within a Randomized Complete Block Design (RCBD). The factors considered in this design are variety and length of cuttings, each with two levels, respectively. The experiment was replicated three times. The treatment combinations include:

- Two newly released cassava varieties (Dixon (V1) and Poundable (V2))
- Two planting Lengths (L1=25cm, L2=12.5cm)

Data Collection

Primary data generated covered sprout count at 1WAP and 1MAP, plant height at harvest (cm), number roots per plot, root weight per plot, number of stem per plot, stem weight per plot, biomass weight per plot, number of rots per plot, total root yield per plot and total seed yield. These data was subjected to analysis using simple descriptive statistics such as graphs and Analysis of Variance (ANOVA) was employed.

RESULTS AND DISCUSSION

Effect of variety type on plant height

The result of the analysis showing the effect of variety on plant height is shown in Figure 1. The result indicates that variety influenced plant height significantly (P<0.005). Poundable which is one of the newly released varieties had a mean height of 168.7cm whereas Dixon had an average height of 124cm. Variety is therefore shown to influence overall yield of the stem. This is in accordance with a-priori expectation as most cassava varieties are phenotypically taller while others are shorter. This corroborates the findings of Dimkpa *et al.* (2021), who found out that the height of eight out eleven cassava varieties were taller in a study to determine their growth performance and susceptibility to some insects and diseases in humid tropics in River State.

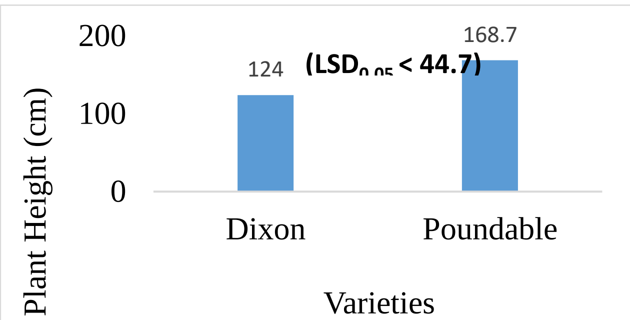

Figure 1. **Effect of fertilizer rates on plant height**

Figure 2 shows the effect of fertilizer rate on plant height. According to the result, the effect of different rates of fertilizer application on plant growth shows that R3 (800kg) gave the highest (160.6cm) followed by R2 (400kg) with the height of 152.7cm and R1 (200kg) with the height of 145.8cm respectively. This is in line with a-priori expectation and agrees with the study by Temegne *et al.* (2019), on appropriate fertilizer rates for cassava production in the humid forest agro-ecological zone of

Cameroon. This implies that holding other treatments constant, the higher the fertilizer rate, the higher the plant height, which also influences the seed yield.

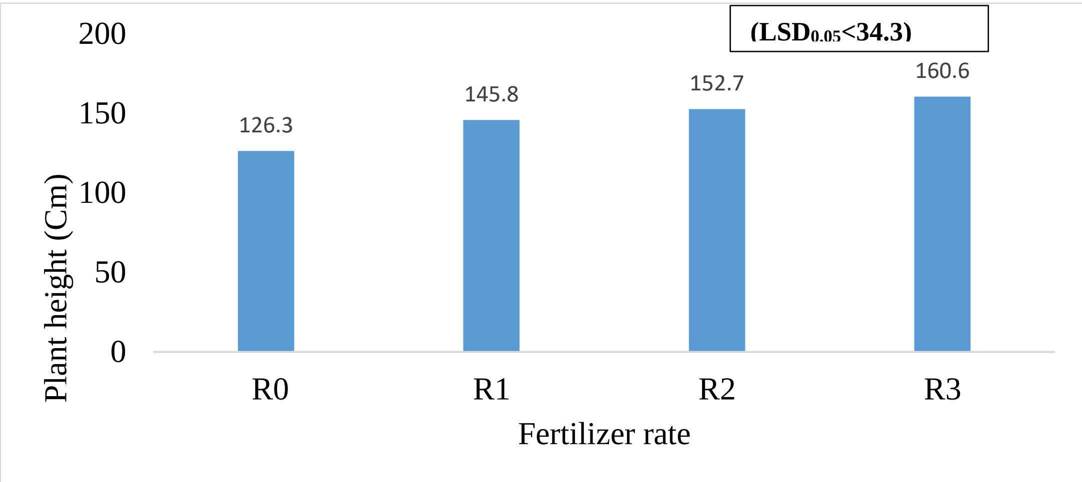

Figure 2: Effect of fertilizer rates on plant height.

Effect of length of cassava cuttings on plant height

The result of the analysis on the effect of length of cassava cuttings on plant height as presented in Figure 3 shows a difference in the mean of L1 (25cm) which is the recommended length and L2(12.5cm). Both had 148.9cm and 143.8cm means respectively. However this difference was not statistically significant at $p<0.05$.

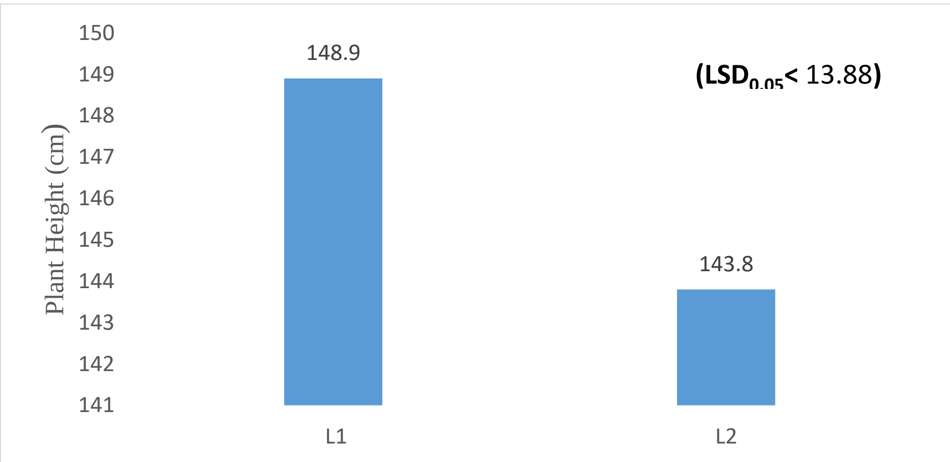

Figure 3: Effect of length of cassava cuttings on plant height

The implication is that a seed entrepreneur could use the second length (L2=12.5cm) which gives the entrepreneur twice the quantity of cuttings that could be used to plant up larger area of the land and still get the stem yield that is obtainable with (L1 =25cm). This finding corroborates the study of Onunka *et al.* (2016), who found that a particular cassava variety (TME419) generated much quantity of cassava cuttings, the length of stakes notwithstanding. Effect of length of cassava cuttings on the number of roots and weight obtained from the two cassava varieties

The result shows that for game changer, the highest number of roots (350) was obtained from L1 (25cm) while L2 (12.5cm) gave 250 roots. Furthermore, the total weight of the roots gotten from L1 (25cm) was 116kg while that gotten from L2 (12.5cm) was 119kg. The implication of this outcome is that although the number of root obtained from the L1 was higher, it did not translate to higher weight and for the fresh root entrepreneur, the weight not just the number of root matters as this determines how much monetary value is attached to the produce.

For the poundable, the outcome follows a-priori expectation as the number of roots obtained in L2 (12.5cm) gave the highest weight (141kg) while that of L1 (25cm) gave 216 roots and 132kg respectively. This shows that a fresh root entrepreneur can leverage on and use the L.2(12.5cm) and still make maximum profit and also reduce cost of production.

	L1(GC25cm)	L2(GC12.5cm)	L1(P25cm)	L2(P12.5cm)
Series1	116	119	132	141
Series2	350	250	216	246

Figure 4: Effect of length of cassava cuttings on number and weight of fresh root obtained from the two cassava varieties.

CONCLUSION

From the study results, it is evident that plant height has been influenced largely by the type of cassava variety and the fertilizer rates. The effect of the stake length of cuttings was not statistically significant. Furthermore the weight of the roots obtained from the different levels of cuttings, did not show any marked difference. Hence, this paper concludes that a seed entrepreneur, given the treatments above, can actually use the second stake length i.e. 12.5cm and still get reasonable root yield as one who uses 25cm.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study determined the socioeconomic characteristics of turmeric marketers and evaluated their performance in, South East, Nigeria. A multi-stage sampling procedure was used in selecting one hundred and ninety-two (192) respondents for the study. A structured questionnaire was used to collect data from the respondents. The data collected were analyzed using frequency distribution, net returns, marketing margin, and marketing efficiency and ols regression. The result shows that the majority of the marketers were female (65.10%) and are married; they are still in their active age. The result of the performance of turmeric marketers shows that turmeric marketing was profitable. The educational level attended by the turmeric marketer increased the performance level of the marketers. It is therefore recommended that males should be encouraged to market turmeric since it is profitable and a source of livelihood.
Keywords: *Socioeconomic characteristics, Performance, turmeric, marketers*

INTRODUCTION
Turmeric (botanically known as Curcuma longa Linn), the 'golden spice of life', is a root crop in the same family as ginger. Yet, it receives less attention from Nigerian farmers despite having enormous potential for local industries and exports. It is used in the food, cosmetic and pharmaceutical industries. It is used as a spice and is the major curry powder component. Turmeric is also used in cosmetics for its brilliant yellow and characteristic perfume. And also being used as a dye for colouring fabrics.

According to Njoku and Nwosu (2000), inadequate market information constitutes a problem for marketers as they cannot take advantage of favourable opportunities arising from price differences between producing and consuming areas. The problems of turmeric marketing include a lack of improved processing methods that can add value and increase product selling prices.The objective of the study is to determine the socioeconomic characteristics of turmeric marketers, to estimate the performance of the turmeric marketers and estimated the determinants of the performance of turmeric marketers in the study area.

METHODOLOGY
The study was conducted in the Southeast of Abia, Ebonyi and Imo of Nigeria. The areas lie between Latitude 5.4527^0N, Longitude 7.5248^0E, and Latitude 6.2649^0N, Longitude 8.0137^0E, and Latitude 5.5720^0N, Longitude7.0588^0E respectively. The states have a total land mass of 10,952,400ha. The zone has over 16 million resident populations (NPC, 2014). The zone comprises five states: Abia, Anambra, Ebonyi, Enugu, and the Imo States. It also has a rural population density of 173 persons per square kilometre. About 60-70% of the inhabitants are engaged in agriculture, mainly crop farming, animal rearing, food processing, and farm produce marketing.

A multi-stage sampling procedure was used in selecting the respondents for this study. The target population was turmeric marketers. The turmeric marketers were randomly sampled. The first stage involved a purposive selection of three states, Abia, Imo, and Ebonyi, out of the five states in the Southeast geo-political zone. These states were chosen based on their high-level activities in turmeric marketing. In the second stage, four LGAs were purposively chosen from each of the states, giving a total of twelve LGAs. In the third stage, four communities were purposively selected from each LGA, giving a sample of 48 communities. In the fourth stage, each community randomly selected one market to give 48 markets. In the fifth stage, a multi-stage random sampling technique selected three turmeric marketers from each community. It was compiled with the aid of the community residents, extension agents and turmeric marketers in the areas. This gave 144 turmeric marketers in the areas.

Primary data were collected using structured questionnaires administered to turmeric marketers. The data collected from the turmeric respondents were analyzed using descriptive statistics such as percentage, frequency distributions, mean, multiple regression techniques, marketing margin, and marketing efficiency.
Objective one was achieved using descriptive statistics such as percentage, frequency distribution, and mean. Objective two was achieved using marketing costs, net returns analyses, marketing margin and marketing efficiency models. The relationships between the models were shown using Equation 1.

$$NR = TRS - TMC \quad (1)$$

Where
NR = Net Return
TRS =Total Revenue Sales
TMC = Total Marketing Cost
The formula for calculating the marketing margin is shown in Equation 2

$$M_M = \frac{S_P - P_P}{S_P} \times \frac{100}{1} \quad (2)$$

Where
M_m =Marketing Margin
S_p = Selling Price
P_p = Purchase Price
The marketing efficiency is obtained using (Adekanye, 1988) equation 3.

$$M.E = \frac{\text{value added by marketing(Net Return)}}{\text{Total marketing cost(TMC)}} \times \frac{100}{1} \quad (3)$$

M,E =Marketing Efficiency
Objective three, estimated the determinants of performance of turmeric marketers, and was assessed using the ordinary least squares regression equation expressed implicitly in equation 4;

$$Y = f(X_1, X_2, \ldots X_{10}) \quad (4)$$

From equation (4), the model is specified in equation 5 explicitly as,

$$Y = a + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + b_5x_5 + b_6x_6 + b_7x_7 + b_8x_8 + b_9x_9 + b_{10}x_{10} + b_{11}x_{11} + b_{12}x_{12} + U \quad (5)$$

Where,
Y = Marketing Efficiency (see equation 3)
X_1 = age (yrs)
X_2 = Gender (1=female; 0 = male)
X_3 = Educational level (yrs);
X_4 = Extension Visits (number)
X_5 = experience in processing/marketing (yrs)
X_6 = Household Size (Number);
X_7 = Membership of Cooperatives dummy (Member =1; Not member = 0);
X_8 = Distance to Source of Credit (km)
X_9 = Income (₦)
X_{10} = Transportation cost (₦)
X_{11} = Storage cost (₦)
X_{12} = Selling Price (₦)
U_i = error term

RESULTS AND DISCUSSION

The Socioeconomic Characteristics Of Turmeric Marketers

The results of the socioeconomic characteristics of turmeric marketers are presented in Table 1.

Source: Field survey data, 2020

The turmeric marketers in Table 1 shows that the majority (65.10%) of marketers are females. This could be because the marketing of turmeric requires less effort and less energy for women to engage in. This is in line with the findings of Ezra *et al*. (2017), which indicated that women dominate turmeric marketing due to the low demands of time and effort required to work in the enterprise. The results show that the mean age of turmeric marketers was 38.40 years. It was observed that those between the age bracket of 31 and 50 of turmeric marketers had the highest representatives (63.54%). This implies that turmeric marketers are within the active working bracket. The results obtained align with the findings of Kantiok (2007), who opined that most agricultural enterprise actors are in their working age. Also, this is in line with the findings of Udoh and Nyienakuma (2008). They opined that agriculturists within the active age groups could withstand stress and put more time into various agricultural operations.

The result of the marital status shows that the majority (53.65%) of turmeric marketers were married. This implies that turmeric marketing is a source of income to the families from which they meet their basic needs. This result agrees with Ojo and Jibowo (2008), who reported that married people are responsible, and their views are likely to be respected within the rural communities as they decide on agricultural inputs. The findings agree with the study of Bassey *et al.* (2015), who reported that most agricultural product marketers were married. The result shows that most turmeric marketers (89.54%) had one form of formal education or the other. The result shows that literacy levels among them could enhance marketing technology. This could enhance the management of the turmeric business in the study area. In marketing, formal education allows turmeric marketers to understand the

Performance of Turmeric Marketers

In this study, the performance of turmeric marketers was measured using net returns, marketing margin, and marketing efficiency. The results showing the performance of turmeric marketers are presented in Table 2. The result indicates that the turmeric marketers incurred, on average, a total cost of ₦74,290.00 and obtained an average total revenue of ₦100,000.00.

Table 2: Net returns of turmeric marketers (Average quantity per week)

Variables	Quantity (kg)	Unit Cost (₦)	Total cost (₦)
Variable cost			
The purchase price per kg	100	700.00	70,000.00
Cost of transportation		21.00	2,100.00
Cost of sorting	100	6. 50	650.00
Cost of marketing materials	100	10.30	1,030.00
Total Variable Cost			73,780.00
Fixed Cost			

Cost of Rent	100	5.10	510.00
Total Cost			74,290.00
Selling price per kg of dried turmeric	100	1000.00	100,000.00
Revenue			100,000.00
Net Return			25,710.10
Performance Indicators			
Marketing margin (%)	25.71		
Marketing efficiency (%)	34.61		
Return on Naira investment (₦)	1.35		

Source: Field survey data, 2020

The marketers made a net return of ₦ 25,710.00, meaning the turmeric marketing was profitable. The marketers had marketing margins of 25.71% and marketing efficiency of 34.61%. The result shows that marketers were efficient in marketing. The rate of return on investment of ₦1.35 for marketers' which means that for every Naira invested in the business, the marketers made a return of ₦1.35k. The result in Table 2 shows that the marketers incurred, on average, a total cost of ₦74,290.00 and obtained an average total revenue of ₦ 100,000. 00. The marketing materials used by the turmeric marketers include nylon bags, weighing balance, and sack bags.

Estimate the determinants of the performance of Turmeric marketers using ols regression.

The factors determining the performance level of turmeric marketers were achieved using the OLS regression. The results of the regression analysis are shown in Table 3

Source: Field survey data, 2020 ***, **, * = statistically significant at 1%, 5% and 10% respectively

The semi-log functional form of the regression was chosen as the lead equation. The reason is that R^2 values were higher than the other three functional forms. The value of F-ratio (61%) was significant at the 1.0% probability level. This indicates that the model is a good fit. The coefficient of the level of education, number of extension visits, membership of cooperative societies, and income were all significant at a 1.0% probability level. The coefficients are positively related to the profit level of the turmeric marketers.

The coefficient of education was significant at 1% and positively related to the performance of turmeric marketers. This shows that an increased educational level attended by the turmeric marketer will increase the performance level of the marketers. This is in line with a priori expectations. The acquired education enables the marketers to manage the market techniques, leading to efficient performance. The finding agrees with results of Apata *et al.* (2009) Who reported that better education enables households to access and conceptualize information on improved farming methods and other related issues to enhance their welfare. The coefficient of extension visits was significant and positively related to the performance of marketers. This implies the more the extension visits to the marketers, the better the marketer's performance. This is in line with the a *priori* expectation. The more the extension visits, the better the marketer, as the marketers are being directed, helped to identify their needs, problems, and opportunities that will help for higher performance in marketing.

The coefficient of membership of the cooperative was significant at 1% and positively related to the performance of the marketers. This could be that as a cooperative member, the union is secure and can make a decision that will stand for better members' performance. It may also be that the members know the market techniques and market strategies and, therefore, perform better than their counterparts who are not members. Similarly, the coefficient of marketers' income was significant and positively related to the performance of turmeric marketers. This implies that an increase in the income of the marketers will lead to a rise in their investment. It will encourage their investment in marketing and create more money for saving. The finding agrees with the results of Anyanwu *et al.* (2016) who reported that the increase in the income of the respondents would increase their expenditure on value addition. This finding aligns with a*priori* expectation; an increase in income will enable the respondents to purchase the requisite inputs for enhanced output and income.

The coefficient of transportation was significant at 1% and negatively related to the performance of marketers. This implies that as the cost of transportation increases, the marketing performance decreases. Marketing activities associated with turmeric marketing involve loading, offloading, carry to stores, and the high cost attached will reduce the marketing performance of turmeric marketers. The coefficient of storage cost was significant and negatively related to the performance; it is in line with the a*priori* expectation that much expenses to the marketing will lead to a reduction in performance. The coefficients of distance to the source of credit, transportation cost, storage cost, and purchase price were all significant at a 1.0% probability level and are negatively related to the performance level of the turmeric marketers. The results show that the variables harm the performance level of turmeric marketers. This means that any increase in these variables will lead to a decrease in the performance level of the turmeric marketers. This is in line with *aprior* expectation. The coefficients of age, gender, marketing experience, and household size were insignificant and unrelated to the turmeric marketers' profit level.

CONCLUSION

The study revealed that most turmeric marketers were females and were married. The net return was ₦25,710.00, implying that turmeric marketing is profitable. The education acquired by the marketers enables them to manage the market techniques, leading to efficient performance in turmeric marketing It is therefore recommended that males should be encouraged to market turmeric since it is profitable and a source of livelihood. Awareness campaigns should be made to popularize the crop and its benefits.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The National Root Crops Research Institute (NRCRI) and its partners have been working together to implement gender-inclusive approaches to enhance the effectiveness of breeding. Through the experiences of the crosscutting gender team at NRCRI, this study has documented the successes encountered in this process. The study provides valuable insights and recommendations for future efforts towards achieving gender equality and inclusive development in the field of crop breeding. Prioritizing of desirable traits along the Yam Value Chain in Nigeria to Enhance Demand-led Breeding: Outcomes from the RTBfoods Project refers to a study conducted as part of the RTBfoods project, which aimed to improve the adoption, productivity, and profitability of yam cultivation in Nigeria. The study focused on identifying and prioritizing the most desirable traits in yam varieties, to enhance demand-led breeding efforts. The outcomes of the project provide valuable insights into how targeted breeding efforts can be used to improve the quality and yield of yam crops, and ultimately increase their commercial viability and adoption. One of the key strategies for improving food security, income, and nutrition at the household level, as well as the overall well-being of various value chain actors, is to introduce yam varieties that are tailored to meet the preferences of consumers. By incorporating preferred traits into the product profiles, it is expected that the adoption of these varieties will be widespread. This will result in significant benefits for farmers, traders, and consumers alike, all of whom will enjoy the positive impacts that come with having access to high-quality and nutritious yams. The success stories that highlight the achievements in the RTBfoods project reveal that effective communication and cooperation within the gender cross-cutting team and farmer groups play a crucial role in achieving better results. When gender specialists, food scientists, and breeders work together, they create innovative solutions that help overcome challenges and promote the sharing of information. Such collaborations bring a unique perspective to the table and help in achieving sustainable development goals.
Keywords: *Multidisciplinary team, plant breeding, traits, consumers, RTBfoods Project*

INTRODUCTION
According to the FAO, Nigeria produces about 50 million metric tons of yam annually, followed by Ghana (85.3 million tons), Côte d'Ivoire (77 million tons), and Benin (32 million) (FAO, 2021). The National Root Crops Research Institute (NRCRI) has been developing yams that are suitable for production and use. Yams are a particularly important root and tuber crop in Nigeria, although demand for them is influenced by both their short shelf life and the variety of dishes that households create with them. In Nigeria, yam is widely grown in regions where women contribute more farm labor, managing the use of the crop and adding value to it (Rahman *et al*., 2006). Despite the yam's nutritional importance (Bradbury and Holloway, 1988) and contribution to calorie intake in West Africa (Asiedu and Sartie, 2010), Barlagne *et al*. (2016) highlighted the lack of understanding of consumers' preferences for yam features and product quality. According to Madu *et al*. (2021a), breeding programs have historically prioritized yield and other agronomic traits at the expense of post-harvest and consumer preferences, so there is a knowledge gap regarding preferences for root, tuber, and banana (RTB) crops among various user groups, such as food processors, retailers, and consumers. Additionally, explanations of product characteristics are frequently overly brief and oversimplified, leaving out details on the ideal range of an attribute that users require. Additionally, little to nothing is known about the interactions between gender relations and norms.

The International Institute of Tropical Agriculture (IITA), the National Root Crops Research Institute, Umudike, Nigeria, Ebonyi State University, Abakiliki, Nigeria, two Research Institutes under the Council for Scientific and Industrial Research (CSIR) in Ghana (the Crops Research Institute in Kumasi and the Savanna Agricultural Research Institute in Tamale), the Centre National de Recherche Agronomique (CNRA) in Côte d'Ivoire and l'Université d'Abomey-Calavi (UAC), Dassa, Benin are the institutional actors driving a change in the breeding of yams. In recognition of the increasing popularity of yams in East and Central Africa, the National Crops Resources Research Institute (NACRRI) in Kampala, Uganda also joined the effort. This breeding project became a multidisciplinary effort involving breeders, geneticists, food scientists, agronomists, social scientists and end users. It is worth noting that research organizations outside the sub-region also played major roles in the project, including the Centre de Coopération Internationale en Recherche Agronomique pour le Développement (CIRAD) in Montpellier, France; the Iwate Biotechnology Research Center (IBRC) in Japan; the James Hutton Institute (JHI) in the UK; Japan International Research Center for Agricultural Sciences (JIRCAS) in Japan; and the Boyce Thompson Institute for Plant Research (BTI) at Cornell University in the USA.

METHODS AND APPROACHES

The team in this particular study followed the RTBfoods method for integrating gender into product profiles for boiled and pounded yam from 2018 to 2022 (Forsythe *et al*., 2021). This method consists of four steps that help to identify and prioritize the food product profile. The first step is to establish the scope of the study and identify the gaps in research, i.e., the state of knowledge (SOK) for boiled and pounded yam (Madu *et al*., 2019; Otegbayo, 2018). The second step is to elicit a set of ranked quality characteristics from users who play different roles in the value chain and gain an in-depth social context on boiled (Madu *et al*., 2021a) and pounded yam (Otegbayo *et al*., 2021). Experienced processors are consulted in the third step to identify more quality characteristics of boiled and pounded yam, as they possess crucial knowledge about the market and consumers' expectations. In this method, the processors, who are predominantly women, prepare the boiled and pounded yam in their local fashion (Madu *et al*., 2021b). In the fourth step, questionnaires are developed based on the results of Step 3 to collect robust data on preferences for the final product among a diverse set of consumers (Otegbayo *et al*., 2020; Madu *et al*., 2021c; Madu *et al*., 2021d). The results from all the steps are then triangulated to prioritize the food product profile. This integrated method enables a deep understanding of the quality characteristics, translating tacit knowledge into data that can be further investigated by scientists. The team also used laboratory-based sensory evaluation to corroborate the results from Steps 3 and 4, using scientific and industry-standard methods to support breeding and product development work. Overall, this method provides a comprehensive approach to integrating gender perspectives into product development, ensuring that the final product meets the diverse needs and preferences of all consumers.

DISCUSSION

The RTBfoods project was instrumental in bringing together a multidisciplinary team of experts from various fields including breeders, agronomists, pathologists, food scientists, socio-economists, and gender specialists. The project aimed to bridge the gap between understanding consumer preferences and packaging that knowledge into a breeding framework that could increase the efficacy of selection and adoption of improved root and tuber crop (RTC) varieties in Africa. The project commenced in 2017 and focused on four food product profiles, namely boiled yam, pounded yam, fufu, and gari. The multidisciplinary team worked together to achieve the project's objectives, and their efforts proved to be highly successful. As a result, the team evolved into a gender team, which included gender specialists, socio-economists, food scientists, and breeders. The team recognized the importance of gender considerations in demand-driven and targeted breeding for breeders, as the data on gender differences and dynamics were highly convincing. Overall, the project was a great success and helped to bring together experts from multiple fields to achieve a common goal. The team's focus on gender considerations has proved to be crucial in driving demand-driven and targeted breeding for breeders, and will likely have a lasting impact on the field for years to come.

The outcome of the team's baseline survey using social survey research, e.g., focus group discussions, key informant interviews, individual interviews and market interviews was documented. We documented key priority traits desired by the farmers, consumers and marketers and found that different sections of the country have their similarities and differences (Madu *et al*., 2020; Otegbayo *et al*., 2020). Also, quality traits (Study of trait preferences) were found to vary by region; in the west of Nigeria, a food called *amala* is made from dried yam, ground into flour. Drying the yams makes them dark, so the colour of the tubers does not matter. But in South-East Nigeria, white tubers were important for making pounded and boiled yams. These traits were also emphasized within the triangulation and G+ tools. The product chain includes production, usually men assisted by women and youths on male-owned farms. Adult men usually harvest and transport the yams, while men and women sell them. Marketers and consumers include hoteliers, households, food vendors, schools, hospitals etc. (Madu *et al*., 2018). In the South-East and South-West regions consumers have preferences for certain yam traits at various stages: 1) agronomic and postharvest, 2) processing, and 3) prepared foods (Otegbayo *et al*., 2021). Men, who produce yams, emphasize yield and colour, while women processers pay attention to texture, taste, ease of peeling, aroma, mealiness, poundability, and color.

We set up our research so that each member of the gender team focused on their area of expertise. Farmers were divided into gender groups for FGDs by some researchers (gender specialists, extension specialists). Other researchers conducted individual, key informant, and market interviews, including economists, food scientists, enumerators, etc. For instance, in Ebonyi State, different Igbo dialects presented a communication challenge for our enumerators, but this was resolved by the guide interpreter that we used for the studies. The farmers were able to be understood by tour guides and extension specialists who were fluent in the regional dialects.

Lessons learned and outcomes

The approach used in the breeding protocol involved a combination of methods that were effective in promoting a better understanding of the process. The bottom-top approach was used to develop demand-led, gender-intentional product profiles. The use of pair-wising, hedonic scales, scores, percentages, and ranks was instrumental in rating the importance of choice traits. Additionally, the G+ tool was employed to help trade off traits. In future yam studies, economic values will be assigned to traits to prioritize their preferences. This method changes the traditional economic approach to ranking tools, balances economic and non-economic drivers, and quantifies views of participants by gender and social strata. The multidisciplinary approach was employed from the start of breeding to select the traits that end-users prefer and involve these actors in the process. The focus is on breeding for the end-users and facilitating the release and adoption of new varieties. Holistic information from all stakeholders is provided, and women are involved in the different stages, not just cultivation, which is typically dominated by men. High and medium-throughput methods, such as Near-Infrared Spectroscopy (NIRS), were developed and used to save time and money when making breeding decisions. The correlation of consumer-preferred traits with the biophysical properties identified in the lab was used to obtain a threshold for selection. This has already been developed for rapid characterization of the colour and texture of gari-eba.

The RTBfoods project has been successful in achieving its goals, and the success stories that highlight these achievements reveal some valuable insights. One of the most crucial factors that contribute to the success of this project is effective communication and cooperation within the gender cross-cutting team and farmer groups. When gender specialists, food scientists, and breeders work together, they create innovative solutions that help overcome challenges and promote the sharing of information. The collaboration between different groups brings a unique perspective to the table, which helps in achieving sustainable development goals. The success stories of the RTBfoods project demonstrate how such collaborations have led to improved crop yields, reduced crop losses, and better nutrition outcomes. These achievements are a testament to the power of effective communication and cooperation in achieving common objectives. The project is a remarkable example of how diverse groups can work together to achieve sustainable development goals. The project's success stories demonstrate that professionals from different domains, such as gender specialists, food scientists, and breeders, can create innovative solutions by collaborating and sharing information. This project's achievements are a result of effective communication and cooperation among the team members. Their commitment to the shared vision of sustainable and equitable agricultural practices has helped pave the way for more environmentally friendly and socially just food production systems. The project is a testament to the power of collaboration and the potential of interdisciplinary approaches to drive meaningful change.

CONCLUSION

The RTBfoods project aimed to develop a breeding framework for improved root and tuber crop varieties in Africa, focusing on four food product profiles: boiled yam, pounded yam, fufu, and gari. A multidisciplinary team, including breeders, agronomists, pathologists, food scientists, socio-economists, and gender specialists, documented key priority traits and regional preferences. The breeding protocol employed a bottom-top, gender-intentional approach, balancing economic and non-economic drivers. A multidisciplinary approach was used to select preferred traits, involving stakeholders and utilizing high and medium-throughput methods like Near-Infrared Spectroscopy. The project serves as a great example of how different groups can work together to achieve sustainable development goals. The success stories of this project demonstrate that gender specialists, food scientists, and breeders can create innovative solutions by collaborating and sharing information. Through effective communication and cooperation, the RTBfoods project has been able to achieve great results and pave the way for more sustainable and equitable agricultural practices.

ACKNOWLEDGEMENTS

We acknowledge the RTBfoods Project for providing the required data, information and experience for the successful execution of this project. Many thanks to Vivian Polar, Jacqueline Ashley, Hale Ann Tufan, and Michael Friedmann for their professional guidance and supervision in completing this case study. Jeffery Bentley read and commented on an earlier version of this paper. We also extend our appreciation to the Executive Director, NRCRI, Umudike for providing the enabling environment for completing this project. The support provided by Nextgen facilitated the installation of the texture analyzer (for rapid throughput) at NRCRI, Umudike.

ABSTRACT
This study analyzed the Adoption of Cassava Value Chain among Women Cassava Farmers in Ebonyi State. Structured questionnaire was administered on 270 respondents selected using multistage random sampling. Descriptive statistics was used to analyse the data. Result collected showed that mean age and cassava farm size of the respondents were 48.54 years and 0.42 hectare respectively. 65.93% of them were married, with 81.11% attaining different levels of formal education. Meanwhile, 54.44% and 46.67% of them obtained information on cassava value addition technologies from Agricultural developmental programme. Cassava value added technologies such as garri ($\bar{X}$ = 4.30), cassava fufu ($\bar{X}$ = 3.66), high quality cassava flour ($\bar{X}$= 3.02), cassava chips ($\bar{X}$ = 3.18) and fermented flour ($\bar{X}$ = 3.01) were adopted by the women farmers. It was recommended that training on cassava value added technologies and provision of credit facilities to women cassava farmers should be intensified. This will enable them adopt value added technologies and improve their welfare.
Keywords: *Adoption, cassava, value added technologies, women farmers.*

INTRODUCTION

Cassava (*Manihot* species) is the most popular and widely cultivated crop in Nigeria in terms of area planted and total number of farmers involved in its cultivation (Ebewore and Okedo-Okojie, 2016; Oyelere, 2020). Nigeria produces over 54 million metric tons (MT) of cassava per annum (FAOSTAT, 2021), making her the highest cassava producer in the world, producing about a third more than Brazil and almost double the production capacity of Thailand and Indonesia. Cassava value chain is the act of adding value to a product with the view of improving certain characteristics (FAO, 2011). Cassava value chain helps to reduce bulk and improve product quality. It facilitates transportation and marketing, reduce cyanide content and improve palatability of the product (Odebode, 2008).The need to add value to cassava is made more imperative by the global demand for cassava and its products, which competes with local demand (Agbarevo and Okeke-Sam, 2015)

RESEARCH METHODOLOGY

Area of Study

The study was carried out in Ebonyi State of Nigeria. The State is located between latitude $5^{0}41'$ and $6^{0}50'$N of Equator and Longitude $5^{0}25'$ and $7^{0}30$E of Greenwich Meridian. Its rainfall ranges from 1500 mm-2500 mm per annum, temperature of 28-48^{0}C and average relative humidity of 75%. It is bounded in the North by Benue State, South by Abia State, in the East by Cross River State and in the West by Enugu State. Ebonyi State is made up of three Agricultural zones namely North, Central and South. The North agricultural zone consists of four local government areas: Abakaliki, Ebonyi, Izzi and Ohaukwu. The Central Agricultural zone has four Local Government Areas: Ezza North, Ezza South, Ikwo and Ishielu, while the South agricultural zone has five local government areas: Afikpo North, Afikpo South, Ivo, Ohaozara and Onicha. Among the crops planted in the area are cassava, yam, sweet potato, rice, maize and tomato.

Sampling Technique

The population for this study consists of all women cassava farmers in the study area who had benefitted from training on cassava value addition organized by government and/or private agencies. Multistage random sampling technique was used to select respondents for the study. In the first stage, two agricultural zones were randomly selected from the three agricultural zones that make up the State. In stage two, three extension blocks were selected from each of the selected zones. This gave six extension blocks. Stage three involved random selection of three extension circles from each of the blocks to give eighteen extension circles. List of women cassava farmers who had benefitted from cassava value addition trainings in each selected circle was formulated with the help of extension agents. The list served as the sampling frame from which 15 women cassava farmers were randomly selected from each of the eighteen extension circles to give a sample size of 270 women cassava farmers who served as respondents for the study.

Method of Data Collection

Primary data were used and were collected from the women farmers on socio-economic characteristics such as age, household size, marital status, education level, cassava farm size, quantity of cassava produced, membership to cooperative societies, access to credit and access to extension agents. Also, data on sources of information on cassava value addition technologies, types of cassava value addition technologies practiced, level of adoption of cassava value addition technologies and welfare indices to adoption of cassava value addition technologies were collected.

Method of Data Analysis

Descriptive and inferential statistics were used in analyzing the data on socio-economic characteristics of the respondents and to identify sources of information on cassava value added technologies were analyzed using descriptive statistics. Level of adoption of cassava value added technologies was determined using adoption scale analysis. It was achieved with the aid of a 7-point Likert type scale graded thus; unaware = 0, Aware = 1, interest = 2, evaluation= 3 trial = 4, accept = 5 and satisfaction = 6. In accordance with Okoye *et al*., (2009) the mean adoption level was determined as follows:

$\bar{X_s} = \Sigma x/n$ ……………… (1)

Mean score was computed by multiplying the frequency of each response pattern with its appropriate nominal value and dividing same with the number of respondents to the terms. This is summarized with the equation below.

$\bar{X_s} = \Sigma fn/nr$ ………………. (2)

Where: $\bar{X}$ = Mean score; $\sum$ = summation; F = frequency; n = Likert nominal value;
nr = Number of respondents. $\bar{X} = (0+1+2+3+4+5+6)/7 = 21/7 = 3.0$

Decision Rule: Below 1.0 = Unaware stage; 1.0 - 1.49 = Awareness stage; 1.50 - 1.99 = Interest stage; 2.0 - 2.49 = Evaluation stage; 2.50 - 2.99 = Trial stage; 3.0 and Above = Adoption of cassava value added technology

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Respondents

The distribution of the respondents according to their socio-economic characteristics is shown in Table 1. It shows that 33.33% of the women cassava farmers were within the age range of 40 - 49 years. The mean age of the women cassava farmers was 48.54 years. Drawing from Pandey and De (2015) classification of farmers by age (< 36 years = young farmers; 36 – 50 years = middle aged farmers; > 50 years = old farmers) the mean age of the women cassava farmers indicates that they were mostly middle aged and still energetic and capable of withstanding any stress associated with practice of adding value to cassava. The Table also shows that 65.93% of the farmers were married, while 17.78% were single. This shows that the married class dominated among the women farmers who received training. The result further indicates that 47.41% of the respondents had secondary education, 23.33% had primary education, 6.67% had tertiary education, while 22.59% had no formal education. Ebewore and Okedo-Okojie (2016) asserted that widespread illiteracy among farmers hinders understanding of information at their disposal. Therefore, educated farmers are expected to be more receptive to technologies, while farmers with low level of education or without education would be less receptive to utilization of new technologies (Okoye, 2009).

Table 1: Distribution of the respondents according to socio-economic characteristics

Variables	Frequency	Percentage (%)	Mean
Age (years)			
20-29	27	10.00	
30-39	51	18.89	
40-49	90	33.33	48.54
50-59	57	21.11	
60-69	27	10.00	
70 and above	18	6.67	
Marital Status			
Single	48	17.78	
Married	178	65.93	
Widow	42	15.56	
Divorced/separated	2	0.83	
Education Level			
No formal education	51	18.89	
Primary school education	63	23.33	
Secondary School education	138	51.11	

Tertiary school education	18	6.67	
Size of Cassava Farm (hectare)			
0.1 - 0.5	153	56.67	0.42
0.6 - 1.0	98	36.30	
>1.0	19	7.03	
Membership of Cooperatives			
Yes	132	48.89	
No	138	51.11

No	150	55.56	

Source: Field survey data, 2022

Additionally, the mean size of the respondent's cassava farm was 0.42 hectares, indicating that the respondents were majorly small-scale farmers. The few respondents (7.03%) who allocated more than 1.0 hectare to cassava production may be the ones that produce cassava for commercial purposes. About 48.89% of the respondents belonged to cooperative societies, while, 51.11% of them did not belong to cooperative societies. Belonging to cooperative societies enhances participation in an intervention programme, as well as access to information on improved technologies (Odoemenam, 2007). Farmers communicate most frequently and effectively with those who are familiar to them and are more likely to obtain information from and be influenced in their adoption decision by other farmers. The table reveals that 55.56% of the respondents had no access to credit. Access to credit makes it possible for farmers to purchase inputs including equipment used in cassava value addition and this helps to increase quantity of cassava to which value is added. The result is in support of earlier finding by Awotide *et al.* (2013) that many farmers in Nigeria had no access to credit facilities.

Sources of Information on level of Adoption of Cassava Value Chain

The distribution of the respondents according to sources of information on cassava value added technologies is shown in Table 2. The table shows that 54.44% of the women cassava farmers obtained information and training on cassava value chain from extension agents domiciled within Agricultural Development Programme (ADP), while 46.67% of them received information on cassava value added innovations from private farms. The greater number of respondents that obtained information and training on cassava value chain from ADP and private farms confirms their statutory mandate and contribution towards improving welfare of rural farmers through training and extension programme. Internet as a source of information has the least number of respondents (5.56%) indicates that the level of ICTs use as a means of sourcing agricultural information among rural women in the study area was still low and lends credence to Osondu and Ijioma (2015) assertion that level of use of ICTs among women farmers in Nigeria was low.

Table 2: Distribution of the respondents according to source of information on level of adoption of Cassava Value Chain

Extension Access	* Frequency	Percentage

Level of Adoption of Cassava Value Chain by women cassava farmers

The level of adoption of cassava value added technologies among the women cassava farmers was investigated and the result presented in Table 3. Table 3 shows that garri ($\bar{X}$= 4.30), cassava fufu ($\bar{X}$ = 3.66), high quality cassava flour ($\bar{X}$ = 3.02) cassava chips ($\bar{X}$= 3.18) and fermented flour ($\bar{X}$ = 3.01) all had mean score values that are greater than the Likert critical score of 3.0, implying that these cassava value added technologies were adopted by the women farmers. Adoption of these post-harvest value added technologies is expected to increase shelf life, income and food security of the rural poor (Carolyn, *et al.*, 2015). The table also shows that the grand mean score ($\bar{X}$= 2.22) for adoption of cassava value added technologies by the women farmers was low, suggesting that there were still gaps in adoption of most of the other cassava value added technologies extended to the women farmers. This implies that ample opportunities exist to increase level of adoption of cassava value chain among women farmers by exposing them to more information and training.

Table 3: Level of Adoption of Cassava value chain by the women cassava farmers

Cassava Value Added Technologies	Unaware (0)	Aware (1)	Interest (2)	Evaluation (3)	Trial (4)	Accept (5)	satisfaction (6)	Total	Mean Score
Cassava fufu	0(0)	60(60)	27(54)	30(90)	42(168)	51(255)	60 (360)	987	3.66
HQCF	72 (0)	24(24)	24(48)	15(45)	33(132)	45(225)	57 (342)	816	3.02

***Source:** Field survey data,*

CONCLUSIONS

Level of Adoption of Cassava value chain by the women cassava farmers improved, though some gaps still exist in the study. Significantly as a result of adoption of Cassava Value Chain among Women Cassava Farmers. Factors such as age, education level, extension contact, processing cost, annual income, group membership, access to credit and quantity of cassava produced significantly influenced the women farmers level of adoption of Cassava value chain.

RECOMMENDATIONS

Based on the findings of this study, the following recommendations suffice:

i. level of Adoption of cassava value chain impacted positively on women cassava farmers welfare by exposing them to more information and training.

. Government at all levels should promote policies and implement actions that will enhance access of women cassava farmers to trainings on cassava value chain. To this end, government should take measures that will enhance extension service delivery to women farmers. This will enable women farmers earn more income and improve their welfare.

ii. Policy makers should come up with loan packages intended specifically for people interested in adding value to agricultural products through their cooperative societies. Mechanisms should also be put in place to monitor how the funds borrowed are used. This will reduce the financial encumbrances associated with adoption of cassava value chain and increase adoption rate.

iii. Women cassava farmers should be encouraged to form and belong to cooperative societies. This will avail them access to various opportunities such as training, credit facilities, inputs and markets.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analyzed the effect of Socio-economic characteristics on adoption of cassava value added technologies on welfare of women cassava farmers in Ebonyi State, Nigeria. Structured questionnaire was administered on 270 respondents selected using multistage random sampling. Descriptive statistics, and adoption scale analysis, were used to analyse the data. Result collected showed that mean age and cassava farm size of the respondents were 48.54 years and 0.42 hectare respectively. 65.93% of them were married, with 81.11% attaining different levels of formal education. Meanwhile, 54.44% and 46.67% of them obtained information on cassava value addition technologies from Agricultural developmental programme. Cassava value added technologies such as garri ($\bar{X}$ = 4.30), cassava fufu ($\bar{X}$ = 3.66), high quality cassava flour ($\bar{X}$= 3.02), cassava chips ($\bar{X}$ = 3.18) and fermented flour ($\bar{X}$ = 3.01) were adopted by the women farmers. It was recommended that training on cassava value added technologies and provision of credit facilities to women cassava farmers should be intensified. This will enable them adopt value added technologies and improve their welfare.
Keywords:** Adoption, cassava, value added technologies, women farmers.**

INTRODUCTION
Cassava (*Manihot* species) is the most popular and widely cultivated crop in Nigeria in terms of area planted and total number of farmers involved in its cultivation (Ebewore and Okedo-Okojie, 2016; Oyelere, 2020). Nigeria produces over 54 million metric tons (MT) of cassava per annum (FAOSTAT, 2021), making her the highest cassava producer in the world, producing about a third more than Brazil and almost double the production capacity of Thailand and Indonesia.

Value added technologies are the processes of changing or transforming a product from its original state to a more valuable state (Mmasa, 2013). It is the act of adding value to a product with the view of improving certain characteristics (FAO, 2011). Cassava value added technologies helps to reduce bulk and improve product quality. It facilitates transportation and marketing, reduce cyanide content and improve palatability of the product (Odebode, 2008).The need to add value to cassava is made more imperative by the global demand for cassava and its products, which competes with local demand (Agbarevo and Okeke-Sam, 2015).

RESEARCH METHODOLOGY
Area of Study
The study was carried out in Ebonyi State of Nigeria. The State is located between latitude $5^0$41' and $6^0$50'N of Equator and Longitude $5^0$25' and $7^0$30E of Greenwich Meridian. Its rainfall ranges from 1500 mm-2500 mm per annum, temperature of 28-48^{0}C and average relative humidity of 75%. It is bounded in the North by Benue State, South by Abia State, in the East by Cross River State and in the West by Enugu State. Ebonyi State is made up of three Agricultural zones namely North, Central and South. The North agricultural zone consists of four local government areas: Abakaliki, Ebonyi, Izzi and Ohaukwu. The Central Agricultural zone has four Local Government Areas: Ezza North, Ezza South, Ikwo and Ishielu, while the South agricultural zone has five local government areas: Afikpo North, Afikpo South, Ivo, Ohaozara and Onicha. Among the crops planted in the area are cassava, yam, sweet potato, rice, maize and tomato. Multistage random sampling technique was used to select respondents for the study. In the first stage, two agricultural zones were randomly selected from the three agricultural zones that make up the State. In stage two, three extension blocks were selected from each of the selected zones. This gave six extension blocks. Stage three involved random selection of three extension circles from each of the blocks to give eighteen extension circles. List of women cassava farmers who had benefitted

from cassava value addition trainings in each selected circle was formulated with the help of extension agents. The list served as the sampling frame from which 15 women cassava farmers were randomly selected from each of the eighteen extension circles to give a sample size of 270 women cassava farmers who served as respondents for the study. Primary data was collected from the women farmers on socio-economic characteristics such as age, household size, marital status, education level, cassava farm size, quantity of cassava produced, membership to cooperative societies, access to credit and access to extension agents. Also, data on sources of information on cassava value addition technologies, types of cassava value addition technologies practiced, level of adoption of cassava value addition technologies and welfare indices to adoption of cassava value addition technologies were collected.

Descriptive and inferential statistics were used in analyzing the data on socio-economic characteristics of the respondents and to identify sources of information on cassava value added technologies were analyzed using descriptive statistics. Level of adoption of cassava value added technologies was determined using adoption scale analysis. It was achieved with the aid of a 7-point Likert type scale graded thus; unaware = 0, Aware = 1, interest = 2, evaluation= 3 trial = 4, accept = 5 and satisfaction = 6. In accordance with Okoye *et al*., (2009) the mean adoption level was determined as follows:

$\overline{(X\_s)}=\Sigma x/n$ ……………… (1)

Mean score was computed by multiplying the frequency of each response pattern with its appropriate nominal value and dividing same with the number of respondents to the terms. This is summarized with the equation below.

$\overline{(X\_s)}=\Sigma fn/nr$ ………………. (2)

Where: $\bar{X}$ = Mean score; $\sum$ = summation; F = frequency; n = Likert nominal value;
nr = Number of respondents. $\bar{X}$ = (0+1+2+3+4+5+6)/7=21/7 = 3.0

Decision Rule: Below 1.0 = Unaware stage; 1.0 - 1.49 = Awareness stage; 1.50 - 1.99 = Interest stage; 2.0 - 2.49 = Evaluation stage; 2.50 - 2.99 = Trial stage; 3.0 and above = Adoption of cassava value added technology

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Respondents

The results in Table 1revead that 33.33% of the women cassava farmers were within the age range of 40 - 49 years. The mean age of the women cassava farmers was 48.54 years. Drawing from Pandey and De (2015) classification of farmers by age (< 36 years = young farmers; 36 – 50 years = middle aged farmers; > 50 years = old farmers) the mean age of the women cassava farmers indicates that they were mostly middle aged and still energetic and capable of withstanding any stress associated with practice of adding value to cassava. The table also shows that 65.93% of the farmers were married, while 17.78% were single. This shows that the married class dominated among the women farmers who received training. The result further indicates that 47.41% of the respondents had secondary education, 23.33% had primary education, 6.67% had tertiary education, while 22.59% had no formal education. Ebewore and Okedo-Okojie (2016) asserted that widespread illiteracy among farmers hinders understanding of information at their disposal. Therefore, educated farmers are expected to be more receptive to technologies, while farmers with low level of education or without education would be less receptive to utilization of new technologies (Okoye, 2009).

Table 1: Distribution of the respondents according to socio-economic characteristics

Variables	Frequency	Percentage (%)	Mean
Age (years)			
20-29	27	10.00	
30-39	51	18.89	
40-49	90	33.33	48.54
50-59	57	21.11	
60-69	27	10.00	
70 and above	18	6.67	
Marital Status

Additionally, the mean size of the respondent's cassava farm was 0.42 hectares, indicating that the respondents were majorly small-scale farmers. The few respondents (7.03%) who allocated more than 1.0 hectare to cassava production may be the ones that produce cassava for commercial purposes. About 48.89% of the respondents belonged to cooperative societies, while, 51.11% of them did not belong to cooperative societies. Belonging to cooperative societies enhances participation in an intervention programme, as well as access to information on improved technologies (Odoemenam, 2007). Farmers communicate most frequently and effectively with those who are familiar to them and are more likely to obtain information from and be influenced in their adoption decision by other farmers. The table reveals that 55.56% of the respondents had no access to credit. Access to credit makes it possible for farmers to purchase inputs including equipment used in cassava value addition and this helps to increase quantity of cassava to which value is added. The result is in support of earlier finding by Awotide *et al.* (2013) that many farmers in Nigeria had no access to credit facilities.

Sources of Information on Cassava Value Added Technologies

The distribution of the respondents according to sources of information on cassava value added technologies is shown in Table 2. The table shows that 54.44% of the women cassava farmers obtained information and training on cassava value addition technologies from extension agents domiciled within Agricultural Development Programme (ADP), while 46.67% of them received information on cassava value added innovations from private farms. The greater number of respondents that obtained information and training on cassava value addition technologies from ADP and private farms confirms their statutory mandate and contribution towards improving welfare of rural farmers through training and extension programme. Internet as a source of information to the least number of respondents (5.56%) indicates that the level of use of ICTs as a means of sourcing agricultural information among rural women in the study area was still low and lends credence to Osondu and Ijioma (2015) assertion that level of use of ICTs among women farmers in Nigeria was low.

Source: *Field survey data, 2022* Figures in parenthesis are Likert nominal score Decision Rule: > 1.0 = unaware; 1.0-1.49 = aware; 1.50-1.99 = interest; 2.0-2.49 = evaluation; 2.50-2.99 = trial; 3.0 and above = adopted

Level of Adoption of Cassava Value Added Technologies by Women Cassava Farmers

The level of adoption of cassava value added technologies among the women cassava farmers was investigated and the result presented in Table 3. Table 3 shows that garri ($\bar{X}$= 4.30), cassava fufu ($\bar{X}$ = 3.66), high quality cassava flour ($\bar{X}$ = 3.02) cassava chips ($\bar{X}$= 3.18) and fermented flour ($\bar{X}$ = 3.01) all had mean score values that are greater than the Likert critical score of 3.0, implying that these cassava value added technologies were adopted by the women farmers. Adoption of these post-harvest value added technologies is expected to increase shelf life, income and food security of the rural poor (Carolyn, *et al.*, 2015). The table also shows that the grand mean score ($\bar{X}$= 2.22) for adoption of cassava value added technologies by the women farmers was low, suggesting that there were still gaps in adoption of most of the other cassava value added technologies extended to the women farmers. This implies that ample opportunities exist to increase level of adoption of cassava value added technologies among women farmers by exposing them to more information and training on these technologies.

CONCLUSION

Several cassava value addition technologies had been adopted by the women cassava farmers but adoption gaps of cassava value addition technologies still exist in the study area. The welfare of the women farmers improved significantly as a result of adoption of cassava value added technologies. Factors such as age, education level, extension contact, processing cost, annual income, group membership, access to credit and quantity of cassava produced significantly influenced the women farmers adoption of cassava value added technologies.

RECOMMENDATIONS

Based on the findings of this study, the following recommendations are made:

i. Adoption of cassava value added technologies impacted positively on women cassava farmers welfare. There is need for the Government at all levels make policies and implement actions that will enhance access of women cassava farmers to training on cassava value added technologies. To this end, government should take measures that will enhance extension service delivery to women farmers. This will enable women farmers earn more income and improve their welfare. Thus, helping to reduce level of poverty amongst them.

ii. Different cassava processing equipment should be made available to women cassava farmers at subsidized rate. This will increase rate of adoption of cassava value added technologies among women cassava farmers.

iii.Policy makers should come up with loan packages intended specifically for people interested in adding value to agricultural products. Mechanisms should also be put in place to monitor how the funds borrowed are used. This will reduce the financial encumbrances associated with adoption of cassava value added technologies and increase adoption rate.

iv. Women farmers need to be sensitized on the importance and impact of adopting value added innovations. To this end, seminars on adoption of value-added innovations should be held in designated venues in all rural communities of the study area. Attempts should be made to motivate women farmers to attend in mass.

v.Women cassava farmers should be encouraged to form and belong to cooperative societies. This will avail them access to various opportunities such as training, credit facilities, inputs and markets.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The role of women in meeting family needs and improving on their livelihood status can be achieved through their participation in different organizations whose activities are majorly farm related. However, women's level of participation is influenced by their attitude and some other factors. The study examined rural women participation in farmers' local organizations: A paradigm shift to improving their livelihood status in Edo and Delta States, Nigeria. The sample size of 295 respondents was drawn using the multi-stage sampling technique. Descriptive statistics was used to analyze the objectives of the study while inferential statistics was used to analyze the hypothesis. Results showed that respondents showed favourable attitudes of the farmers which have improved the livelihood status of the respondents. Prevalence of corruption and dishonesty of leaders (mean = 4.13), membership poor response to loan repayment (mean = 4.08) and lack of government assistance (mean = 4.08) were some of the challenges limiting the farmers from participating in FLOs. Based on results, the study recommended that there is need for the leaders of the FLOs to keep clean and transparent practices that can help to instill confidence amongst the people so that they can be encouraged to improve in their level of participation.
Keywords: *Rural women attitude, participation, farmers' local organizations, livelihood status, farmers' income, production level*

INTRODUCTION
Nigerian women have played significant role in the practice and development of agriculture. They actually constitute a large group with diversity in culture and class and are also bound by common issues and experiences which they encounter in different stages of their lives (Izekor and Ilavbarhe, 2021). Izekor and Ilavbarhe (2021) stated that 60 – 80% of the food produced and marketed are carried out by women. This assertion underscores women's essential contributions to the agricultural and rural economies both to the developing nations in particular and the rural economies in general. Nnadi *et al.* (2021) stated that women, within their abode work round the clock, from dawn to dusk and that they do well in getting themselves involved in different tasks within the farm environment with a particular purpose of ensuring that they meet up with their family needs. Okwuokenye *et al.* (2023) opined that the role of women in this regard (meeting family needs) and improving on their livelihood status is achieved through their participation in different organizations like Community Agricultural Workers, Model Farmers, Farmers Local Organizations, etc. whose activities are majorly farm related. The women's level of participation is however influenced by their attitude and some other factors. Against this background, this study sought to: determine the attitude of the rural women farmers towards participating in farm local organizations (FLOs), determine the livelihood status of rural women farmers before and during participation in FLOs and identify the challenges limiting the rural women from effectively participating in FLOs.
The hypothesis of the study**:** There is no significant difference between rural women farmers' livelihood status before and during membership of farmers' local organization

METHODOLOGY
Area of Study
The study was carried out in Edo and Delta States. They both belong to the South-South States of Nigeria Edo state was carved out of defunct Bendel State in August 1991. It has 18 local government areas (LGAs) with Benin

City as its capital. Its estimated population size as at 2022 according to NPC (2022) was 4,777,000 people spread over about 19,639.7 square kilometers. Several mineral endowed in the State are quartzite, marble, limestone, lignite, gold. Petroleum is found in Ovia and Orhionmwon areas of the State (Okwuokenye and Akintoye, 2015). Delta State has 25 Local Government Areas with the capital seat at Asaba. The state has a total land area of 17,698 Km^2 and an estimated population of 5,636,100 people as at 2022 (Delta State, Nigeria - Population). It actually occupies a land area of 17,698 Km^2 with most of the land most suitable for agricultural production activities like production of crops, fish and livestock for food and industry and this stands as the predominant occupation of the people (Okwuokenye and Akintoye, 2015).

A multi-stage random sampling technique was adopted in selecting the sample of the study. In the 1st stage, there was purposive selection of the States (Delta and Edo). This was followed by the 2nd stage that has to do with random selection of 2 agricultural zones from each State, thus making it 4 zones that were used for the study. Stage 3 involved the random selection of two (2) LGAs from each agricultural zone, thereby making it a total of 8 LGAs that were randomly selected for the study. In stage 4, there was random selection of three (3) communities from each of the LGAs and this made the communities used to be twenty-four (24). It was from each of these villages that thirteen (13) farmers were randomly selected (stage 5). The researcher ensured that the respondents used were farmers and membership of FLOs in the area of study. The total number of farmers sampled was 312 and from this two-hundred and ninety-five (295) of the instruments that were suitable for analysis was then used for the study.

Data collected were analyzed using descriptive and inferential statistics. Descriptive statistics was used to analyze rural women farmers' livelihood status before and during their participation in FLOs and this was achieved using the livelihood status index (Mohammed *et al.*, 2019). The index involved presenting the list of 38 likely accrued benefits acquired from the extra or difference in production and income since they became members of FLOs. The assets include: tables, chairs, televisions, decoders, radios, water pumps, purchases of land, block made houses, mattresses, sewing machine, cattle, sheep, plough, ox-plough, fine clothing. It is believed that social benefits such as above mentioned, derived from participation in FLOs can improve productivity, encourage knowledge sharing, promote more rural women farmers participation, improved the people's wellbeing, develop and strengthen relationship among the participants, increased income generation activities and promote diversification and can even give room for off-farm business activities.

Livelihood index was obtained using the model as:

$$LSI = \frac{\text{Number of livelihood factors benefited by } i^{th} \text{ respondent}}{\text{Total number of livelihood benefits}} \quad \text{-----------------------------} (1)$$

Where: LSI = Livelihood status index.

The categorization is stated as: ≤ 0.25 = Very low livelihood; 0.26 – 0.49 = Low livelihood; 0.50 – 0.75 = Moderate livelihood and > 0.75 = High livelihood.

Challenges limiting rural women from active participation in farmers local organization were analyzed using a five – point Likert type scale, coded 5, 4, 3, 2 and 1 for Strongly Agree, Agree, Undecided, Disagree and Strongly Disagree respectively. Factors whose value are equal to 3.0 and above were considered as challenging factors to women participation in FLOs. Contrarily, the factors with values less than 3.0 were regarded as non-challenging factors

Inferential statistics involved the use of Binomial test statistics. Binomial test statistics was used to analyze the hypothesis. The statistics was used to determine the significant difference in proportion of respondents' livelihood status before and during their membership in farmers' local organizations (FLOs). The formula for binomial distribution is given as follows:

b(x;n,p) = nCx*px *(1-p) n-x --(2)

Where:

b = binomial probability; x = total number of successes (livelihood status before and during their membership); p = probability of success on an individual trial; n = number of trials

RESULTS AND DISCUSSION

Attitude of rural women farmers towards participating in farm local organizations

Table 1 shows the results on analysis of the attitude of the rural women towards participating in FLOs. It revealed that a larger fraction (87.46%) of the respondents indicated that the farmers attitude towards participation were favourable, while few (12.54%) of them indicated unfavourable attitude towards participation in FLOs activities. Drawing inference, it could be deduced that a good proportion of the farmers developed a positive attitude to themselves and practices in the groups they belong. The favourable attitude exhibited is an indication that the groups they belong are meeting with their needs or purposes of purpose of registering with the group they belong. This result aligns with assertions of Okwuokenye *et al.* (2023) which stated that that rural farmers need are mostly met in their social groups.

Table 1: Categorization of the respondents based on their attitude towards participation in FLOs

Levels	Frequency	Percent
Unfavourable (score: 18 & below)	37	12.54
Favourable (score: >18)	258	87.46
Total	295	100.0

Source: Field survey, 2023

Rural women farmers' livelihood status before and during membership of farmers local organizations

The livelihood status of the rural women farmers is examined and this was ascertained before and during their membership in FLOs. Table 2 revealed that most (50.51%) of the rural women farmers had low livelihood. On the other hand, during the period of their membership with FLOs, most (56.95%) of the rural women farmers livelihood status improved to a high livelihood status level. The result implies that as members of FLOs, they are able to organize thrift activities from where the farmers are able to obtain finance to improve on their farming activities, access to extension agents who make improved agricultural information and technology available to them which helps to improve their farm output, which consequently translates into increased income, welfare and livelihood. . In addition, in most of the FLOs the rural women are members to have outlets for conduction of thrift activities or "osusu" from where the farmers are able to obtain finance to improve on their farming activities. This result was supported by that of Mohammed, et al. (2019) who reported that farmers' livelihood status gets improved when they participate well in community organizations.

Table 2: Respondents livelihood status before and during membership of FLOs. N=295

Livelihood status of rural women farmers	Livelihood class	Before membership of FLOs		During membership of FLOs	
		Freq.	Percentage	Freq.	Percentage
Very low	0.0 – 0.25	102	34.58	22	7.46
Low	0.26 – 0.50	149	50.51	84	28.47
Moderate	0.51 – 0.75	30	10.17	168	56.95
Very high	0.76 – 1.00	14	4.75	21	7.12

Source: Field survey, 2023

Challenges limiting respondents from participating effectively in farmers local organizations

The challenges limiting the rural women farmers' participation in farmers' local organizations (FLOs) is shown in Table 3. The factors are: prevalence of corruption and dishonesty of leaders (mean = 4.13), membership poor response to loan repayment (mean = 4.08), lack of government assistance (mean = 4.08) and presence of political influence (mean = 4.01). They respectively ranked the 1st, 2nd, 2nd, and 4th most serious challenge limiting rural women farmers from effectively participating in FLOs. This result is consistent with the findings of Okwuokenye *et al*. (2023) that identified similar factors constraining farmers' participation in community based extension organizations (CBEOs). The 5th, 6th, 6th and 8th most serious constraints to rural women farmers participation in FLOs are financial challenges (mean = 3.89), poor access to credit and other agricultural inputs (mean = 3.81), poor leadership style of the executives (mean = 3.81) and lack of awareness (mean = 3.76). These results support the findings of Abdullahi *et al*. (2015) that the later mentioned factors constrained the effective beneficiaries' participation in women non-governmental organizations.

Other constraining factors to rural women participation in local organizations include: socio-economic barriers like age, marital status and educational level (mean = 3.73), time and duration of organization's activities (mean = 3.66), cultural and traditional norms and values (mean = 3.60), poor dissemination of meeting days (mean = 3.41) and clashing of organization's meeting days and communal market days (mean = 3.24). Findings of Deekor (2019) confirmed this result as important factors that actually affect rural farmers' participation in community development projects

Table 3: Challenges limiting respondents from participating effectively in farmers local organizations

Challenges to farmers participation	Mean	Standard Dev.	Rank
- Prevalence of corruption and dishonesty of leaders	4.13*	0.58	1st
- Members poor response to loan repayment	4.08*	0.58	2nd
- Lack of government assistance	4.08*	0.61	2nd
- Presence of political influence	4.01*	0.56	4th
- Financial challenges	3.89*	0.61	5th
- Poor access to credit and other agricultural inputs	3.81*	0.66	6th
- Poor leadership style of the executives	3.81*	0.69	6th

- Lack of awareness	3.76*	0.62	8th
- Socio-economic barriers like age, marital status and educational level	3.73*	0.74	9th
- Time and duration of organization's activities	3.66*	0.73	10th
- Cultural and traditional norms and values	3.60*	0.78	11th
- Poor dissemination of meeting days	3.41*	0.81	12th
- Clashing of organization's meeting days and community market days	3.24*	0.88	13th
- Poor flow of communication and information	2.8	0.83	14th
- High monthly dues	2.4	0.78	15th

**Agreed (mean ≥ 3.0)*

Source: Field survey, 2023

Difference between rural women farmers' livelihood status before and during membership of farmers' local organization

The hypothesis of the study was analyzed with Binomial test and the result is presented in Table 3. As revealed in Table 2, a larger fraction (50.51%) of the rural women farmers indicated that their livelihood status was low before becoming members of FLOs. The livelihood status became high after becoming members of FLOs as indicated by majority (56.95%). In a dichotomy consideration (Table 4) majority (56.95%) indicated high livelihood status level, while the other fraction (43.05%) indicated low livelihood status. Statistically, the result was significant at the 1% level of probability. For this reason, the alternative hypothesis (there is significant difference between rural women farmers' livelihood status before and during membership of farmers' local organization) was accepted against the null. The result thus suggests that being members of FLOs, perhaps provides them the opportunity to have access to extension services that link them to improved farm technology and innovations that is sufficient to improve their farm output and income as well as their livelihood. This assertion was supported by Mohammed *et al.* (2019) who stated that participating in community organizations help to improve farmers' productivity, income and standard of living.

Table 4: Difference in rural women farmers' status before and after membership of FLOs

Status level	:y	ɔns	. Level
- Low Status (Status before membership of FLOs)			
- High Status (Status during membership of FLOs)			
Total			

Source: Field survey, 2023

CONCLUSION AND RECOMMENDATIONS

The rural women farmers showed their attitude to participation in FLOs was favourable and so capable to influencing their participation level. This participation in FLOs helped to alleviate the livelihood status of many of the rural women. The participation level would have been higher with more of their livelihood statues improved if not for the several limiting factors that constrained their participation level.

The study thus recommended that:

i. There is need for the leaders of the FLOs to be more transparent in the execution of their groups' activities as this will help to instill confidence amongst the people and encouraging improvement in their level of participation.

ii. The executives need to put in place strong strategies and modalities through which loans given out could be paid back by beneficiaries. This is necessary so that more money can be made available to give to others in need and have them encouraged to participate more, and;

iii. The FLOs need to be free from all political affiliations so that it will not suffer government neglect, should in case the group appear to be on the other side of the government in power.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study advocates for rural women participation in community organizations: A strategy to increased economic empowerment amongst women in South-South States, Nigeria. The study used 295 respondents drawn through the use of multi-stage random sampling technique. Descriptive and inferential statistics were respectively used to analyse the objectives and hypothesis of the study. Results showed most (45.76%) of them are effective in their groups and are willing to continue their participation in Farmers Local Organizations (FLOs). Financial and material benefits, rural women farmers empowerment and educating the women were some of the factors enabling participation in FLOs. Average income earned before and during rural women participation in their various community groups was ₦213,266.54 and ₦275,810.79 respectively. Impliedly, participation in community groups have resulted to an average increase of ₦62,544.25. The study recommended that there is a need to empower the women beyond all limits through provision of training skills and needed materials so that they can be encouraged to participate in FLOs.
Keywords: *Rural women farmers, farmers local organizations, economic empowerment, farm production, farm income, participation*

INTRODUCTION
The role of women both at local and international level cannot not be overemphasized. Nnadi *et al.* (2021) stated that women make essential contributions to the agricultural and rural economies. Despite the lofty role of women in our society, their importance to food production and rural development is yet to be appreciated. Nnadi *et al.* (2021) stated that the role of rural women in the rural development effort has been less encouraging when compared to their number and strength. Okwuokenye *et al*. (2023) stated that one of the most reliable ways of overcoming challenges limiting women's participation in social groups is their genuine participation in the group they belong and such enables them not only to function well but also meeting up with their expectations. Against this background, the study advocates for rural women participation in community organizations to enable them get empowered so that they can be able to meet up with their numerous roles both at the family and community level. Specifically, this study determines the effectiveness of rural women participation in the local groups they belong, assess the rural women farming income before and during their participation in community groups, determine the women that are willing and those not willing to continue participating in community groups and identify the enabling factors to women's participation in community organizations. Hypothesis of the study: There is no significant difference between rural women farmers that are willing and those not willing to continue participating in farmers local organizations.

METHODOLOGY
Area of Study
The study was carried out in Edo and Delta States of Nigeria.
Edo State is one of the South-South States of Nigeria, having 18 local government areas (LGAs) with Benin City and it was carved out of defunct Bendel State in August 1991. The estimated population size as at 2022 according to NPC (2022) was 4,777,000 people spread over about 19,639.7 square kilometers (Edo State, Nigeria - Population). The main occupation of most of the people is farming and they are also rich in agricultural production. Edo State is blessed with several mineral resources like quartzite, marble, limestone, lignite, gold. Petroleum is found in Ovia and Orhionmwon areas of the State (Okwuokenye and Akintoye, 2015).

Delta State, one of the six States in the South–South geopolitical zone of Nigeria is the remnant of the defunct Bendel State after State creation in 1991. The State has 25 LGAs with Asaba being the capital seat. Its population size as at 2022 was 5,636,100 people spread across 17,698 Km^2 (Delta State, Nigeria - Population). The inhabitants are mostly farmers of crops and livestock. Others are either into oil prospecting or civil service jobs (Okwuokenye and Akintoye, 2015).

Multi-stage random sampling technique was used in gathering the sample of the study. The first, second and third stages respectively had to do with the purposive selection of the Edo and Delta States which were selected due to their contiguous nature, random selection of two (2) agricultural zones from each of the States, thus making it four zones and the random selection of two (2) LGAs from each agricultural zone and this resulted to making a total of eight (8) LGAs selected for the study. Next was the random selection of three (3) communities / villages from each of the LGAs and this made the communities used to be twenty-four (24) (Stage four). It was from each of these villages that thirteen (13) farmers were randomly selected (stage 5). The researcher ensured that the women used for the study were farmers and are members of any farmers organization's that is still functional in their community where they live. The total number of farmers then became three hundred and twelve (312) and they were the ones administered with the question instrument. From the returned instruments, two-hundred and ninety-five (295) of them suitable for analysis provided the primary data of the study.

The study adopted the use of descriptive statistics which was used to analyze the objectives while inferential statistics (Binomial test) was used to analyze the study's hypothesis. Factors enabling participation in groups were analyzed using a five – point Likert type scale, coded 5, 4, 3, 2 and 1 for Strongly Agree, Agree, Undecided, Disagree and Strongly Disagree respectively. The weighted mean score of 3.0 which was obtained as follows: [5 + 4 + 3 + 2 + 1] / 5) was used to determine if the farmers agreed to the enabling factors or not. Factors whose value are equal to 3.0 and above were considered as enabling factors to women participation in community groups. Contrarily, factors with values that are less than 3.0 were regarded as non-enabling factors. Binomial test statistics was used to analyze if there is no significant difference between rural women farmers that are willing and those not willing to continue participating in farmers local organizations. The formula for binomial distribution is given as follows:

B (x;n,p) = nCx*px *(1-p) n-x ; Where:

b = binomial probability; x = total number of successes (livelihood status before and during their membership); p = probability of success on an individual trial; n = number of trials

RESULTS AND DISCUSSION

Effectiveness of rural farmers' participation in community groups

The level of effectiveness of the rural women farmers' participation in the different groups they belonged was determined and the result is shown in Table 1. Level of effectiveness was described as to the extent the participants were meeting up with their respondents in terms of paying their dues, abiding to the group's rules, etc. The result revealed that most (45.76%) of the respondents indicated that they were very effective in their group's activities. Generally, a larger fraction (91.19%) of the respondents indicated that their level of participation was of average level and above. Impliedly, the respondents are effective in their various groups and this perhaps is linked to the functionality and roles played by the groups to their members. This result is in semblance to the assertion of Usman *et al.* (2022) that cooperative societies are planned to cater for varying needs of her members engaged in agricultural activities.

Table 1: Effectiveness of rural women farmers in their groups

Effectiveness level	Frequency	Percentage	Mode
Very effective	62	21.02	
Just effective	135	45.76	
Averagely effective	72	24.41	
Low effective	18	6.10	
Poorly effective	8	2.71	
Total	295	100.00	Just effective

Assessment of rural women farmers' farm income

Table 2 shows the income of the members of the various groups and this was determined by ascertaining their income level before and during membership of the groups they belong. The result showed that, before the respondents' participation, most (31.19%) of the farmers earned between ₦200,001 – ₦300,000 while most (32.20%) of them earned between ₦300,001 – ₦400,000 during their participation in their various community group. The average income earned before and during rural women participation in their various community groups was ₦275,810.79 and ₦213,266.54 respectively. The result implies that participation in groups have resulted to an average increase in participants income of ₦62,544.25. The result implies that rural women participation in community groups has enhanced farming activities of the farmers by bring about increased production and income. The influence of community social groups is confirmed by Usman *et al.* (2022) who identified increase in yield, income, easy access to extension services and encouragement of self-help and cooperation as some of the benefits derived from being members of cooperative societies.

Table 2: Distribution of the assessment of rural women farmers' farm income

Farm income (₦)	Before membership of social group			During membership of social group		
	Frequency	Percentage	Mean	Frequency	Percentage	Mean
≤ 100,000	28	9.49		17	5.76	
100,001 - 200,000	65	22.03		30	10.17	
200,001 - 300,000	92	31.19		71	24.07	
300,001 - 400,000	81	27.46		95	32.20	
400,001 - 500,000	22	7.46		62	21.02	
> 500,001	7	2.37		20	6.78	
Total	295	100.00	₦213,266.54	295	100.00	₦ 275,810.79

Difference before & during membership of FLOs = ₦275,810.79 – ₦213,266.54 = ₦62,544.25
Source: Field survey, 2023

Rural women farmers' willingness to continue participating in farmers local organizations
Results on rural women farmers willingness to continue participating in farmers local organization revealed that most (35.25%) of the respondents' willingness to continue participating was just high (see Table3). The other rural women farmers willingness to continue participating in FLOs was very high (26.10%), average (23.05%), low (11.86%) and poor (3.73%). On general note, a very high fraction (about 84.4%) and a low fraction (15.59%) of them were respectively willing and not willing to continue participating in FLOs. The result implies that most of the farmers are willing to continue participating in rural women farmers organizations. The reason may not be unconnected to the various benefits they are deriving from their high level of participation, which would have eluded them if they were non-participants. Similar results on high level of participation and farmers willingness to participate and continue participating in social group was observed Okwuokenye and Iduseri (2021) and attributed it to its impact on the economic development of the members. Usman *et al.* (2022) finding also agreed with this result on willingness of rural farmers to participate in social groups since they benefit several

T able 3: Categorization of the respondents on their willingness to continue participating in FLOs

Levels of willingness to participate in FLOs	Frequency	Percentage	Mode
Very high	77	26.10	
Just high	104	35.25	
Average	68	23.05	
Low	35	11.86	
Poor	11	3.73	
Total	295	100.00	Just high

Source: Field survey, 2023

Enabling factors of rural women farmers' participation in farmers local organizations.
Table 4 shows the enabling factors encouraging rural women farmers' participation in FLOs. The factors are arranged in the order of the size of their means. The factors are: financial and material benefits (mean = 4.03), empowering women politically and allowing them some level of social exposure (mean = 3.42), educating the women (mean = 3.41) and breaking the barriers of socio-economic issues (mean = 3.32). Other agreed factors include: breaking the barriers of socio-cultural issues (mean = 3.05), leadership status (mean = 3.05), leadership training (mean = 3.05), motivating women by providing them with incentives (mean = 3.02) and issues of organizational change (mean = 3.01). Financial and material benefits was agreed to give the women some kind of economic empowerment that encourages them to participate in groups. The result is supported by Waweru (2015). The issue of empowering women politically will afford them the opportunity to address their confronting issues. Educating the women was agreed because it is seen as a tool that helps to broaden farmers' horizon and reasoning, develop skill and instill confidence in them. Breaking the barriers of socio-economic issues helps the farmers to overcome certain constraints and enhance efficiency and production. Organizational changes involve structural and institutional changes which are needed to promote members active participation. Women empowerment, educating the women, socio-economic factors and organizational changes were all supported by findings of Mutongu (2012) who concurred with these results and assertions. Socio-cultural issues may include factors that have to do with the norms, values, interactions, customs, etc which have to be broken in order to encourage the rural women farmers participate more in their groups. This assertion is in line with that of Asante *et al.* (2017). Leadership status is in line with the fact that those who hold leadership positions associate and participate more

in community organizations. Leadership training is another factor that has enabled people to become more aware of how to pilot the affairs of their group, handle the members, encourage their participation and derive the necessary potential benefits. Leadership status and leadership training was supported by the findings of Derkyi (2021). Motivating women and providing them with incentives is another way of empowering them and it goes a long way in enabling them to participate effectively in their group, get them more interested and carried along in the group they belong.

Table 4: Enabling factors to respondents' participation in farmers local organizations.

Enabling factors encouraging participation in FLOs	Mean	Standard Dev.	Remark
- Financial and material benefits	4.03*	0.56	Agreed
- Empowering women politically and allowing them some level of social exposure	3.42*	0.52	Agreed
- Educating the women	3.41*	0.57	Agreed
- Breaking the barriers of socio-economic issues	3.32*	0.62	Agreed
- Breaking the barriers of socio-cultural issues	3.05*	0.65	Agreed
- Leadership status	3.05*	0.62	Agreed
- Leadership training	3.05*	0.70	Agreed
- Motivating women by providing them with incentives	3.02*	0.77	Agreed
- Issues of organization change	3.01*	0.75	Agreed
- Domestic and family responsibility	2.47	0.78	Disagreed

**Agreed (Mean ≥ 3.0); Source: Field survey, 2023*

Test of difference in rural women farmers' willingness to continue participating in farmers local organizations

The relationship of rural women farmers' willingness to participate in FLOs was analyzed using binomial test and is shown on Table 5. The results revealed that a larger proportion (89.83%) of the respondents were willing to continue participating in farmers local organizations. Result shows that most of the rural women farmers are willing to continue participating in their social groups. Respondents' unwillingness to continue in groups may be traced to unpleasant past experience that perhaps relate to the social groups not meeting their needs. In line with the proportion of rural women farmers that are willing been 89.83% is an indication that the rural women farmers willing to continue participating in FLOs is significantly high. By implication, the groups are meeting up with their responsibilities to members. Against this background, the alternative hypothesis was adopted. This result is in conformity with findings of Okwuokenye and Iduseri (2021) who revealed farmers' willingness to participate in social group and attributed it to economic impact it has on members.

Table 5: Categorization of respondents' willingness to continue participating in FLOs

Categorization of willingness to continue participating in FLOs	Frequency	Proportion	Prob. Level
- Willing to continue participating in FLOs	265	89.83	0.001
- Unwilling to continue participating in FLOs	30	10.17	
Total	295	100.00	

Source: Field survey, 2023

CONCLUSION AND RECOMMENDATIONS

The study advocated and examined rural women farmers in FLOs in South-South States with a focus in Edo and Delta States, Nigeria. It found that most of the rural women are effective in their groups. The average income earned before and during rural women participation in their FLOs was ₦275,810.79 and ₦213,266.54 respectively and this implies that participation in community groups have resulted to an average increase of ₦62,544.25 in income earned by the farmers. Rural women participation in groups has enhanced farming activities of the farmers by bring about increased production and income.

Based on findings, the study recommends that:

There is a need to empower the women beyond all limits through provision of training skills and needed materials just to encourage their participation in FLOs. Also, rural women farmers need to be encouraged to get themselves educated through free or adult education programme so as to enhance their interest and potential need of participating in FLOs.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined the assessment of women empowerment status in Ibarapa Central Local Government Area of Oyo State, Nigeria. Primary data were used for the study. One hundred and twenty women were interviewed using multistage sampling techniques. The socioeconomic characteristics of the women revealed that the mean age was 36 years old. The mean household size was three About 90.83% of the women were married, 55.83% of the respondents had secondary school education, the average number of children was four. Primary occupation of the respondents revealed that 45% were Artisans while the highest secondary occupation of the respondents was trading (36.67%). The mean income of the respondents was ₦6,883.33. The average income from secondary occupation was ₦21,075. The empowerment programmes benefited by the women through their Local Government Areas were: Workshop by extension Personnel, (85.83%) Agricultural facilities, (85.83%), access to Micro-credit programme (80.83%), Adult literacy programme (45.83%), access to media (63.33%), and Skill/ technical training. (76.67%). The result revealed that majority of the respondents (70.83%) were moderately empowered,, 9.11% had the privilege of participating in almost all the empowerment programme,s while 20% of the respondents had a very low access to empowerment programmes. The result also revealed that age was negatively significant while primary occupation, secondary occupation, number of children and rating of women involvement were positively statistically significant to women economic status in the study area. Women were involved in empowerment programme on the average and it has helped them to be more established in their businesses but their income is not justifying these efforts and therefore, that empowerment programme should be reviewed to formulate constructive policy that will improve economic empowerment of rural women and promote the economic development of the country.
Keywords: *Assessment, Economic, Empowerment, Women*

INTRODUCTION
Women's economic empowerment means expanding women's economic opportunities in terms of both labour market access and productivity (Peters *et al*., 2016). It also involves the creation of an environment within which women can make strategic life choices and decisions in a given context (Leder, 2016). . Empowering women especially in rural communities does not only increase the wealth of the nation but bridges the gap of gender inequality where women also own means of production and can be employers of labour (Oluwatoyin, 2013). Empowerment has been observed to be one of the major concerns when addressing the issue of human rights and development (Tripathi, 2011). Women's empowerment is one of the priorities of the proponents of development approach, and has been a major area of investigation in human development research in the last two decades (Acharya *et. al*., 2010; Khan and Awan, 2011; Wiklander and Thede, 2010; Batool and Batool, 2018).

Women's empowerment could be characterized into four major domains: socio-cultural, economic, education, and health (Ashaolu *et al*., 2018). There are different concepts in measuring women empowerment, but similarities can be found in literature. Some of the themes frequently used to conceptualize women's empowerment are household decision-making, economic decision-making, access to resources, and physical mobility (Hameed *et, al.*, 2014; Sharma, 2015; Mahmud, 2012; Yaya *et al.*, 2018). Thus study is based on the empowerment programmes benefitted by the women in the Local Government Area this study was conducted.

Different statistical techniques have been used by researchers to find out the determinants of women's empowerment. Most of the researchers preferred to use descriptive statistics and Ordinary Least Square analyses e.g., Haque et al. (2011), Khan and Maan, (2008), Sheikh et al. (2015), without giving justification to use a particular method for particular data analysis. Whereas, some of the researchers do not support the use of Binary Logit Regression as it restricts the dependent variables (e.g., women's empowerment) to dichotomous categories: least empowered and highly empowered that would result in a loss of very vital information about the dependent variable. This study uses ordered probit regression due to the case of more than two outcomes of an ordinal dependent variable (a dependent variable for which the potential values have a natural ordering, as in poor, fair, good, excellent). The general objective of this study was to assess the empowerment status of women in Ibarapa Central Local Government of Oyo state. The specific objectives were to:

i. describe the socio-economic characteristics of the respondents;
ii. identify the Government empowerment programmes available in the study area ;
iii. estimate the empowerment status of rural women in the study area; and
iv. analyze the effect of socio-economic characteristics on the empowerment status of women in the study area.

MATERIALS AND METHODS

The study was conducted in Ibarapa Central Local Government Area of Oyo State of Nigeria. Oyo State is one of the 36 States in Nigeria and it lies in the South- western part of the country. The state with two ecological zones is well suited for food crop production. Food crops grown in the area include Yam, maize, cassava, cowpea, plantain and rice. The LGA came into existence in 1996. According to the 2006 census, it has population of 102,979. The study area shares boundary with Ogun state in south, bounded in the east by Ibarapa East LGA, to the west by Benin Republic and to the North by Ibarapa North Local Government.

The Local Government is heterogeneous and dominated by the Yorubas, others include Ghanaians, Hausa, Fulani and Agatu residing in the area. The location enjoys the wet and dry seasons and the rainfall in the follows a topical type with an average annual rainfall that ranges from1850mm to 2250mm and the average annual temperature between 27oC and 27^0C. Primary data were used for this study with the aid of a well-structured questionnaire. Multi-stage sampling techniques were used to collect data for the study. Idere and Igboora are the two main towns in Ibarapa central L.G.A. Igboora has 7 wards while Idere has 3 wards making 10 political wards. The first stage was random selection of 4 wards from the 10 political wards. The second stage wass random selection of 32 households from each of the selected wards. The third stage was purposive selection of women in each household. The second stage was random selection of 2 households from each of the six (6) wards. The third stage was random selection of 12 women from rural households. Altogether, 128 women were interviewed and a total of one hundred and twenty (120) respondents were found worthy for this study. The information was gotten through the Local Government list of rural households.

Descriptive Statistic such as frequency count, percentage and mean scores were used for objectives 1 and 2, likert scale was used for objective 3 while inferential statistics i.e. ordered probit regression was used for objective 4.

Following William (2012) and Diebold (2014), suppose the underlying relationship to be characterized:

$Y^* = X^T\beta + \varepsilon$

Where Y* is the exact but unobserved dependent variable and perhaps the exact level of improvement by the respondent. X is the vector of independent variables and β is the vector of regression coefficients which we estimate.

While we cannot observe Y*, instead we can only observe the categories of response:

$$Y = \begin{cases} 0 \ \text{if } y^* \le 0 \\ 1 \ \text{if } 0 < y^* \le N_{1,} \\ 2 \ \text{if } N < y^* \le N_2 \\ \\ N \ \text{if } N_{N-1} < y^* \end{cases}$$

=> Then the ordered probit technique will use the observations on y which are forms of censored data on y* to fit the parameter vector β.

Note: The model cannot be consistently estimated using OLS; it is usually estimated using maximum livelihood.

Measurement of Variables

Empowerment Status: Government Empowerment Program (Social factors) available in the Local Government Area for this study was used to generate empowerment status of the respondents and doubles as the dependent variable. The independent variables include the demographic factors and economic factors. (Didana, 2019; Liddell and Kruschke (2018)

Indicators: Access to resources, social factors, economic factors, demographic factors

ORDERED PROBIT MODEL:

Y = Empowerment Status (1 =low, 2= medium/ moderate , 3 = high).

X_1 = Age (years), X_2 = Household size, X_3= Marital status, X_4 = Primary Occupation X_5= Secondary occupation

X_6 = Educational level (year), X_7= Number of children, X_8 = Rating of women involvement, e = error term

RESULTS AND DISCUSSION

Objective 1: Socioeconomic Characteristics of the Respondents

Table 1 revealed. 24.17% of the respondents were less than or equals to 30 years old, 53.33% were between the ages of 31 and 40 years, 16.67% were between ages 41 – 50 years while 5.83% were above 50 years of age. The mean age was 36years old. This implies that most of the women were in their economic active age. Household size of the respondents revealed that 22.5% of the respondents had less than 3 members in their household, 62.50% of the respondents had between 3 – 4 household size, 14.17% had household size of 5 and 6 members while 0.83% of the respondents had household size of just 1 member. The mean household size was three.

The marital status of the respondents revealed that 90.83% of the women were married, 7.5% were widowed while 1.67% were divorced/separated. It implies that majority of the women in the study area were married. Educational status of the respondents revealed that 30% of the respondents had primary school education, 55.83% of the respondents had secondary school education, 10% of the respondents had tertiary education while 4.17% of the respondents had no formal education. It implies that greater percentage of the respondents had Secondary school education. The religion of the respondents revealed that 42.5% of the respondents were Christians, 43.33% were Muslims while 14.17% of the respondents were traditional worshipers. The number of children in the household revealed that 41.67% had less than or equals to 3 children, 50.83% had between 4 and 6 children while 7.5% of the respondents had 7 or more children in their household. Primary occupation of the respondents revealed that 45% were Artisans, 14.17% were traders, 25.83% were farmers while 15% were Civil Servants. The secondary occupation of the respondents revealed that 31.67% were Artisans, 36.67% were into trading, 18.33% were into farming while others were 13.33%.

Income from primary occupation revealed that 29.17% earned less than or equals to #10, 000 per month, 54.17% of the respondents earned between #10, 001 and N20, 000 per month, 14.17% had income range of #21, 000 – #30, 000 per month, 1.67% earned between #30, 001 and #40,000 per month while 0.83% of the respondents earned #40, 000 and above per month. The mean income of the respondents was #16,883.33.

The Secondary occupation of the respondents revealed that 6.67% of the respondents earned less than or equals to #10, 000 per month, 56.67% earned between #10, 001 and #20, 000 per month, 33.33% earned between #21, 000 and #30, 000 per month, 1.67% of the respondents had an income range of #30, 001- #40,000 per month and greater than #40,000 per month respectively.

Objective 2: Government Empowerment Programs Benefited by Women

The result in Table 3 revealed that 85.83% of the respondents benefited from Workshop by extension Personnel, 85.83% had access to Agricultural facilities, 80.83% had access to Micro-credit programme, 45.83% had access to Adult literacy programme, 63.33% had access to Access to media while 76.67% benefited from Skill/ technical training.

Table 2. Government Empowerment Program Benefited by the Women

Empowerment Prog	Yes Frequency/Percentage	No Frequency/ Percentage	Total
Workshop by extension Personnel	102(85.83)	8(14.17)	120/100
Provision of Agricultural facilities	103(85.83)	7(14.17)	120/100
Micro- credit programme	97(80.83)	23(19.17)	120/100

Skill/ Technical Training	92(76.67)	28(23.33)	120/100

Source: Field survey, 2019

Objective 3: Estimation of Empowerment Status of the Women.

To estimate the empowerment status of the respondents, empowerment index was firstly generated through the weighted average of the responses to empowerment programmes and benefits. The index was between 0 and 1. Empowerment benefits/ programmes: Workshop by extension Personnel, Provision of Agricultural facilities, Micro-credit programme, Adult literacy programme, Access to media and Skill/ technical training.

Table 3.1 : Empowerment Index(EI)

Empowerment Index	FREQUENCY	PERCENTAGE(%)
0	-	-
0.1666	6	5.00

TOTAL	**120**	**100.00**

Empowerment Status of the Women

Table 3.2 Empowerment Status (ES)

Empowerment Status was categorized into low (1), medium (2) and high (3) of the weighted average of the responses. The result revealed that majority of the respondents (70.83%) were moderately empowered in the study area, 9.11% had the privilege of participating in almost all the empowerment programme, while 20% of the respondents had a very low access to empowerment program in Ibarapa Central Local Government area of Oyo State.

Table 3.2: Distribution of the Empowerment Status of the Women

Empowerment Status	Frequency	Percentage (%)
1 (LOW)	24	20.00
2 (MEDIUM)	85	70.83
3 (HIGH)	11	9.17
TOTAL	**120**	**100.00**

Objective 4: Determine the effect of some socioeconomic characteristics on empowerment status of women in the study area

Ordered probit model was used for this objective. The dependent variable (Y) is the empowerment status (1=low, 2= moderate, 3= high) while the independent variables $X_1 \ldots X_8$ are age, household size, marital status, educational level, primary occupation, secondary occupation, women's involvement and number of children, which were used as inputs for the ordered probit model. The factors were tested for statistical significance (p value < 0.05) to find out the factors that significantly influenced the empowerment status on some socioeconomic characteristics of women in Ibarapa central local Government area of Oyo State.

The result revealed that the age, primary occupation, secondary occupation, number of children and rating of women involvement are statistically significant. The age is negative and statistically significant at 1%. Increase in age decreases empowerment status at 0.08 and implies that the aged were not opportune to participate in empowerment program. Primary occupation is positive and statistically significant at 5%, having a primary occupation influence positively the empowerment status of the respondents at 0.24. This is in line with the study carried out by Ahmed (2013) that employment/ doing any paid work is the identified determinants of women economic empowerment and also, women carrying out these income generating activities always look for new income generating activities. So, they readily become empowered.

For a one unit increase in secondary occupation, we would expect 0.20 decreases in the log odds of empowerment status. Also, for a one unit increase in rating women involvement, we would expect 0.76 decrease in the log odds of empowerment status of the respondents and lastly, the number of children is positively significant, increase in number of children increase the empowerment status of the respondents at 0.15 given that all of the other variables in the model remain constant.

Table 4. Ordered probit regression

Number of obs = 120		LR chi2(8) = 36.47

SUMMARY AND RECOMMENDATION

Summary

The summary of the socioeconomic characteristics of the women revealed that the mean age was 36years old. The mean household size was 3. 90.83% of the women were married, 55.83% of the respondents had secondary school education, the average number of children was 4. Primary occupation of the respondents revealed that 45% were Artisans while the highest secondary occupation of the respondents was into trading (36.67%), 18.33%. The mean income of the respondents was #16,883.33. The average income from secondary occupation was #21,075.

The empowerment programs benefited by the women through their Local Government areas follow: 85.83% benefitted from Workshop by extension Personnel, 85.83% had access to Agricultural facilities, 80.83% had access to Micro-credit programme, 45.83% had access to Adult literacy programme, 63.33% had access to Access to media while 76.67% benefited from Skill/ technical training. Empowerment Status was categorized into low (1), medium (2) and high (3) of the weighted average of the responses. The result revealed that majority of the respondents (70.83%) were moderately empowered in the study area, 9.11% had the privilege of participating in almost all the empowerment programme, while 20% of the respondents had a very low access to empowerment program in Ibarapa Central Local Government area of Oyo State.

Orderd probit was used to determine the effect of some socioeconomic characteristics on empowerment status of women in the study area The result revealed that age was negatively significant while primary occupation, secondary occupation, number of children and rating of women involvement are positively statistically significant to women economic status in the study area. In summary, women were involved in empowerment programme on the average and it has helped them to be more established in their businesses but their income is not justifying these efforts and therefore, that empowerment programme should be reviewed.

RECOMMENDATIONS

Based on the findings of this study, the following recommendations were made:

1. Women empowerment programs should cut across all age categories
2. Government and non -governmental organizations should intensify more efforts to review the existing empowerment programs so that most women will benefit maximally to improve the well-being of their household.
3. The empowering agencies (e.g. governments, non-governmental bodies, individuals) should create necessary awareness on the availability of the existing empowerment initiatives so that women can take advantage of these initiatives.
4. Access to financial credits and facilities will boost their day to day activities and economy.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study analyzed the socio-economic factors influencing adoption of recommended cassava processing technologies among women cassava processors in Federal Capital Territory, Abuja, Nigeria. A multi-stage sampling was used to draw a sample size of 153 respondents for the study. Data were collected through the use of questionnaires. Both descriptive and interferential statistics were used to analyze the data collected from the field. The results showed that majority (76.5%) of respondents were within the age range of 20 – 40 years with a mean age of 35 years and majority (75.2%) had various forms of formal education with at least secondary education with a mean household size of 7 persons. Majority had the mean years of 8 years' experience in processing cassava. The coefficient of determination (R^2) was computed at 0. 637. The variables; level of education (sig.=0.070), years of cassava processing experience (sig.=0.037), and number of extension contacts (sig.=0.053) exhibited positive significant relationship at p-value less than or equal to 0.05 while age (sig.=0.051), though significant was negatively related at p-value less than or equal to 0.05. It was recommended that Stakeholders and government agencies with requisite mandate to increase investment on processing technologies and subsidize processing machines in order for women to access them and increase the level of adoption.

Keywords: *Smallholder farmers, agricultural credit, determinant, accessibility, formal agricultural credit*

INTRODUCTION

In Nigeria Cassava production and processing has boosted agriculture and it is traditionally regarded as the mainstay of the Nigeria economy as it supplies food, raw materials and generates household income for the majority of the people. Cassava processing is important in making food available and is often carried out by women. Ogadinma *et al.* (2019) stated that women in cassava production and processing could be developed by the provision of improved cassava varieties, use of fertilizer, use of agro-chemicals, and use of mechanized farming equipment and modern processing techniques. The traditional processing techniques are laborious, time wasting and may result in poor products.

Mechanization of cassava processing can solve these constraints of cassava processing. The choice of machines for making a cassava product depend on the unit operations involved in its production process. Emphasis is therefore placed on appropriate technology for increasing food availability through increased processing, quality control, and preservation. Modern processing technologies such as the mechanical grater, power screw dehydrating press, mechanical sifter, fryer (toaster) and stitching machine have been introduced by Fadama II programme to some women cooperatives in Gwagwalada Area Council. The extent to which these technologies are being adopted by processors to reduce drudgery during processing and increase output is not yet clear. Studies that will reveal the level of adoption of recommended cassava processing technologies by women processors and how they affect the quality and quantity of the processed products is important. Therefore, the need to probe into the level of adoption of recommended cassava processing technologies by women especially in the study area to give a direction on how to guide women processors of cassava on where and how to access them makes this study imperative.

This study, therefore, was designed to analyze the socio-economic factors influencing adoption of recommended cassava processing technologies among women cassava processors in Federal Capital Territory, Abuja.
Hypothesis was designed as tested in null form as presented below;.
Ho: There is no significant relationship between the women's socio-economic characteristics and the adoption of recommended Cassava processing technologies in the study area.

METHODOLOGY

The study was conducted in the Federal Capital Territory (FCT) which is located in the North Central Nigeria. The Federal Capital territory Abuja is located in the center of Nigeria, between latitudes 8^o 25^1 and 9^o 25^1 north and longitudes 6^o 45^1 and 7^o 45^1 east. The territory covers an area 8,000 square kilometers, laying in the centre of the country and is bordered on all side by four states namely; Niger, Nasarawa, Kogi and Kaduna (Dawan, 2000). A multi-stage sampling procedure was used to select the respondents. Stage I: Three area councils were purposively selected out of the six (6) area councils of Federal Capital Territory (FCT). The 3-area councils (Gwagwalada, Kwali and Abaji) were purposively selected due to cassava processing activities common to the areas. Stage II: Random selection of 4 villages in each of the 3 councils to give a total of 12 villages and followed by proportionate selection of 50% of the sample frame from each of the 9 villages to give a total sample size of 153 respondents for the study.
Data collection was achieved using questionnaires administered to respondents through the agricultural extension agent and analyzed using both descriptive and inferential statistics.
Linear production function will was used to determine the socio-economic factors influencing adoption of recommended cassava processing technologies by respondents. The linear production function is expressed as shown below:

$Y = a + b_1X_1+b_2X_2+ b_3X_3+ \_\_\_\_ + b_{12}X_{12} + e$

Where Y = Number of adopted recommended processing technologies adopted by respondents expressed in percentage

$$Y = \frac{\text{No. of recommended technologies adopted}}{\text{Total available recommended cassava processing technologies}} \times 100$$

X_1 = Age (in year)
X_2 = Marital status (Single = 1, Married = 2, Divorced = 3, widowed = 4)
X_3 = Educational level (No. of years spends in school)
X_4 = Household size (in number)
X_5 = Processing experience (No. of years spend in processing)
X_6 = Contact with extension agent (No. of visit)
X_7 = Access to credit (amount in ₦)
X_8 = Membership of cooperative group (No. of years)
X_9 = Amount of income (in naira)
X_{10} = Affordability of technologies (if yes = 1, no = 0)
X_{11}= Compatibility of technologies (compatibility = 1, not compatibility = 0)
X_{12} = Complexity of technologies (complex = 1, if not complex = 0)
b_1– b_{12}= régression coefficients
a = constant
e = error term

RESULTS AND DISCUSSION

Socioeconomic characteristics of respondents

Results in Table 1 shows a mean age of 35 years with about 22% attained secondary school education having an average household size of 7 with majority (56.2%) polling a household size of 6-10 persons. Majority (43.8%) of respondents have spent 6 – 10 years in cassava processing with an average 8 years' experience. Also, Table 1 revealed 53.6% were members of cooperative societies whereas 46.6% do not belong to any cooperative societies with the majority (66.0%) having contact with extension agents who come regularly to discuss the availability of rice processing technologies and how to access them. Most (53.6%) of respondents have access to credit facility from various informal credit sources, the bulk of the credit comes from relatives and friends (15.0%). Table 1 also showed that majority of the respondent (65.4%) received training, which has helped in improving their processing activities and the quality of cassava products they produced.
These results showed that respondents were youthful and in their active years with various forms of formal education, as such could undergo the rigors of cassava processing and could make informed decisions in adopting recommended best practices. Years of experience in cassava processing also reflect their occupational commitment and efficiency on the employment of processing technologies. Ezeano *et al.* (2017) reported that women processors were experienced in cassava processing experience and experience plays a significant role in adoption of technologies.

Table 1: Socio-economic Characteristics of Respondents in the Study Area

Socio-economic variable	Frequency	Percentage (%)	Mean

Socio-economic Determinants of the adoption of recommended cassava processing technologies by respondents in the study area.

The results of the regression analysis as presented in Table 2 show that the coefficient of determination (R^2) was 0.637 implying that the independent variables explain 63.7% of the variability of the dependent variable. The variables of level of education (sig.=0.070), years of cassava processing experience (sig.=0.037), and number of extension contacts(sig.=0.053) exhibited positive significant relationship at p-value less than or equal to 0.05 while age (sig.= 0.05), though, significant was negatively related at p-value less than or equal to 0.05.

The variable of education was positive and significant at 5%. This show there exists positive and significant relationship between years of education and adoption of recommended cassava processing technologies among women cassava processors in the study area. The estimates of the probit analysis by Akinloye (2014) showed how the coefficients of the independent variables influenced the adoption of improved cassava technologies of the small-scale women entrepreneurs. The results showed that educational status was one of major determinants of adoption at 5% significant level in the study area. This means that the more educated the women entrepreneurs are, the likelihood of being able to adopt improved cassava processing technologies. **Y**ears of experience was positive and significant at 5%. This implies that the more experienced the women cassava processors are, the more the likelihood of being able to adopt improved cassava processing technologies. This also implies that the more experience women acquire in processing cassava will lead to increases in knowledge, confidence and perfection, which will invariably increase their participation level.

The variable of contacts with extension workers was positive and significant at 5%. Extension contact is one of the main sources of production and technologies information for improved methods of agricultural activities for farmers. The significant effect of contacts with extension agents in the study area could also result to women cassava processors having professional and technical information/advice on their cassava processing activities. Age was negatively significant at 5%. Age had a negative regression coefficient meaning that as age increases, adoption of improved cassava processing technologies decreases. The implication of this result is that cassava processing in the study area was done by young women who were in their productive age. Their energies could be utilized in the handling of improved cassava processing technologies. Augustine (2015) showed that age had a negative regression coefficient of 0.048 and had significant influence on the adoption of improved cassava processing technologies at 1% level of probability. This implies that the adoption of the improved cassava processing technologies decreases with an increase in age.

Table 2: Regression Results on Socioeconomic Characteristics on Adoption of Technology

Model	**Unstandardized Coefficients**		**Standardized Coefficients**		
	B	**Std. Error**	**Beta**	**T**	**Sig.**
(Constant)	4.138	1.889		2.190	.071

Complexity	.099	.466	.084	.212	.839

Source: Field survey, 2019

Test of Hypothesis

The results of the f-statistics showed that there was significant interaction between respondents' level of education, years of experience and extension contacts were significant and positive determinants of adoption of improved cassava technologies at p-value less than or equal to 0.05. The t-value that is absolutely greater than 2 shows that years in cassava processing is the most determinant factor. Age had a negative regression coefficient of -1.5 meaning that as age increases, adoption of improved cassava processing technologies decreases. Therefore, based on the F-statistics on the ANOVA table, the null hypothesis is rejected.

Table 3: Relationship between the women's socio-economic characteristics and the adoption of recommended Cassava processing technologies

Model		Sum of Squares	df	Mean Square	F	Sig.

	Residual	2.110	8	.264		
	Total	5.810	20			

Source: Field survey, 2019

CONCLUSION AND RECOMMENDATIONS

There is no significant relationship between the women's socio-economic characteristics and the adoption of recommended Cassava processing technologies in the study area and recommends the need to train more women on the available improved cassava processing technologies as knowledge precedes adoption. Stakeholders and government agencies with requisite mandate need to increase investment on processing technologies and subsidize processing machines in order for women to access them and increase the level of adoption.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted to assess women farmer's activities in food crops production in Lafia Local Government Area of Nasarawa State, Nigeria. Primary data were collected with the use of structured questionnaire employed to select 120 respondents for the study using a simple random sampling technique. Descriptive and inferential statistics were employed to analyze the data collected. The result of the study revealed that the mean age of the respondents was 42 years, which were found to be married. It was also discovered that respondents carried out farming activities such as land clearing, cultivation/ridging/heaping, seed planting, fertilizer application, chemical application, processing and marketing. Major crops identified in the study area were maize, yam, cassava, sorghum and rice. Result from the Cobb Douglass production function on factors that influence the income of the farmer were farm size (0.33), level of education (0.171), extension visit (0.017), membership of farmers association (-0.459), labour (0.573), transportation (-0.243) and age (0.038). Major constraints faced by the respondents were inadequate capital, high cost of input and inadequate extension visit in the study area. Furthermore, it is observed that women farmers engaged in various farming activities. It was recommended that the Government need to distribute farm inputs to women farmers at a very subsidized price and at appropriate time to boost production.
Keywords: *Assessment, women farmers, food, crop production*

INTRODUCTION
Agriculture contributes immensely to the Nigerian domestic production with the sector accounting for about 25.52 % of the GDP and employ over 50 % of the labour force (Elijah, *et al.*, 2017; NBS, 2019). It plays important roles in the socio-economic development of developing countries such as Nigeria in the provision of food for the increasing population, supply of raw materials and a major source of employment, generation of foreign exchange earnings, and provision of market for the products from the industrial sector (Eze *et al.*, 2010). In Nigeria, women's contribution to agriculture is estimated at 60-79 percent of labour, especially for food production, processing and marketing (FAO CPF, 2012-2017) and participate in sowing, weeding, harvesting and storing crops and other, they also carry out non-farm activities such as food processing and trade in agricultural products (Houinsa, 2013). Many women are farmers in their own right, as well as working on family farms.
The activities that women involve in meeting the challenges of agricultural production and rural development are quite enormous (Nuhu *et al.*, 2014; Egwuonwu, 2017) and their relevance and significance is therefore prominent in Nigeria. The rural women play key role in supporting their households and communities in achieving food and nutrition security, generating income and improving rural livelihoods and overall wellbeing (Nnadi *et al.*, 2012). Women are the key to the well- being of their families (UNESCO, 2017).
As of 2020, around 32 percent of women in Nigeria were employed in agriculture, forestry, and fishing. The share slightly decreased from the previous year. Generally, since 2000, Nigeria's female employment in agriculture, forestry, and fishing has declined. (Sasu, 2023) Women are responsible for about 50 per cent of the world's food

production and in some countries of sub-Saharan Africa (including Nigeria), women provide between 60 and 80 per cent of the food for household consumption. Women's contribution to agricultural production varies from country to country, crop to crop and task to task (Marilee, 2009). Hence, no meaningful household food security can occur without women who make up more than one half of the rural population. Exact data is very hard to come by but FAO estimated that women are the main producers of the world's staple foods like maize, cassava, wheat and rice. Most of the activities which women engaged in are not defined as economically active employment in national account systems, yet are crucial to the wellbeing of household members (FAO, 2010).. They also perform tasks in household crop production; including sowing seeds, weeding, applying fertilizers and pesticides, harvesting and threshing of the crops. They are also responsible for post-harvest food processing, storage, transport and marketing. In addition to producing staple crops, women in many countries also grow legumes and vegetables to feed their families (Marilee, 2009).

For some years now, the various layers of government have made massive transformative effort towards modernizing agriculture to transform it to modern contemporary systems of food crop and livestock production by Government. Resources have been invested in different phases of agricultural enterprises in an attempt to improve the necessary input, distribution and marketing systems to increase yields yet. The controlled by men. Of these resources mostly invested in men. Women are discriminated against in ownership of land, production resources and farm decision making. This attitude stands from ignorance of the roles women play in agricultural production. This poor recognition inevitably results in loss of interest in farming and non-acceptance of innovations on the part of women. Inspite of the established Women in Agriculture (WIA) programmes was established to create awareness and about the level of women's participation in agriculture. The WIA has been on for more than 2 decades..However, the women farmers are still experiencing challenges of accessing production inputs, new inovations among others. The need therefore, to assess the activities of women farmers in food crop production in Lafia local Government area of Nasarawa State**.** To achieve this there is need to find answers to the following research questions.

i. What are the socioeconomic characteristics of women farmers in food crop production activities in the study areas?
ii. What are the major activities carried out by women farmers?
iii. What are the major food crops planted by women farmers?
iv. What are the factors that affect income generated by women farmers?
v. What are the constraint facing women farmers in the areas?

Objectives of the Study

The broad objective is to assess women farmers' activities in food crop production in Lafia Local Government Area of Nasarawa State. While, the specific objectives are to;

i. describe the socioeconomic characteristics of women farmers in food crops production.
ii. identify major activities carried out by women farmers.
iii. identify major food crops grown by the respondents.
iv. determine factors that affect income generation by women farmers.
v. identify constraints facing women farmers in the areas

METHODOLOGY

The study area

The study was carried out in Lafia local Government Area (LGA) of Nasarawa State, Nigeria. It is bounded by Obi LGA in the South, Nasarawa-Eggon LGA in the North, Doma LGA in the West. Lafia is located on latitude: 8° 29'38.04"N and longitude 8° 30'55.15"E.The mean monthly maximum and minimum temperature at 35.06 ^{0}C and 20.16 ^{0}C respectively while rainfall is about 168.90mm (NIMET, 2008). It has a population of 330,712 people (National Population Census, 2006). The people are mainly farmers. They grow food crops, cash crops and rear animals.

Sampling technique and sampling size

The study employed multi-stage sampling techniques for the selection of respondents. The first stage was the purposive selection of Lafia LGA. The second stage involved the purposive selection of 8 wards due to high concentration of women farmers. The third stage was the random selection of 15 women farmers from each of the selected wards making a total of 120 women farmers and used as the respondents for the study.

Method of data collection

Primary data that was used for the study and was collected with the use of structured questionnaire. The information that were collected were on the socioeconomic characteristics of the women farmers.

Method of data analysis

Descriptive and inferential statistics were used to analyze the data. Descriptive statistics were used to satisfy objectives i, ii, and iii while double log production function was used to achieve objective iv of the study. The model is of double log is specified as follows:

Double log: $Y= ax_1^{b1}x_2^{b2}e$

$Logy=loga+logb_1x_1+logb_2x_2+logb_3x_3+logb_4x_4+logb_5x_5+logb_6x_6+logb_7x_7+loge$

Where

Y= Income in naira (Outputs)
X_1= Farm size (hectare)
X_2= Level of education (year spent in school)
X_3 = Extension visit (number if times visited by extension in year)
X_4 = Membership of farmers association
X_5 = Labour (man/days)
X_6 = Transportation cost (in Naira)
X_7 = age of farmers (in years)
*U*e = Error Term
β_1- β_7 = Regression Co-efficient
B_0= Constant terms

Objective (v) was achieved using Likert scale such as; Very high (3), High (2) and Low (1)

Likert scale

Weighted mean measured through Likert-type three-point continuum scale was used to achieve objective vi. Respondent were asked to indicates the extent of their perception about a statements on a 3-point likert scale using Very high (3), High (2) and Low (1) as a form of measuring degree. Weights of 3, 2 and 1 were assigned. For each indicator a weighted mean obtained as follows:

$$WM= \frac{[(fVS*3)+(fS*2)+fNS*1)]}{N}$$

Where:
WM= Weighted mean, f= frequency, Values 3, 2, 1 = Attached weights; VS, S and
NS= Constraints of very high, high and low
N= Sample size

Deduced following the formula of Bagheri *et al*. (2010) on the perception analysis, the mean(s) for all indicators were measured thus;
The mean(s)
1.00-1.49 (low)
1.50-2.49 (High)
2.50-3.00 (Very High)

RESULTS AND DISCUSSION

Socioeconomic Characteristics of Respondents

The socioeconomic characteristics of the respondents are presented on the table 1. The socioeconomic characteristics of the respondents are an excellent medium for establishing the assessment of women farmers. Socioeconomic characteristics establish behavior patterns that are fundamental to farmers' activities in food crop production.

Age distribution of the respondents: Table 1 shows that 50 respondents representing 41.66 %were within the age range of 21-40 years suggesting the population was young age categories that facilitate the energy demanding labour in crop production activities. About 65 respondents representing 54.19% were between the ages 41-60 years suggesting that the population are still in their active age categories. While those that aged greater than 60 years made up 4 %. The mean age of the respondents in the study was 42 years, the age distribution suggest that population was young.

Distribution of the respondents according to Marital Status: Table 1 shows that most of the respondents (62.50 %) were married while 12.50 %, 10.00 % and 15.00 % of the respondents were single, widow and divorced respectively. This mean that women farmers are mostly married followed by significant proportion of divorced, single and widows. Married women farmers often have greater engagement and more likely participated in agriculture as a means to support the family and they also have the advantage of applying family labour to their operations and likely to dedicate more land to farming.

Distribution of the respondents according to Educational Qualification: Table 1 also indicated that most 50(41.67%) of the respondents had acquired primary education, likewise 25(20.83%) of the respondents had acquired secondary education and 15(12.50%) of the respondents acquired tertiary education while 30 (25.00%) of the respondents were non-formal educated.

Distribution of the respondents according to Farming Experience: The farming experiences of respondents are presented in table 1. The mean years of farming experience among the respondents was 15 years suggesting a spread of the farming experience of the respondents. Most 55 (45.83%) of the respondents had farming experience between 11-20 years and another 39 (32.50%) had farming experience of 1 to 10 years. The least category was respondent with 31-40 years representing 3.33% of the respondents. The findings implies that the respondents have a robust farming experience and with farming experience comes the ability to make better decisions and use the network one has to increase on production activities.

Distribution of the respondents according to Farm Size: The distribution of respondents according to their farm size as depicted in table 1. The mean farm size of the respondents in the study area was 2.32ha which represent an even size of the respondents' farms. It shows that 65.83% of the respondents have 1-5 hectares of land under cultivation. Those with 6-10 hectares of land were 27.5% and those with 11-15 hectares contributed 6.67%. The distribution shows that majority of the respondents' cultivated small hectare of land and such they are mostly small-scale farmers. This could be attributed to the fact that a number of studies have indicated that agricultural production in Nigeria is still characterized by small farm holders.

Extension Visit: The numbers of extension visits received by respondents per annum are presented in table 1. Majority (57.50%) of the respondents had no access to extension visit within the calendar year while only above (42.50%) had access to extension in the same period. This implies that most respondents had no access to extension; their level of access to information about existing new ideas, technology, objects etc will be equally limited.

Membership of Cooperative: Majority (79.17%) of the respondents were members of cooperative while 20.83% were not members of cooperatives. Cooperatives membership is of great advantage to farmers as majority of the lending scheme of formal financial institutions are accessed through the cooperatives platform.

Access to Credit: The accessibility to credit facility by the respondents is presented in table 1. It shows that reasonable percentage (79.17%) of the respondents do not have access to credit facility while (27.5%) have access to credit facility. This indicated that majority of the respondents do not have access to credit facility in the study areas.

Method of acquiring farm: Further analysis of those that owned farms revealed that (66.76%) of the respondents acquired their land through inheritance, (8.33%) acquired their land through gift, (4.17%) acquired their land by share cropping from other individual, 12.50% acquired by lease, (8.33%) of the respondents acquired their land through purchase. Land ownership acquired through inheritance and purchase guarantee production security and freedom and also aid in the acquisition of credit facilities.

Activities carried out by women farmers on the farm

Table 2 presents the involvement of women farmers in cropping activities.

Land clearing/cultivation: Land clearing requires the removal of native cover including trees, stalks, and bushes from the land surface. All the respondents were involved in land clearing as the activities carried out on their farm. It has been done to create a workable bed into which a crop can be seeded. Cultivation involved the loosening and breaking up (tilling) of the soil. All the respondents were involved in cultivation, ridging and heaping operation on their farm by hand using hoe while few of them using machine. This is done to destroy weeds and to prepare soil for the planting of crops.

Seed planting/fertilizer and chemical applications: All the respondents were engaged in seed planting, which is done to enable the establishment of the crop on the field. Fertilizer application is indispensable for the proper establishment of the crop on the field. Without fertilizer, the growth of the crop will be affected visa-vis the output at harvest. 100 numbers of the respondents applied fertilizer on their crops for optimum yield. Pre and post emergence herbicide were applied respectively especially rice farmers. 80 numbers of the respondents applied herbicide on their field. Agricultural herbicides are important for weeds control on the farmer's field and for the promotion of plant growth and establishment.

Weeding/harvesting/storage/processing/marketing: Weeding is one of the most important practices in crop production. This entails the removal of unwanted plants from the field. Weeding is necessary because weeds compete with main crop planted for water; sunlight, nutrients and space, hence affect plant growth. Harvesting is the process of removal of entire plants or economic parts after maturity. The economic products maybe grains, seed, leaves, roots and tubers or entire plant. The remaining portion of the stem that is left on the field after harvest is known as stubble. 120 of the respondents were involved in harvesting. Storage means the phase of the post-harvest system during which the produces are kept in such a way to guarantee food security other than during the period of agricultural production. 70 of the respondents stored their produces after harvest. Agricultural processing means transporting, packaging, sorting or grading. Agricultural commodities or plant produces are transforming into goods that are used for intermediate or consumption including goods for non-food uses. Agricultural marketing comprising of all activities involved in supply of farm inputs to the farmers and movement of farm produces from the farm to the consumer. An efficient marketing system ensures higher levels of income for the farmers. 95 of the respondents were involved in marketing their produces.

Table 2: Activities carried out by Women Farmers on the farm

Type of Activities	Frequency

Major crops grown in the study area

Table 4 presented various major crops grown in the study areas in different cropping pattern.

Maize: all respondents were involved in the production of maize. This means that all respondents in the study area were into maize production being the most common and staple arable crop grown by women farmers. Maize is used for human food, livestock feed and export. Maize being an important crop is also among the major crops of comparative advantage in the study area. Yam: 65 of the respondents engaged in the production of yam representing (15.51%), this is because it is the most expensive crop grown in the study area simply because of the cost of its planting material. This implies that not all the farmers can afford yam seeds for yam production. Cassava: 60 (19.09%) of the respondents were engaged in the cassava production. Despite the rapid growth in cassava production, the cassava subsection in the study areas is the cuttings constraint. Rice: 70 (16.71%) of the respondents were involved in rice production which is among the major crop grown in the study area. Some respondents are involved in swamp rice production while others are engaged in semi-swamp and upland rice production. Nevertheless, reasonable numbers of them were into swamp rice farming. Sorghum: 84 (20.05%) of the respondents were involved in sorghum production. Sorghum is a very simple crop that can be grown with little fertilizer and has multifarious usages which is utilized as sorghum meal, malt beer, beer powders, livestock feed among others. It is the most cultivated crop following maize in the study area. Farmers practicing mixed cropping believed that they did so in order to guard against risk of failure of one crop and it diversify their sources of income

Table 3: Major Crops grown in the study area

Types Crops	Frequency
Maize	120
Yam	65
Cassava	80
Rice	70

Estimate of the Parameters of the Double Log Function on Factors that Influence Income of the Farmers

The result of the Cobb-Douglas production function for input-output relationship in food crop production of women farmers is presented in table 5. The result revealed that the coefficient of multiple determinants (R^2) was 0.719 implying that 71.9% of the variation in the output was explained by the independent variables included in the model. The implication is that the model is good fit. Education, labour, farm size, transportation and membership cooperative were the socioeconomic characteristics determining the respondents income generation. Meanwhile, the regression coefficient for Membership cooperative, labour, farm size and transportation were significant at ($p<0.01\%$).

Labour (0.573) and farm size (0.33) were positive and significantly related to income generated. This implies that 1% increase in labour, farm size and transportation the income will increase by 57.3%, 3.3% respectively. This result highlighted the importance of these variables for increased income generated by women farmers. Similarly, membership of cooperative (-0.459) and transport (-0243) were negative and significant, thus reduction of these variables could lead to decrease in income generated by women farmers.

Education (0.171) was positively related to income generated, this implies that an increase in education the income will increase by 17.1%. However, extension visit and age had positive and not significant influence on income generated; this implies that extension visit and age were not important to income generated by the respondents..

Table 4: Estimate of the Parameters of the Double log Function on Factors that Influence Income of the Farmers

Model	B	Std. Error	t. value
Constant	7.05	1.600	4.407

Adjusted R^2= 0.486 F ratio= 17.106

Constraints Facing Women farmers in the Study Area
The major constraint faced by women farmers in the study area as indicated in table 6 are as thus;
Inadequate capital: the ability for the women farmers to source for capital for their farming activities has been a major constraint that hampers the progress of the farming operation. Table 6 indicate the mean was 2.40, which showed that inadequate capital in the study area was a big problem. Adequate capital is important for the general farm operation. This is because capital is needed from the onset of the farm operation to the harvest.
High cost of input: the high cost of input of the respondents is presented in table 6. The mean score of high cost of input among the respondents was 2.33 accepting an even spread of high cost of input of the respondents. This implies that there is high cost of input of the respondents. The high cost of inputs such as fertilizer, pesticides, herbicides, improved seed variety the most significant factors constraining sustainable women farmers in farming activities in the study area.
Extension visit: the number of extension visit received by the respondents per annum was low with the mean score of 1.64. This implies that since most respondents had no access to extension, their level of access to information about existing new ideas, technology, objects etc will be equally limited. Exposure to extension has also proved to have positive influence on productivity capacity of women farmers.
Scarcity of improved seeds: the scarcity of improved seeds of respondents is presented in table 5. The mean score of scarcity of improved seeds among the respondents was 1.61 rejecting the even spread of scarcity of improved seeds of the respondents. Effective technology of improved seeds can results in higher agricultural production and increased income of farming families, which has positive impact on rural poverty. Seed is the key input for improving crop production and productivity. Increasing the quality of seeds can boost increase the yield potential of the crop by significant sold and thus, is one of the most economical and efficient input to agricultural development. .
Cost of transportation: cost of transportation of the respondents is presented in table 5. The mean score was 1.98, which indicated low. Findings show that transportation plays an important role in the distribution of agricultural product, helps in creating market for agricultural products and reduce spoilage and wastage of farm products. It also shows that improvement in transportation can encourage farmers to work hard in increasing production,
Poor storage facilities: the mean score of poor storage facilities was 1.79. This implies that the poor storage facilities of the respondents are low. Storage of produce is almost as important as growing of crop because when crops are harvested and not stored properly. They are prone to be attacked by storage pest and diseases, which reduce the quantity and quality of the farm produce, thus reducing the income of the farmers.
High incidence of pest and diseases: the mean score of high incidence of pest and disease were 1.78 and 1.30 respectively, meaning that incidence of pest and disease was low in the study area. Outbreaks and upsurges can cause huge losses to crops and pasture threatening the livelihoods of vulnerable farmers and the food and nutrition security of million at a time.
Theft of Products: mean score of theft of products was 1.29 indicating low theft of products. Agricultural crimes includes crops, equipment, chemical and pesticides as well as vandalism and other forms of property crime

Table 5: Constraints Facing Women farmers in the Study Area

Variable Frequency	3	2	1	Score	Mean score	Remark
Inadequate capital	69	32	14	285	2.40	High
High cost of input	50	60	10	280	2.33	High
Inadequate extension visit	53	57	10	197	2.36	High
Scarcity of improved seed	16	41	63	193	1.61	Low
Cost of Transportation	17	83	20	237	1.98	Low
Poor storage facilities	15	65	40	215	1.79	Low
High incidence of pest	14	65	41	213	1.78	Low
High incidence of disease	3	15	102	141	1.30	Low
Theft of products	5	25	90	155	1.29	Low

Source: Field survey, 2021 3- Very High, 2-High, 1- Low,

CONCLUSION

From the result of the study, it is observed that the women farmers engaged in various farming activities. However, they are faced with various degree of constraint in food crop production. Therefore, there is need for the government's response is needed to distribute farm inputs to them at a very subsidized price and at appropriate time to boost production. iii). Extension visit was found to be significantly low, hence, information and messages on improved agricultural innovation that were supposed to be provided and recommendations by the extension officers was discovered to be very inadequate. Therefore, there is an urgent need for by the government to train more extension officers to enable our women farmers have access to improved technologies to boost their farming business. iv). It is obvious that the level of education by respondents is low; therefore women farmers education/training should be given priority. In addition, there is the need for more awareness creation for our educated women to embrace farming as a business. v). One of the major constraint faced by the women farmers is inadequate capital. However, Government should empower them through provision of soft credit facilities with single digit interest rate and anchor borrowers to improve on their income generating activities.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Women participation is essential in household development and sustenance. This study therefore analyzed the factors affecting rural women participation in maize production in Jos North Local Government Area, Plateau State, Nigeria. Questionnaire was used to collect data from a sample of one hundred and eight (108) respondents selected using multi-stage sampling techniques. The first stage involved the purposive selection of eleven (11) communities out of twenty-two (22) communities in the study area based on high participation of women in maize production, while the second stage was the random selection of 11 respondent from each of the selected communities. Data were analyzed using mean scores, standard deviation and factor analysis. Results indicated that the respondents partook in all labour activities involved in maize farming with high-level participation except in very energetic undertakings like earthening – up. Five major factors that affected women participation include Processing/Storage, Soil/Climatic, Labour/Agronomic Technologies, Institutional, and socio-economic factors. The study recommends that respondents should be exposed to scientific and mechanized methods of maize cultivation, harvesting and processing to lessen the drudgery associated with manual labour in maize production practices and gender equality should be advocated to promote equal ease of access to resources and opportunities for women to participate actively in maize production and community development.
Keywords: *Analysis, factors, rural women, participation, maize production*

INTRODUCTION
Maize (*Zea mays* L.) is an important stable cereal crop cultivated in various ecological zones in Nigeria. It plays an important role in the diet and economy of the people especially those in rural communities (Karamara *et al*., 2020). Women play essential roles in maize production - planting, harvesting, processing and preparing of maize based products. Throughout Nigeria, men and women often have complementary roles in maize production activities and in some regions in Nigeria women have distinctly different task and responsibilities in maize production. Rural women have been observed to work side by side with men in maize production with some marked division of labor; while the men performed the tedious tasks of land clearing, gathering, burning of bush and making ridges, women carryout most of the other maize production activities and undertake the general processing (Mba *et al.,* 2017; Marechera *et al.,* 2022). Rural women play a vital role, which is crucial to the overall success of maize production and agricultural development. The role rural women play and their position in meeting the challenges of maize production and development are quite prominent and prevailing. Although both men and women play critical roles in maize farming, harvesting, processing and storage, rural women are usually underprivileged in access to all factors of production and processing in spite of their involvement in general farming operations.

Rural women participation in maize production in Jos North has not only improved food supply but has helped boost food security, reduce poverty, hunger and has enhanced livelihood for rural households. The motivation of rural women to partaking in maize production in the study area is opposed by several constraints, which are likely to affect effort at effectively contributing to food security and sufficiency at both LGA and State level. The question is could high illiteracy rates, poverty, gender biases, discriminatory policies, access to land, funds, extension services and resources or access to key inputs, cultural/religious barrier, herder trespass and conflict, inheritance, lack of storage facilities, low level mechanization, poor post-harvest management, affect women participating in maize production? This paper is an analysis of factors affecting rural women participation in maize production in Jos North LGA, Plateau State. Specifically the study identified perceived labour activities performed by rural women; determined level of rural women participation; and analyzed factors affecting rural women participation in maize production in the study area.

METHODOLOGY

The study was conducted in Jos North Local Government Area of Plateau State, Nigeria. The area is located between latitudes $9^0 82' - 9^0 90'$ North and longitude $9^0 86' - 9^0 90'$ East, with an estimated population of 729, 300 (National Population Census (NPC), 2006). It has a land area of 291 km^2 and is bounded in the north east by Toro LGA in Bauchi State, in the South by Fabur and shere districts of Jos East, on the east by Du and Gyel districts and west by Pengana Irigwe and Rukuba chiefdoms in Bassa LGA of Plateau State Nigeria. The major ethnic group in the study area is the Anaquata's beside other minor settlers like the Igbo, Hausa, Fulani, and Yoruba among others. The main occupation of the people is farming; crops like maize, millet, green pepper, carrot and animal like cattle, load fowl, pigs, goats are reared in the study area. Jos North LGA has one district consisting of 22 communities.

The study covered eleven (11) communities out of the twenty-two (22) in the study area using multi-stage sampling techniques. The first stage was the purposive selection eleven (11) communities based on high level of women participation in maize production activities, while the stage two (2) involved the random selection of 11 respondents from each of the selected 11communities giving a total number of one hundred and twenty-one (121) respondents for the study. Out of the one hundred and twenty-one (121) copies of questionnaire administered; one hundred and eight (108) copies were retrieved and used for analysis. Data for the study were collected using a structured questionnaire, which contained three sections (A, B and C). Section A focused on the labour activities performed by rural; Section B was on level of rural women participation while Section C centered on factors affecting rural women participation in maize production. Data obtained were analyzed using descriptive statistics (mean scores and standard deviation) and inferential statistics (Factor Analysis).

RESULTS AND DISCUSSION

Perceived Labour Activities Performed By Rural Women in Maize Production

Result in Table 1 discloses that women partook in all labour activities involved in maize production in the study area. This agrees with Amah *et al.* (2005) that 60-90% of total farm task especially in maize production such as land clearing, land tilling, planting, weeding, fertilizer application/manure to harvesting, food processing, threshing, winnowing, milling, transportation, marketing as well as management of livestock are performed by women.

Table 1: Perceived labour activities performed by women in maize production in Jos North LGA

Labour Activities	Mean Score ($\bar{x}$)	Standard Deviation
Land clearing	2.34	0.538
Ridge making	2.76	0.489
Planting operations	3.32	1.091
Manual weeding	3.25	0.479
Fertilizer application	3.51	0.878
Supplying	3.66	0.953
Earthening-up	2.99	1.063
Manual harvesting	3.52	0.698
Threshing	3.36	0.728
Winnowing	4.04	1.080
Storage and conservation	3.29	0.794
Marketing	3.06	1.079
General maize processing	3.99	1.816

Level of Rural Women Participation in Maize Production in Jos North LGA

Entries in Table 2 reveal earthening up **($\bar{x} \geq 1.85$)** as the only farm operation below the cut-off mean of ($\bar{x} \geq 2.00$), indicating low level participation of women in it while all other operations recorded high level participation of women (Table 2). This suggests that women engage more in painstaking activities in maize farming and less in tedious and energetic operations. This finding is in line with Olaniyi and Adewale (2012) that in maize production, women usually engage in land clearing, preparation of the land, traditional hoeing and post-harvest operations.

Table 2: Level of rural women participation in maize production in Jos North LGA

Farm Activities	Level of Participation Mean Score ($\bar{x}$)	Standard Deviation
Land clearing	2.34	0.916
Ridge making	2.16	0.893
Planting operations	2.87	0.878
Manual weeding	2.75	1.079
Fertilizer application	2.50	0.549
Supplying	2.46	0.993
Earthening-up	1.85	0.860
Manual harvesting	2.79	0.938
Threshing	2.54	1.063
Winnowing	3.66	0.816
Marketing	2.93	1.051
General maize processing	2.66	1.081

Analysis of Factors Affecting Rural Women Participation in Maize Production in Jos North LGA

Table 3 shows analysis of factors affecting rural women participation in maize production. The analysis reveals five classes of factors as deduced from the respondents' responses. Based on the item loadings, factors 1, 2, 3, 4 and 5 were named processing and storage, soil and climatic, labor and agronomic technologies, institutional and socio-economic, respectively. These represent the major factors affecting rural women participation in maize production in the study area. Factors equal to or greater than 0.50 are said to be significant. Factors which loaded high under Processing and Storage include manual processing (0.767), poor storage facility (0.897) and lack of processing technologies (0569). Storage generates a serious limitation to rural women farmers and storage facility is considered a major challenge to women investment in farming. Agbor and Eteng (2018) identified storage as a major setback to rural women in agricultural production.

Soil and climate factors include climate change (0.579), land inheritance and limitations (0.804), low soil fertility (0.635) and poor crop yield. Poor yield of crops soil fertility reduces the quality of crops produced and thus decreases market value. Land tenure/ limitations constitute a major problem for women contribution to crop food production in Nigeria (Kemi, 2017; Agbor and Eteng, 2018).

Labour and Agronomic technological factors were access to/ key supply of farm inputs (0.647), high cost/lack of seeds (0.816), labour shortage (0.764), lack of planting technology (0.633), poor fertilizer application (0.774), poor knowledge and use of agronomic methods (0.849), weed control (0.530) and unavailability of labour saving technologies (0.732). Rural women in crop production are engaged in wide range of long hours of laborious tasks but lacks labour saving technologies needed for production, processing and storage (Mbah *et al.*, 2017).

Institutional factors comprise discriminatory policies (0.584), gender biases (0.631), poor market information and outlet values (0.510), limited capital and access to credit (0.709). Discrimination against women in agriculture is still common and widespread (Michalopoulos, 2018). Men's control of decision-making and allocation limit women independence and hinder women's progress in a male dominated society.

Socio-economic factors include herder-farmer conflict (0.895), herder trespass (0.529), illiteracy (0.633), land inheritance (0.564), poor extension- farmer contact (0.556) and poverty (0.572). Study by Marechera *et al.* (2022) observed that certain social, cultural and religious orientations of the people in northern Nigeria place restrictions on women, which exclude women from benefiting sufficiently from various programs and interventions that were designed to empower them and guarantee equitable access to productive resources together with men.

Table 3: Analysis of factors affecting rural women participation in maize production in Jos North LGA

CONCLUSION

Results of the study show that the respondents were involved in all farming operations with high-level participation in maize production except in energetic undertakings like earthening – up. The study identified five major classes of factors affecting rural women participation in maize production in the study area. The factors include Processing and Storage, Soil and Climatic, Labour and Agronomic Technologies, Institutional, and socio-economic factors. The study recommends that;

i. Efforts should be geared toward the use of scientific and mechanized method of maize cultivation, weed control, harvesting and processing to reduce the drudgery associated with manual labor in maize production practices.
ii. Gender equality should be encouraged to ensure equal ease of access to resources and opportunities to enable women participate actively in maize production.
iii. Women farmers should be trained in good agronomic practices (GAPs) to ensure cost-effective maize production and food sufficiency.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined the resource use efficiency of fluted pumpkin production (Telfairia occidentalis) among women in Chikun Local Government area of Kaduna State. Purposive sampling was used to select one hundred women farming fluted pumpkin and they were interviewed using questionnaire. Data collected were analyzed using descriptive statistics, gross margin analysis and multiple regression. The finding revealed that 40.86% of the women fall between the age of 31-40years, 69% of the respondents were married, 70% has a household size of between 6-10 persons,43% of the respondents had primary education, 58% of the women had experience in fluted pumpkin production of between 1-3 years and 59% of the respondents had access to credit. The results indicated that cost of seed, farming experience, and cost of labour were significant at 1% level of probability and influence the profitability of fluted pumpkin among the women in the study area. The efficiency ratio for costs of seed, labour, and chemical showed that these resources were underutilized while the efficiency ratio for fertilizer revealed an efficient use of fertilizer resource. To increase fluted pumpkin production, it is recommended that funds or financial assistance be provided to farmers to produce more fluted pumpkin and enhance economic empowerment, expand their production capacities, policies that tend to reallocate land and inputs, particularly fertilizer and credit, to fluted pumpkin production, and particularly to female farmers, are necessary.
Keywords: *Profitability, fluted pumpkin, production, women, resource use*

INTRODUCTION
Fluted pumpkin is a very important vegetable that is popular in West Africa. It belongs to the family *Telfaria occidentalis* Hook F. cucurbitaceae. For the Igbo people it is the most popular leafy vegetable that produces fruits (Enabulele and Uavbarhe, 2001; Ehiagbonare, 2008). Locally, it is called ugwu'by Igbos in eastern part of Nigeria, Yoruba, Egusiiroko' and Benin, uwmenkhen' (Verla, Sui., Li, Su, Li, and Zhou, (2014). It is called fluted gourd or fluted pumpkin in English (Saalu, Kpela, Benebo, Oyewopo, Anifowope, and Oguntola, 2010). The main use of *T. occidentalis* is as a leaf and seed vegetable. The tender shoots, succulent leaves and immature seeds are cooked and consumed as a vegetable. The leaves are used alone or together with okra (*Albelmos chuscaillei* (A. Chev.) or egusi seeds (*Citrullus lunatus*). They are often cooked with fish, meat, and tapioca. The leaves are rich in iron and are used to cure anaemia. The oily seeds also have lactation promoting properties and are widely consumed by nursing mothers. The plant also contains considerable amount of anti-nutrients such as phytic acid, tannin and saponin which could also have some health benefits (Egbekan, Ada-sulelman and Akinyeye, 2013; Balogun *et al*, 2006). The flesh of the fruit has good oil content which can be used as cooking oil. Although fluted pumpkin is a minor oil crop it possesses healing properties that have been found effective in boosting blood levels and in maintaining bone mineral density in older men when more of the seeds are consumed.
According to Chiebowska (2010), women living in rural areas account for 60 per cent of the world's female population with as much as 70 per cent of them found in less developed countries. Women in large proportion have lived continually in geographically adverse or remote areas and have engaged in unsophisticated agriculture especially in fluted pumpkin production. More specifically, they remain food in-secure farmers (Von Braun, 2005). Some scholars, like Momsen (2004) and Whitehead (2015), posit that the reason for this emanate from inadequate knowledge about the regional differences of these women amidst climate change, soil fertility,

accessibility of credit facilities, family structure, farming systems, among others (Momsen, 2004). Women play vital role towards fluted pumpkin production, producing about 70% of its total production, engaging in land clearing, planting, weeding, harvesting, processing and selling of fluted pumpkin, they believed is an economize and marketable product, because its content the most desirable medicinal value as a vegetable (Schippers, 2004). Despite the high nutritional, medicinal and economic value of *Telfairia occidentalis*, its production in Nigeria has failed to meet the domestic demand for its consumption (Opadode and Adeboye, 2005). It is estimated that over 90% of the total land cultivated in Nigeria is in the hands of men farmers who also account for up to 90% of the total agricultural output (Onokerhoraye, 2015). In Nigeria, the output of fluted pumpkin has not been able to meet the demand for human food not to mention that for livestock feed, because of the growing need of vegetables thus the task of producing enough fluted pumpkin pose an increasing challenge (Ojo, 2002). In most rural communities of Chikun Local Government Area where this study is based, traditional agriculture prevails and farming is seen as a way of life rather than a business venture and often these farmers have no knowledge of advanced management techniques, they do not keep proper farm records and depend mainly on family labour. They are also faced with problems like pest and disease attack, high cost of agro-chemical, poor market structure, poor storage facilities, inadequate credit facilities, bad roads, high cost of hired labour, poor infrastructure/transport and land tenure systems problems.

Fluted pumpkin production is one of the major activities performed by rural women in Nigeria, women believed to be among the major producers of fluted pumpkin, accounting for about 20% of its total production (FAO, 2014). Fluted pumpkin is very important in the diet of children, men, women, nursing mothers as well as livestock due to its high nutritive value. In Chikun Local Government Area, fluted pumpkin plays an important role not only as the major source of vitamins in diets but also as a source of livelihood for most women/farmers who grow and sell this vegetable. But in Nigeria, women need to be giving serious support and attention towards fluted pumpkin production which in turn will provide output that will be able to meet the demand for human food and that of livestock feed as well. As a result of the growing need, the task of producing enough fluted pumpkin by women will increase the total agricultural production in Nigeria and provide job opportunities.

Efficiency of resource use is defined as the ability to derive maximum output per unit of resource, is the key to effectively addressing the challenges of achieving food security Efficiency of resource use is a very fundamental strategy that leads to increase in productivity. Efficient use of farm resources is an important part of agricultural sustainability. One way peasant farmers can achieve sustainability in agricultural production is to raise the productivity of their farms, by improving efficiency in the use of the existing limited resource base and technology (Udoh, 2005). Efficiency of resource use can be assessed from the productivity of the output. This is an important issue of the present time, because resource use efficiency issues are the core elements of sustainable crop production of small-scale farming activities. Efficient use of resources is a prerequisite for optimum farm production since inefficiency in resource use, can distort food availability and security (Etim *et al.*, 2005; Udoh and Akintola, 2001). It is therefore imperative to know whether resources are used efficiently in fluted pumpkin production among the women in the study area. In view of this, this study focuses on resource use of fluted pumpkin production among women in Chikun Local Government Area and prefer solutions that will contribute to the policy formation and implementation that will better the lot of fluted pumpkin farmers and most importantly meeting consumer dietary requirements.

Objectives of the study are to describe the socio-economic characteristics of the respondents in the study area, determine the profitability of fluted pumpkin production among the women in the study area and determine the resource use efficiency in fluted pumpkin production among the women in the study area.

MATERIALS AND METHODS

Study Area: This study was carried out in Chikun Local Government Area (LGA) of Kaduna State. The Local Government Area covers an area of about 445,659km and lies between the latitude and longitude 10^{O}N and 8^{O}E of the equator, (NPC, 2006). Chikun Local Government Area is situated in Northern Guinea Savanna Zone, and shares boundaries with Igabi and Kaduna South Local Government Areas to the North-East and with Kajuru to the East, Birnin Gwari and Giwa local government areas to the North-West and Kachia Local Government Area to the South-East. The ethnic group in the study area comprises of Gbagyi predominantly, Hausa, Kataf, Igbo, Fulani, and Yoruba. Their main occupation is farming, and they plant rice, yam, fluted pumpkin, maize guinea corn, millet and cassava they also reared ruminant animals such as; goat, sheep, and cow, they practice traditional and modern agroforestry system in the area and they are also civil servant and traders.

Sampling Procedure: A multi-stage sampling technique was used for the study. First stage involved the selection of fourteen (14) districts in the Chikun (LGA), The second stage involved a purposive selection of five (5) villages from the fourteen (14) districts which include; Kujama, Chikun village, Sabon Tasha, Gayan and Unguwan Sunday. While the final stage involved a purposive selection of twenty (20) women farmers from each of the villages, to give a total of sample size of hundred (100) respondents respectively.

Method of Data Collection

Primary data was used for this study. The primary data was collected through the use of well-structured questionnaires. This involved the socio-economic characteristics of the respondents (age, sex, marital status etc.), the input and output of fluted pumpkin production, the profitability of fluted pumpkin production in the study area and the constraints facing fluted pumpkin production.

Analytical tools

To achieve the objectives of the study, descriptive and inferential statistics as well as budgeting technique was employed.

Descriptive Statistics

Descriptive statistics such as frequency distribution, percentages were employed. These tools were used to describe the socio-economic characteristics of the respondents, such as marital status, farmers' sex and age distribution, level of education, and household size.

Regression Model

The regression model was used to achieve objective iii stated in the study.

The implicit form of the cost functions is stated as $Q = F(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, U)$ ---------------------(1) where; Q =Total revenue (₦), X_1= Age (Years), X_2 = Farm size (ha), X_3= Cost of seed (₦), X_4= Household size (number of person)X_5= Farming experience (Years), X_6=Cost of Labor (₦), X_7=Cost of fertilizer (₦), X_8=Cost of chemical(₦), U=Error term, B_0= constant term and B_1 to B_8= coefficient of the independent variables stated above.

Economic Efficiency of Resource use

The following ratio was used to estimate relative efficiency of resource use (r).

$r = \frac{\text{MVP}}{\text{MFC}}$……………………………………………………………………… (2)

Where:

r = efficiency ratio, MFC = Cost of one unit of a particular resource and MVP = value added to vegetable output due to the use of an additional unit of input calculated by multiplying the MPP by the price of output i.e.

X_{i} = various input used

MPP_{Xi} x P_q……………………………………………………………... (3)

MPP_{Xi}= dy = b $\overline{Y}$ /$\overline{xi}$……………………………………………………………………… (4)

Where,

$\overline{Y}$ = mean value Y output

$\overline{x}$ = mean value x input

Where linear equation is the lead equation

$MPP_{Xi} = \frac{dy}{dx} = \frac{bi}{xi}$ ………………………………………………………………….. (5)

(Direct elasticity from the double log form)

Decision rule

If r = 1 Resource is efficiently utilized, r = >1 Resource is under-utilized and r = <1 Resource is over-utilized

Economic optimum takes places where MVP-MFC if r ¹1, it suggests that resources are not efficiently utilized. Adjustments could therefore be made in the quantity of inputs used and costs in the production process to restore r = 1.

RESULTS AND DISCUSSION

Socio-economic Characteristics

The results from the table 1 shows the age distribution of the sample producer 6.45% are within the age of 21-30 years, 40.86% are within the age of 31-40 which is the highest range, 32.56% are within the age 0f 41-50 years, 12.90% are within the age of 51-60 years and 7.53 are within the age of 61-70 years. The table below revealed that (65.50%) of the farmers were aged between 31-50 years. This implies that at least two thirds of the women farmers were still economically active and in their productive stage. This is According to Emenyonu *et al* (2010). From the table below, it was discovered that majority of the women were married with 68.82%, and 26.88% was widow, 3.23% were single, while 1.08% were divorced. It means married women are actively involved in the production of Fluted pumpkin. From the table below, it was revealed that 24.73% of the women farmers had between 1-5 family size, 68.82% was the highest with the family size of 6-10 while 5.38% was the least with family size of 11-15 persons. This is an indication that a large family is still a common practice among farmers as they often depend on family labour. According to Ahmed (2006) household size to a very large extent determines the income level to household. This could also be a strategy to assist in family upkeep. The level of education of farmers increases their farm production and enhances the ability to understand and evaluate new technology. Table 4 below shows that the respondents have varying degree of educational background ranging from non-formal education to post-secondary education. The result show that 27.96% of the farmers have non-formal education, 43.01 have primary education and 29.03% respondents have post-secondary education a positive correction between level of education and adoption of innovations and formal education had a positive influence on adoption of innovation Nasiru *et al,* (2005) stressed that attendance to formal education is a prerequisite for getting a secure or a regular employment which leads to a more stable income from which marginal propensity to save increase. Table 1 shows that 58.1% of respondents had 1-3 years of experience in fluted pumpkin production, 31.3% has 4-6 years of experience while 9.8% has 7-9 years of experience and about 1.1% has I years farming experience. According to Asogwa (2005) years of farming experience is one of the variables that significantly influence efficiency among farmers in Nigeria. The results also show that the farmers are experienced and knowledgeable in Fluted pumpkin production. Table 1 below shows that 59.2% of the fluted pumpkin farmers has access to credit while 40.9% of the respondents has no access to credit. This implies that, access to credit by fluted pumpkin farmers is poor in the study area.

Table 1: Socio economic characteristics of the respondents

Age group	Frequency	Percentage	Mean
21-30	6	6.45	
31-40	38	40.86	
41-50	30	32.56	44.05
51-60	12	12.90	
61-70	7	7.53

Total	**93**	**100**	

Determinants of profitability

The result in table 2 shows that the multiple regression analysis estimate of profitability of Fluted pumpkin among women in Chikun Local Government Area was done in four function forms (linear, semi log, double log, and exponential forms). The result of the analysis showed that the linear function had the best fit and was therefore chosen as the lead equation. R^2 of 0.4806. This implies that 48% variability in profitability was explained by the explanatory variables while the remaining 52% was due to error term. The coefficient of cost of seed (X_1) significant at 1% has a positive relationship with Fluted pumpkin production. This implies that the more seed, used for production, the increase in the women production in Fluted pumpkin the efficient of farming experience X_5 has a direct relationship with output of the women farmers and significant at 1%. The more experienced a farmer the higher his production. The cost of labour (X_6) was also positive and significant at 1% level of probability. The results indicated that quality of cost of seed (X_3), farming experience (X_5) and cost of labour (X_6) are significant and influence the profitability of fluted pumpkin production among women in the study area. That is 05702, 4710.822 and 1.3973unit increase in each of X_3, X_5, and X_6 will bring about one unit increase respectively in the output.

Table 2: Estimate of Production Function of Fluted Pumpkin Women Farmer in Chikun Local Government Area of Kaduna State

Variable	Coefficient	t-value	Standard error	Significance
Age (X_1)	-468.6298	-0.37	1250.66	0.709
Farm size (X_2)	-9652.21	-0.25	38968.82	0.850

,* at 1%, 5% and 10% level of significance

Determination of resource use efficiency

The concept of efficiency indicates the maximum benefits derived from allocation and use of resources. The result in table 3 showed that the ratio of the marginal value product (MVP) to Marginal factor cost (MFC) was; 0.1023, 0.1256 and -6.6019 for cost of seed (X_3), cost of labour(X6) and cost of chemical(X8). Cost of seed, cost of labour and cost of chemical were less than 1 which implies that farmers are still facing problems of inefficiency of resource allocation in the study area. while fertilizer was 1 for fertilizer (X_7) and equal to 1, it implies the efficient utilization of this resource due to availability of fertilizer to carry out farming.

Table 3: Determination of resource use efficiency

Variables	B	Y	X	MVP	MFC	MVP/MFC	Efficiency
Seed	2.360424	202752.6	10580.11	10.231	100	0.1023	Underutilized
Labour	3.275747	202752.6	46779.57	62.775	500	0.1256	Underutilized
Fertilizer	7.023853	202752.6	8462.37	168.27	220	1	Efficiently utilized
Chemical	-7.531185	202752.6	1927.42	-792.233	120	-6.6019	Underutilized

CONCLUSION AND RECOMMENDATIONS

In conclusion, majority of fluted pumpkin women farmers are married, young, educated, experienced and small-scale female farmers producing mainly for household consumption on part time basis. Seed, labour and chemical which are major predictors of production. All these variables must be considered when designing a technological package for this resource and should be further exploited to improve productivity level of the women farmers in the study area.

Based on the findings the following recommendation were made.

i. To increase Fluted pumpkin production, fund or financial assistance should be provided to the farmers in other to produce more Fluted pumpkin and enhance economic empowerment, expand their production capacities.

ii. Policies that tend to reallocate land and inputs especially fertilizer and credit to fluted pumpkin production and particularly to the female farmers are necessary. Such policies should be targeted more at experienced farmers with large household sizes, and small farm size. They should seek to improve the functioning of credit disbursement mechanisms especially through functional cooperative societies.

iii. The various problems and constraints limiting production could be reduced or avoided if the government harness resources towards rural infrastructural development of the communities, empowerment of the farmers through capacity building on integrated pest management, improved cultural practices to reduce their cost of production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study aimed at examining the gender differentials in poverty among rice farming households in Niger State. Multi stage sampling technique was used to select 130 male and 106 female household heads involved in rice farming. A well-structured questionnaire and interview schedule was used to obtain information on socio economic characteristics and other quantitative variables of interest for the study. Data collected were analysed using Foster-Greer-Thorbecke (FGT) model, and Oaxaca-Blinder (OB) Decomposition. Poverty incidence, poverty depth, and poverty severity of 0.27, 0.5, and 0.25 respectively were higher than that of male headed households with 0.14, 0.1262 and 0.0159 respectively. The major cause of differential in poverty is caused by endowment effect which was in favour of male farmers. Based on these, the study concluded poverty is higher among female headed households. The poverty differential was in favour of male farmers. It was recommended that government and traditional institutions should promote equality through the removal of all forms of barriers and limitations which reduces the productivity of the females. Rice farmers especially women need to adopt smart innovative production technologies to enhance productivity and consequently reduce poverty. Farmers should be encouraged to further engage in non-agricultural activities due to the seasonal nature of rice farming in Nigeria.
Key words: *Rice farming, Gender, Differentials, Poverty, Households*.

INTRODUCTION

Rice is a food crop widely produced and consumed globally, rice alongside maize and wheat provide at least 42% of the world caloric intake, it can also be said that rice serves as staple food to more than 3.5 billion people which is more than half of the world's population (Lanessa, 2017). Although rice is an important crop for household food consumption and combating poverty, production has not kept pace with demand and not being gender sensitive in policy making characterised Nigeria situation **(**Ajewole *et al.,* 2016**).** Nigeria's extreme poverty rate is high and increasing. Despite its middle-income status, almost four out of 10 Nigerians lived below the national poverty line in 2016. Measured at international poverty line of US$ 1.90 per day, Nigeria is home to the largest number of extremely poor people, overtaking India in 2018. The increase in poverty rate observed in Nigeria is higher when compared with neighboring countries. The poverty rate increased from 35.0 to 38.8 percent of the total population from 2011 to 2016 (World Bank, 2019).

It is common knowledge that gender inequality is one of those issues encountered as it cut across different roles, norms, and values, govern the gender division of labour and gender distribution of resources, responsibilities, agency and power (Edeoghon, 2019). Though many studies on gender differentials have been conducted in Nigeria, the focus has being on productivity (Idumah *et al.,* 2015, Agada *et al.,* (2018), Bassey *et al.* (2019) and Ahmed and Deji (2020). Only very few (Ajewole *et al.(*2016), Buba *et al.* (2018); has been done on poverty in different parts of Nigeria, little is known to the researchers in the study area. Therefore, there is a need for more research in the area of gender differential in poverty.

This study tends to achieve these objectives;

I. Analyse the poverty status of farmers in the study area; and
II. Decomposition of gender differentials of poverty in the study area

METHODOLOGY

The study was conducted in Niger State, Nigeria and the State was created in 1976. It is located in Guinea Savannah Region and lies between latitude 80^0 to 11^0 30'North and longitude 03^0 30' to 07^0 40' East of the equator. Multistage sampling technique was used for this study. In the first stage, one Local Government Area was purposively selected from zone namely: Lavun, Paikoro and Wushishi. In the second stage, random sampling was used to select two communities from each Local Government Area. The third stage involves the stratified random selection of male and female headed households. A total of 236 farmers were selected for this study. Yamane, (1973) formula was used to estimate the sample size from the sampling frame. Foster Greer and Thorbecke (FGT) index model was used to analyse poverty status of respondents while Oaxaca-Blinder (OB) threefold for decomposition of the gender differences in poverty.

Model specification

Foster-Greer-Thorbecke (FGT)

Poverty Index was used to evaluate the poverty status of rural household and to disaggregate them into poor and non-poor categories. It has become customary to use the Pα measures in analyzing poverty. The measures relates to different dimensions of the incidence of poverty P0, P1 and P2 was used for head count (incidence) depth and severity of poverty respectively. The mathematical formulation of poverty measurements as derived from Foster, Greer and Thorbecke (1984) is estimated as:

$$P_{ai} = \frac{1}{n}\sum_{i-1}^{q}\left[{(z-y)}/{z}\right]^{\alpha} \qquad (1)$$

Where:

α = degree of poverty

n = number of households in a group

q = the number of poor households

y= the per capita Income (PCI) of the i^{th} household.

z = poverty line

α values of 1, 2, 3 were used in measuring poverty incidence or head count, poverty depth and poverty severity respectively

Oaxaca-Blinder (OB) Decomposition

Oaxaca-Blinder decomposition approach for non-linear regression by Bauer and Sinning (2008) was used to breakdown the poverty disparity as follows:

$E(P_m) – E(P_f)= [E(X_m) – E(X_f)]\beta_f + E(X_f)(\beta_m - \beta_f) + [E(X_m) – E(X_f)](\beta_m - \beta_f)$ (3.8)

$E(P_m) – E(P_f)$ = mean difference in poverty between male headed and female headed household

$E(X_m) – E(X_f)$ = expected variable factors of male and female that contribute to differences in poverty.

$\beta_{m.}$ and β_f estimated parameters for male and female

RESULTS AND DISCUSSION

Poverty status of the Respondents

The poverty status of the respondents was analysed using Foster-Greer-Thorbecke (FGT) model. The result is as presented in Table 1. Findings revealed the head count incidence of poverty for male and female household heads was 0.14 and 0.27 respectively. This means that 14% of the male household heads and 27% of the female household heads were poor or had per capital income below the poverty line. The result shows that female household heads were poorer than male household heads. This result is in agreement with the findings of Oluwatayo (2014), Edet and Etim (2014).

Table 1: Distribution of respondents based on Poverty status and indices

	Male		Female	
Indices	Freq.	%	Freq.	**%**
Poor	18	13.85	29	27.36
Non poor	112	86.15	77	72.64
Poverty line	₦ 30,570.42		₦ 27,229.59	
Poverty Incidence	0.1385		0.2736	
Poverty gap index	0.1262		0.5	
Poverty Severity index	0.0159		0.25	

Source: Field Survey, 2021

Note: Freq implies frequency, % implies percentage.

The higher poverty observed in women rice farmers could be attributed to social norms and limitations of women from equal access to productive resources like men, other reasons may be large household size, restrictions in use of farm land for farming activities and higher dependency on farming as only means of livelihood. However, the result disagrees with the findings of Eduomiekumo *et al.*, (2014) and Ajewole *et al.* (2016) who reported that male headed households were poorer than female headed households. More so, the poverty gap for male headed households and female household heads was 0.1262 and 0.5 respectively, this finding imply 12.62% and 50% of the per capita income are required to raise poor male and female household heads from below the poverty line to the poverty line.

Decomposition of Gender Differentials in Poverty

Table 2 provides the result of the threefold Oaxaca-Blinder decomposition of the gender differential in poverty among the rice farming households, it summarizes main findings by grouping covariates (see Table 2) the first panel of the decomposition presented in table 2 reveals the mean gender estimates for poverty levels by groupings and their variations. It reveals a poverty differential gap of 0.2548, the poverty prediction level by groups and differential gap was significant at 1% level of probability. This finding is in line with findings of Mukasa and Salami (2015) and Morgrado and Salvucci (2016).

The decomposition result of second panel is divided into three parts. The endowment effect, which represents the first component, indicates the rise in poverty of the rice farming households if the male and female household heads had the same endowment. The second part is the coefficient effect which quantifies changes in the female poverty when applying the male coefficients to current level of female characteristics. The third component is the interaction term, which calculates the joint impact of variations in endowments and household head coefficients. According to the decomposition analysis, there are gender disparities of -0.1632551(64.06%) due to endowment, -0.1401766(55.00%) due to coefficients and 0.0485697 (-19.05%) due to interaction of endowment and coefficient effect. Accordingly, the part due to endowment effect was positive and significant at 1% probability level. Also, the part due to coefficient effect was positive and significant at 5% probability level. Consequently, the coefficient for interaction was positive but not significant. This implies that the major cause of differential in poverty is caused by endowment effect, it also implies the male farmers have more endowment benefit and have more structural advantage (coefficient effect) in comparison to the female farmers.

In panel 3, a detailed breakdown of the endowment effect, structural effect, and interaction effect is presented. The endowment effect is mostly explained by differences in household size which was positive and significant at 1%. This suggests that the size of the household tends to have a greater impact on households headed by male farmers. None of the variables had a coefficient effect (structural) that was significant. However, the majority of the variables' magnitudes had a positive sign. Household size, Education, cooperative membership, access to credit, land ownership, household income, household expenditure and remittance were all positive but not significant. Also, the constant was positive but not significant. This suggests that, compared to their female counterparts, male farmers gain more from the return to observable characteristics.

Furthermore, none of the variables had any significance in the interaction impact. However, the majority of the variables' magnitudes had a negative sign. Hence, for poverty to be reduced, policy creation and interventions should be focused on integration, granting women access to resources and opportunities for engagement of women in policy formulation and execution, as well as effective monitoring of programmes aimed for their welfare. This is consistent with findings of Aguilar *et al*. (2014) Mukasa and Salami (2015) and Lubrano (2016).

Source: Field survey, 2021

CONCLUSION AND RECOMMENDATION

Based on the study it can be concluded that poverty incidence was higher among female headed households in comparison to the male headed households. Furthermore, the study revealed the poverty differential was largely due to differential in endowment effect which was in favour of the male headed households.

From the findings of the study the following recommendation were made.

(i) Women should be given equal access to production inputs such as land, fertilizer, use of modern farm tools and machines as this would increase the productivity of the female household heads as most times women are marginalized in the use of farm inputs;

(ii) Rice farmers especially women need to adopt smart innovative production technologies to enhance productivity and reduction in poverty.

(iii) Farmers should be encouraged to further engage in non-agricultural activities, the seasonal nature of rice farming in Nigeria limits the earning potential of farming as a source of livelihood. More engagement in non-agricultural activities would complement in areas of earning deficiency.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was conducted to determine the poverty status of women farmers in Development Exchange Centre Microcredit of Kaduna state, Nigeria. The study utilized primary data collected through questionnaires administered to 420 respondents (210 DEC participants and 210 non-participants) were selected using purposive and random sampling procedures. Data were analyzed using simple descriptive statistics, the FGT poverty model and Logit regression model. The result of the FGT poverty model revealed that the incidence of poverty among the farming households was 40% and 50% of participants and non-participants. Implying that 60% and 50% of the respondents' farm households were not poor. The result of the Logit regression showed that age, education, farm size, farm experience, income, crop output, level of living and access to DEC microcredit were significantly related to the poverty level of the women farmers. This implies that a unit increase in these variables will likely lower household's head of being poor. It is therefore recommended that amount of credit facilities provided should be increased so as to increase productivity, time for repayment of credit facilities should be extended to more than one year and the programme should be extended to other farming communities in the State, so as to accelerate the reduction of poverty among rural women in the state and nation at large.
Keywords: *Determinants, poverty status, women farmers, development exchange centre, microcredit*

INTRODUCTION
Poverty is a problem affecting every nation of the world (Chen and Ravallion, 2016). Poverty has been aptly summarized in both absolute and relative terms, as a state where an individual is not able to cater adequately for his/her basic needs of food, clothing and shelter; meet social and economic obligations, lacks gainful employments, skills, assets and self-esteem and has limited access to social and economic infrastructure. In other words, "the poor lacks basic infrastructure, such as education, health, potable water, and sanitation, and as a result has limited chance of advancing his/her welfare due to limited access to social and economic infrastructures (Adamu and Michael, 2019). Many people all over the world live in absolute poverty and suffer from chronic hunger. Statistics shows that about 3.1 billion people (55%) in rural areas are poor women with about 1.4 billion living in less than US $1.25 (₦197.50) a day while 70% of these very poor people rely on farming and agricultural labour (Simpa,2014; World Bank, 2016. Women poverty status has received increased attention of the economists and policy makers since 1990 after the Fourth World Conference on women at Beijing, 1995 (World Bank, 2007). Efforts to reduce poverty was further intensified by world leaders after the World vision 2020 African Conference held in Uganda in 2003 and it was also the first of target among the agenda of Millennium Development Goals (MDGs) with the aim of reducing extreme poverty and hunger by half in year 2015 (Vincent, 2006; Simpa, 2014). Poverty reduction is a priority task facing Nigerian government and Non-governmental organization. The incidence, depth, and severity of poverty among women farmers are such that poverty reduction strategies are synonymous with economic growth and development strategies.

Development exchange centre microcredit programme (DEC) is a non-governmental organization who is concerned about worsening rural poverty and the marginalization of women. Its main objectives includes efforts to strengthen access to credit, participation in decision-making, access to agricultural extension services, access to improved farm inputs and tools, traditional thrift and savings. DEC is committed to strengthening rural financial services and improved access to credit, as a key to reducing poverty among women farmers (DEC Newsletter, 2014). Since poverty is a major constraining factor among women farmers (Olawuyi and Adetunji, 2013), it is still important to investigate how socio-economic factors and other related variables that determine poverty among women farmers in rural areas in Nigeria. This study looks at poverty as lack of necessities based on individual's perspective and status. Identifying the determinants of poverty in rural areas is very crucial to understanding the causes of poverty, and for formulating policies directed at its reduction. Therefore, the broad objective of this study is to assess the determinants of poverty among women farmers DEC microcredit participants in Kaduna State, Nigeria, while the specific objectives are to: identify socio-economic characteristics of the women farmers DEC microcredit participants in the study area.; and, Determine the poverty status of the women farmers DEC microcredit participants' in the study area

METHODOLOGY

The study was conducted in three local governments' areas (LGAs) of Kaduna State. The LGAs are Sabon-Gari in the northern, Kaduna-South in the central and Jema'a in the southern Senatorial District of the state. These LGAs were randomly selected out of nine LGAs participating in DEC microcredit programme in the State. Kaduna State is in north-western Nigeria, located between Latitudes 9° and 12°N and Longitudes 6° and 9°E of Greenwich Meridian. It shares boundaries with Abuja in the east and Katsina, Kano and Zamfara in the north, Nasarawa and Plateau in the northeast and Niger in the northwest. The mean annual rainfall is between 1500mm and 2000mm in north and south respectively. Kaduna State has an estimated population of 6,066,562 (NPC, 2006) out of which the female population is 2,954,534(48.7%) (National Commission for Mass Literacy Adult and Non-formal Education, 2008). It is estimated that the population has increased to 8,578,657 by 2017 based on the National Population Commission (NPC) annual growth rate of 3.2%. while the female population will be 4,177,947 at the same growth rate. The state covers an area of about 45,786 km^2, (Federal Office of Statistics, 2006).

Multistage sampling technique was used for this study. In the first stage, three Local Government Areas (Sabon-gari, Kaduna south and Jema'a) were randomly selected from the nine LGAs participating in DEC microcredit programme in the state. In the second stage, two villages each were randomly selected from each of the three LGAs. In the third stage, from a sample frame of 2,103 women participating in the DEC programme, 210 participants, representing 10% were randomly selected. The list of participating women was obtained from the DEC microcredit office in Kaduna. Finally, the list of two hundred and ten (210) non-participant women farmers was also obtained from Kaduna Agricultural Development Project (KADP) extension agent. This was randomly selected to obtain a total sample size of 420 respondents. Primary data were used for this study. The data were collected from the respondents with the aid of a structured questionnaire. Analysis of data collected from the field was done using mean, percentages and frequency, Foster-Greer-Thorbecke (FGT) poverty model and Logit regression model.

RESULTS AND DISCUSION

Socioeconomic characteristics of respondents

Table1 shows that majority (45%) of respondents were between the age of 31 to 40 years for participants and about 50.4% for non-participants. Mean age of participants was 37years while non-participants were 38 years. About 72% and 69% of participants and non-participants respectively, had one form of education or another. 60% of participants and 47 % non- participants had a mean of 6 persons per household. 71% of participants and 62 % non- participants cultivated land areas of between 2 to 4 hectares while approximately 22% of non-participants cultivated less than 2 hectares. The mean farm size for participants and non-participants was 2 hectares. Majority of the cropping season in the study area. The result in Table 1 shows that, 71% of programme participants received between ₦40, 001 – ₦50 with a mean amount of ₦45, 580.95.

Poverty status of the farmers in the study area

Determination of poverty line

The result in Table 2 give estimation of the poverty line that was used to determine the poverty status of DEC microcredit participants and non-participants in the study area. The poverty line formed the basis for further analysis. The Foster-Greer-Thorbecke (FGT) class of poverty measures was employed to estimate the poverty status of the respondents. The result showed household food and non-food expenditure, total expenditure, per capita and mean per capita expenditure and the poverty line. The poverty line was constructed as two-thirds of the mean per capita household expenditure (MPCHE) of all households. This approach has been used by several researchers and institutions (NBS, 2012; Oni and Yusuf, 2008) as a measure of welfare. Households were then classified into their poverty status based on the poverty line. Hence, non-poor households were those whose per capita expenditure was above or equal to two-third of the mean per capita expenditure of all households while those whose per capita expenditure was below two-thirds of the mean per capita expenditure were classified as poor. Based on this, the poverty line constructed as two-third of the mean per-capita expenditure for participants and non-participants households was ₦159,880 (monthly). This implies that households whose monthly per capita expenditure fell below ₦159,880 were classified as poor while households whose per capita expenditure equaled or was above the poverty line were classified as non- poor.

Table 2: Determination of participants' and non-participants poverty line

Type of expenditure	Participants	Non-participants
Household food expenditure	230,283.71	152,766.37
Household non-food expenditure	184,729.51	71,300.94
Household total expenditure	415,013.22	224,067.31
Per capita household expenditure (PCHE)	104,033.47	66,717.23
Mean Per capita household expenditure (MPCHE)	2,092.23	1,187.41
2/3 MPCHE (Poverty line)	159,880	159,880

Effect of DEC microcredit on poverty status of the programme participants

The Logit regression model was used to estimate the determinants of poverty status of the women DEC participants with particular interest on the influence of DEC microcredit on their poverty level. Entries in Table 3 shows the likelihood ratio Chi-square was significant (p<0.01) with Chi-square value of 201.40, which means the model is a good fit. Age, education, farm size, farm experience, credit, income crops output and level of living. Household size, indicates that age has a positive coefficient (0.054) and is significant at P<0.05 level of probability. This implies the age of farmer will significantly influence his or her poverty status. The age of the respondents were found to be positively correlated to their poverty status, indicating that as a household head got older, the livelihood of being poor increased. This position is consistent with that of Gang *et al.* (2002), and Garza-Rodriguez (2021) that poverty increases with old age, as the productivity of the individual decreases.

The coefficient of education was also significant (p<0.05). This implies that a year increase in years of schooling will decrease the probability of been poor among participant households. This may be attributed to the fact that educated household heads tend to adopt improved farming techniques better and faster than uneducated ones. This raises the productivity and income of the educated heads and subsequently alleviating poverty among their households. Farm size had a positive coefficient (0.435) and was significant at P<0.01 level of probability. This implies that farm size is an important poverty status determinant in the study area and significantly influences the probability that a household would be poor or non-poor. The coefficient of farm experience was found to have a direct relationship with the poverty status of programme participants in the study area and is statistically significant at 1% level of probability. This implies that farm experience is an important determinant of poverty status in the study area and significantly influences the probability that a household would be poor or non-poor. Moreover, Farm inputs was important factors in farm productivity among participants' households but was insignificant in determining poverty. Although labour was an important asset in farm productivity with a positive coefficient (0.012), it was also not a significant variable in poverty status determination among participants' households. Access to market also had positive coefficient (0.006), but was insignificant variable in determining poverty status. Credit assists the farm households in the purchase of farm inputs such as fertilizers, herbicides, improved seeds and investment demand to increase productivity. The coefficient of access to credit was significant at 5% level and negatively related to the poverty status of the farm households. This implies that access to credit in the study area reduces the likelihood of a women DEC participant's household being poor and this is because access to DEC credit gives the women farmers the opportunity of enhancing their production capacity through purchase inputs such as improved seeds and fertilizer. This is not surprising, as credit can reduce liquidity constraints and increase the capacity of households to start off-farm businesses. This is in line with the findings of Babatunde and Qaim (2009) who reported that access to credit has a positive influence on income of women households. Farm income had a positive coefficient (26.562) and was significant at P< 0.01 level of probability. This implies that farm income is an important variable in poverty status determination and that it significantly influenced the probability that a household was poor or non-poor. Increased income enables the households to move out of poverty. Crop output had a positive coefficient (0.375) and was significant at P<0.010 level of probability. Crop output is a variable in poverty status determination. Therefore, a unit increase in the crop output increased the probability of the farming households moving out of poverty by 99.9%. Living standard of the households was found to be positive and significant at P<0.01 level of probability. Thus a unit increase in the households' living standard increased the probability of households escaping from poverty by 0.6%. The model accounted R^2 (0.693) for 69% of the variation in poverty status of DEC microcredit programme participating households.

Table 3: Result of the factors influencing poverty status of respondents

Source: Field survey, 2015 *** P< 0.01, ** P<0.05 and * P<0.10

CONCLUSION

Based on the findings of this study, it can be concluded that 4% and 48% of the participants and non-participants' farm households were poor, implying that 96% and 52% of participants and non-participants of the farmers households were non-poor. Age, farm size, farm experience, income, crop output, access to DEC credit and standard of living, significantly determined the poverty status of farming households in the study area. Access to DEC microcredit by the farm households decreased the farm households' probability of being poor implying that access to DEC microcredit offers an opportunity for alleviating poverty among the farm households in the study area. Therefore, it is recommended that the programme should be replicated in other communities in the state to achieve poverty reduction among the women folks in the state and nation at large.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An investigation into the gender analysis of the cassava cultivation system and the rural farmers' livelihood activities was carried out in the Imo state. Four communities that are prominent in cassava production were selected from three agricultural zones of the state. The respondents' responses were elicited using a mixed method that included individual interviews, key informant interviews, focus groups, and market interviews. Transcribing discussant responses allowed for data analysis. The findings from the focus group discussions reveal that Imo State's male and female farmers almost always practice intercropping cassava with other crops because it increases crop yields and makes weeding easier than planting on flat land. This is especially true of the women farmers. Some male farmers cultivate cassava, rice, and yam solely. In all four communities surveyed, farming was shown to be the primary source of income, although only a small number of farmers are also engaged in non-farm pursuits like trading, fishing, and livestock raising.
Key words: *Gender, Farming system, livelihood activities, cassava farmers*

INTRODUCTION
In Nigeria, cassava is one of the principal crops grown for food staples. Due to Nigeria's strategic position as the world's greatest producer, it is well acknowledged to have significant potential to improve the nation's economy (FAO, 2016). According to FAOSTAT (2019), Nigeria produced 59.4 million metric tons alone (20.4% of the global production). According to Ewubare and Ologhadien (2019) evaluation of the cassava sector's potential in Nigeria's national economy, the industry has the ability to provide 1.8 million employment, guarantee food security, raise farmers' incomes, and generate foreign exchange gains, among other things. Nigeria is in a prime position to gain from the global cassava value chain due to her position in the world's cassava output.
Additionally, the demand for alternative energy sources, fuel, animal feed, and beverages, as well as the Nigerian government's drive to replace imported wheat and food (especially for gluten-free diets), are driving up other economic opportunities in the cassava sector globally. Cassava is presently the most widely grown crop in Nigeria after changing over time from a low yield famine reserve crop to a high yielding cash crop (Apata, 2019). Smallholder farmers in Nigeria account for 95% of all cassava production, and they are the main producers and growers of the crop (Otekunrin and Sawicka, 2019).
Cassava is grown in Nigeria either as a single crop or in combination with other crops as part of intercropping farming techniques. Because cassava is a year-round crop that provides household food security, reduces poverty, and provides a stable source of income, it integrates well into the farming systems of the smallholder farmers in Imo State, South-East Nigeria. Cassava is more tolerant of low soil fertility and more resilient to drought, pests, and diseases than cereals are. The predominant use of this system is due to Nigeria's primarily tropical environment, which is excellent for the cultivation of cassava. In addition to providing the farmer with a secure and consistent income, intercropping cassava with other arable crops protects against crop failure that could result from pest and disease infestation or natural disasters. Additionally, it offers rural households a balanced diet. In many agricultural farming systems in the southeast of Nigeria, maize, yam, melon, okro, and vegetable are interplanted with cassava, which is typically the base crop. One of the two popular crop combination systems used in Imo State, Nigeria, is the cassava-based crop system (CBCM) (Osuji & Onubuogu, 2018).
It is obvious that farm-based businesses and non-farm activities provide a living for rural households. According to Mgbada (2010) and Olawuyi and Rahji (2012), farming of crops like cassava, maize, yam, and vegetables,

raising livestock like chickens, sheep and goats, and raising pigs, and fishing are the main sources of income for rural households. Petty trade, teaching, basket making, palm wine tapping, masonry, food vending, tree felling, food processing, farm labor, carpentry, and tailoring are some further professions. According to the International Centre for Development Oriented Research in Agriculture (ICRA, 2015), livelihood is best understood in this context as primarily including earning money, which serves as a way of achieving other goals. It encompasses aspects of ensuring access to food, housing, healthcare, security (reduced vulnerability to climatic, economic, or political shocks, etc.), sustainability (the capacity to continue to earn a living that is satisfying), and other factors power (the capacity to shape one's own future), as well as others. Gender issues are heavily impacted by Nigeria's ability to boost food production. According to FAO (2006), the reason food security policies and programs fail is because it is assumed that vast populations of people are homogeneous rather than made up of diverse socioeconomic groups with varied demands and interests.

In Nigeria, women perform the lion's share of the labor involved in growing and processing cassava. Cassava is therefore perceived as a "women's crop" in some ways (Otunba-Payne, 2020). Cassava is crucial to ensuring food security in the home, which is frequently the responsibility of women. Additionally, cassava is a low-risk and low-input crop, which is crucial for women who face more severe barriers to accessing agricultural inputs than men (Osuji, & Onubuogu). Men control more productive resources and make more decisions about farming than women do. Women's ability or inclination to adopt innovations is impacted by the disparity in decision-making power and one-sided access to agricultural inputs and technologies, which reduces yield potential (Olaosebikan et al., 2019).

The study of gender focuses on how men and women interact in terms of their roles, needs, and access to and control over scarce resources. Therefore, one of the main causes of gender disparity is thought to be the limited access that women have to some productive agriculture inputs. Differences in home welfare, functions, enterprise, farm sizes cultivated, and profit-maximizing conduct are taken into account in this case (Amah et al. 2020). In order to produce agricultural products, women must plant, cultivate, harvest, process, and prepare them (Ajani 2008). In Nigeria, geography, culture, and religion all play a significant part in determining how women are represented in agriculture. Among other communities, like the Igbo and Yoruba, gender-differentiated cropping patterns frequently endure. For instance, transitory crops like cassavas, melons, beans, maize, and cocoyams are regarded as feminine crops while yams, the prestige crop, is viewed by agriculturalists as a masculine crop. In the state of Imo, both men and women work as farmers, raising crops like cassava and others for a living. They engage in additional activities to earn money. Gender inequalities in farming systems, labor tasks, access to and control over resources utilized in the production of cassava and other livelihood activities must be included in agricultural research and extension. This study is undertaken to examine gender differences in farming system of cassava as well as other livelihood activities performed by farmers in Imo state to ensure food security and poverty alleviation in their rural communities.

METHODOLOGY

The survey was conducted in Imo state with all the three agro-ecological zones that made up the state inclusive. The communities studied were Uzoagba, Ikeduru, selected from Owerri zone, Akwakuma, Owerri North from Owerri zone, Amandugba Isu from Orlu zone, Isinweke, Ihitte Uboma, from Okigwe zone. All these areas were well known for production of cassava in large quantity. Purposive sampling technique was used to select key informants who are knowledgeable about cassava production and farming system in their various communities. Some of the key informants are traditional rulers, councilors and primary and secondary school teachers. From each community, one male and one female key informants were selected to represent the community making a total of (8) key informant interviews for the four (4) communities selected for the study. In-depth interview with eight (8) Key informants from the four selected communities was carried out. Ten individual interviews were also conducted for each community making a total of fourty (40) individual interviews, market interview was also conducted for each community studied. Two (2) focus group discussions were carried out in each community studied, one male group and one female group making a total of eight (8) Focus group interview. Each group was comprised of Ten (10) discussants /respondents making a total of eighty (80) respondents that participated in Focus group discussion. Thus, a sample size of one hundred and thirty two respondents (132) was used for the study. Separating the male group from the female group enable the researcher in eliciting quality response from the farmers because every respondent will be free and willing to give correct information without the fear of being confronted by her husband at home after the meeting. The collected data were analysed by transcribing the responses of the discussants.

RESULTS AND DISCUSSION

It was discovered from table 1 that both gender groups (men and women) farmers in various community mainly plant their crops on mounds and ridges because it yields more crops and ease weeding unlike planting on flat land, some still plant on flatland because they do not have enough money to hire labourers to make mounds or ridges for them but it was reported in women FGD Umundugba that why some people plant on flat land is because some areas are very soft that cannot permit any form of land preparation, also, most communities practice intercropping mainly peasant farmers because they do not have enough land, rotational cropping is practiced by female farmers in Ihitte Uboma that have enough land. It was also discovered that some crops like cassava, rice and yam are planted sole in Men FGD in Ihitte Uboma. Even though that men and women perform most activities in the farm together, Men are mostly involved in land preparation activities like bush clearing, ploughing, harrowing and ridging / mound making while women are mostly involved in planting, maintenance of the farm like fertilizer application and harvesting.

Table 1: Farming practices

Male/female FGD + Community name	Farming practice	People who practice
Women's FGD, Uzoagba (Umuloboagwu)	In this community, mounds are preferred due to their higher yields, less weeds, and ease of weeding, while flat ones are preferred due to their lower cost.	Women, Men, Men do the cleaning of bushes
Men's FGD, Uzoagba,Ikeduru	Cultivation methods include ridges, mounds, flat soils, and single or multiple cassava stems, with flat ones being preferred due to cost-effectiveness.	Women, Men, Youth and Migrant farmers. But women does the farming more than the men..
Women's FGD, Akwakuma, owerri	Farming practices vary based on social segmentation, with peasant farmers using intercropping for land conservation and commercial farmers using mono-cropping and tractor cultivation for large land expanses.	Men plant yam, they cut the wood, make the mounds and stake them. Men do the strenuous work and slash the farm land. The women weed the farm, plant the cassava and also uproot the cassava mainly
Men's FGD, Akwakuma, owerri	Making of ridges, mounds, we also have the cassava planted on flats and covered with soil. To ease work and conserve land.	Both the men women perform the task.
Women's FGD, Umundugba Isu	Farmers use ridges, heaps, or flat ground for planting due to soil fertility in soft areas, allowing stems to grow without creating ridges or heaps.	In a community, men and women work on farms, with women mainly involved in slashing and removing bamboo trees. Age doesn't stop them, and some even sit on chairs.
Men's FGD, Umundugba Isu	We plant on ridges, heaps, small mounds and on flats, but majorly on ridges and heaps.	Men plant on ridges, while women plant in mounds. Men plant on ridges, while women plant short, 2m-long ridges due to stumps.
Women's FGD Isinweke ihitte uboma	We use mounds to plant. We do crop rotation here, but some who have no land do not practice it. Generally we lack land.	Men traditionally clear bushes and plant, but women now do these tasks. Most men are lazy, except for those in agriculture, who don't like to help. Only 5 men assist their wives.
Men's FGD Isinweke Ihitte Uboma	Family members farm together, planting crops like cassava, yam, and rice on ridges mounds, depending on soil type and topography.	Men prepare land, plant yams, and perform weeding, clearing, and harvesting, with women mainly handling weeding and fertilizer application.

Field Survey, 2018

Table 2 revealed that farming was the major livelihood activities for all the communities in the sample. They specialized in the production of mainly food crops like cassava, plantain, maize, yam, vegetables and oil palm that provides them with food for the family and serves as source of income for their livelihood. However, men in Umundugba and Ihitte Uboma reported fishery and other livestock like poultry, sheep and goat production as an additional means of livelihood activities. Women group in Umundugba reported that cassava and other food crops are majorly produced by women while men specialises in yam production. The four communities studied also process their cassava into gari and sell to meet up with other household needs of the family. Very few people in Uzoagba are involved in trading.

Table 1: Livelihood activities

Male/female FGD + Community name	Livelihood activities and people they are involved
Women's FGD, Uzoagba (Umuloboagwu	Majority are farmers few people are tailors and hair dressers. They produce palm oil, trade, they also sell plantain and bananas, they grow mainly food crops. Only few people trade.
Men's FGD, Uzoagba,Ikeduru	The main livelihood activities is all about farming in which they produce palm fruit, cassava, poultry, vegetables and some others engage in labouring work as a means of livelihood.

Women's FGD, Akwakuma, owerri	They plant food crops like maize, cassava, yam, cucumber, plantain, pumpkins, pineapple etc. They also process cassava into garri, they make it for them to have food in their homes. They also plant to help their family members that do not have enough and also for exercise. when we farm in large quantity, we get money to pay school fees of our children. Farming also keeps our youth busy and not wait until government give them white collar jobs.
Men's FGD, Akwakuma, owerri	They plant lots of crops, like cassava, yam, plantain, vegetables, maize, okro, melon
Women's FGD, Umundugba Isu	Production of cassava, yam, plantain, banana, cocoyam (we used to plant this, but now we don't because it always dies off), akidi, cucumber, water melon, garden egg. Men specialises more in yam, while women focus more in cassava and the rest.
Men's FGD, Umundugba Isu	Livelihood activities include farming-cassava, cocoyam, yam, plantain, palm, livestock etc. we also engage in fishery production
Women's FGD Isinweke ihitte uboma	They plant many crops and we also engage in the production of food crops. we also process them and sell in the market to make money which we will use to buy other things we need.
Men's FGD Isinweke Amakohia Nkwumeato ihitte uboma	They produce Cassava, plantain, Oil palm, plantation, yam, maize, rice, they also process palm fruit into red oil, They rear livestock such as: poultry production sheep and goats,

Field Survey, 2018

CONCLUSION

Though it was also discovered that some who have very soft land also plant on flat land and few who cannot afford to hire labor for cultivation, they also practice intercropping particularly women and those who do not have enough land. It is clear from the study that male and female farmers in Imo state almost have the same farming practice where they plant their crops on mounds and ridges because it yields more crops and eases weeding unlike planting on flat land. Cassava, rice, and yam are reportedly solely planted, according to some men. Some communities that have land also practice rotating crops. Most of the land preparation activities like bush clearing, ploughing, harrowing, ridge and mound making are done by men while planting and maintenance operation like wedding, fertilizer application are done by women. Farming was also found to be the major livelihood activities for all the communities studied but few farmers are involved in non-farm activities like trading, fishery and livestock production like poultry, sheep and goat rearing as additional means of livelihood.

ACKNOWLEDGEMENTS

We acknowledge the RTB foods Project for providing the required data, information and experience for the successful execution of this project. We also extend our appreciation to the Executive Director, NRCRI, Umudike for providing the enabling environment for completing this project.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A research was conducted to identify the constraints militating youth's engagement in agribusiness activities. Three hundred and sixty respondents were randomly selected from three agricultural zones in Zamfara State. Majority (43.1%) of the respondents agree that the problem militating against youths' engagement in Agri–business activities is lack of interest. The "poor or wrong counseling towards Agribusiness" activities is another constraint where majority of the respondents (40.6%) in the study area agreed with the statement to be one of the constraint militating youth engagement in agribusiness activities. Recommendation made is that all stake holders especially policy makers, religious leaders as well as the community leaders should developed training and retraining of youth with the aim of sensitization and awareness of the important of their engagement in any legitimate agribusiness activity
Keywords: *Youth, Agribusiness, Engagement Activities*

INTRODUCTION
One of the pitfalls of the global economic crisis is the rising of unemployment, particularly among the youth. Despite the percentage of youth and their contribution to national development, there are challenges facing youth in the society. Today, millions of youths including young university and polytechnic graduates are roaming the streets without any hope of getting white collar jobs or business to do. In fact, there has been a growing commitment across Nigeria and Africa in engaging youth in agribusiness as cited by Mastewal *et al*. (2019) which include several initiatives such as N- power (i.e. N-agro) in (2016 to date), Fadama guys program in (2016), the adoption of the African Youth Charter (AYC) by the African Union in 2006, the declaration of the Youth Decade Plan of Action (2009 to 2018), the establishment of the Youth Desk in the New Partnership for Africa's Development (NEPAD, 2017) and the Comprehensive African Agriculture Development Program (CAADP) (AGRA, 2016). Despite all the efforts made by several governments, in engaging the youth to participate in agribusiness, the outcome of their efforts is less satisfactory. This research is trying to find out factors or constraints militating youths' engagement in agribusiness.

METHODOLOGY
Study Area
Zamfara state is one of the thirty-six states of Nigeria. It is located in the north-western zone of Nigeria between latitude 12.1844^0 N and longitudes 6.2376^0 E with and altitude (feet), 1049 (FRN, 2006). The state has a total land area of 384.18 square kilometers and with a population of 3,602,356 according to the 2006 census. The arable land includes a large expanse of Fadama area (FRN, 2006).
Multistage sampling technique was used in selecting the respondents for the study. . The first stage is the purposive selection of the agricultural zones (zone A, Zone B and Zone C) in the state. The second stage involve random selection of the respondents living in those selected locations. Initially, a respondent will be ask about his age before proceeding to the actual interview. Any respondent whose age is above 30 years will not be allowed to participate in the interview. One hundred and twenty respondents were randomly selected in each of the three agricultural zones making the total of three hundred and sixty respondents used for the study in providing the necessary information for the research.

Descriptive statistics such as frequency distributed count, percentages were used in analyzing the data. Likert scale was developed for measuring the constraints militating youth engagement in agribusiness related activities by asking people to respond to a series of statements about a topic, in terms of the extent to which they agree with them. Likert-type or frequency scales use fixed choice response formats and are designed to measure attitudes or opinions (McLeod, 2008). These ordinal scales measure levels of agreement/disagreement. A Likert-type scale assumes that the strength/intensity of experience is linear, i.e. on a continuum from strongly agree to strongly disagree, and makes the assumption that attitudes can be measured.

RESULTS AND DISCUSSIONS

Table 1 shows the constraints that militating against youth's engagement in Agri – business activities in the study area (i.e. Lack of interest, poor or wrong counseling towards Agri – business activities, societal norms/values and Religious purpose).

Table 1. The Constraints Militating Youths Engagement in Agribusiness Activities

Variables	Frequency	Percentage
Lack of Interest:		
SD	67	18.6
DA	33	9.2
UD	26	7.2
A	155	43.1
SA	79	21.9

Source: Field survey 2020

On "lack of interest" majority 43.1% of the respondents agree that the problem militating against youths engagement in Agri – business activities is lack of interest, 21.9% undecided, 18.6% of the respondents strongly disagree while 9.2% of the respondents disagree and also 7.2% of the respondents undecided with the statement. The finding is in consonance with those of Adekunle *et al,* (2009) identified lack of interest, as the most important factor militating youth in engaging agribusiness activities.

The "poor or wrong counseling towards Agri – business" activities, majority of the respondents (40.6%) in the study area are agreed with the statement, (22.2%) of the respondents strongly agreed, while (15.0%0 of the respondents disagreed second to the least is (14.4%0 of the respondents are undecided and (7.8%) of the respondents are strongly disagreed, that poor counseling toward Agri – business is a constraints that militating youths engagement toward Agri – business activities in the study area.

Majority of the respondents (42.8%) agreed that the "societal norms and value" is a constraints toward Agri – business activities, 19.4% of the respondents strongly agree, 17.2% of the respondents are undecided with the societal norms and values and both disagreed and strongly disagreed having the same percentage of (10.3%) of the respondents. This finding is also in line with the research conducted by Adekunle *et al.* (2009) who classified the constraints hindering, youth's to engage in Agri – business activities into economic factors, social factors and environmental factors.

"Religious purpose" of the respondents indicated the majority of the respondents (36.7%) agreed that religion have influence on what to buy and sale, 30.0% of the respondents in the study area are Strongly agreed while both undecided and disagreed have the same percentage (11.4%) of the respondents and 10.6 of the respondents strongly disagreed that religion is not constraints towards youths engagement in Agri – business activities. This research is also in line with the study conducted by Oneukwusi and Attan (2006) stated that lack of incentives, religious purpose, insufficient land, lack of infrastructure in the rural areas, inadequate training and extension sources and inadequate labour reduces rural youth's participation in agricultural activities.

RECOMMENDATIONS

Based on the findings the study recommend that all stake holders especially policy makers, religious leaders as well as the community leaders should developed training and retraining of youth with the aim of sensitization and awareness of the important of youth engagement in any legitimate agribusiness activity regardless of the position of the business at societal level. This will reduce dependency of youth waiting for lucrative job.

ACKNOWLEDGEMENT

We are very thankful to the TETfund who sponsored this work of identifying socio economic factors influencing youth engagements in Agribusiness activities, under Institutional-Based Research (IBR)

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The analysis of cost and returns on investment, and investment challenges among youth entrepreneurs involved in Orange-fleshed Sweetpotato (OFSP) vine production enterprise in North Central, Nigeria was carried out. Multistage sampling was used to select 139 youth entrepreneurs in Benue, Kwara and Nasarawa. A structured questionnaire designed for a single visit was used for data collection. Descriptive statistics was used to analyze cost and returns in OFSP vine production and double log regression determine the investment challenges among Youth entrepreneurs involved in OFSP vine production in North Central Nigeria. The result shows that OFSP vine production is a profitable venture with 74%, 76% and 66% return on investment in Benue, Kwara and Nasarawa states respectively. The regression analysis result shows that the amount of savings, access to credit, access to market, access to information, vine output price, access to land and farm experience were very significant in positively influencing investment in OFSP vine production in North Central, Nigeria. The cost of inputs and taxes were significant but negatively influencing investment challenges in OFSP vine production among youth. Policies aimed at enhancing saving habits among young people, access to credit, access to market, access to information and other measures that will enhance and sustain investment in OFSP vine production in Nigeria.

Keywords: *Investment Challenges, Youth Entrepreneurs, Orange-Fleshed, Sweetpotato Vine, Production*

INTRODUCTION

Orange-Fleshed Sweet potato (OFSP) is an improved breed of sweet potato (*Ipomea batatas* [L.] *Lam.*) cultivated in tropical and semi-tropical regions of the world for food and source of income especially among the rural dwellers (Adebisi, *et al.*, 2015; Padmaja, 2009; Mitra, 2012). Sweetpotato is one of the most important and versatile root crop in the world (Udemezue and Eluagu, 2021). Globally, sweetpotato is cultivated in eleven countries producing approximately 88.9 million metric tons (Shahbandeh, 2023). According to the Food and Agriculture Organization statistics (FAOSTAT) in 2022 reported that Nigeria is the third largest producer of sweetpotato in the world after China and Uganda with an annual production estimated at 3,867,871 tons.

In 2021, the annual export value of raw potatoes amounted to about 4.32 billion United State dollar worldwide. The export value of sweetpotato is an indication that there is a huge economic potential that present investment opportunities for young entrepreneurs. Sweetpotato health and nutritional benefits have expanded globally owing to rising popularity and demand. According to Data Bridge Market Research (2022), Sweetpotato market globally is expected to account for 50,534.33 million United States Dollar by year 2029. Some of the factors driving the market growth are awareness of sweetpotatoes' health benefits, increasing applications of sweetpotato in food and beverages, and growing consumers' awareness about the health benefits. Investment in OFSP vine is attractive because of the growing market of functional food dietary supplements, various product launches and development and government home grown school feeding programme. Therefore, promoting increased youth investment in Orange-fleshed Sweetpotato (OFSP) vine production has significant health and nutrition as well as employment generation and poverty reduction implications.

This observation aligned with the finding of Adesina *et al.* (2018) that there is low level of investment in OFSP production in spite of its huge economic potential. However, in spite of the potential benefits of youth entrepreneurship in agribusiness, there are no sufficient empirical studies on investment challenges among sweetpotato vine multipliers. Therefore, it has become imperative to investigate investment challenges affecting youth entrepreneurs in OFSP vine production. This study seeks to analyse investment challenges among young OFSP Vine multipliers in North Central Nigeria. This paper attempts to fill the knowledge gap by specifically: (i) analyse the cost and returns in OFSP vine production, and (ii) determine the investment challenges among Youth entrepreneurs involved in OFSP vine production in North Central Nigeria.

METHODOLOGY

The study was conducted in Benue, Kwara and Nasarawa states in North Central geo-political zone of Nigeria. This geo-political zone was chosen based on the intensity of orange-fleshed sweetpotato production. A multistage sampling procedure was employed in selecting the respondents in this study. The first stage involved the purposive selection of three states out of six states in the North central based on their distinct OFSP production (NRCRI, 2012). The three states were Benue, Kwara and Nasarawa. The second stage involved the purposive selection of Local Government Areas (LGAs) from the three selected states based on the intensity of OFSP production namely: Gboko, Konshisha, Kwande, Makurdi and Vandeikya in Benue while; Edu, Ifelodun, Illorin East, Irepodun and Patigi in Kwara state; and Karu, Lafia, Keffi, Nasarawa Egon and Obi in Nasarawa State. In the third stage 139 OFSP vine multipliers who were not older than 35 years were selected from the sampled local government areas based on sampling frame from the respective ADPs for the analysis of investment challenges in OFSP vine production. Data were collected with the aid of structured questionnaire. Descriptive statistics was used to achieve objective one and regression models were used to achieve objective two. Following Odoemenem *et al*. (2013) who investigated the saving and investment pattern of small-scale farmers in Benue state Nigeria, regression model was adopted for the analysis and specified as follows:

$$\ln Yi = b_0 + b_1 \ln X_1 + b_2 \ln X_2 + b_3 \ln X_3 + b_4 \ln X_4 + b_5 \ln X_5 + b_6 \ln X_6 + b_7 \ln X_7 + b_8 \ln X_8 + b_9 \ln X_9 + b_{10} \ln X_{10} + b_{11} \ln X_{11} + + e_i \quad (1)$$

Where:Yi = investment challenges proxies by OFSP vine share of farm investment (₦), X_1 = amount of savings (₦), X_2 = access to credit (1 = yes, 0 = otherwise), X_3 = access to market(1 = yes, 0 = otherwise), X_4 = inputs cost (₦),X_5 = access to market(1 = yes, 0 = otherwise), X_6 = Vine output price (₦), X_7 = access to market(1 = yes, 0 = otherwise), X_8 = farm experience (years), X_9 = risk management (high = 1, low = 0), X_{10} = taxes (high = 1, low = 0), X_{11} = Security (existence of security = 1, otherwise = 0), ln = natural logarithm, b_0 = intercept on dependent variable, $b_1 – b_{11}$ = parameters to be estimated, and e_i = error terms.

Equation (1) predicted that investment challenges will be positively affected by all the independent variables. The model linearized so as to standardize the variables

RESULTS AND DISCUSSION

The result in Table 1 shows the mean of total revenue (TR), total variable cost (TVC), gross margin (GM) and return on investment (RoI) in orange-fleshed sweetpotato vine production of the sample households. The result indicates that an average OFSP vine entrepreneur in Benue state spent an average of ₦95,116.15 on OFSP vine production. The result also reveals that the average variable cost in OFSP vine production in Nassarawa and Kwara States are ₦195,300.00 and ₦80,700.00 respectively. An average OFSP vine entrepreneur in Benue, Nassarawa and Kwara States obtained ₦166,172.31, ₦323,600.00 and ₦142,250.00 revenue respectively from OFSP vine production.

Table 1: Summary of total revenue, total cost, gross margin analysis and returns on investment in orange-fleshed Sweetpotato vine enterprise of the sample Households (n=139)

		Total Revenue (₦)		Total Variable Cost (₦)		Gross Margin ₦/ ha		Return on Investment (%)
State	N	Mean	±SD	Mean	±SD	Mean	±SD	
Benue	13	166172.31	80774.67	95116.15	43502.63	71056.15	48272.78	74
Kwara	4	142250.00	58823.89	80700.00	34996.57	61550.00	25989.93	76
Nassarawa	5	323600.00	98431.70	195300.00	82379.91	128300.00	38742.10	66

Source: Computed from updated field Survey data (2022)

The gross margin for orange-fleshed sweetpotato vine enterprise in Benue state is ₦71,056.15 per hectare. This shows that OFSP vine enterprise is a profitable venture in Benue state. The result of return on investment shows 74 percent return on investment from OFSP vine production in Benue state. This implies that one naira invested in OFSP vine production in Benue state will yield a return of seventy four (74) kobo. In Kwara state, the gross margin is ₦ 61,550.00 per hectare and return on investment is 76 percent from OFSP vine production. This implies that one naira invested in OFSP vine production in Kwara state will yield a return of seventy six (76) kobo. In Nassarawa state, the gross margins for OFSP vine enterprise is ₦128,300.00 per hectare and return on investment is 64 percent from OFSP vine production. The implication is that any one naira invested in OFSP vine production in Nassarawa state will yield a return of sixty four (64) kobo. The result of the ordinary least squares (OLS) estimates of the investment challenges among OFSP vine entrepreneurs is presented in Table 2. The double log regression model was accepted as lead equation based on its high value of R^2 adjusted and minimum standard error.

Table 2: Ordinary least square estimates of investment challenges among orange-fleshed sweetpotato vine entrepreneurs (n=139)

***Sig. At P≤0.01; **Sig. at P≤0.05; *Sig. at P≤0.10. Figures in parenthesis are t-test statistics. Accepted Model is double log regression.

Majority of the variables have positive elasticities which implies that most of the variables have positive influence on investment challenges among OFSP sweetpotato vine entrepreneurs. The coefficients of amount of savings, access credit, access market, access to information, vine output price and access to farm land are positive and statistically significant at 1 % level of probability indicating that 1 % increase in amount of savings, vine output and vine price will increase OFSP vine farm investment by 0.078 %, 0.075 %, 0.056 %, 0.011 %, 1.592 % and 2.006 % respectively. The coefficients for input prices and taxes are negative and statistically significant at 1 % level of probability. This implies that a 1 % increase inputs cost would lead to 0.013 % decrease in OFSP vine farm investment when other variables are constant. The inverse relationship between OFSP vine farm investment and variable inputs cost goes to explain the impact of escalating cost of inputs on agricultural productivity and investment. The implication is that any policy decision geared towards encouraging investment in OFSP vine production must enhance OFSP vine entrepreneurs' access to low cost inputs market.

CONCLUSION

The study analysed the profitability of OFSP vine production enterprise and investment challenges proxies as OFSP vine share of farm investment among youth entrepreneurs involved in orange-fleshed sweetpotato vine multiplication enterprise in North Central, Nigeria. It is concluded that OFSP vine production is a profitable venture with high return on investment in the study area. It is also concluded that amount of savings, access to credit, access to market, access to information, vine output price, access to land and farm experience are major challenges affecting youth entrepreneurs in investment in OFSP vine production in North Central, Nigeria. The cost of inputs and insecurity variables were significant but negative suggesting that an increase in cost of inputs and taxes will reduce amount of farm investment in OFSP vine production among youth. The policy implication is that efforts aimed at enhancing saving habits among young people, access to credit, access to market, and access to information should be encouraged. Therefore, in order to achieve sustainable youth participation in strengthening agriculture for food and nutrition security, the escalating cost of inputs and worrisome taxes should addressed to increase investment in OFSP vine production among youth in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was carried out to assess youth's participation in cassava value chain activities in Kogi State, Nigeria. A multi-stage sampling technique was used to select 172 young cassava farmers and data collected were analyzed using simple descriptive statistics and probit regression analysis. The level of value addition was measured using Net Income analysis. The result showed that Cassava value chain activities were highly participated by youth with garri (31%) and cassava flour processing (21 %) were the most involved by the youths. the Net Income analyses showed a Benefit cost ratio of garri (1.54), cassava flour (1.89) and akpu/fufu (1.34) with cassava flour being the most profitable among the value chain. The probit analysis showed that age, household size, ownership of processing equipment, amount of value added to cassava, credit access and availability of public infrastructure were the factors that influenced youth participation in cassava value chain activities. Constraints to youth participation were; Lack of technical-know-how to adopt cassava technologies and poor access to credit facilities. It was recommended that government should increase access of farmers and agricultural processor to credit facility with low interest rate and that the capacity of the youth should be developed in cassava value activities in the study area.
Keywords: *Participation, Value Chain, Activities, Youth*

INTRODUCTION
The bedrock of Nigeria economy is the Agricultural sector. It makes up about 30 percent of total GDP (NBS, 2023), in addition to the extensive employment opportunities it offers to the majority of Nigerian citizens (70 percent of the employed population) and it is seen as an activity that cuts transcends every facet of the country (Osinowo, 2012). In spite of all the agricultural interventions and policy in Nigeria, the number of food insecure households was estimated below 20% in 1986 (Babatunde *et al.*, 2015) this figure had increased to 40% in 2005 and much higher in the subsequent years (Edache, 2013; Folorunsho, 2015). This predicament stemmed from events such as deterioration in Agricultural productivity, decline in the use of agricultural technology, limited value addition to farm product and insignificant focus on youth in agriculture. This has accumulated to the incapability of the Agricultural sector in providing adequate food in quantity and quality to feed the teeming population. Value chain includes all the procedure that begins with the production of a raw commodity and ends with the consumption of the final product and this also encompasses all the value addition undertaken between these phases such as: processing, delivery, wholesaling, and retailing (Bellù, 2013)

Recent statistic reveals that Nigeria waste around 9 billion dollars annually due to inadequate post-harvest crop management. A very easy way to alleviate the increasing level of unemployment in Nigeria is to concentrate effort in value addition. International Institute of Tropical Agriculture (IITA) reported by Abubakar, (2013) specified that value addition to cassava is an easy way to change the fortunes of farmers and give them impressive opportunities that would in turn widen the country's economic growth and improve its competitiveness especially in the non-oil sector. Therefore, efforts geared toward adding value to crops, especially cassava require focus now than ever to guarantee the progress of Nigeria's agricultural sector.

Cassava has been depicted as a vital source of energy with very significant food security value similar to most cereal crops (Achinewhu, 2010). It's a special crop that helps farmers to improve their income and possesses unique qualities, which include; ability to produce tubers even at severe weather conditions; tolerance to adverse conditions like barely productive soil, low soil PH and drought; its suitability to food systems in Africa and various farming, little or no external input requirements for its production, ability to produce all year round. These special attributes single cassava out as ideal crop for the tropics (Awah, 2012).

The possibility of converting cassava to various alternative through value addition has resulted in creation of wide food recipes through processing which entails conversion of edible food into another form more receptive or more convenient to the consumer. Examples of value-added products from cassava are starch, flour, chin-chin, bread, chips, flakes, odorless fufu, doughnut, cake, biscuit and salad cream. It is granted that the value addition technology in cassava possesses huge potentiality for rising cassava consumption, varying its uses as well as enhancement of livelihoods of farm families through providing employment opportunities; small agro ventures development income and boosting resources of rural households (Alkali, 2010).

Youth is the state of being young It is a mid-time in personality development that connects the years between childhood and adulthood. The youths are the generation that inherit farming and therefore the future of food security in Nigeria. They may have their farms close to their parents' and supplement their parents' effort by participating in almost all the farm operations. Youths readily adopt technologies and are very innovative but despite their contributions to household agriculture, there exist little empirical data to back it up. Thus, an assessment on the level of youth's participation in cassava value chain activities becomes relevant. This study is significant in order to design appropriate intervention policies and redesign strategies that will involve more youth in agricultural programs. To this end, this study aims at assessing the determinants of youths' participation in cassava value chain activities in Kogi State. Specifically, the objectives of the study are to;

i. profile cassava value chain activities engage by youth in the study area
ii. identify cost and return of cassava value chain activities by youth in the study area
iii. examine level of youth involvement in cassava value chain activities in the study area.
iv. examine the determinant of youth participation in cassava value chain activities in the study area
v. identify constraint faced by youth in cassava value chain activities

MATERIAL AND METHODS

Study Area and Sampling technique

This study was conducted in Kogi State. It consists of 21 Local government Areas with two major season; rainy season and dry season. The sampling technique used for selecting respondents for this study comprised of Multi-stage, purposive and simple random sampling. The state is divided into four Agricultural zone namely; Zone A, B, C, and D respectively. In the first phase,,three (3) Zones was randomly selected (These are zone A, B, and C). In the second stage, two LGA was also randomly selected from each zone giving a total of 6 Local Government Area. Three (3) communities where also randomly selected from each Local Government Area in the third stage giving a total of eighteen (18) communities respectively for the study. Ten (10) youth respondent was randomly selected from each community, these gives a total of 180 respondents in the area.

Method of Data Collection

Primary data and Cross-sectional method was used to collect information from 180 youth's farmers in the study area. Data were sourced directly from the respondents using well-structured questionnaire complemented with interview sessions. These activities were conducted with the assistance of different professional in the survey teams which consist of well-trained enumerators and supervisors who were graduates of agriculture and other related discipline. Local language was mainly used for this interview and occasionally using English language for some respondents who seems educated which help to facilitate their understanding of the survey questions, which allows more accurate responses.

Note: 180 questionnaires was administered to the youth, however, 172 was returned and well filled.

Data analysis

The Data for this study was estimated using descriptive and inferential statistics. The specific objectives of the study were achieved with the following methods: - Objective (i), (ii), and (v) was achieved by using descriptive statistical tools such as frequency distribution, means, percentage and Likert Rating Scale Technique. Objective (iv) was estimated using Probit regression analysis and finally objective (iii) was achieved using Net Income Analysis respectively.

Probit Regression:

The use of Probit model was determined since the response dependent variable is a binary one. Dependent variable of the model comprised of a dummy variable that represents participation of youth in cassava value chain activities (y=1) which signifies that they are participating in cassava value chain activities and the alternative (y=0) when the youth are not participating in cassava value chain respectively. Identified Independent variables included for this model include; age, gender, household size, educational attainment, cassava processing experience, amount of value added, ownership of processing equipment, access to water, access to credit, access to public infrastructure respectively. The model is appropriate since it can resolve the problem of heteroscedasticity and satisfies the assumption of cumulative normal probability distribution (Gujarati, 2004).

The probit model can be specified as shown below:

$$Yi = F(Xi\beta) + \varepsilon i \qquad (1)$$

Y i = (1, if participated 0, otherwise)
where,
ε~N(0,1); β = maximum likelihood; ε = error term; X = set of independent variables included in the model.
Since estimates of the probit model provide only direction of effects, the marginal effects are usually calculated to interpret the actual change in probability of independent variables. Marginal effects = $\beta i\phi(z)$ (2)
where, βi = coefficients of the variables; ϕ(z) = cumulative normal distribution value associated with the mean dependent variable from the probit estimation.
The explanatory variable includes;
X_1 = Age (years)
X_2 = Gender (dummy; female = 1, and otherwise =0)
X_3 = Household size (number of persons)
X_4 = processing experience (years)
X_5 = Educational levels (number of years acquiring formal education)
X_6 = Ownership of processing equipment (dummy; ownership = 1, otherwise = 0)
X_7 = Amount of value added (naira)
X_8 = Credit access (naira)
X_9 = Access to water; (dummy; yes = 1; 0 otherwise)
X_{10} = Members of cooperative (dummy; members = 1; 0 otherwise)
X_{11} = availability of public infrastructure such as good road network, health facility, electricity (dummy; yes = 1 ;0 otherwise)

Net Farm Income

A budgetary technique such as Net Farm Income (NFI) was used to estimate the cost and return of youth in cassava value chain activities. It can be denoted by; -
NFI = TR – TVC – TFC
Where;
NFI = Net Farm Income (₦)
TR = total revenue (₦)
TVC = total variable cost (₦) and
TFC = total fixed cost (₦)
Note: Total revenue was realized from sales of processed cassava tuber and cassava peels which was valued at current market price. Variable cost includes for cassava value chain activities include; cost of grating cassava tubers, cost of cassava tubers, cost of firewood, cost of labour etc., while the fixed cost includes cost of depreciation of assets which include; measuring bowl, frying pan, grating machine screw Jack, knife etc

Likert Rating Scale Technique

In order to determine the level of contribution by youths in cassava value chain activities, four point likert rating scale was adopted. The 4-point scale was graded as High Contribution = 4, Moderate Contribution = 3, Low Contribution = 2 and No Contribution = 1. The level of contribution was ranked using weighted mean (X).
The mean score is 4+3+2+1 = 10/4 = 2.5 (cut-off point). Therefore, using the cutoff point value of 2.50, any item with mean value of 2.50 and above was regarded as" youth participation in cassava value chain activities" while items with mean value of less than 2.50 was regarded as no participation.
The same technique was used to identify constraint militating the youth in cassava value chain activities in the area.

RESULTS AND DISCUSSION

Forms of Cassava value addition participated by Youth

Results from Table 1 shows that majority 31 % of the youth were involved in Garri processing only, 21 % were involved in cassava flour only, 9 % Akpu/Fufu only, 10 % Garri + Flour only, 5 % Garri + Akpu/Fufu only, 11 % involved in Flour + Akpu/Fufu, 7 % in Garri + Flour + Akpu/Fufu, 6 % for Others while none of the youth was not involved in any of the cassava value chain respectively. This shows that processing of Garri and Cassava flour are the most prevalent value chain activities engaged by youths and that cassava value chain activities cut across the length and breadth of the study area.

Table 1: Forms of Cassava Value Addition

S/N	Value addition	Frequency	Percentage (%)
a	Garri Only	53	31
b	Cassava Flour Only	37	21
C	Akpu/Fufu Only	15	9
C	Garri + Flour	17	10

Cost and Return in cassava value chain

(A) Garri: The results in Table 2 show the Net Income (NI) analysis of garri processing activities engaged by the youth in the study area. In the result, the total cost (TC) of garri processing is ₦67,150 per ton with Total variable cost (TVC) of ₦65,000 per ton (96.7% of the TC) and Total Fixed Cost (TFC) of ₦2,150 per ton (3.2%) respectively. The sum of ₦100,000 was generated from the sale of garri per ton (this constituted 96.6% of the total revenue) while revenue derived from cassava peel for animal feed is ₦3,500 per ton (3.4%). Total revenue (TR) of ₦103,500 was generated per ton with a total cost (TC) of ₦67,150 respectively. This gives a Net income (NI) of ₦36,350 per ton. Benefit Cost Ratio (B/C) of garri processing is 1.54 with Return on Investment (ROI) of 54k respectively. This shows that garri processing by youth is profitable in the study area.

(B) Cassava Flour: Results from Table 2 on cassava flour processing showed that the total cost (TC) of cassava flour production is ₦63,320 per ton. Breakdown of the cost include total variable cost of ₦61,620 per ton (97.3% of the total cost of production) and total fixed (TFC) of ₦1,700 per ton (2.7%) respectively. Revenue generated from cassava flour is ₦116,300 per ton (96.9% of the total revenue) while ₦3,700 revenue was derived from cassava peel for animal feed per ton (3.1%). Total revenue (TR) generated from cassava flour is ₦120,000 per ton with a total cost of ₦63,320 per ton respectively. This give a resultant Net income of ₦56,680 per ton. The financial analysis further gives the Benefit Cost Ratio (B/C) for cassava flour processing of 1.89 and Return on Investment (ROI) of 89k respectively. This shows that cassava flour processing by youth is profitable in the study area.

(C) Akpu/Fufu: The result in Table 2 showed the Net Income analysis of Akpu/Fufu processing in the study area. Total cost of Production of Akpu/Fufu per ton is ₦68,900. The Total variable cost is ₦67,250 per ton (97.6% of the total cost of production) with total fixed cost of ₦1,650 per ton (2.4%) respectively. Revenue generated from Akpu/Fufu is ₦89,000 per ton (96.2% of the total revenue) while revenue derived from cassava peel for animal feed is ₦3,400 per ton (3.8%). Total revenue generated from Akpu/Fufu is ₦92,480 per ton with a total cost of ₦92,480 per ton respectively. This gives a profit level of ₦23,580 per ton in Akpu/Fufu. Benefit Cost Ratio (B/C) of Akpu/Fufu is 1.34 and Return on Investment (ROI) of 34k respectively. This shows that Akpu/Fufu processing by youth is profitable in the area.

Level of participation by youth in cassava value chain activities

Table 3 described the roles played by youth in cassava value chain activities in the study area.

(A) Level of participation by youth in garri processing activities

The result revealed that the level of participation of youth in garri processing activities were moderately high in 6 out of the 10 identified stages of cassava processing to garri as shown by their respective means which are more than the cut-off point value of 2.50 on 4-point rating scale. The identified stages with their corresponding mean values include: grating (3.4), fermentation (2.7), dewatering (3.2), sieving/sifting (2.9), packaging/bagging (3.3) and storing (3.0) respectively. This indicates that the roles played by youth in garri processing activities are moderately high. However, the involvement of youth was low in pelling (2.2), washing (1.7) frying/roasting (1.4) and drying (2.1) of cassava respectively.

(B) Level of participation by youth in Cassava Flour processing activities

The result showed that 8 out of 10 known stages of cassava flour processing were actively involved by the youth. This is shown by their corresponding means which are more than the cut-off point value of 2.50 on 4-point on the rating scale. This shows that cassava flour processing activities by youth were high in in the study area. The identified stages include; pelling (2.6), chopping (3.2) dewatering (3.6), drying (2.5), pounding (3.0), milling (3.2), sieving/sifting (3.0), packaging (2.9) and storing (3.1) respectively. Only few washing (1.7) and soaking/fermenting (2.3) of the activities were not participated by the youth.

(C) Level of participation by youth in Akpu/Fufu processing activities

The result in Table 3 also showed the level of involvement of youth in Akpu/fufu processing. It showed that 7 out of the 9 identified stages of cassava processing to Akpu/fufu as shown by their means which are more than or equal to the cut-off point value of 2.50 on 4-point rating scale. The identified stages and their mean values are: pelling (2.9), washing (3.1), sieving (2.8), first pounding (3.2), second pounding (2.6) respectively. This shows that the roles played by youth in Akpu/fufu processing activities are moderately high. However, the involvement of youth in soaking and/fermenting (2.1), bagging (2.4), first boiling (2.0), second boiling (1.9) and packaging (1.9) was low respectively.

Table 3: level of participation by youth in cassava value chain activities

S/N	Activities	X	SD	Remarks
(A)	**Garri processing**			
1	Pelling	2.2	0.748	Low
2	Washing	1.7	0.656	Low
3	Grating	3.4	0.980	High
4	Fermentation	2.7	0.611	High
5	Dewatering/pressing	3.2	0.307	High
6	Sieving/sifting	2.9	0.187	High
7	Frying/roasting	1.4	0.454	Low
8	Drying	2.1	0.491	Low
9	Packaging/ bagging	3.3	0.917	High
10	Storing	3.0	0.388	High
(B)	**Cassava Flour processing**			
1	Pelling	2.6	0.440	High
2	Washing	1.7	0.741	Low
3	Chopping/cutting into pieces	3.2	0.728	High
4	Soaking/fermentation	2.3	0.631	Low
5	Dewatering/pressing	3.6	0.317	High
6	Drying	2.5	0.203	High
7	Pounding	3.0	0.454	High
8	Milling	3.2	0.590	High
9	Sieving/sifting	3.0	0.514	High
10	Packaging	2.9	0.361	High
11	Storing	3.1	0.721	High
(C)	**Akpu/Fufu processing**

Determinant of youth participation in cassava value chain activities

Table 4 showed the result of the probit analysis which explained the determinants of youth's participation in cassava value chain activities in Kogi State. The result showed that the Pseudo R2 is 0.4216 which implies that about 42 percent of variations that occurs in youth participation were explained by the independent variables included in the model. However, the remaining 58 percent could be due to other externalities factors that were not included in the model by the researcher. Also, the chi–squared showed gave a statistic of 52.04 which was significant at 1% level of probability indicating the goodness of fit of the overall model over all fitness of good. The t- values shows that six variables; age, household size, ownership of processing equipment, amount of value added, credit access and availability of public infrastructure out of the eleven (11) variables included in the model six (6) were statistically significant at 1%, 5% and 10% level of probability respectively. The coefficient of age was negative and statistically significant at 10 percent level of probability, this signified that age of the respondents had inverse relationship with youths' participation in cassava value chain activities. As the youth's advance in age, the likelihood of their participation in cassava value chain activities decreases in the study area. These can be due to the fact that cassava processing activities is energy snapping enterprise which could be difficult for older people to participate as such should be reserved for young or middle aged farmers. This finding conformed with Nandi et al., (2011) where he observed that farmers within the age of 30-59 are more productive than those farmers above the age of 60 years and above.

In addition, the coefficient of Household size stands positive and statistically significant at 5 percent level of probability. As farmer's household size increases, it increases the affinity with which youth's participate in cassava value chain activities. This could be considered as common norms among rural areas where farmers keep larger household size in other to acquire family labour for farm operation and post-harvest activities.

The results further showed that ownership of processing equipment was positive and statistically significant to youth participation in cassava value chain activities. This suggest that as youth acquire and owned more processing equipment by themselves, it increases their participation in cassava value chain activities. Ownership of processing equipment by farmers increases their chances of making more money when they help in processing cassava for other processor and thus encourage them to participate more in the enterprise.

Amount of value added in cassava value chain activities was also positive and statistically significant to youth participation in cassava value chain activities. This shows that as the youth increases their profits level in cassava value chain activities, it would invariably increase their involvement in cassava value chain activities in the study area. Profits could be considered as the major motivation that enticed an entrepreneur into a business. This results suggest that the more profitable cassava value chain activities, the more time and energy that the youth would be willing to invest in cassava value chain activities in the study area.

The result further revealed that the coefficient of credits access is positive and statistically significant to youth participation in cassava value chain activities. This shows that as youth's have more access to credit facilities in the area, it would increase their participation in cassava chain activities. It was observed that Farmers Productivity, income and welfare can be enhanced when they have access to credit. Quick and timely Access to Short term credit can help farmer to alleviate the problem arising from crop failure, sickness within the family and unexpected social commitment and seasonal needs for working capital. This result is consistence with Philip, Ike, (2012) that reported that when more famers have access to credit supply to farmers, it is widely believed as an effective strategy that increased agricultural productivity. In conclusion, availability of public infrastructure in the study area is positive and statistically significant to youth's participation in cassava value chain activities. This also implied that as level of social infrastructural facilities such as electricity, pipe born water, roads and internet network increases, youth involvement in value chain activities will also increase. This could be premised on the fact that availability of these social infrastructural facilities will encourage youth to stay back in the rural community and participate in agricultural activities instead of running to urban cities in search of collar job that is almost unavailable.

Constraints by youth in cassava value chain activities

The result in table 5 shows a four point likert Rating Scale on eleven (11) variables that were used to identify relevant variables that acted as a constraint to youth participation in cassava value chain activities. The result showed that, major problems affecting youths participation in cassava value chain activities include; Lack of technical-know-how to adopt cassava technologies **(3.4),** High cost of processing inputs **(3.3),** Lack of access to credit facilities **(3.2),** Poor road network for transporting fresh and processed Products (3.2), High cost of transportation **(3.1),** Lack of capital for business expansion **(3.1),** Lack of access to market information **(2.9),** Problem of labour shortage in cassava processing activities **(2.7) and** Unstable weather condition **(2.5) respectively.** However, other issues that were not considered as major problem include; poor storage facilities and techniques (2.3) and lack of access to supporting facilities such as extension services (2.1)

Table5: constraints affecting participation of youth in cassava value chain activities

S/N	Constraints	Mean Value (X)	Decision	Ranking
1	High cost of processing inputs	3.3	Accepted	2nd
2	High cost of transportation	3.1	Accepted	5th
3	Poor storage facilities and techniques	2.3	Rejected	10th
4	Lack of access to credit facilities	3.2	Accepted	3rd
5	Poor road network for transporting fresh and processed Products	3.2	Accepted	4th
6	Lack of technical-know-how to adopt cassava technologies	3.4	Accepted	Ist
7	Unstable weather condition	2.5	Accepted	9th
8	Problem of labour shortage in cassava processing	2.7	Accepted	8th
9	Lack of capital for business expansion	3.1	Accepted	6th
10	Lack of access to supporting facilities such as extension services	2.1	Rejected	11th
11	Lack of access to market information by the youth	2.9	Accepted	7th

Source: Field survey, 2023

SUMMARY AND CONCLUSION

Based on the findings of this research work, it can therefore be concluded that major value chain activities engaged by youth in cassava vale chain activities are garri and cassava flour respectively. Similarly, cassava value chain activities participation by youth were found to be profitable and described as a high yielding venture considering the Net Income of garri, cassava flour and akpu/Fufu which was found to be very high. Also, youth participation in cassava value chain activities was moderately high. Therefore, to encourage more youth’s participation in cassava value chain activities, it is recommended that change agent should help to canvass for youth involvement in agricultural activities more especially in cassava value chain activities and also government should increase access of farmers and processor to credit facility with low interest rate (single digit interest rate). It is also suggested that the capacity of the youth should also be developed in the area of cassava value addition, this will help to reduce unemployment and increase food security in the area and Nigeria at large.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Youth's knowledge and entrepreneurial development through agriculture value chain is increasing gaining prominence as a sustainable livelihood. The study examined youth involvement in the activities of agricultural entrepreneurial development center. Define the socioeconomic characteristics of the respondents, determine the extent of skill acquisition in the chosen EDC'S Programme, and determine the level of participation in agricultural activities. Multi-stage sampling strategy was used in the selection of 240 respondents. Data collection involved using a set of questionnaires. Both descriptive and inferential statistics were applied to the data analysis. The key data showed that 49.2% of the population was between the ages of 31 and 40 with a mean age of 30 years. Over 91% had completed tertiary education, and 33.3% were married. About 33.3% of the population were female, with a male preponderance of 66.7%. Within one to two years, majority of young people (50%) had no job. About 58.3% of the population had entrepreneurial experience between 0 and 5 years; of these, 16.7% were full-time farmers and 50% worked part-time. Youth demonstrated a high level of participation in the areas of livestock production ($x = 2.77$) and crop production ($x = 3.44$) as measured by the overall mean score of 2.61 and the benchmark mean score (decision cut point) of 2.50. Majority of young people (36.7%) were involved in livestock production. Youth should be encouraged by providing various forms of financial support so they can participate in agricultural operations.
Keywords: *Assessment, youth participation, agricultural activities, agricultural entrepreneurship, development centre*

INTRODUCTION
Youth are individuals between the ages of 15 and 24 (UN, 2012). The country definition of youth starts with a lower age from as young as 7 years and some give an upper age limit as high as 39 (Onuekwusi, 2005). This group includes teenagers aged 15 to 19 and young adults aged 20 to 24. The Youth have also been identified as constituting the major Resource base for any country which wants to embark on any meaningful Agricultural and Rural Development Projects (Onuekwusi, 2005). Ugwokwe, *et al.,* (2005) also noted that Youths have been part of the overall agricultural development process in Nigeria because of the immense contribution of Agricultural to the Economy. For enhanced agricultural productivity, youths' strength and energy must be properly channeled and harnessed (Ogunbameru, 2001). For any nation that wants to start any significant agricultural and rural development projects, the youth have also been identified as representing the key resource base (Onuekwusi, 2005).
The National Unemployment Rate in Nigeria in 2016 was 68.1 percent, with youth accounting for more than 40.6 percent of those between the ages of 20 and 34 years (Nigeria Bureau of Statistics - NBS, 2016). Entrepreneurship is the ability and willingness to plan, organize, and run a business enterprise, taking on any risks necessary to do so, with the goal of turning a profit. The creation of new firms is the most obvious illustration of entrepreneurship (Adepeju, 2009). Agriculture-related entrepreneurial endeavors can significantly advance youth development and provide them influence. These initiatives help to reduce youth delinquencies and poverty by giving young people access to employment possibilities. Therefore, it is crucial to promote young people's participation in agricultural entrepreneurial activities (Ogunbameru, 2001).
Youths may find prospects for entrepreneurship in agriculture in the following sectors: crop production (including root and tuber crops), livestock production, agriculture forestry, beverage production, and agro-allied (Glynnis, 2002).

The National Research Council (NRC, 2010) estimates that 2% of the country's population lives in agricultural enterprises, but that percentage is dwindling every year as more farms are becoming urbanized. As a result, many young people have left the agricultural sector. Future leaders and government decision-makers who have an impact on agricultural enterprises are these same kids. The need for rapid development through deliberate policies on agricultural improvement and entrepreneurship skills, developing entrepreneurship spirit among Youth, and providing functional areas of business enterprises including production, marketing, personnel, and finance are just a few of the reasons why this study is thought to be timely.

This study's overarching goal was to evaluate young people's involvement in agricultural entrepreneurial development activities in South East geopolitical Zone.

METHODOLOGY

The South-East Zone of Nigeria, one of Nigeria's six geopolitical zones, is where the study was carried out. The South-Eastern region of Nigeria is made up of the following five (5) states: Abia, Anambra, Ebonyi, Enugu, and Imo. Data for this study were generated from primary sources, and Abia State represents the Centers where the program is carried out. A Proportionate Sampling technique was employed. In the first stage, GEO-EDC were purposively selected because Abia State represents the Centres through which the programme take place. The second stage involved selection of Participants in each Quarters of the programme. South-East Entrepreneurial Development Center (SEEDC), 1st quarter, 2nd quarter, and 3rd quarter. The final stage involved random selection of 20 rural youth's participants in each of the sampled EDC's centres as respondents for the study. The respondents comprises of two hundred and forty (240) end users.

RESULTS AND DISCUSSION

Socioeconomic Characteristics

Age: The South-East Entrepreneurial Development Center's data shows that 49.2% of its participants were between the ages of 31 and 40. The Youths were 30 years old on average. The conclusion is that the majority of responders (49.2%) come within the South-East EDC age group of 26 to 30 years, indicating that they are in their youth and quite productive. In confirmation of Nigeria's National Youth Development policy (2001), the Youth comprises all young persons of age 18-35, who are citizens of the Federal republic of Nigeria. This category represents the most active, the most volatile and yet vulnerable segment of the Nigeria population.

Level of Education: The outcome also reveals that more participants (91.7%) in the South-East zone of EDC had tertiary education attainment. This suggests that implementing modern agricultural technologies and innovations in the training center won't pose too much of a challenge for the trainees (ILO, 2012).

Marital status: The majority of respondents in the South-East zone were married (33.3%), and roughly (40.8) were not married. This tends to agree with the assertion of Odhiambo, (2001), youths are key players in family agricultural and social development activities

Sex: The results also indicated that men made up roughly 66.7% of participants in the South-East EDC Program, while women made up 33.3%. According to the results, more men participate in the EDC Program than women.

Major Occupation: It was also observed that 33.3% engaged in farming and trading, 17.5% took part in farming only while 15.8% hold on to trading, and 15.8% for civil servant respectively in South-east Entrepreneurial activities. This implies that trading is the most prevalent activity in the study area.

Unemployment: The South-East zone had the highest rate of youth unemployment in the study areas, at 50%, within a year to two years. The initiative was created primarily in order to clearly address the issue of rising youth unemployment and its danger to political stability, social cohesion, and the nation's economic growth.

Results indicate that, on average, a youth in the South-East Entrepreneurial Development area of the study had entrepreneurial experience ranging from 0 to 5 years, with 58.3% in that category. The outcome made it abundantly evident that the adolescents are not recent arrivals to the study area's agricultural entrepreneurial activity.

Nature of Participation: In the South-East Entrepreneurial Development Center, half of the young people interviewed (50%) were part-time farmers and (16.7%) were full-time farmers.

The Distribution of Mean Score for the Level of Participation in Agricultural Entrepreneurial Activities of South-East EDC were Presented in Table 2.

Benchmark mean score (decision cut point) was 2.50, while overall mean score was 2.61. According to the aforementioned table, 2 out of the 5 statements on determining the level of participation in agricultural entrepreneurial activities in South-East EDC had a high level of response from youngsters in South-East EDC. Particularly, the youths actively participated when the following assertions were made: Production of livestock ($\bar{x}$ = 2.77); production of crops ($\bar{x}$ = 3.44).

To determine the extent of participation in agricultural entrepreneurial activities in the South-East EDC, the youth disagreed with 3 of the 5 claims. A low degree of participation in agricultural entrepreneurship was specifically evoked for the South-east EDC by the following statements: agriculture forestry ($\bar{x}$ = 2.39); beverage production ($\bar{x}$ = 2.32); and agro allied ($\bar{x}$ = 2.15).

These results demonstrate that the majority of young people have a negative opinion regarding measuring the amount of participation in agricultural entrepreneurial activities in the South-East EDC. These suggest that young people might not comprehend the significance of agricultural entrepreneurial activities in the research area.

Table 3. The Rate of Skills Acquisition in The Selected EDC's Program for South-East.

The majority of young people in the South-East EDC's chosen skills acquisition program (36.7%) are involved in the production of livestock. The conclusion of the study is that the majority of young people in the chosen EDC were engaged in livestock production. This may be due to the lucrative nature of livestock farming, which offers returns on relatively small investments.

Table 4. Socioeconomic characteristic of Youths has no significant influence on Youth Participation in agricultural activities of EDC in the study areas, was tested using regression analysis.

According to the z-test results, youth participation in agricultural operations of EDC in the selected zones had a mean response of 2.61 while youth participation in selected socioeconomic characteristics of youths had a mean response of 2.31. The discrepancy between the mean scores for Selected Socio-Economic Characteristics of Youths and Youth Participation in Agricultural Activities of EDC in the study regions was significant ($\bar{x}$ = -8.41) at P ≤0.05. This suggests that South East EDC'S has made all the numerous activities for youth training in the program as stated mandate available to them. Additionally, it is clear from the program that the trained adolescents in the south-east EDC have not received money to the fullest extent possible, which has had a significant negative impact on their ability to participate effectively in program activities. We reject the null hypothesis that "Selected Socio-economic Characteristic of Youths has No Significant Influence on Youth Participation in Agricultural Activities of EDC in the Study Areas" and accept the alternate hypothesis that "Selected Socio-economic Characteristic of Youths has Significant Influence on Youth Participation in Agricultural Activities of EDC" because the computed z-value of -7.57 was less than the tabulated z-value at (5%) = 3.69 and at (1%) = 11. The investigation came to the conclusion that, despite receiving training, youngsters in the south-east EDC in particular have not received funding to launch any of their numerous agricultural businesses.

Source: Field survey, 2018 Tabulated value (2-tails) at 5% = 3.69 at 1% = 11.26

CONCLUSION

Since the mean age of the respondents was calculated and showed that they are in their youth and very productive, it can be stated that the majority of the respondents fell within the age range. The respondents' high level of education was evident in the fact that more men than women participated in the program's agricultural activities. The majority of young people in the study areas were unemployed for five years or longer, and most young people in the South-East EDC had zero to five years of entrepreneurial experience. It may be due to the lucrative nature of livestock and agricultural production, which offer returns on little money invested in it, that skills obtained in this sector were highly valued. Selected socioeconomic characteristics of youths have a considerable impact on youth participation in agricultural activities, according to the alternative hypothesis, which was approved. The investigation came to the conclusion that although youth in the south-east EDC receive training, money has not been given to them to launch their various agricultural businesses.

RECOMMENDATIONS.

The following recommendations where suggested:

- Given their strength and energy, unemployed youth in the South-East should be encouraged by providing loans so they can engage in agricultural enterprises.
- It is advised that EDC provide the youths with the appropriate incentives to increase their involvement in agricultural entrepreneurial activity. Facilitating land purchase for persons interested in crop production is one of these incentives.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Youth participation in agricultural activities is one of the major drivers of empowerment, job creation, income generation, and livelihood improvement through attainment of food security. The study was conducted to determine youth participation in cassava production under FGN/IFAD-VCDPin Nasarawa State, Nigeria. A multi-stage random sampling procedure was used in selecting 180 respondents for this study. A structured questionnaire was used to collect data from the respondents in the study area. Data were analyzed using both descriptive and inferential statistics. The variables of years of farming experience (t = 3. 329) and level of education (t = 2.057) were the socio-economic variables influencing youths participation in the programme in the study area. The challenges faced by respondents include weak distribution of inputs on time (80.0%), difficulty in raising funds for matching grant (69.2%) and inadequate inputs (60.0%). It was recommended that the programme and all other programmes including relevant institutions' should distribute inputs to youths at the right time, place, and quantity for timely agricultural production in the study area and youth farmers on the other hand should form cooperative groups and pool their resources together for easy access to funds for matching grant.
***Key words:** Determinants, participation, cassava production, rural youth, value change development programme*

INTRODUCTION
The Value Chain Development Programme (VCDP) was a six-year programme of the Federal Government of Nigeria funded by the International Fund for Agricultural Development (IFAD). The programme aims to improve income and food security of poor rural households engaged in production, processing and marketing of rice and cassava on a sustainable basis. VCDP was originally implemented in six states of Anambra, Benue, Ebonyi, Ogun, Niger and Taraba. Because of the programme success, VCDP received additional finance in 2021 for expansion into three states of Kogi, Nasarawa and Enugu making nine participating states (Sallawu *et al.*, 2019) .The goal of the programme is to reduce rural poverty, increase food security and accelerate economic growth on a sustainable basis (Sallawu *et al.*, 2019). In Nasarawa State, five (5) Local Government Areas of Lafia, Doma, Wamba, Karu and Nasarawa were selected for the implementation of the programme in 2021.
Cassava (*Manihot esculenta*) is a starchy root crop and a major source of food security in Africa because of its ability to grow in low quality soil, its resistance to drought and disease, and flexible cultivation cycle (Jirgi *et al.*, 2019). Cassava, which is rich in starch in the form of carbohydrate, has multiple uses. It is consumed in many processed forms, in the industry and as livestock feed (Oruonye *et al.*, 2021). Cassava production in Nigeria plays a crucial role in the country's agricultural sector and economy. Nigeria is the world's largest producer of cassava, with the crop serving as a vital staple food for millions of people (Oruonye *et al.*, 2021).
Youth in Nigeria are identified as all young males and females within the age bracket of 18-35 years, who are citizens of the Federal Republic of Nigeria (Nigerian National Youth Policy (NNYP), 2019). The definition by NNYP (2019) was adopted for this study. Participation is the act of working with others, making value judgments and determining causes of actions within a social situation or structure (Isa *et al.*, 2021).

This study holds considerable significance for various stakeholders, including policymakers, agricultural development agencies, and the youth population in Nasarawa State, Nigeria. By assessing youth participation in cassava production within the framework of IFAD-VCDP programmes, the findings of this research will provide a deeper understanding of the current dynamics and challenges faced by young individuals engaging in cassava production. The outcomes will aid policymakers and program implementers in designing more targeted strategies to increase youth involvement in the cassava value chain.

Problem statement

Youths' participation in cassava production can serve as a means of employment, source of income, provide food security for their families and reduce their poverty level. Youths are constrained in participating in agricultural activities by a host of challenges including limited access to productive assets and inputs; inadequate support services (extension); limited access to rural financial services; inadequate market and rural infrastructure; post-harvest losses and a constrained enabling environment (NBS, 2018). IFAD-VCDP in Nigeria deals in value chain activities of cassava and rice enterprises on a sustainable basis, which provides participants with inputs, capital supports, and adequate support services such as extension services, and adequate market for cassava and rice products. It is in recognition of the noble goals of the programme that the study assessed the determinants of youth participation in cassava production within the context of the IFAD-Value Chain Development Programme (VCDP) initiatives in Nasarawa State, Nigeria.

Objectives of the Study

The broad objective of the study was to determine youth participation in cassava production under FGN/IFAD-VCDP in Nasarawa State, Nigeria.

The specific objectives are to:

i. describe the socio-economic characteristics of the youths cassava farmers participating in VCDP in the study area;
ii. determine the effect of the socio-economic characteristics of youth cassava farmers' participation in the VCDP, and;
iii. identify the constraints to effective participation of youths cassava production in the VCDP in the study area.

METHODOLOGY

Study Area

The study was conducted in Nasarawa State, Nigeria. Nasarawa state is located within latitude: 7° and 9^0 N and longitude of 8^0 and 32^0 E. The state has a land mass of about 27,117km^2 (Wikipedia, 2022). The population of the study comprised all the 378 (Lafia 86, Doma 75, Wamba 68, Nasarawa 74 and Karu 75) registered youths participating in IFAD-VCDP cassava production in Nasarawa State. A multi-stage sampling technique was used to select respondents from the population for the study. In the first stage, a random selection of three (3) out of the five (5) participating LGAs in the state. The selected LGAs include: Lafia, Doma and Karu. In second stage, a purposive selection of 3 cassava enterprise communities known for participating in IFAD-VCDP in each of the three (3) LGAs selected. This gave 9 cassava enterprise communities that were used for the study. In stage three, a random selection of 50 percent of youths from the total youth population in each of the selected communities and this gave 116 youths that were used for the study. The data was obtained by the use of structured questionnaire administered to the respondents. Descriptive statistics such as percentage, frequency, mean and ranking order was used to analyze objectives 1 and 3. Multiple regression model was used to capture objective 2.

RESULTS AND DISCUSSION

Socio-economic Characteristics of Respondents in the Study Area

Sex: Table 1 shows the results of sex of respondents in the study area. Majority (86.2%) of the respondents were male while, 13.8% of the respondents were female. This implies that majority of the youth cassava farmers in the study area who participated in IFAD-VCDP were male. The high percentage of male youth cassava farmers maybe due to the fact that cassava production activities are generally strenuous and women may not be fit enough to carry out the operations hence the high gender disparity.

Level of Education: The results in Table1 reveals that 40.5% of the respondents had tertiary education, 20.7% and 16.4% of the respondents had secondary education and primary education respectively, while 22.4% of the respondents had no formal education. This implies that 75.0% of the youth cassava farmers had one form of education or another. The level of education attainment enables farmers to understand better the techniques involve in cassava production and adoption of improved cassava production technologies.

Farming Experience of the Respondents: The results in Table 1 also shows that marginal above half (51.7%) of the respondents had between 1 and 10 years of rice farming experience, while 26.7% had experience of between 11 and 20 years. Similarly, 21.6% of the respondents had experiences of 21years and above in cassava farming. The average cassava farming experience was computed at 15 years. This implies that youth cassava farmers participating in IFAD-VCDP were experience in cassava production in the study area. The years of experience provides the ability to understand production and to try other improved technologies while still ensuring the profitability of the enterprise.

Annual Income from Cassava Production of Respondents: Table 1 further shows that majority (88.8%) of the respondents had annual income of between ₦1,000 and ₦500,000, 7.8% had annual income of between ₦501,000 and ₦1,000,000; and 3.4% of the respondents had annual income of ₦1,001,000 and above. The mean annual cassava income of respondents in the study area was estimated at ₦313, 016. 67. This implies that youth cassava farmers earn low income annually in the study area. This would definitely drive poor households not to save more and therefore they require financial capacity to invest in technology adoption for improved production.

Table 1 Socio-economic Characteristics of Respondents in the Study Area

Variables	Frequency	Percentage	Mean
Sex			
Male	100	86.2	
Female	16	13.8	
Level of education			
No formal education	26	22.4	
Primary education	19	16.4	
Secondary education	24	20.7	
Tertiary education	47	40.5	
Years of farming experience (in years)			
1-10	60	51.7	**15 years**
11-20	31	26.7	
21 and above	25	21.6	
Annual income from cassava production (naira)			
1,000-500,000	103		**₦313,016.67**
501,000-1,000,000	9	88.8	
1,001,000 and above	4	7.8	
		3.4

Determinants Effects of Socio-economic Variables Influencing Youths' Participation in Cassava Production under IFAD-VCDP in the Study Area

The result of the regression analysis as presented in Table 2 shows that the coefficient of determination (R^2) was 0. 365. This implies that 36.5% of the independent variables influenced the dependent variable. The variables of years of cassava production experience (t = 2. 329), and farm size (t = 2.057) exhibited positively significant relationship.

Years of Cassava Production Experience: The variable of years of cassava production experience was positive and significant at 5%. This implies that increase in years of cassava production experience in IFAD-VCDP will increase the probability of more participation by youth cassava farmers in the study area. This also implies that the more experience youth cassava farmers acquire in cassava production, the more the increase in knowledge, confidence and perfection level.

Farm Size

The coefficient of farm size was found to be positive and statistically significant at 5% level of significance. This means that as the farm size increases, the probability of cassava production under IFAD-VCDP will increase. Farm size has bearing on the capacity of farmers to possibly look for and adopt improved technologies and new farm practices and likely to devote more of their farmland for cassava production under IFAD-VCDP if they and sees they appreciate the volume of output/yield, returns, profitability, and availability of market.

Table 2: Determinants Effects of Socio-economic Variables Influencing Youths' Participation in Cassava Production under IFAD-VCDP in the Study Area

Variable	β- value	Standard error	t-value
Constant	1.424	.173	8.137
Age	21.999	35.447	.621
Level of education	-6.233	34.544	-.180
Years of experience in cassava production	.010	.004	2.329**
Farm size	202.853	98.633	2.057**
Household size	35.890	63.451	.566
Annual income	-3.569	24.850	-.144
Sex	-58.643	655.548	.304
Marital status	217.638	715.723	

Source: Field survey, 2023 ** = significant at 5% level of significance

Note: R^2 .365 (36.5%)

Dependent variable = Yield (kg/ha)

Challenges Faced by Respondents in the Study Area

Challenges faced by the youth cassava farmers are captured in Table 3 and it revealed that the respondents were faced with a number of challenges in the study area. These challenges include weak distribution of inputs on time, and space (80.0%), difficulty in raising funds for matching grant (69.2%), inadequate inputs (60.0%), inadequate equipment (27.5%), and tedious nature of some agronomic practices (15.0%). This shows that youth cassava farmers in the study area had challenges in terms of weak of distribution of inputs on time and space, difficulty in raising funds for matching grant and inadequate inputs in cassava production under IFAD-VCDP and may tend to discourage participation and expansion.

Table 3: Challenges Faced by Respondents in the Study Area

Challenge	Frequency	Percentage
Weak distribution of inputs on time and space	96	80.0
Difficulty in raising funds for matching grant	83	69.2
Inadequate inputs	72	60.0
Inadequate equipment	33	27.5
Tedious nature of some agronomic practices	18	15.0

Source: Field survey, 2023

Note: Less 40% = not serious challenge, 40%-69% = serious challenge, 70% above = very serious challenge

CONCLUSION

Based on the findings of the study, it can be concluded that years of cassava production experience and farm size were the socio-economic variables influencing youths' participation in cassava production under IFAD-VCDP in the study area. Weak distribution of inputs on time and space, difficulty in raising funds for matching grant, and inadequate inputs were some of the challenges faced by respondents in the study area.

RECOMMENDATIONS

Based on the findings of this study, it was recommended that;

i. IFAD-VCDP should distribute inputs to youth cassava farmers at the right time and space for timely cassava production in the study area.

ii. Youth cassava farmers should form cooperative groups and pool their resources together for easy access to funds for matching grant.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study assessed rural youth's challenges within cassava value chain in Ebonyi state, Nigeria. Multi stage sampling technique was employed to sample and collect primary data from 120 respondents. Instrument used for data collection was structured interview schedule and Focus group discussion in twelve communities of the four LGAs selected for the study. Descriptive statistics such as percentage and mean scores were used for data analysis. The FGD was analyzed by transcribing responses of the discussants. The study revealed that the average age of the respondents was 31.6 years). They had average household size of 5 persons. They had average farming experience of 11 years. The Youth participated in most of the cassava value chain activities and they also encountered many challenges ranging from inadequate finance for cassava production, high cost farm labour, high cost of processing equipment, land tenure problem and inadequate and expensive transportation of products to the market as well as poor access to market information. It was recommended that credit facilities/loan should be provided to young farmers to enable purchase of farm inputs as well as processing equipment to add value to cassava value chain activities. There is also need for market information to enable off-takers come and purchase cassava in bulk which will benefit the farmers and reduce youth challenges in cassava value chain.

INTRODUCTION
Agriculture is a big industry that ought to attract a lot of young people, but due to the primitive methods employed in the field, most people see it as a job for the elderly, retirees and the aged in society (Attamah *et al*., 2023 & Bello *et al.,* 2021). For the majority of rural residents, agriculture is a source of employment and income. According to Osondu *et al*. (2023), in terms of area planted and total number of farmers engaged in its production, cassava (*Manihot* species) is the most well-liked and widely cultivated crop in Nigeria. Cassava is produced in Nigeria annually in excess of 54 million metric tons (MT) (FAOSTAT, 2021). The majority of the youngsters' activities are within the cassava value chain. Many people are directing the various branches of the government with little to no regard for the needs of the young. The youth are the group most impacted by these difficulties, and despite all the progress, this has caused great anxiety because it could have a negative impact on Nigeria's future. According to Oviawe (2010), continuous poverty, which is primarily observed among young people, is unquestionably the cause of the rising rates of crime, including armed robbery, advance fee fraud (419), corruption, prostitution, nepotism, drug trafficking, and other social vices.
Some scholars describe youth as the time in a person's life that occurs between the end of childhood and the beginning of adulthood. The person has reached adulthood, but he has not yet attained all of the responsibilities and rights that come with being an adult, such as getting married and providing for one's family and oneself (Onuekwusi, 2005). According to the United Nations definition, youth are defined as people under the age of 39 and beginning at 15 years old.
Nigeria is equipped with abundant natural and human resources, which can inspire young people to make significant contributions to agriculture and the growth of the country, particularly in the production of cassava. The youth currently make up roughly 60% of Nigeria's population and have significantly aided in national development over time (Vision 2010 report, 2005). To stimulate the interest of our youth in agricultural production, the government must put in place specific measures that will eliminate the associated constraints in the sector. Unfortunately, the current environment makes it even more difficult to explore their full potential in the industry. Youth participation in agricultural production has declined recently, particularly in rural regions (Koledoye and Olagunju, 2017).

Despite the rapidly expanding chances in this field, it is disturbing and pretty astounding to witness how many young people in rural areas are choosing to leave farming in favor of cities where there are no available white-collar employment, resulting in an unprecedented amount of rural-urban migration. Clearly, this poses a serious threat to the government's goal of achieving food security. Since they make up a larger portion of the workforce in agricultural production, youths play a significant role in agricultural growth, which merges with rural development (Odakara, 2005). However, they face several difficulties along the cassava value chain. According to Njoku (1999), these include the labor-intensive nature of agriculture due to the dependence on hand tools; investment practices in developing countries that typically discriminate against agriculture; the backwardness of the rural areas where farming activities predominate; and the lack of social amenities like electricity, good roads, pipe-borne water, transportation, schools, markets, hospitals, and communication facilities. The drab and boring way of life in rural areas that is linked to agriculture and, by extension, the cassava value chain presents a challenge for young people who are socially and fashionably minded.

Any nation that is devoted to sustainable agricultural and rural development policies may draw heavily on its youth population. Youths are heavily involved in all aspects of the cassava value chain in Ebonyi State, from land preparation to harvesting and processing to sale of both raw roots and finished cassava products. They deal with numerous well-known difficulties as well. However, it appears that there is a knowledge gap regarding the severity of the difficulties they face, which made the current study necessary. Therefore, the purpose of this study was to assess the difficulties faced by rural young people in rural areas in Ebonyi State's cassava value chain.

METHODOLOGY

This study was conducted in Ebonyi state. Multistage sampling technique was employed for the study. Two out of the three agricultural zones of Ebonyi state were used for the study, Ebonyi north and Ebonyi central. Two (2) Local Government Areas each in the two (2) Agricultural zones of the study area were selected to give a total of four LGAs selected. They are Ohaukwu and Izzi LGAs for Ebonyi North while for Ebonyi Central, Ishielu and Ezza north LGAs were selected. In the selected Local Government Areas, three (3) communities were purposively selected.The communities include: For Ohaukwu LGA, Ngbo, Ezzamgbo and Effium communities were selected, for Izzi LGA, Ndieze, Agbaja and Igbagu communities were selected,For Ishielu LGA, Nkalaha, Obeagu and Umuhuali communities were selected while for Ezza north LGA, Oshiegbe, Ndiaguazu and Umuogharu were selected.

Twelve (12) Communities were therefore selected to represent four (4) Local Government Areas in the two (2) agricultural zones selected for the study. Ten (10) youths from each community were systematically selected in twelve (12) communities giving a total of one hundred and twenty (120) respondents for the study. One focus group discussion was carried out in each of the LGAs selected for the study. Data was collected with the use of interview schedule and Focus group discussion. Analysis was done using descriptive statistics. FGD was analyzed by transcribing responses of the discussants.

RESULTS AND DISCUSSION

The results in Table 1 show the socio-economic characteristics of the respondents in the study area. From the data obtained majority (59.3%) of the respondents were males while 40.7% were females. This implies that gender distribution among youth farmers in Ebonyi State was dominated by males in cassava value chain. The study also revealed that 50% of the respondents were within the age range of 31-40 years while the average age was 31years. This implies that youth were actively engaged in activities of cassava value chain in the study area. The results also show that majority (59.3%) of the respondents were married, with average household size of 5 persons that encourages alternative source of labour *in-lieu* of hired labour. Educational status of respondents indicated that the respondents had varying levels of education were majority (91.5%) had formal education. This implies that majority of them were literate with average farming experience of eleven 11 years.

Respondents' annual income distribution indicated that their average annual income was ₦270,000.The implication of this result is that majority (84.7%) of the respondents earned between ₦200,000-₦400,000 annually which still indicated that they were low income earners.

Table 2 shows that inadequate finance for cassava production with a mean of (M=3.83) was the major challenge confronting the respondents. This is a big problem because finance is important to enhance access to farm inputs. Similarly, respondents identified high cost of farm labour and high cost of processing equipment as 2nd and 3rd challenges to cassava value chain with means of (M= 3.77) and (M= 3.72) respectively. With the rising cost of farm labour, rural farmers can hardly sustain their farming system. As a result of this, many famers use their family members mostly in activities like planting, fertilizer application and harvesting while the strenuous job will be done by hired labourers. This result is in conformity with the works of Churchill and Marisetty (2020) who discovered that capital is one of the major drivers of productive ventures globally. Land tenure system problem with mean (3.71) ranked 4th. Land tenure system in the study area was mainly by inheritance, it can be leased, individual owned or communally owned in the study area. Some land according to the respondents are mostly located in thick forest that is not developed then making it inaccessible, also some parents have sold off their land because of hardship or lost it on the process of using it as collateral for bank loan. Inadequate and expensive transport of products to the market with mean 3.65 and inadequate marketing information for products with mean 3.60 ranked 5th and 6th. constraints confronting youths in cassava value chain. Young rural farmers in Ebonyi state face additional constraints in accessing markets, market information can all facilitate youth's access to markets, with niche markets offering particularly significant opportunities for young farmers. Major marketing challenges that were common across communities included low prices for cassava produce on the market, lack of decent markets, and lack of adequate transport, including bad roads and accessibility. This position was supported by an FGD (2022).

A 22-year-old male farmer with the ambition to become a large-scale cassava farmer summarizes the marketing problem facing his community Nkalaha in Ishielu Local Government Area:

Firstly, we face the problem of transporting our farm produce from our villages here to the relevant destination (market locations). That is to say, the problem of the lack of road is the major problem. For instance, last year, I planted cassava and harvested, but sometimes what remained a problem was transporting it to the market. And secondly, the price in the market is too cheap considering the expenses involved from the beginning to the end of the season." Low and unstable produce prices, as well as challenges in finding buyers were the most mentioned marketing issues across communities in the Ebonyi state (FGD,2022)

In a similar response, a 24 year old female respondent in Agbaja community of Izzi Local Government Area stated thus:

Lack of market demand of what we have been able to produce" is a major challenge for a young man in Ndieze. Women in the Igbagu FGD believed the issue is that "there is no fixed price for commodities in this community." Another woman in umuoghara community in Ezza North Local Government Area believes that the problem is oversupply of their crops in accessible markets, forcing farmers to sell at cheaper rates. This is especially problematic with mobility restrictions (FGD, 2022).

A 27- year old female farmer with secondary school education in Ngbo community of Ohaukwu Local Government Area who finds it difficult to sell her produce notes:

We don't have buyers or markets for our farm produce. Sometimes you will do your farming activities, but you won't find the person who will buy the farm produce even if you carry it to the market." We lack off-takers who can buy our cassava in bulk (FGD, 2022).

Decline in soil fertility with mean 2.78 ranked 7th as one of the challenges confronting youth in cassava value chain activities in the study area. Respondents reported that when a piece of land is used for a long time without any form of soil fertility amendment practice like application of poultry manure, rice mill waste, animal dungs and compost manure, the nutrient in the soil will deplete thereby affecting the productivity of the crops. Also pest and diseases with mean 2.69 ranked 8th as another constraints to cassava value chain in the study area.

Lastly was inadequate extension visit with mean (2.18) ranked 10th this challenge is not seen as a major challenge in the study area because the youths are highly involved in all the activities involved in cassava value chain and do not place much value on the visit of extension personnel or agency.

CONCLUSION AND RECOMMENDATIONS

The study concluded that youth were involved in all activities along the cassava value chain in the study area. They also faced many challenges. Most especially inadequate finance for cassava production and high labour cost, high cost of processing equipment and land tenure system problem. All these problem areas must be looked into in order to encourage greater participation of youth in cassava value chain in the study area. There is need for provision of credit facilities/loan to enable farmers purchase inputs and processing equipment to add value to cassava There is also need for market information to enable farmers know where the demand is high to be able to sell their produce on time.

Table I: Socio-economic characteristics of the respondents

Variable	Frequency N= 118	Percentages (100)	Mean

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Micro-nutrients especially vitamin A, Iron and Zinc are essential to the healthy well being of man and animals. However, most staple food crops like sweet potato are low in these essential nutrients. Base on this, a trial was conducted at the western experimental field of National Root Crops Research Institute, Umudike Umuahia, Abia State with the aim to generate botanical seeds for evaluation for high micro-nutrient density progenies, to increase the genetic base of sweet potato genotypes enabling screening for high micro-nutrient density progenies and to select seeds with heavy weight which will ensure good germination during evaluation for micronutrient density progenies. The ten parents were planted 30cm within row and 100cm between rows in a plot size measuring 3m x 3m in an RCBD design with 3 replications. Data collected were on total number of capsules harvested, total number of seeds harvested, total number of good seeds, percentage number of the good seeds extracted, weight of 100 seeds per parent. Data collected were subjected to Analysis of Variance and means were separated using Standard error (SE±)). Results obtained indicated that 3638 healthy botanical seeds were generated for progeny evaluation and selection for micro-nutrient dense genotypes. The seeds realized will increased the sweet potato genetic base for screening for high nutrient dense progenies. Seeds with heavy weights should be considered for next generation seedling evaluation for micro-nutrient dense progenies. The varieties with heavy seed weight were NRSP/AYT/19/805, NRSP/AYT/19/420 and NRSP/AYT/19/603 with weight 769g, 648g and 550g, respectively These three parents could be included in future generation advance for micro-nutrient dense progenies.

Keyword: *Sweet potato, micronutrients, seed weight, botanical seeds and progeny.*

INTRODUCTION

Sweet potato (*Ipomoea batatas* L.) is well known as nutritious food. It is cultivated as annual crop due to its capacity to produce storage root at a shorter period of 3.5 to 4 months unlike cassava a root crop and yam a tuber crop that matures in 10 and 7 months respectively depending on the variety. Sweet potato is a rich source of proteins, minerals and vitamins for human nutrition. Sweet potato foliage and roots are also a valued animal feed. Today, sweet potato is an important food eaten with rice and other food products, used in making bread, doughnuts, cakes and juice. In fact the crop plays an important role in human and animal health improvement. Sweet potato is grown in every part of the country with a particular concentration in the northern part of the country due to its short growing period of 4 months using the available short season rainfall in that area. Currently, there has been renewed interest at national and international levels to enhance the nutrient content in our foods. One of the approach is to develop nutrient-dense cultivars in our staple foods. In this endeavour, the first step is to characterize the genetic diversity for nutrient content that exists in current cultivars and genotypes, and use the information in breeding for high micro-nutrient genotypes. ICARDA (2007) reported a preliminary screening of 645 maize accessions comprised of breeding lines, land-races and released cultivars with iron (Fe) content varied from 41 to 132 mg/ kg and zinc (Zn) content ranged from 22 to 78 mg/kg, which suggest scope of improvement of these traits through plant breeding. The most commonly grown improved sweet potato cultivars are also being crossed with micronutrient-dense accessions to enrich the progenies with higher micronutrients. The high content sweet potato lines are being crossed to develop transgressive segregants with even higher contents of micronutrients. For example, parents with an Fe content of 60 mg/kg are being used to develop progenies with an Fe content of >60 mg/kg. Similarly, high Zn content accessions are included in a crossing block to develop progenies high in Zn. Nutrient-dense sweet potato varieties could provide marketing opportunities for producers, baby food industrialists and others thereby increasing sales. An additional benefit to farmers is that under some soil conditions (e.g. low mineral availability), nutrient-dense cultivars have the potential to improve seedling establishment and resistance to certain diseases (ICARDA, 2007). Due to the escalating costs to purchase micro-nutrient capsules from Pharmaceutical shops, and an increasingly nutritious conscious consumer society, has collectively given a brighter future for a highly nutritious food produced by hybridization without fear of intragenic. The new progenies realized from crosses are predicted to have high micro-nutrients and could be adapted to the farming systems of the people for sustainability (ICARDA, 2007). Adequate variability for many of the sweet potato genetic constraints exists within the crop gene pool allowing manipulation through breeding. However, several other important traits such as biomass yield, resistant to sweet potato virus disease (SPVD), micronutrients are not currently addressable by breeding because of insufficient genetic variation for such traits. Within an agro-ecological zone, traits may provide benefits for adaptation over large areas such as with water stress in some soils. Flowering time in sweet potato is important for adaptation as it determines the length of the vegetative phase and determines the climatic conditions that the crop will be exposed to during reproductive growth. Sweet potato genotypes that adapted to rainy season flower late and produce few capsules than during dry season because reproductive development begins when conditions are increasingly hot and dry.

According to Wera et al (2014). Correlations between traits must be given careful consideration during crossing block establishment. This is because number of capsules per plant, number of seeds per capsule, secondary lateral branches per plant and vine length have significant positive correlation with number of botanical seeds produced by the sweet potato plant. However, number of capsules to reach maturity are the most important characters that contribute positively to botanical seed yield. Early maturing sweet potato parent plants having early growth vigour and a greater number of capsules should be selected for short season environments, as they will be able to escape terminal dry season stresses. Semi-spreading cultivars such as UMUSPO/1 and TIS8164 are grown under normal but late sown situations, have stable botanical seed yields because the plants are able to fill the available space by initiating lateral branches and compensating for poor emergence if any. Early flowering combined with early growth, vigour and early maturity leads to, large seeds which are some of the desirable attributes of a plant (Ratna et al, 2019), for crops under late sown conditions. In sweet potato, it is easy to create genetic variation via hybridization because this species is generally self-incompatible, so seeds do not develop from self-fertilization. The choice for parents was focused mainly on flowering ability, storage root flesh colour, and storage root yield. All flesh colours as well as genotypes with high, and low yield were planted as parents. In this study recurrent mass selection in an open pollinated block was used with the following objectives: to generate botanical seeds for evaluation for high micro-nutrient density progenies, to increase the genetic base of sweet potato genotypes enabling screening for selection for high micro-nutrient density progenies and to select seeds with heavy weight which will ensure good germination during evaluation for micronutrient density progenies.

MATERIALS AND METHODS

The trial was conducted at the western experimental field of National Root Crops Research Institute, Umudike Umuahia, Abia State in the rainforest agro-ecology of Southeastern Nigeria. The site for the experiment was a hydromorphic soil which was slashed, ploughed, harrowed and ridged. The area was then divided into plots and the plots were grouped into blocks. The 8 parents were recurrent selection which comprised current breeding lines at AYT (Advance Yield Trial stage) and two released varieties (UMUSPO/3, and TIS8164) were also included as parents totaled ten parents and were planted on the crest of the ridges 30cm within row and 100cm between rows in a plot size measuring 3m x 3m and replicated three times which gave a total of 30 plots which was fitted in the Randomized Complete Block Design (RCBD) with 3 replications. The trial was established in 15th of September 2022. Sweet potato is grown in Nigeria as a rainy season crop and mostly under rain fed conditions in areas where scanty rainfall is frequently observed. However, the crop is planted in September to experience terminal drought. This will force the sweet potato (to maturity through flower production.

The plots were not staked. The crop were allowed to spread on the soil surface to act as live mulch to conserve soil moisture because of the nature of the soil which is a hydromorphic soil. The whole plots were kept weed free throughout the trial. The parents were subjected to polycross for generating open-pollinated seeds under natural setting (Degrass, 2003). The dried capsules when turned brown while on the parents were regularly harvested, sun dried for at least one week, then, threshed, packed in well labeled envelope and stored in a glass container. All seeds collected from each of the parents were packed in a well labeled envelope.

No fertilizer was applied to prevent the crop from growing too luxuriantly and delay flowering. The following data were collected: total number of capsules harvested per parent, total number of seeds harvested per parent, total number of good seeds, percentage number of the good seeds extracted, weight of 100 seeds per parent.

Data collected were subjected to Analysis of Variance and means were separated using Standard error of difference (S.E.D).

RESULTS AND DISCUSSION

The major characteristics of parents used in the crossing block are presented in Table 1.

Table 1: Sweet potato Used as Parents in the Crossing Block and their major traits

Name	Origin	Status	Flowering habit	Skin colour	Flesh colour
NRSP/AYT/19/420	Nigeria	Breeding lines	Moderate	Red	White
NRSP/AYT/19/490	Nigeria	breeding lines	Sparse	White	Cream
NRSP/AYT/19/851	Nigeria	breeding lines	Profuse	purple	Deep orange
NRSP/AYT/19/603	Nigeria	breeding lines	Sparse	White	White
NRSP/AYT/19/805	Nigeria	breeding lines	Profuse	Orange	Dark orange
NRSP/AYT/19/852	Nigeria	breeding line	Sparse	purple	Pale orange
NRSP/AYT/19/6O1	Nigeria	breeding line	Profuse	Cream	Pale orange
NRSP/AYT/19/5211	Nigeria	breeding lines	profuse	pink	orange
TIS8164	Nigeria	released	Profuse	Cream	Pale orange
UMUSPO/3	Nigeria	Released	profuse	brown	deep orange

Three of the parents were of cream/white fleshed colour while seven of the parents were of pale orange, orange and deep orange.

Table 2: Results of the number of capsules and botanical seeds

Parents	Total number of capsules	Total number of seeds collected per parent	Number of good seeds collected per parent	% Good seeds collected	Number of bad seeds	Weight of 100 seeds per Parent (g)
NRSP/AYT/19/420	401	618	512	14.1	106	648
NRSP/AYT/19/490	223	512	482	13.2	30	191
NRSP/AYT/19/851	131	342	214	5.9	128	261
NRSP/AYT/19/603	269	431	328	9.0	103	550
NRSP/AYT/19/805	113	226	206	5.7	20	769
NRSP/AYT/19/852	431	532	492	13.5	40	344
NRSP/AYT/19/6O1	211	338	301	8.3	37	266
NRSP/AYT/19/5211	151	387	322	8.9	65	244
TIS8164	221	434	368	10.1	66	309
UMUSPO/3	262	473	413	11.4	60	309
Total	**2413**	**4293**	**3638**	**100**	**655**	**3891**
Mean	**241.3**	**429.3**	**363.8**	**10.0**	**65.5**	**389.1**
Range	113-431	226-532	206-512	=	=	=???
SED	16.4	21.8	=	=	=	=???
Sig. level	P<0.01	P<0.01	=	=	=	=???

Total number of capsules collected: The total number of capsules collected was 2413 with mean of 241.3. The number of capsules produced by the parents varied significantly ($P<0.01$) from 113 (NRSP/AYT/19/805) to as high as 431 (NRSP/AYT/19/852. Number of seeds per capsules varied from one to four. However, more number of seeds are obtained per capsules when parents are allowed to inter-mate under natural conditions. That is when pollinating agents such as insects are allowed to do the pollination. This is because in search for nectar, insects constantly visited a flower and in that process more pollen are deposited on the stigma resulting into many seeds per capsules. Capsules obtained under controlled crosses do not contain as many seeds per capsules. Parents with more number of capsules showed that it flowered profusely and will produce large quantity of seeds.

Total number of seeds: The total number of botanical seeds produced by the sweet potato plants was 4293 with mean of 429.3 seeds. The number of seeds produced by the parents varied significantly ($P<0.01$) from 226 for NRSP/AYT/19/805 to as large as 512 as produced by NRSP/AYT/19/852. The parent with the highest number of seeds was NRSP/AYT/19/420 with 612 seeds followed by the parent NRSP/AYT/19/490 with 512 seeds. While the least seed production was from the parent NRSP/AYT/19/805 with 226 seeds of the total number of seeds produced. Parent with high number of seed production indicated that it could be constituted in the breeding block for progeny production. However, number of seeds produced depended on the number of good quality seeds. Most Sweet potato seeds are susceptible to pest injury and unfilled as a result of other mechanical and genetic problems.

Number of good seeds: Number of good seeds generated was 3638 with mean of 363.8 which was 10% of the total number of seeds produced by the parents. Number of sorted good botanical seeds ranged from 206 to 512 seeds. However, the parent with the highest number of healthy botanical seeds was NRSP/AYT/19/420 with 512 seeds which accounted for 14.1%, followed by NRSP/AYT.19/852 with 492 seeds which represented 13.5% while the least was NRSP/AYT/19/805 with 206 seeds which accounted for 5.7% of total number of good seed produced. Seeds are materials for genetic transfer.

Good quality botanical sweetpotato seeds are foundation for good sweetpotato progeny development and their products. Good quality botanical seeds were for the evolution and introduction of high yielding sweetpotato varieties (Rahman, 2018, Ratna et al 2019). The productivity of sweetpotato can be increased by the farmers by using quality good botanical seeds which were evaluated and selected for superior performance in terms of yield and other desirable attributes. The country will have high potentials to grow wide varieties of sweetpotato if botanical seeds were readily available for field evaluation and suitable genotypes are made available for different agro-climatic conditions ranging from rainy to dry seasons (Purchase, 2000).

Total number of bad/defected seeds was 655 with mean of 65.5 defected seeds. The Parents with the highest number of bad seeds was NRSP/AYT/19/851 with 128 bad seeds, followed by NRSP/AYT/19/420 with 106 bad seeds while the least was NRSP/AYT/19/805 with 20 bad seeds. Bad/defected seeds means loss of genetic factor. The sweetpotato defected botanical seeds produced were affected by a number of factors ranging from inherent genetic incompatibility among the varieties, climatic factors when there were not enough soil moisture to enable the seeds to fill up, to entomological problems when insects feeds on the botanical seeds creating hole and destroying the botanical seeds. All these factors affect the transfer of genetic material of the parents to progenies for new varietal development. Anything that may lead to loss of genetic factor must be avoided.

Seed weight: Hundred seeds were taken from each family and weighed, NRSP/AYT/19/805, although had the least number of produced seeds, had the heaviest seed weight of 769g followed by NRSP/AYT/19/420 with 648g, while the least seed weight was obtained from NRSP/AYT/19/5211 with 244g and a general mean of seed weight of 389.1g. Seed weight is a measure of high percentage of germinability and survivability of the crop into seedlings. It contributed in seedling vigour and speed of growth as a result of the reserved food. Seed weight is the first indication that the seed is alive and contributes to the productivity of the crop at harvest. Seeds that has low weight should be especially taken care of to ensure its survivability especially if the variety has the traits that are highly sort for by end users. They should be given enough nutrients to increase their vigour and survivability.

CONCLUSION

Total of 3638 healthy botanical seeds were generated for progeny evaluation and selection for micro-nutrient dense genotypes. The seeds realized will increased the sweet potato genetic base for screening for high nutrient dense progenies. NRSP/AYT/19/805 with weight 769g, NRSP/AYT/19/420 which weighed 648g and NRSP/AYT/19/603 with weight 550g were identified and recommended for 2023 nursery evaluation. These three parents could also be included in future hybridization block for future botanical seed production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was conducted at the Western farm of National Root Crops Research Institute Umudike, Abia State, Southeastern Nigeria with the aim to select genotypes with high number of storage root per plant, storage root size above 100g, genotypes free from biotic stresses and to select genotypes with marketable attributes such as: smooth skin and appealing storage root flesh colour. Data were collected and analyzed with ANOVA. Results obtained indicated that Genotypes selected for having high yielding potential was PYT/21/075 with 7.0 number of storage roots per 1000 plants per hectare while the least was PYT/21/040 and PYT/21/028 with 0.5 storage roots per 1000 plants per hectare respectively. These genotypes have storage root size of above 100g, they were also free from cracks, oxidation and possess unique flesh colour that appeals to the eye which accounts for good marketable attributes. Genotypes with number of storage roots higher than the two check varieties UMUSPO/3 and TIS78/0087 would be advanced to the next stage of evaluation- Advance Yield Trial.
Keywords: *Storage root, root size, number of roots per stand, marketable attributes and preliminary yield.*

INTRODUCTION

Sweet potato although can grow in marginal soil but is also sensitive to poor soil deficient in soil nutrients. The productivity of sweet potato_in Sub-Sahara Africa (SSA) are still remarkably low, with an average of 6 t/ha compared to 13 t/ha in South America, 22 t/ha in China, and 25 t/ha in Northern America (FAOSTAT, 2019). Average of sweet potato root yields are 8t/ha in East Africa, 7.5t/ha in Central Africa, 3t/ha in South Africa, and 3t/ha in West Africa, respectively (FAOSTAT, 2019), which are far below attainable yield levels. Attainable yield is defined as the mean on-farm yield plus three times the standard deviation (Van Vugt and Franke, 2018). Attainable root yields in experimental farms under rainfed conditions were from 18 to 32t/ha among districts in Malawi (Van Vugt and Franke, 2018), 25–29t/ha in South Africa (Laurie et al., 2017), 27t/ha in Mozambique (Andrade *et al*., 2017), and 39t/ha in Nigeria (Uwah *et a*l., 2013). Moreover, the productivity of sweet potato in African countries of Uganda, Nigeria, Tanzania, Angola, Burundi, Mozambique, Madagascar, Rwanda, Ethiopia, Kenya and Cameroon is very low (< 10 t/ha), and hence improvement in the yield traits of sweet potato is of prime importance to plant breeders (Andrade *et al*., 2016; Rukundo *et al*., 2013). Other causes of low storage root yield in sweet potato are pathogenic and entomological stresses.

Sweet potato virus disease (SPVD) are widespread diseases inflicting serious yield losses across the country and are also of economic importance. Among insects, weevil (*Cylas* spp.) is an important field pest which causes serious losses of storage roots in the field during dry spell. These stresses appear individually and/or in combination with varying intensity depending on the location, season and year, thus, causing great fluctuation in sweet potato roots and vine production in the country. Hence, development of resistant varieties against major diseases and realizing the yield potential of existing commercial cultivars are being given priority towards breaking yield barriers in sweet potato breeding. The scope of selection for desirable sweet potato genotypes depends on the extent of exploitable genetic variability. Some of the promising traits in the indigenous gene pool are early maturity and more number of storage roots and /or cluster of roots per plant stand. Sweet potato genotypes have been reported to mature within 4 months and are considered to be short season crop.

The average yield of sweet potato in Nigeria is 6t/ha which is 86% lower than the world average (46t/ha) (FAOSTAT, 2019). The reasons for low yield are occurrence of various biotic, abiotic and edaphic factors at different growth stages. Being a rainy season crop, sweet potato is grown on conserved soil moisture during the rainy season. As a result, soil water deficit during crop establishment and storage root bulking emerges as the

major yield constraint along with the rising temperature leading to field pests' infestation. Soil nutrients deficiencies are also observed locally in most sweet potato growing zones. Sweet potato virus disease complex are widespread diseases inflicting serious yield losses across the country. Fungal diseases such as *alternaria* leaf blight disease and leafspot are also of economic importance.
Among Insects such as storage root weevil, aphid and Cylass *species* is an important field pest. These stresses appear individually and/or in combination with varying intensity depending on the location and year and time in the year, thus, causing great fluctuation in sweet potato production in the country. Hence, development of high yielding genotypes with resistance against major diseases and to realize the yield potential for commercial cultivars should be given priority. This could be done towards breaking yield barriers in sweet potato development. However, the aim of this study was to select genotypes with high number of storage root per plant, storage root size above 100g, genotypes free from biotic stresses and to select genotypes with marketable attributes such as: smooth skin and appealing storage root flesh colour.

MATERIAL AND METHODS

The experiment was conducted at the Western farm of the NRCRI Umudike**.** Land was prepared by first slashing the area, ploughed, harrowed before ridging. The area was marked into three blocks and each block was subdivided into plots with each plot measuring 3 x 1m, which was $3m^2$ per plot. The 104 sweetpotato genotypes selected from clonal evaluation were evaluated at PYT stage using 4 nodes seed cuttings from symptomless mother plant. Each varietal line were planted per plot and replicated three times. The planting spacing was 1.0 x 0.3m within plot and 1.0m between plots. This gave a total of 312 plots. The experimental design used was RCBD. Inorganic fertilizer NPK 15:15:15 was applied at four weeks after planting to enable the plants to express its storage root yield potential. Manual weeding was done at 4 weeks after planting and rouging was carried out at 8 weeks after planting until harvest. Standard check varieties used were UMUSPO/3 and TIS 87/0087.
Data were collected on:, mean number of storage root per genotype per $6m^2$, mean number of storage root per stand, mean weight of fresh storage root in t/ha and size of storage root.

Data on marketable attributes collected were on;

(a) **Size of storage root**: The largest root from each genotype was weighed.
(b) **Oxidation in storage root flesh**: The freshly harvested storage root was cut in cross section and the surface was allowed to come in contact with the fresh air. The amount of browning is observed within 5 to 10 seconds and rated as follows: 1 = no browning, 2 = very little browning, 3 = little browning, 4 = moderately browning, 5 = abundant browning
(c) **Storage root cracking**: Ten plants were selected for observation of cracks on the storage roots. The average of the ten plants were scored using the following scale: 1= no cracks, 2= very few cracks, 3 = moderate cracks, 4 = medium cracks, 5 = many cracks.
(d) **Entomological reactions:** Storage root weevil infestation severity rating using Scoring scale 1 to 5. Where, 1 = no symptom, 2= symptom present, 3= symptom mild, 4= symptom severe, 5= symptom very severe.

Data collected were subjected to analysis of variance and Mean separation was done using **standard error of means.**

RESULTS AND DISCUSSION

The results of the storage root yield characteristics and Marketable storage root attributes of the PYT sweetpotato genotypes evaluated are presented in Table 1.The yield data of the genotypes were sorted in order from the least to the greatest. The arrangement splits the yield data into two equal halves with 50% of the data below the median and 50% above the median. The yield data from the middle value to the greatest value is presented in Table 1.

Table 1: Storage root yield characteristics and Marketable storage root attributes of the PYT sweetpotato genotypes evaluated

Note; PYT= Preliminary Yield Trial

Number of storage roots per plant: The number of storage roots per plant per every 1000 plants per hectare ranged from 0.5 to 7.0 with mean of 2.2 number of storage roots per stand, and with coefficient of variation of 28.4%. This percentage of coefficient of variation presented huge genetic variability to select large number of genotypes with high number of storage roots per stand. The genotypes with the highest number of storage root per stand was PYT/21/075 with 7.0 number of storage roots followed by PYT/21/095 with 3.3 number of storage roots per stand per every 1000 plants per hectare. These two genotypes produced more number of storage roots higher than the two check varieties- TIS87/0087 with 1.5 and UMUSPO/3 with 1.8 number of storage roots per stand. The genotypes that produced very low number of storage roots per stand was PYT/21/028 with 0.5 number of storage roots per stand per 1000 plants per hectare.

Fresh weight of storage roots: This was the fresh weight of the storage roots. The weight of the fresh storage roots varied from 1.4 to 5.7t/ha with coefficient variation of 32.1% which indicated a huge genetic variability for selection. The genotype that gave the highest fresh storage root weight was PYT/21/014 with 5.7t/ha followed by PYT/21/007 with 5.6t/ha while the genotypes that gave the lowest fresh matter yield were PYT/21/048 and PYT/21/028 with 1.4t/ha respectively. All these yields are too low when compared with other regions. FAOSTAT (2019) reported of fresh storage root yield gap in Sub-Sahara Africa (SSA) that average yield in SSA are still low 6t/ha compared to South America which is 13t/ha, China 22t/ha to North America 25t/ha. The yield gap between average yields in SSA on small holder farms in South Africa 60 to 80t/ha is huge (Low *et al* 2020). According to Jones *et al* (1986), organic and inorganic fertilizer should be used as a synergistic component of crop improvement programme through breeding. In other words, crops should be assisted to reach its genetic potentials. He advised the Crop Improvement Programmes to depend largely on the scope and efficiency of breeding work and fertilizer use. A good knowledge of the crop characteristics and nutritional requirements is necessary also the crop environment which would transform the inherent crop genetics characteristics into desirable qualities for increased yield and growth performance. The desired genetic potentials of crops can only be fully expressed under adequate and balanced plant nutrition. The medium of growth of improved crop varieties accounts for over 95% of the factors of productivity of the crops. It is requirements therefore imperative that breeding programmes should be backed up with full knowledge of the crops nutrition. Plant nutrients such as organic and inorganic fertilizers should be supplied to crops under improvement at the right time and condition and should not be supplied arbitrary but should be punctuated to elicit optimum performance of the improved variety.

Size of storage roots of genotypes: The largest storage root yield per genotype was weighed. Any storage root that weighed above 100g is regarded as commercial root (Loebenstein and Thottappilly, 2009; Degrass, 1998). The storage root sizes of the genotypes ranged from 102.4 to as heavy as 183.3g with mean of 134.9g. The genotype with the heaviest marketable attributes was PYT/21/002 with weight of heaviest root of 183.3g followed by PYT21/003 with weight of heaviest storage root of 174.9g while the genotype with the least heavy root of 102.4g was UMUSPO/3. The single storage root weight from each of the genotype was heavier than that of the check varieties. The check variety TIS87/0087 with one of its largest root weighed 122.4 and another check variety UMUSPO/3 had its largest root that weighed 102.4g. This indicated that the genotypes produces storage root sizes which were of marketable root attributes.

Entomological reactions and other Storage root marketable attributes of the PYT sweetpotato genotypes: The entomological reactions and other Storage root marketable attributes of the PYT sweetpotato genotypes evaluated are presented in Table 2.

Table 2: Entomological reactions and other Storage root marketable attributes of the PYT sweetpotato genotypes evaluated

PYT/21/090	1.0	W	C	1.0	1.0
Mean	**1.2**	=	=	**1.0**	**1.1**
Range	**1.0-1.5**	=	=	**1.0-1.0**	**1.0-2.0**

Note: PO = pale orange, IO = intermediate orange, DO = dark orange, PY = pale yellow, DY = dark yellow, DC=dark cream, O = Orange, Y = Yellow, W = White, C = Cream

Entomological reaction: The entomological reactions of the PYT genotypes indicated that the only pest present at the time of harvest was the storage root weevil *Cylas ponticollis.* The severity score ranged from 1.0 to 1.5 with mean of 1.2. This showed that most of the genotypes were not attacked at the time of harvest. This confirms the advice of many researchers that sweetpotato genotypes should not be allowed to stay more than necessary in the soil especially in storage root weevil prone areas, plan not to harvest during hot dry spell, cover cracks properly with sod during storage root bulking and avoid hydromorphic soils (Schalk and Jones, 1985).

Storage rook skin colour: The PYT sweetpotato genotypes have wide range of skin colours from cream, white, pink, orange to brown. Although, white/cream colour attracts to the eye, it has no special contribution to the quality of the flesh storage roots. However, skin colour is an array of choice for various consumers roaming the markets.

Storage root flesh colour: There were various storage root flesh colour segregation due to gene reshuffling. The colours are of various intensity ranging from cream to white and pale white, to white, orange to dark orange, pale yellow to yellow and deep yellow. The more pale the lower the intensity of the colour and the lower the beta-carotene. The consumers has array of sweetpotato flesh colour to choose from. However, majority of the consumers prefer white flesh colour to other colours.

CONCLUSION

Farmers and breeders priority for any new crop is higher yield. However, breeders are unsatisfied with the yield of any current crop and continued to develop new varieties to be superior to the existing ones. Reason being that any new clonally propagated plant breakdown every seven years due to accumulation of diseases. Genotypes selected for having high yielding potential was PYT/21/075 with 7.0 number of storage roots per 1000 plants per hectare while the least was PYT/21/040 and PYT/21/028 with 0.5 storage roots per 1000 plants per hectare respectively. These genotypes have storage root size of above 100g, they were also free from cracks, oxidation and possess unique flesh colour that appeals to the eye which accounts for good marketable attributes. However, genotypes with number of storage roots higher than the two check varieties UMUSPO/3 and TIS78/0087 would be advanced to the next stage of evaluation Advance Yield Trial.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analyzed the effect of use of improved sweet potato production technologies by farmers in South–East, Nigeria. Multi-stage and proportionate sampling methods were used to collect data for the study. Three States, namely Abia, Anambra and Ebonyi States were purposively selected, two agricultural zones were randomly selected from each of the States to give a total of six (6) zones, two (2) blocks were randomly selected from each of the zones to give a total of twelve (12) blocks, finally, proportionate sampling technique was used to select farmers from the circles to give a sample size of 364 sweet potato farmers. List of sweet potato farmers from sweet potato farmers' association, Abia State, Extension Services Programme office of NRCRI Igbariam outstation, Anambra State and Sweet potato farmers' association, Ebonyi State served as the sampling frame. Data for this study were collected using structured questionnaire and analyzed using descriptive statistics such as frequency, percentages, meanwhile inferential statistics used was ANOVA. Result showed that majority (72.25%) of the farmers were females while few (27.75%) were males, the mean of annual income was ₦579,395.6. Good number (69.23%) of the farmers had farm sizes of less than 1 hectare (0.1-0.9 ha). The result also revealed that 47.25% and 26.37% of the farmers participated always and often respectively in the farmers' association where they belong. The farmers' roots yield before use of improved sweet potato production technologies was mean of 14,795.30 kg/ha, while farmers' root yield after use of improved sweet potato production technologies was mean of 28,511.92 kg/ha. This result showed that use of improved sweet potato production technologies has greatly increased the yield of sweet potato root. The F-value (117.900) obtained from ANOVA result showed significant difference (P< 0.05) in root yield produced across the States. The study concluded that there was significant difference in sweet potato root yield across the States and there was also difference in sweet potato root yield before and after utilization of improved sweet potato production technologies disseminated to farmers in South-East, Nigeria. Therefore, it is recommended that sweet potato farmers should use the improved sweet potato production technologies disseminated to them for increased root yield.
Keywords: *Farmers, Use, Improved Sweet potato, Production Technologies*

INTRODUCTION
Sweet potato (*Ipomoea batata* (L) Lam) is an important tropical staple food crop, belonging to the morning-glory family known as *convolulaceae* and is originated from Latin America. Nigeria is the third largest producer of sweet potato in the world with china leading, followed by Uganda (FAO, 2004). Sweet potato is mainly propagated by vine-cuttings, planted on mounds and ridges and in single or double rows. The best yields occur in areas with 750 to 1,000 millimeters of annual precipitation, with at least 500 mm falling during the growth season. However, sweet potatoes do not grow well in water logged soil as it may cause tuber rots and reduce storage roots if aeration is poor (Mbanaso *et al.*, 2012). It can be cultivated twice a year (i.e. April to August and August to December (Ehisianya *et al.*, 2014). In general, planting takes place from February through July in the central and south, where rainfall is heavier. But planting along rivers in the central part of the country or swampy areas in the north can extend the planting season from September to December. Sweet potatoes are often intercropped as the secondary or minor crop.
Sweet potato is an important food security crop in Nigeria and Africa at large, and it is known as the crop that is there when the maize fails (Jia, 2013). Sweet potato leaves have added nutritional value, with greater amounts of protein and crude fiber. The leaves, skin and tender shoots of sweet potato are also eaten and are very nutritious. One hundred grams of fresh sweet potato leaves contain more iron, vitamin C, folates, vitamin K, and potassium.

The roots have high level of carbohydrates for daily energy production. Sweet potatoes are appropriated for meeting the nutritional needs of malnourished children and elderly populations who need high-energy foods that are also suitable for small stomachs. The crop is grown for multipurpose, its roots and vines are used both for human food and for animal feed. Sweet potato is used in a variety of ways for food, feed and processed products such as bread, ready-to-eat breakfast, French fries, syrup, starch and beverages (Walker *et al.,* 2014). It can be eaten boiled, baked or fried and can be sliced, sun-dried, used for the production of chips which are sometimes ground into flour. The dry matter content of sweet potato is one of the important traits that influence its acceptability, of which processing industries require high dry matter greater than 30%, also high quality starch. Besides carbohydrates, it is a rich source of protein, lipid, calcium and carotene. It is good source of carbohydrate as well as raw material for the manufacturing of industrial starch, glucose and alcohol (Udo *et al.,* 2005). Sweet potato production technologies such as improved sweet potato varieties, sweet potato intercropping, land preparation methods, vine cutting (3 and 4nodes), plant spacing (30cm x 30cm), planting time, use of herbicide, weeding regime (1^{st} and 2^{nd}), use of fertilizer, earthing-up (mean), use of insecticide and proper harvesting time. have been developed and disseminated in South-East Zone of Nigeria, but there is still dearth of information on the effect of use of the production technologies on root yield in the study area. Hence the study on comparative analysis of effect of use of improved sweet potato production technologies by farmers in South-East, Nigeria. Specific objectives of the study are: to describe the socio-economic characteristics of the farmers; estimate farmers' root yield before and after use of improved sweet potato production technologies disseminated; and ascertain the difference in root yield across the States.

METHODOLOGY

The study was conducted in South-East, Nigeria. Multi-stage and proportionate sampling methods were used to collect data for the study. Three States, namely Abia, Anambra and Ebonyi States were purposively selected, two agricultural zones were randomly selected from each of the States to give a total of six (6) zones, two (2) blocks were randomly selected from each of the zones to give a total of twelve (12) blocks, finally, proportionate sampling technique was used to select farmers from the circles to give a sample size of 364 sweet potato farmers. List of sweet potato farmers from sweet potato farmers' association, Abia State, Extension Services Programme office of NRCRI Igbariam outstation, Anambra State and Sweet potato farmers' association, Ebonyi State served as the sampling frame. Data for this study were collected using structured questionnaire. Data were analyzed using descriptive such as frequency, percentages, meanwhile inferential statistics used was ANOVA (Duncan Multiple Range).

Duncan multiple range test model is as follows:

$DMRP = QP\sqrt{MSE/r}$

Where

DMRP = Duncan Multiple Range

QP = Shortest Significant Range

$\sqrt{MSE}$ = Mean Square Error

r = Number of States.

RESULTS AND DISCUSSION

Table 1 result shows that majority (72.25%) of the farmers were females while few (27.75%) were males. This result implies that female folk were involved in sweet potato farming more than their male counterparts. The finding is in agreement with (Anyaegbunam *et al*., 2019) who reported in their study that sweet potato are traditionally viewed as women crop, grown predominantly by women farmers. The mean of annual income was ₦579,395.6. This implies that the farmers' income was low. Good number (69.23%) of the farmers had farm sizes of less than 1 hectare (0.1-0.9 ha). This result reveals that the sweet potato farmers were small holder farmers. The result corroborates that of Abudu *et al.* (2014) who reported that majority of farmers in the South-East Nigeria were small scale farmers, on the average cultivate less than 2 hectares of land. The result also shows that 43.68% of the respondents had farming experience of 6-10years, indicating that the farmers had enough farming experience on sweet potato farming. According to Arimi (2014), who opined that higher number of years of experience in farming help farmers in use of technology. The results also revealed that 47.25% and 26.37% of the farmers participated always and often respectively in the farmers' association where they belong. Few of the farmers (18.13%) and (8.24%) represent those who participated sometimes and never respectively in the community association. This result indicates that the farmers participated in the activities of the association where they belong.

Table 1: Distribution of farmers according to their socioeconomic characteristics

Variables	Abia (n=64)	Anambra (n=99)	Ebonyi (n=201)	South-East Pooled (n=364)	Mean

Estimated farmers' root yield before and after use of improved sweet potato production technologies

Table 2 shows the farmers' root yield before and after use of improved sweet potato production technologies disseminated. The farmers' sweet potato roots yield before use of improved sweet potato production technologies was mean of 14,795.30 kg/ha, while farmers' sweet potato root yield after use of improved sweet potato production technologies was mean of 28,511.92 kg/ha. The difference was 13,716.62kg/ha. This result shows that use of improved sweet potato production technologies has greatly increased the yield of sweet potato roots. This is in agreement with Guneberg *et al.* (2015) that progress in yield can be achieved by breeding through replacing old varieties with new varieties.

Table 2. Estimated farmers' root yield before and after use of improved sweet potato production technologies

Source of Variation	Abia (n=64) $\bar{X}$	Anambra (n= 99) $\bar{X}$	Ebonyi (n=201) $\bar{X}$	South-East (n=364) Pooled $\bar{X}$ root yield (kg/ha)
Root yield before	14,002.15kg/ha	14,427.50kg/ha	15,956.25kg/ha	14,795.30 kg/ha
Root yield after use of improved sweet potato production technologies	27,589.16kg/ha	28,123.10kg/ha	29,823.50kg/ha	28,511.92 kg/ha
Difference	13,587.01kg/ha	13,695.6kg/ha	13867.25kg/ha	13,716.62kg/ha

Analysis of Variance Showing the Significant Difference in Sweet potato Root Yield across the States

The F-value (117.900) obtained from Analysis of Variance shows significant difference ($P< 0.05$) in root yield produced across the States. The post hoc result shows that there was significant difference in sweet potato root produced cross the States (Abia, Anambra and Ebony). This implies that across the three States, sweet potato root yield produce by farmers were of different quantities. This finding agrees with Birhanu *et al.* (2014) who reported in their study that an environmental condition resulting from variation amount of temperature, soil fertility, moisture and other factors may be the cause of difference in root yield of sweet potato in different locations.

Table 3: Analysis of variance showing the difference in sweet potato root yield by the farmers across the States

CONCLUSION AND RECOMMENDATION

The study concluded that there was significant difference in sweet potato root yield across the States. Also, there was difference in sweet potato root yield after use of improved sweet potato production technologies dissemination in the study States. Therefore, it is recommended that sweet potato farmers should use the improved sweet potato production technologies disseminated to them for increased root yield.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The role of biotechnology in addressing food and nutritional security has become increasingly significant for the sustainability of agriculture in the globe of which Nigeria is not an exception. With the growing global population, limited access to arable land and climate change challenges, it is highly imperative to explore and adopt biotechnology as innovative approach to enhance agricultural productivity that will enhance access to safe and nutritious food. Biotechnology also offers promising solutions by leveraging the understanding of genetic and molecular mechanisms in plants, animals, and microorganisms. The involvement and adoption of biotechnology will help to leverage the food insecurity and thereby promote a hunger free Nigeria. Therefore, this article is an attempt to review the prospects and challenges of implementing biotechnology in Nigeria to enhance food and nutritional security.
Keywords: *Biotechnology, Nutritional food Security and Sustainable Agricultural Development*

INTRODUCTION
In recent years, the global population has been steadily increasing, leading to greater demands for food and nutritional security. This challenge is particularly significant in developing countries like Nigeria, where agricultural practices often struggle to keep pace with population growth. However, biotechnology has emerged as a powerful tool to enhance agricultural productivity, improve crop yields, and address the issues of food and nutritional security (Ajeigbe *et al.,* 2019). By harnessing the potential of biotechnology, Nigeria can achieve sustainable agriculture and ensure an adequate and nutritious food supply for its population. Biotechnology encompasses a range of techniques and technologies that involve the use of living organisms or their components to develop beneficial products and processes. In the context of agriculture, biotechnology offers various applications, including genetic engineering, tissue culture, marker-assisted breeding, and bioinformatics. These tools enable scientists and researchers to modify crops for improved resistance to pests and diseases, enhanced nutrient content, increased yield potential, and better adaptation to environmental stresses (Nweke *et al.,* 2019, Falusi *et al.,* 2020). Biotechnology has facilitated the development of genetically engineered crops with built-in pest and disease resistance traits. By reducing crop losses due to pests and diseases, farmers can produce more food with fewer inputs, contributing to improved food security (Qaim,2016). By leveraging biotechnology, Nigeria can overcome many of the challenges it faces in the agricultural sector, such as low crop productivity, post-harvest losses, and inadequate access to nutritious food (FAO, 2008; Ojo *et al*., 2020).
Biotechnology enables biofortification, a process of increasing the nutrient content of food crops through conventional breeding or genetic engineering. This approach has been used to enhance the levels of iron, zinc, vitamin A, and other essential nutrients in staple crops like rice, wheat, and maize. Biofortification offers a sustainable and cost-effective strategy to improve the nutritional status of vulnerable populations (Bouis and Saltzman, 2017). Biotechnology offers tools to develop crops with enhanced resistance against diseases and pests. By introducing genes conferring resistance into crop plants, biotechnology can reduce the reliance on chemical pesticides, making agricultural practices more sustainable and environmentally friendly (Crossa *et al.*, 2017). This approach can contribute to increased crop yield and reduced post-harvest losses caused by diseases and pests. Biotechnology also plays a role in enhancing nutritional security in the aquaculture sector. Genetic improvement programs for farmed fish and shellfish aim to develop breeds that grow faster, are disease-resistant, and have better nutritional profiles. Some of these biotechnology tools like selective breeding, genetic engineering, and genomics assist in achieving these goals, supporting sustainable aquaculture production and food security (Hellberg and Morrrissey, 2007; Parvez *et al.*, 2021).

In spite of the potentials of biotechnology in leveraging food and nutritional security in Nigeria, its adoption is still untapped. Therefore, it is imperative to create more public awareness to address safety concerns, risk assessments, ethical considerations, potential environmental impacts accompanied by proper regulatory frameworks. By harnessing the potential of biotechnology, Nigeria can achieve sustainable agriculture and ensure an adequate and nutritious food supply for its population, and overcome many of the challenges it faces in the agricultural sector, such as low crop productivity, post-harvest losses, and inadequate access to nutritious food. Overall, biotechnology plays a vital role in promoting sustainable agriculture, enhancing crop productivity, improving nutritional quality, and ensuring food security in Nigeria. More, so by integrating biotechnology into agricultural practices, Nigeria can now achieve long-term food and nutritional security goals while mitigating the challenges posed by climate change, pests, and diseases. This paper therefore, reviewed the role and challenges of biotechnology on food and nutritional security for sustainable agricultural development in Nigeria.

METHODOLOGY

Secondary data was used to elicit information from textbooks, journals, proceedings, guides bulletins and some national dailies.

RESULTS AND DISCUSSION

Biotechnology and Agricultural Transformation:

Improved crop varieties: Biotechnology enables the development of genetically modified (GM) crops with enhanced traits such as resistance to pests, diseases, and environmental stresses. These crops can withstand harsh conditions, produce higher yields, and have improved nutritional content. For example, GM crops like insect-resistant cotton and pest-resistant cowpea (beans), yellow root cassava and orange fleshed sweet potato fortified with beta carotene have been developed in Nigeria to combat yield losses and increase nutrition and productivity (Paine *et al*., 2005).

Disease and pest control: Biotechnology offers tools to manage crop diseases and pests through techniques like genetic engineering can introduce genes into crops to confer resistance against specific pathogens or insects. This reduces the reliance on chemical pesticides and promotes environmentally friendly pest management practices.

Crop adaptation: Climate change poses a significant threat to agricultural productivity. Biotechnology can contribute to developing climate-smart crops that are resilient to changing climatic conditions, including drought, heat, and salinity. By enhancing the adaptive capacity of crops, biotechnology helps ensure a more stable food supply (Qaim, 2016).

Nutritional enhancement: Biotechnology enables the development of crops with improved nutritional profiles, addressing nutrient deficiencies in diets. For instance, biofortification techniques can enhance the nutritional content of staple crops such as rice, maize, and cassava by increasing the levels of essential vitamins and minerals. This helps combat malnutrition and improves public health (Bouis and Saltzman, 2017).

Disease resistance in livestock: Biotechnology can also contribute to livestock health and productivity. Genetic improvement techniques can enhance disease resistance in livestock, improving overall animal health and reducing economic losses. For instance, biotechnology can be used to develop vaccines and diagnostic tools for livestock diseases prevalent in Nigeria. (Onyimba *et al.,* 2020).

Sustainable agriculture practices: Biotechnology facilitates the adoption of sustainable agricultural practices. By reducing the need for chemical inputs, such as pesticides and fertilizers, it helps minimize environmental pollution and preserve biodiversity. Biotechnology can also contribute to reducing post-harvest losses through the development of crops with improved shelf life and resistance to spoilage.

Capacity building and knowledge transfer: Harnessing biotechnology for food and nutritional security requires skilled personnel and institutional capacity. Efforts should be made to invest in research and development, provide training programs, and promote knowledge transfer to ensure the effective and responsible use of biotechnology in agriculture (Okeniyi *et al.,* 2021).

Challenges of Biotechnology

Biotechnology has immense potential to contribute to food and nutritional security in sustainable agriculture. However, it also presents several challenges that need to be addressed.

Public perception and acceptance: Biotechnology, particularly genetically modified organisms (GMOs), has faced public concerns regarding safety, environmental impact, and ethics. To overcome this challenge, it is crucial to enhance public awareness and understanding of biotechnology through effective communication and transparent information sharing. Engaging with stakeholders, including consumers, farmers, scientists, and policymakers, can help build trust and create a supportive environment for biotechnological advancements.

Regulatory frameworks: The development and commercialization of biotech products are subject to stringent regulatory frameworks in many countries. While regulations ensure safety and environmental protection, they can also slow down innovation and make the approval process lengthy and expensive. Governments and regulatory bodies should strive to establish science-based and streamlined regulatory systems that foster innovation while addressing safety concerns.

Intellectual property rights (IPR): Intellectual property protection is crucial for incentivizing investment in biotechnology research and development. However, IPR issues can sometimes hinder access to biotech tools and technologies for small-scale farmers in developing countries. Encouraging technology transfer, promoting licensing agreements, and ensuring fair and equitable benefit-sharing mechanisms can help address IPR challenges and ensure access to biotechnology for all.

Capacity building and infrastructure: Biotechnology requires skilled scientists, technicians, and infrastructure for research, development, and implementation. Building technical capacity, particularly in developing countries, through training programs, knowledge sharing, and infrastructure development is vital. Collaborative efforts between developed and developing countries, international organizations, and academia can support capacity building initiatives and promote technology adoption.

Environmental impacts: Biotechnology should be implemented with careful consideration of its potential environmental impacts. The release of genetically modified organisms into the environment must be accompanied by rigorous risk assessments to ensure minimal ecological disruption. Promoting sustainable farming practices, such as integrated pest management, precision agriculture, and conservation agriculture, can complement biotechnology approaches and minimize environmental risks.

Socioeconomic equity: Biotechnology has the potential to address food and nutritional security, but its benefits must be accessible to all farmers, regardless of their scale of operation or location. Ensuring equitable access to biotech products, technologies, and knowledge, particularly for small-scale farmers, can help bridge the socioeconomic divide and promote sustainable agriculture on a broader scale (Ojo *et al.*, 2020).

CONCLUSION

Biotechnology plays a vital role in promoting sustainable agriculture, enhancing crop productivity, improving nutritional quality, and ensuring food security in Nigeria. By integrating biotechnology into agricultural practices, Nigeria can achieve long-term food and nutritional security goals while mitigating the challenges posed by climate change, pests, and diseases.

RECOMMENDATIONS

The way forward, food and nutritional security for sustainable agriculture lies in embracing biotechnology as a tool; while addressing the associated challenges.

i. More public awareness to address safety concerns, risk assessments, ethical considerations and potential environmental impacts accompanied by proper regulatory frameworks.

ii. Collaborative efforts among scientists, policymakers, farmers, consumers, and other stakeholders are crucial to creating an enabling environment that promotes responsible and inclusive biotechnological innovation for a more sustainable and food-secure in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Field experiment were conducted at Umudike a rainforest agro ecological zone of South-Eastern Nigeria during the 2022 and 2023 cropping seasons tomto study the evaluation of advanced white yam genotypes (D. rotundata) for the growth and yield. The experiment was laid out as a 4 x 5 factorial in a randomized complete block design (RCBD) with three replicates. The treatments were 20 genotypes of white yams. The high number of tuber per plant of the advanced white yam could be obtained from TDr1439027 genotype and the highest tuber yield could be obtained from genotype TDr0900061 and is recommended.
Key words: *Advanced white yam, genotype, growth, yield, southeastern Nigeria.*

INTRODUCTION
Yam plants are monocotyledons which belongs to the genus *Dioscorea* and family *Dioscoreaceae* . Out of the 600 cultivars of yam recorded, only six species are important and staple food in the tropics. These include white yam (*D. rotundata*), yellow yam (*D. cayenensis),* water yam (*D. alata*), trifoliate yam (*D. dumentorum*), aerial yam (*D. bulbifera*) and Chinese yam (*D. esculenta*). (Asiedu, 2010) (*D. rotundata*) is a native to West Africa, and the yam of preference in the region. Its cultivation has spread to other parts of the world including the Caribbean, Asia, and South America (FAOSTAT, 2020). In West Africa, yams are major source of income and have high cultivated values, being celebrated in the annual new yam festivals and used in marriage ceremonies. The tuber is the edible portion of yam and has high carbohydrate content, serving as a major source of energy but, low in fat and protein. Yam is consumed as boiled yam, pounded yam and fried yam or processed into flour. Several genotypes of white yam have been developed, but farmer requires information on the performance of the genotypes in various agro-ecological zones. The objective of this study was to evaluate advanced white yam genotypes for their growth and yield in Umudike southeastern Nigeria

MATERIALS AND METHODS
The field trial was conducted at the farm of the National Root Crops Research Institute (NRCRI), Umudike, South Eastern Nigeria in 2022 and 2023. The field was prepared by slashing, ploughed and harrowed. The field was marked out into three replications and each replicate was divided in to 20 plots measuring 4m x5m (20m^2). The spacing between each replicate was 1m and the spacing between each plot was 0.5m. The sett size was 100g of 20 different genotypes of white yam were the experimental treatments. The experiment was a Randomized Complete Block Design (RCBD) with three replications. Data were collected on the following growth parameters: vine length, vine girth, leaf area, leaf area index, at 3 and 4 months after planting. Yield parameters recorded were number of tubers per plant, weight of tubers per plant and tuber yield in t/ha. Data were analyzed using Genstat Statistical package.

RESULTS AND DISCUSSION
Growth and Yield characteristics
At 3MAP, genotype TDr 09/00082 had significantly longer vines than TDr5, Obiaturugo and TDr1428017 but not others (Table 1). However, at 4MAP, TDr 1440035 had significantly longest vine.
Generally, vines were thickest (girth) in genotypes Obiaturugo (1.9mm) and TDr89/02664 (1.7mm) and others compared to TDr1436015, TDr1429027, TDr1439027 and TDr1428017 at 3MAP (Table 2). At 4MAP, thickest stem were obtained from Obiaturugo (3.3mm) and TDr1401593 (3.0mm) while thinnest vines were from TDr1439027 (1.1mm), TDr1436015 (1.2mm), TDr000021 (1.6mm) and TDr1429027 (1.7mm).

The number of leaves per plant at 3MAP was significantly highest in TDr000078 (254) and TDr09/00082 (249) but lowest in TDr1436015, TDr1439018 and TDr1440035 (Table 3). At 4MAP however, the greatest number of leaves was obtained from TDr1439027 while the least was from TDr1440035 and TDr1401593.

The number of tubers per plant and tuber yield varied significantly with the white yam genotypes (Table 4). The number of tubers produced per plant ranged from 0.92 in TDr1439018 to 3.98 in TDr1439027.Genotypes TDr1429027, TDr1439027, TDr11/00396 and TDr1401593 produced significantly highest number of tubers (3.1 - 4.0). The highest tuber yield was obtained from genotypes TDr0900061 (2.6t/ha), followed by TDr89/02665 (1.7t/ha), and TDr11/00396 or TDr000078 (1.4t/ha) in that order. Generally, the low yields obtained were due to low weight of tuber per plant.

CONCLUSION

From the study, it appeared that the high number of tuber per plant of the advanced white yam could be obtained from TDr1439027 genotype and the highest tuber yield could be obtained from genotype TDr0900061.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Food production is not keeping pace with the rapidly increasing population, and Biotechnology is one of the ways to increase productivity and gradually attain food security .This study evaluated the effects of livelihoods and sustainability practices on biotechnology as panacea for food security in Nasarawa State, Nigeria. Multistage sampling method was employed to select 210 small-scale food crop producers for the study. Primary data were collected with the aid of structured questionnaire administered to the respondents. Methods of analysis used include descriptive statistics and Cobb-Douglas stochastic frontier production function model. The results shows that significant variables in the factors of production of food crop in the area were farm size $p \geq 0.01$, labour supply $p \geq 0.01$ and capital input was significant at $p \geq 0.05$ respectively. The determinant variables among inefficiency factors were gender $p \geq 0.05$, herbicides usage $p \geq 0.05$, sole cropping $p \geq 0.05$, and arable crops production, wages and salary means of livelihood (Ws) $p \geq 0.10$. The studies recommend that, Agricultural biotechnology should be encouraged among the rural farmers to bring about improvement in their general food security and their sustainability livelihood.
***Keywords**: Livelihoods, sustainability, food crop, farmers, biotechnology*

INTRODUCTION
Most of the small scale farm holders over a long period of time have device additional means of meeting up with their needs through carrying out different activities on the farm and off farms to generate more income in addition to their farming livelihood. Livelihoods of individuals have become a deliberate strategy to cope with recent time's life challenges (Samuel *et al.*, 2021).

Diversification of farm and off-farm livelihoods among farmers could relief stress on productive agricultural sectors and decrease degradation as well as increase both economic and environmental efficiency (Anyshchenko, 2019). Furthermore, additional income generated from livelihood diversification enable farmers to invest in sustainability measures to manage land degradation as a measure against economic and environmental inefficiencies. Efficiency in production is improved when additional income generated from livelihood diversification is invested into sustainable land management practices that allow food crop producers to attain efficiency in production (Agata *et al.*, 2023).

Biotechnology and the issue of food security, biotechnology is broadly defined as a "technique that uses living organisms or substances from those organisms to make or modify a product, improve plants or animals, or develop microorganisms for specific uses" (Abah *et al.*, 2010). It also deals with the construction of microorganisms, cells, plants or animals with useful traits by recombinant DNA techniques, tissue culture, embryo transfer and other methods besides traditional genetic breeding techniques (Amin *et al.*, 2019). Although, biotechnology applies across a number of fields, agricultural biotechnology however, appears to be the most crucial for African countries and especially for resource-poor farmers whose sole livelihood depends on agriculture (Abdallah *et al.,* 2015). The technique of biotechnology alone cannot solve all the problems associated with agricultural production but it has the potential to address specific problems such as increasing crop productivity, diversifying crops, enhancing nutritional value of food, and also reducing environmental impacts of agricultural production and promoting market competitiveness (Artem, 2022)..

METHODOLOGY

Sampling Procedure and Sample Size: The respondents for this research were chosen using a multi-stage sampling method. At first stage random selection of 33.3% of respondents from Local Government Areas in Zones I, II, and III. Zone I (South) which comprises of Lafia, Doma, Keana, Awe, Obi LGA, while Zone II (North) which comprises of Akwanga, Nasarawa Eggon, Wamba, Kokona and Zone III (West) which comprises of Keffi, Karu, Nasarawa, and Toto using proportionate Allocation Technique which is shown in equation (1). A total of Six LGAs in Nasarawa State were randomly chosen in stage two, one Extension Block was chosen from each of the selected LGAs which gave a total of six Extension Blocks. To arrive at 12 Extension Cells, the final stage involved selecting two Extension Cells at random from each Extension Block which later result to 33.3% of the Cells in each selected Extension Block.

S_h =

Where: S_h =Number of household heads selected,

n= Total number of household heads for the survey, Nh= Farming households in each selected Sub-Cells, and NT= Sum of the farming households in the selected sub-Cells

Method of Data Collection: Questionnaire was used to collect primary data from all the respondents in the selected agricultural zones in, Nasarawa State. The farm families in the research areas served as the sample unit. Data on livelihood/income strategies, household characteristics such as family composition, education, asset ownership, sources of income, agricultural and livestock product sales, buying and selling livelihood involvement, membership in farmer‘s associations and extension contacts. The output of farmers was measured using scale.

Land tenure, cropping patterns, and agricultural output in (Tons) were among the data gathered at the parcel/plot levels. The utilization of labour supply in man-days and other agricultural production inputs was included in the data that was collected.

Analytical Tools:

Descriptive statistics such as frequency distribution, percentage, mean and Cobb-Douglas stochastic frontier production function were used to analyze the generated data for this study. Because of its potential to provide a higher goodness of fit, the Cobb-Douglas stochastic production function was employed to estimate technical efficiency. Individuals' choices of sustainable land management techniques are influenced by household assets, institutional variables, percentage level characteristics, and livelihood strategies.

The model is as follows:

LnY = ∑ ……………… equ (2)

Y= value of total farm output,

Xs= explanatory variables,

X_1= Farm size (ha),

X_2=Total labour (family and hired labour) (mandays),

X_3= Planting materials (seed) (kg), (Measured from grain equivalent table using biotechnology materials),

X_4= Chemical Fertilizer (kg),

X_5 = Organic Fertilizer (kg)

X_6=Agrochemicals (Liters), and

X_7= Capital input (these include depreciation on fixed cost items such as hoes, cutlasses, wheel barrows, hand trowels e.t.c interest payment on borrowed capital, rent payment plan). This was achieved by using the straight line method given as depreciation and captured in naira.

RESULTS AND DISCUSSION

The results on production factors of food crop producers are shown in Table: 1. Coefficients of explanatory variables showed that the coefficient for farm size was significant at 0.01% level. This implies that if farm size is increased by 1% holding other factors of production constant, it will result in additional output of 0.1391%. This is due to the fact that larger farm size will likely result into more output realized by the farmer (if other factors such as agrochemical, viable seed, fertilizer and agronomic management among others are met). Labour supply inputs are also significant at 0.01% level.

Table 1: Production factors of food crop producers

Production Factors	Coefficient	t - ratio
Constant	3.8027	30.1544***
Farm size (ha)	0.1391	4.3258***
Planting materials (seed)/kg	-0.0278	-1.0563
Total labour/mandays (family & hired)	0.1870	5.7286***
Fertilizer	0.0084	0.9808
Capital input (include depreciation fixed cost)	0.0096	0.5013**
Agrochemical	-0.0508	-2680

Source: Field survey, 2022

Table: 2 shows the inefficiency factors of food crop production which are in control of farmers. The result shows that the estimated sigma squared is 0.5293 and significant at 0.01% probability level. This indicates good fit and correctness of specified distributional assumptions of the composite error term. The finding agrees with report of (Amin *et al.*, 2019) who reported similar result of 0.01% level of significance. Results further showed that gamma is estimated to be high with 76.2%. This suggests systematic influence that was not explained by the production function and dominant sources of random errors. Coefficients of inefficiency factors as shown in the Table: 2 were significant for gender (Z_3) which was 5. Herbicides usage (Z_4) was significant at 5%, mono/sole cropping (Z_5) was significant at 5% and LS (Z_7) i.e livelihood strategy two (LS_7) was significant at 10%. The implication for the result of gender is that, more use of male farmers will reduce the level of inefficiency as males possess the required man energy to carryout farming activities than females. This agrees with report of (Artem, 2022) that male farmers are more fit for labour demand in farming than female farmers. Herbicide usage which was significant at 5% shows that the more the use of herbicides, the likely less the inefficiency because herbicides help farmers to cultivate more hectares of land within short period of time and larger farms mostly results in more output as well as more level of efficiency than small farm size (Omena *et al.*, 2011). Negative significance for coefficient of mono/sole cropping is that the more the practice of mono/sole cropping, the more the inefficiency. At this level, mono/sole cropping is discouraged. This agrees with report of Samuel, (2021) who reported that mono cropping is among practices adapted by farmers in specific locations and caused by condition of soil. Coefficient of (LS_7) which is staple crops, wages and salaries was significant but negatively signed. This implies that more of livelihood strategy two will reduce the level of inefficiency that was experience as a result, staple crops production, wages and salary livelihood strategy should be undertaken more among small holder food crop farmers in the study location to reduce inefficiency in production. The result agrees with research of Abah *et al.*, (2010) who reported that livelihood diversification among staple crop producers reduce the level of inefficiency in production.

Table 2: Inefficiency factors of food crop producers

Production Factors	**Parameters**	**Coefficient**	**t - ratio**
Household size	Z_1	-0.5027	-0.1944
Age	Z_2	-0. 0191	0.3281
Gender	Z_3	-0.0278	-1.0563**
Herbicides usage	Z_4	-0.1560	-1.7556**
Sole cropping	Z_5	0.0084	0.8089**
Arable crops production	Z_6	0.0096	0.5013*
Wages and salary	Z_7	-0.0508	1.0680*

Source: Field survey, 2022

RECOMMENDATION

- ✓ It is therefore recommended that more livelihood means and sustainability practices related to biotechnology should be undertaken among smallholder farmers in Nasarawa State.
- ✓ Also, more resource inputs should be used to reduce inefficiency in arable food crop production.
- ✓ Agricultural biotechnology should be encouraged among the rural farmers to bring about improvement in their general food security and their sustainability livelihood.

CONCLUSION

The study revealed that the significant factors of production included in the production function were farm size and labour significant at P≥0.01 respectively, while capital input was significant at P≥0.05. The inefficiency factors of food crop producers that were significant are gender, herbicides usage and mono-cropping significant at P≥0.05 respectively, while the arable crops production, wages and salaries means of livelihood in respect to biotechnology practice was significant at P≥0.10, this was corroborated with (Omena *et al*., 2011). Resource usage among the respondents was 0.50% which shows that they were inefficient in production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted to assess the effects of hydrothermal treatments on the mineral element bioavailability of dry cocoa beans. Three dry samples of cocoa were used as raw, blanched in water at 50°C and boiled in water at 100°C respectively, dried and ground into powder. Standard methods of analysis were used to determine the parameters and results evaluated. The results showed the following mineral bioavailabilities: [Saponin/Zn^{2+}], (0.140 for raw and 0.170 for 50ºC and 0.150 for 100ºC), for Zn^{2+}, had the highest calculated mole ratio; followed by [Saponin/Fe^{2+}], (0.140 for raw and 0.170 for 50ºC and 0.150 for 100ºC) for Fe^{2+}; [Oxalate/Ca^{2+}], (0.003 for each of the three samples), for Ca^{2+}; [Saponin/Ca^{2+}], (0.004 for raw and 0.005 for both 50ºC and 100ºC), for Ca^{2+} and [Oxalate/Ca^{2+} + Mg^{2+}], (0.000 for raw and 0.001 for both 50ºC and 100ºC) for Ca^{2+} + Mg^{2+} bioavailabilities. The results indicated that there were difference in mineral bioavailabilities based on their ratios. This showed that the bioavailability of minerals was influenced by hydrothermal treatments and indicated that blanching cocoa beans at a temperature of 50ºC is the best method among the methods considered in this work to get better mineral element bioavailability as far as nutrient qualities of cocoa beans are concerned.

INTRODUCTION
Food processing means operations used on raw materials obtained from plants or animals into various food or food ingredients. According to Johnston *et al*. (2014), "Food processing is required to increase shelf life of foods, enhance bioavailability of some nutrients and quality and reduce the post harvest losses and waste''. Burlingame and Dernini (2012); Africa and Asia (2015), stated that, "Reduction in the incidence of food insecurity in present scenario as well as in future require technological approach through collaborative actions among the field of agriculture, food, nutrition and health for improvement of wellness of society''. Kushwaha *et al.* (2021) identified some of the methods that can be used to process food to include traditional processing, heat treatment, low temperature/freezing, drying/dehydration, salting/brining, pickling, curing, fermentation, food additives, thermal processing, among others and they further stated that, "processing causes changes to the components of food and some of these changes can result in both detrimental as well as beneficial effects on the food quality, depending on the process used''. Some of the benefits of food processing include destruction of food-borne microbes and toxins, improved bioavailability of nutrients, extension of shelf-life, improved sensory characteristics and functional properties (van Boekel *et al*., 2010).

Cocoa beans are an important agricultural commodity and also a key raw material in cocoa beverage powder and chocolate production. Numerous studies have been reported on the health benefits of cocoa beans. Wollgast and Anklam (2000), stated that "the polyphenol compounds present in cocoa beans could significantly contribute to their health-promoting activities''. Polyphenols in cocoa had gained much attention recently due to their antioxidant activity and health benefits in the prevention and treatment of cancer (free-radical scavenging activities), cardiovascular diseases and other pathologies (Misnawi and Sulistyowati, 2008).

Studies on cocoa and their related products have become an area of interest owing to their health-promoting properties. Cocoa beans are usually consumed raw or roasted as seeds or in powder form. The aim of the study was to evaluate the mineral element composition, anti-nutritional factor contents and mineral element bioavailability of cocoa beans hydrothermally treated at different temperatures of 50ºC and 100ºC compare the results obtained with those of raw beans (control/standard).

MATERIALS AND METHODS

Area of the study: The experiment was carried out at the Department of Science Laboratory Technology and the Research Laboratory, Oyo State College of Agriculture and Technology. Igboora is in derived savannah zone of 7°15' North and 3°30' East of the equator with an average rainfall of 1278mm and an annual temperature of 27°C (Akamigbo, 2010).

Sample and sample preparation: Ripe mature cocoa pods were obtained from a cocoa farmer in Oyo town, Oyo State, Nigeria. The pods were broken, the beans were scooped out of and and allowed to ferment for six days using the basket fermentation technique. The fermented cocoa beans were sun dried under ambient temperatures (25-32°C) and relative humidity of 85– 100% with stirring four times each day to allow uniform drying of the beans. Cocoa samples were randomly picked at intervals and moisture contents analyzed until moisture content of between 5.5 to 6% was attained. The cocoa beans were immediately packaged in air tight black plastic bags prior to hydrothermal treatments. The cocoa beans were divided into three portions: A portion was left untreated as raw sample, the second portion was blanched at a temperature of 50°C and the third portion was boiled at 100°C.

Determination of some anti-nutritional factor were determined according to the methods described by the methods shown in parenthesis *Tannins* (Joslyn, 1970), *phytate* (Wheeler and Ferrel,1971), *oxalate* (Day and Underwood, 1986).*saponins* (Day and Underwood, 1986) *and hydrogen cyanide contents*(Day and Underwood, 1986).

Determination of some element concentrations: These were determined by the methods of (AOAC, 2012). The minerals were analysed from the solution obtained by first dry ashing the samples at 550°C. The filtered solutions were used to determine Na, K, Ca, Mg, Zn, Fe, Mn, Cu and Co by means of atomic absorption spectrophotometer (Buck Scientific Model -200 A/210, Norwalk, Connecticut 06855) and phosphorus was determined colorimetrically by Spectronic 20 (Gallenkamp, UK) using the phosphovanadomolybdate method.

Calculation/determination of element bioavailability: The bioavailability of elements (calcium, magnesium, iron and zinc) was calculated as reported by Woldegiorgis *et al*. (2015). The molar ratios anti-nutrients (phytates and oxalates) and elements (Ca, Fe and Zn) were obtained by dividing the concentration of anti-nutrient with the concentration of the elements.

Data analysis: The data obtained for the anti-nutrient composition, mineral element contents and mineral bioavailability were statistically analyzed using one way analysis of variance (ANOVA) and reported as mean ± standard error of triplicate data. Duncan's multiple range test was used for mean separation.

RESULTS AND DISCUSSION

Table 1: Anti-nutritional factor (ANF) composition of raw and hydrothermally treated cocoa beans

ANF (mg/100g)	Raw sample	Hydrothermally treated sample	
		50°C	100°C
Tannin	4.614±0.04^{a}	5.115±0.02^{b}	4.927±0.07^{c}
Saponin	14.239±0.01^{a}	16.583±0.17^{b}	16.322±0.02^{b}
Oxalate	0.81±0.02^{a}	0.843±0.05^{a}	0.917±0.02^{c}
Phytate	0.071±1.0^{a}	0.088±0.02^{b}	0.068±0.00^{c}
Hydrogen cyanide	0.004±0.00^{a}	0.006±0.00^{b}	0.002±0.00^{c}

Mean value with different superscript alphabets in each row are significantly different from each other by DMRT (P<0.05)

Table 2: Mineral element composition of raw and hydrothermally treated cocoa beans

Mineral elements (mg/100g)	Raw	Hydrothermally treated	
		50°C	100°C
Sodium	20.166±0.01	19.322±0.01	21.011±0.4

Table 3: Mineral elements bioavailability of raw and hydrothermally treated cocoa beans

Antinutrient to mineral element ratio	Calculated mole ratio (element bioavailability)		
	Raw	50ºC	100ºC
[Oxalate]/[Ca]	0.003^{a}	0.003^{a}	0.003^{a}
[Oxalate]/[Ca+Mg]	0.000^{a}	0.001^{b}	0.001^{b}
[Saponin]/[Zn]	0.140^{a}	0.170^{b}	0.150^{a}
[Saponin]/[Ca]	0.004^{a}	0.005^{a}	0.005^{a}
[Saponin]/[Fe]	0.060^{a}	0.069^{b}	0.066^{b}

Mean value with different superscript alphabets in each row are significantly different from each other by DMRT ($P<0.05$)

DISCUSSION

The results of the anti-nutritional factors composition of raw and hydrothermally treated cocoa beans were shown in Table 1. Quantitatively, cocoa beans hydrothermally treated at 50ºC has the highest value of anti-nutritional factors except for oxalate which is relatively lower. Anti-nutritional factors in cocoa beans (tannin, saponin, oxalate, phytate and hydrogen cyanide) found in varying quantities in raw and hydrothermally treated cocoa beans. Anti-nutritional factors are lethal or poisonous when consumed in large quantity, which have negative effects on mineral bioavailability (Ojiako and Igwe, 2008). Anti-nutritional factors reduces the maximum yield of nutrients especially proteins, vitamins and minerals; thereby, inhibiting the optional exploitation of nutrients by reducing the nutrient values. All the anti-nutritional factors determined in this study were observed to be higher in the sample hydrothermally treated at 50°C except for oxalate. This was in agreement with the finding of Ekholm (2003). The results showed that blanched cocoa beans had the highest value of tannins, saponins, phytate and hydrogen cyanide with the value 5.115±0.002, 16.583±0.169, 0.088±0.002 and 0.006±0.000 respectively, except for oxalate, which is relatively, lower which is 0.843±0.005.

The results of the mineral elements composition of raw and hydrothermally treated cocoa beans were shown in Table 2. Quantitatively, cocoa beans hydrothermally treated at 100ºC had the highest values for mineral element compositions except of copper and chromium, which were relatively lower. The highest levels of mineral obtained in this study were in the samples that were hydrothermally treated at 100ºC while the lowest values for minerals untreated and at 50^{0}C. The mineral element contents of the boiled sample gave the highest values (in mg/100g) of elements sodium, potassium, calcium, magnesium and phosphorous which were 21.011±0.4, 1511.701±1.22, 128.062±0.88, 489.051±0.11, 731.066±0.14, 13.589±0.09 respectively while the blanched gave the lowest values of 19.322±0.001, 1482.515±1.02, 124.184±0.04, 460.775±1.11, 718.102±0.40, 12.960±0.01 respectively.

Table 3 showed the mineral elements bioavailability of raw and hydrothermally treated cocoa beans. Quantitatively, [Saponin/Zn^{2+}], (0.140 for raw and 0.170 for 50ºC and 0.150 for 100ºC), for Zn^{2+}, had the highest calculated mole ratio; followed by [Saponin/Fe^{2+}], (0.140 for raw and 0.170 for 50ºC and 0.150 for 100ºC) for Fe^{2+}; [Oxalate/Ca^{2+}], (0.003 for each of the three samples), for Ca^{2+}; [Saponin/Ca^{2+}], (0.004 for raw and 0.005 for both 50ºC and 100ºC), for Ca^{2+} and [Oxalate/Ca^{2+} + Mg^{2+}], (0.000 for raw and 0.001 for both 50ºC and 100ºC) for Ca^{2+} + Mg^{2+} bioavailabilities with the following values**.** The results indicated a significant difference in mineral absorption based on these ratios. This finding suggests that the bioavailability of minerals was influenced by the presence of oxalate, saponnin, and their interactions with calcium, zinc, and iron.

CONCLUSION

The effects of hydrothermal treatments on cocoa beans was investigated, with the raw sample serving as the reference of comparison, in this study, and the focus on their effects on anti-nutritional factor compositions, mineral element contents and mineral element bioavailability. The results revealed that hydrothermal treatment had significant effects on the levels of anti-nutritional factors in cocoa beans. The findings indicated that cocoa beans subjected to hydrothermal treatment at 100ºC led to an increase in mineral element concentrations compared to the raw sample. Conversely, cocoa beans treated at 50ºC showed a reduction in mineral concentration compared to the raw sample. These observations highlight the temperature-dependent influence of hydrothermal treatments on mineral content in cocoa beans. The results indicated there were difference in mineral bioavailabilities based on their ratios. This showed that the bioavailability of minerals was influenced by hydrothermal treatments and indicated that blanching cocoa beans at a temperature of 50ºC is the best method among the methods considered in this work to get better mineral element bioavailability as far as nutrient qualities of cocoa beans are concerned.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Naturally occurring radionuclide's materials are usually absorbed by the plant through root as nutrients for their growth, which can pose a radiation risk to the human being when consumed as food. This study focused on the gamma dose rate exposure levels in a cultivated water leaf vegetable and was carried out in Oyo State College of Agriculture Technology botanical garden. The vegetable was planted and watered for four weeks in a nursery bed and measurement and recording were taken by the use of Gamma Survey Meter for dose rate of radiation emitted by water leafy vegetable of three times per day for two days were taken Data collected were analysed using descriptive tools tabulated and shown with the aid of Bar chart and compared with United Nation Scientific Committee on the effect of Atomic Radiation (UNCEAR) permissible dose rate of 2.7 µSv per year .The results revealed that all the cultivated vegetable samples had low gamma dose rate compare to UNCEAR permissible limit of 2.7 µSv. It can be concluded that Gamma dose rate does not have effect on consumption of the vegetable produced and pose no risk of any cancer related diseases.
Keywords: *Water leaf vegetable, Gamma dose rate, Exposure, Radiation, Survey meter*

INTRODUCTION
Radionuclide are found in all the environmental elements. They are present in varying amounts in the air, water, vegetables, animals, soil, and rocks (Abdulhussein e.al.2016. .Generally, the vegetables may cause an accumulation of radionuclide in their organs, which may additionally rely on the chemical and physical properties of the soil. So, there may be multiplied risk to the human population via food chain Mustakin et.al. 2018. Humans are exposed to both internal and external radiation from these natural sources. Internal exposure occurs through the intake of primordial radionuclide through inhalation or ingestion Changizi et.al, 2010. Ingestion exposure dose mostly results from 238U and 232Th series radionuclide and 40K in drinking water and foodstuff Khan, et al., 2010.For the derivation of several important minerals, dietary fibres and vitamins, humans rely heavily on vegetables .Anas and Yusuf, 2017. And as such, vegetables have become one of the most important source of food supply and nourishments to humans There have been several studies on radionuclide contaminants of common food stuffs in Nigeria, Amakom *et al*., 2018 investigated the gross alpha and beta activity concentrations in cassava and fluted pumpkin; Arogunjo *et a*l., 2005 determined the radionuclide concentrations from major cereals and tubers consumed in Nige ria. Sometimes, man-made radionuclides contaminate the food chain as a result of fallout from nuclear weapons tests in the atmosphere or from routine and accidental release of nuclear wastes as reported by IAEA 1989. As the spatial distribution of radionuclide varies with respect to the parent soils from region to region Keser *et.al*.,2013, so also, their uptake by plants varies from place to place o also their uptake by plants varies from place to place even among similar cultivars (Pendo and Leonid, 2017).

MATERIALS
Water leaf seed
Cutlass
Hoe
Gamma survey meter

METHODS

Area of Study

The experiment was carried out at Botanical garden, Oyo State College of Agriculture and Technology Igboora. (OYSCATECH)

Sample collection

The viable seed of water leaf was bought from Towobowo market in Igboora, and Nursery bed was prepared for the vegetable.

Experimental procedure

Some portion of the land was cleared and nursery bed made by the use of cutlass and hoe, thereafter the seed of water leaf vegetable was planted at the OYSCATECH Botanical garden. The water (Green leaf) was watered for four (4) weeks before the measurements were taken, the gamma survey meter was used to measure the dose rate in the morning, afternoon and the evening for two days. The measurement and recording were taken with the use of gamma survey meter in Micro sievert. (μSv).

RESULTS AND DISCUSSION

TABLE 1: Gamma dose rate of reading

Table 1 Gamma dose rate of reading in day 1 from planted water leaf vegetable

Day1	Readings μSv					Range	Average
Vegetable	1	2	3	4	5	Min –Max	
Morning	0.026	0.035	0.026	0.025	0.027	0.025-0.035	0.0278
Afternoon	0.024	0.022	0.023	0.025	0.026	0.022-0.026	0.024
Evening	0.021	0.031	0.028	0.020	0.022	0.020-0.031	0.0244

TABLE 2: Gamma dose rate of reading

Table 2 Gamma dose rate of reading in day 2 from planted water leaf vegetable .

Day2	Readings μSv					Range	Average
Vegetable	1	2	3	4	5	Min –Max	
Morning	0.021	0.025	0.017	0.019	0.025	0.017-0.025	0.0214
Afternoon	0.025	0.026	0.024	0.027	0.028	0.024-0.028	0.026
Evening	0.024	0.032	0.023	0.033	0.035	0.023-0.033	0.0274

The table 1 showed above the result of gamma dose rate readings taken and recorded three times from the five samples in a day (morning, afternoon and evening).The result indicated that morning had the highest average value of 0.0278μSv, evening had the average value of 0.0244μSv and afternoon had the lowest average value of 0.024μSv.

The day 2 table showed the results of gamma dose rate of readings taken and recorded three times from five samples (morning, afternoon and evening).The result indicated that Evening has the highest average value of r 0.0274μSv, Morning had the average value of 0.0214μSv and afternoon produced the lowest average value of 0.026μSv. .It can be deduced that gamma dose rate emitted from sampled green leaf vegetable from botanical garden from the reading for the average values from day 1 and day 2 ,the highest average values were compared to the international recommended value by United Nation Scientific Committee on the effect of Atomic Radiation (UNCEAR) have the gamma dose rate within the acceptable and permissible dose rate of radiation. The result is not in line with the finding of Jemila et.al.,2022 which stated that The excess lifetime of cancer risk for some vegetable samples was higher than internationally accepted values. But in line with Amakom *et,al*,.2022 that the absorbent dose rate of sampled vegetable were lower than the permissible values indicating consumption safety for those who do not rely heavily on the consumption of these common vegetables

CONCLUSION

The research carried out based on measurement of gamma dose rate emitted from planted vegetable. It can be deduced that all the green leaf vegetable had low gamma dose rate in the day1and day 2, and are not harmful to the body. The activity of concentration shown by gamma absorbed dose rate from indicated that these vegetable had a level of consumption safety when compared with the world permissible values by UNCEAR

It could be concluded that the these gamma dose rate on leaf vegetable from the sample area would not have effect on consumption on human body and does not pose the risk to any cancer related diseases.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Natural combination and blend of plants, roots and barks are depicted as the full scale blend of medicinal herbs and practices used in hindering or taking out physical, mental or social diseases. Standard methods of analysis were used to isolate, identify, characterise and determine both proximate and phytochemical composition of herbal mixtures sold in selected locations in Abeokuta, Ogun State. The results of this present study revealed that the higher coliform count was recorded at E_2 at (464 cfu/g) while the lowest count at (B_1 and D_2) at (03 cfu/g). The highest aerobic count was at C_2 (148 cfu/g) while the lowest count occurred at B_2 (11 cfu/g). The highest fungi load observed at A_1 (4.0 cfu/g) while the lowest at B_2 (1.0 cfu/g). The probable organisms isolated respectively from this study were Staphylococcus, Streptococcus species and Moraxella species. Manufacturers should ensure the highest possible level of hygiene during manufacturing in order to ensure safety of the products so as to maintain correct quality, safety and efficacy of the final herbal preparations.

INTRODUCTION
The utilization of home grown medication has forever been essential for human culture, as certain plants have significant helpful properties, which can be utilized to fix human and other creature illnesses. The utilization of these home grown cures have expanded essentially in the last a few decades in Nigeria. This has prompted the creation of natural items with counterfeit cases that it can fix all types of infirmities (Oyetayo, 2008).
In this way, the quality and wellbeing of natural arrangements are of extraordinary concern since quality is the premise of reproducible adequacy and security of home grown drugs, and to guarantee the norm of exploration on home grown medications, the nature of the plant materials or arrangements is of most extreme significance and must thusly be examined (Sara, 2023).
Microbial examination is a term that alludes to the recognition of microorganism in a given example or item to discover its sterile state. No matter what the type of natural readiness, some microbial investigation is imperative. The point of this study was to lay out the microbial nature of home grown arrangements got from sellers in Obantoko, South Western part of Nigeria (Joan and Susan, 2021).
Most herbal mixtures do not undergo adequate microbial analysis for effective standardization and good quality control, hence they consist of many pathogens which may consequently damage many important organs in the body such as kidney and liver (Amruta Balekundri and Vinodhkumar Mannur, 2020). It is therefore very important to carry out effective microbial examination in order to be able to isolate, identify and know the characteristics of any micro-organisms present in the herbal mixture for effective control measures.
The Aim of the Study is to isolate, identify and characterize microorganisms present in herbal mixtures sold in selected locations of Ogun State metropolis.

MATERIALS AND METHOD
The study was carried out in the Food Microbiology Laboratory, Food Science and Technology Department, COLFHEC, Federal University of Agriculture, Abeokuta.
Ten different samples of locally prepared herbal mixtures were bought from five different locations in Obantoko, Ogun State metropolis and were designated as A-E.
The herbal mixtures were collected in sterile containers for laboratory analysis.

Isolation of Bacteria and Fungi Cultures in herbal mixtures Sample

Five-fold serial dilutions of samples of the herbal mixtures were prepared 1ml of appropriate dilution (1,2,3) was inoculated into MacConkey Agar and Nutrient Agar using pour plate technique respectively. The inoculated plates were then incubated at 37^0C in an inverted position in the incubator for 24hours. The culture plates were then examined for colony growth and observations were recorded (AOAC, 2006; Hunter and Barnnet, 2012).

Five-fold serial dilutions of samples of the herbal mixtures were prepared and 1ml appropriate dilution (1,2,3) was inoculated into Potato Dextrose Agar (PDA) using pour plate technique. The inoculated plates were then incubated at 25^0C for 72hours for fungi growth and observations were recorded. The fungi and bacteria that grow on the media were identified using standardized procedures (Barnett and Hunter, 2012).

Colonies that appear on the surface of the agar plates were counted and recorded. The coliform colony forming units of each herbal mixture sample was calculated using:

$$Colony\ forming\ units\ = \frac{number\ of\ colomies}{volume\ of\ sample\ inoculated * dilition\ factor}$$

Pure cultures were obtained by sub-culturing from mixed culture plates using streak method (AOAC, 2006).

Characterization of Bacterial and fungi Isolates from herbal mixture samples

Pure aerobic bacterial isolates were characterized using cultural, morphological and biochemical characteristics of isolates in different nutrient media preparations. Pure culture was obtained by sub-culturing using streaking method. The morphological characteristics observed were, shape (circular, irregular, spreading), elevation (flat, slightly raised or markedly raised), pigmentation (red, white, pink, colorless), size (pinpoint, small, medium, large) and texture. Microscopy of the isolates was done and observed for arrangement, gram stain reaction and shape. Biochemical tests such as catalase test, oxidase test, indole test, citrate test and methyl red-Vogas Proskauer test were carried out \zaccording to the procedure described by Tokuyasu *et al.* (2012).

Identification of isolates

Bacterial and fungi isolates characterized above were identified by comparing with Bergey's manual of determinative bacteriology (Bergey, 1994; Hunter and Barnnet, 2012)

Data analysis

The data on bacterial and fungal isolates and characterization were analysed by One Way of Analysis Variance (ANOVA) using SPSS 16.0 version and the percentage of bacteria and fungi occurrence were separated.

RESULTS AND DISCUSSION

Table 1: Colonies Count of Bacterial on Nutrient Agar for Herbal Mixture Samples

Sample Codes	$Na10^3$	$Na10^4$	$Na10^5$	N_a (Control)
A_1	19	05	02	
A_2	20	No growth	No growth	______
B_1	46	10	01	
B_2	11	04	01	______
C_1	36	No growth	No growth	
C_2	148	145	No growth	______
D_1	06	03	No growth	
D_2	19	17	01	______
E_1	138	136	01	
E_2	140	128	35	______

Key words:A1, B1, C1, D1 and E1 represent herbal mixture for gonorrhea treatment.
A2, B2, C2, D2 and E2 represent herbal mixture for syphilis treatment.

A1 shown that there is lesser growth of bacteria while there is more growth of bacterial in C^2 which can be harmful to human, which may be because of the water or the environment in which the herbal is being prepared or the way it being prepared.

Table 2: Colonies Count of Bacterial on MacConkey agar for Herbal Mixture Samples

Sample	$Mac10^3$	$Mac10^4$	$Mac10^5$
A_1	-	-	-
A_2	-	-	-
B_1	03	01	-
B_2	11	04	01
C_1	250	180	-
C_2	305	300	208

E_2	Mold (black) with spores	Mold (white) Mold (black with spores)	Mold (white) Yeast (cream)

This study aimed at isolation, characterization and identification of microorganisms from herbal mixture sold in obantoko, Ogun State, Nigeria. The results of the present study revealed that there was a remarkable bacterial and fungal contamination of the different herbal infusions sampled. The samples were contaminated to varying degrees with pathogenic bacteria and fungi. All the herbal mixture samples was however has bacterial contamination, while all the samples also showed fungal contaminants. The fungal counts ranged from 0 cfu/mL to 450×108cfu/mL and the fungal counts ranged from 3.0×106cfu/mL to 3.5×108cfu/mL. These results differ from the work of Abba et al. (2009) who reported average bacterial counts that ranged between 1.0 x 107cfu/g and 1.8 x 108cfu/g in powdered herbal preparations sold in Kaduna metropolis. The high counts of bacteria detected in the herbal infusion in this present study may be due to poor hygiene, use of contaminated water for washing and preparation, use of contaminated equipment and contaminated packaging materials. Other possible sources of contaminants are the personnel that could introduce the microbes when handling the raw materials during processing. "The presence of microbial contaminants in non sterile pharmaceutical products can reduce or even inactivate the therapeutic activity of the products and has the potential to adversely affect patient taking the medicine" This facts was supported by the article review on "rapid monitoring of microbial contamination "by

Nakayima et al., (2005), Okunlola et al., (2007). The possible contaminated organisms were isolated from these product, are staph, Salerocorcus species and Moraae Moraxella. And the organisms isolated are the same with other finding results from other researchers that work on isolating microorganisms from herbal mistures. And this organisms may have occur, maybe a result of inadequate heat processing, improper handling of products and contamination processing equipment and supported by the work of (Frazier and Westhoff, 2003).

CONCLUSION AND RECOMMENDATION

The whole herbal medicine showed significant microbial growth all the herbal medicine bought from these locations. This could be due to bad manufacturing process and also raw materials used, for this production may have not been properly sterilize, which might lead to increase in the microbial content, and poor handing in preparing and packaging this herbal product. There is need for constant monitoring and quality control of herbal medicinal products sold in Obantoko Metropolis Ogun State.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The experiment was conducted during dry season of 2021 cropping season at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University Keffi, Shabu-Lafia Campus and Akwanga LGA of Nasarawa State. The experiment was laid out in a Randomized Complete Block Design (RCBD) and replicated three times with the treatments as: 40 L/ha hydrate + 1L/2ha propagate stages 1-4,40 L/ha hydrate + 1L/2ha propagate stages 1+2, 40 L/ha hydrate + 1L/2ha propagate stages 3+4, 1 L/2ha propagate stage 1-4, 1L/2ha propagate stage 1+2, 1L/2ha propagate stage 3+4, 4 tons/ha poultry manure 150 kg N.P.K fertilizer and T9= control. Data were collected on plant height, number of leaves, leaves area, stem girth and herbage weight. The result revealed significant (P<0.05) different in the plant height. Application of 40L/ha hydrate+1L/2ha propagate stage 1-4 produced significantly taller plant at 3-5 Weeks After Sowing (WAS) in both Lafia and Akwanga LGA, and at 7 WAS poultry manure produced significantly significant taller plants in both locations. 40L/ha hydrate+1L/2ha propagate stage 1-4 and 4t/ha poultry manure produced statistically the same higher number of leaves at all stage of growth. Poultry manure produced largest leaves area at 3-7 WAS. Application of 40L/ha hydrate+1L/2a ha hydrate stage 1-4 and 4t/ha poultry manure recorded statistically the same biggest stem girth in both locations at all stage of growth. The application of 40L/ha hydrate+1L/2ha propagate stage 1-4 produced significant heavier herbage yield in both locations compared to control.. Based on the result obtained in this study, I will recommend that for good growth and herbage weight of okra application of 40L/ha hydrate+1L/2ha propagate stage 1-4 should be used.
Keywords: *Aliagra, hydrate, propagate, liquid, fertilizer, okra*

INTRODUCTION
Okra (*Abelmoschus esculentus* L. Moench) production has been known to be one of the most important vegetable productions in Nigeria. It is an annual crop which can be grown all year round across Nigeria and it is grown mainly as fruit and leaf, vegetable in both green and dried form, for both human and animal consumption. The crop is planted all year round in both tropical forest zone and humid (Adewole *et al.,* 2012). Okra production in Nigeria is predominantly carried out by the resource poor farmers. According to Awodoyin and Oluseum (2009), the immature fruits and leaves of okra are used in the soup as a thickener because it is a rich source of vitamins and minerals. When cooked, okra can give the following nutrition benefits: Protein, niacin, riboflavin, phosphorus, zinc, copper, potassium, vitamins A, B6, C, and K, thiamine, magnesium, folate, calcium, and manganese (Akanbi *et al.,* 2010). In spite of multiple benefit of okra, because of dependence on the natural soil fertility and labour which is usually very costly and not economically profitable its production is very low in most of developing country (Tiamiyu *et al.*, 2012; Schippers, 2000). Okra yield per hectare in Nigeria is very low and is reported to be at about 2 tons per hectare (FAO, 2007)) compared to other nations where okra crop are been produced, because of low innate soil fertility status among other factors. The increasing demand for okra by the majority of people

for food and domestic purposes in Nigeria in recent time make it necessary to look for way of increasing its yield through liquid organic fertilizer application. Aliagra products (propagate liquid organic fertilizer) is a natural nontoxic liquid formulation. It has four stages management program that promotes outstanding results from planting to harvest, increasing the number of flowers per plant while subsequently increasing fruit yield and delivering the critical biostimulant requirements for overall plant health during the entire growing season. The stages of application slated by the manufacturer are: stage 1, propagate promotes microbial life into tired soils, thereby repairing past damage. Stage 2 propagate is an energy-rich hybrid product to feed the microbial life. Stage 3 propagate promotes induced systemic resistance for plant resilience, promoting heat, drought and disease stress. Stage 4 propagate is a bio-stimulant that extends flowering. Hydrate liquid fertilizer delivers quality turf and plant health by introducing microbes to the soil so that it can hold as much as four-times water while producing enzymes that increase water filtration and absorption. Additionally, these microbes store plant nutrients for slow release feeding, fix nitrogen from the air and solubilizing phosphorus that is trapped in the soil. According to the manufacturer, Aliagra products are derived from calcium nitrate, potassium nitrate, phosphoric acid, and monopotassium phosphate and potassium polysaccharide. Work on the field evaluation of liquid organic fertilizer for adoption into the farming system has been reported by many researchers (Jayasundara *et al.*, 2016; Oluwagbenga and Caleb 2016; Vemaraju, 2014) however, Aliagra liquid organic fertilizers are new products and have not been used in this agro-ecological zone. Therefore, this study seeks to evaluate the efficacy of Aliagra liquid organic fertilizer with poultry manure and N P K fertilizer on the growth and herbage yield of okra.

MATERIALS AND METHODS

Description of the Experimental Sites

The study was carried out in two (2) locations; at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University Keffi, Shabu- Lafia, Campus located on latitude 8^0.33`N and longitude $8^0$.32`E with a mean elevation of 181.53 m above sea level (Jayeoba, 2013), and Akwanga LGA located on Latitude 9^0.176`N and Longitude $8^0$.040`E with a mean altitude of 493 m above sea level. Both areas are located in Nasarawa state, within the Southern Guinea Savanna Zone of North Central Nigeria.

Experimental Design and Treatments

The experiments were laid out in a randomized complete block design (RCBD) consist of nine (9) treatments and replicated three (3) times on 216 m^2 field with plot size of 2 m x 2 m (4 m^2) for each replicate. The treatments were as follow; 40 L/ha hydrate + 1 L/2ha propagate stage 1-4 (complete application), 40L/ha hydrate+ 1 L/2ha propagate stage 1+2, 40 L/ha hydrate+ 1 L/2ha propagate stage 3+4, 1 L/2ha propagate stage 1-4, 1 L/2ha propagate stage 1+ 2, 1 L/2ha propagate stage 3+4, 4 tons/ha poultry manure, 150 kg/ha N P K fertilizer and control (No application).

The experimental area was cleared, tilled and seedbed constructed using manual implement (hoe and cutlass). Poultry manure was incorporated into the seedbed at rate of 4 tons/ha and irrigated with water for two weeks before sowing of okra seed. Three local variety of okra seeds (ladyfinger) was sown per hole at 2 cm depth and at a spacing of 60 cm x 45 cm. Germinated stands were thinned to two plants per stand at 2 WAS. Application of Aliagra Liquid Organic Products, Hydrate liquid organic fertilizer was applied to the soil 1 WAS at a rate of 1litre in 15 litres of water per 250 m^2. Propagate liquid organic fertilizer was applied during different stage of plant growth. stage 1 and 2 were applied to the soil at 1 to 2 WAS and 3 to 4 WAS, respectively at a rate of 1litre in 250 litres of water per two hectares, stage 3 and 4 were applied in the form of foliar application at 5 to 6 WAS (full vegetative growth) and 7 to 8 WAS (at flower initiation) at rate of 1litre in 250 litres of water per two hectares. The NPK fertilizer was applied at rate of 150 kg/ha 1 WAS. Weeding (hoeing) was carried out at 3 and 5 WAS and supplementary hand pulling before the maturity of the okra crops. Data collection was carried out on four randomly tagged plant in each plot, Plant height (cm) was measured from the soil surface to the terminal bud with the aid of meter rule and the mean recorded for each treatment. Number of leaves per plant all fully expanded leaves per plant were counted and the mean recorded for each treatment. Leaf area (cm^2) was determined by measuring the leaf length and width of the tagged plant. The leaf area was estimated by using the equation; leaf area = 0.62 (L x W) (Musa and Hassan, 2016), Stem diameter (cm) was measured using a Vernier caliper. Harvested herbage from each tagged plant in a plot were weighed using an electronic weighing scale and the mean were converted to tons per hectare.

Statistical Analysis

Data collected on growth and herbage yield parameters were compiled and analyzed statistically using GENSTAT software (2008 Ed). Data were subjected to analysis of variance (ANOVA) using the General Linear Model Procedure. Least Significant Difference (LSD) was used to separate the mean for the parameters measured at 5 percent level of probability ($P \leq 0.05$)

RESULTS AND DISCUSSION

Effect of Aliagra liquid organic fertilizer, NKP fertilizer and poultry manure on plant height of Okra

The result of analysis of plant height is presented in table 1. In both Lafia and Akwanga during 2021 cropping season, the result revealed that there was significant ($P<0.05$) different in the plant height of okra. Application of 40L/ha hydrate + 1L/2ha propagate stage 1-4 produced significantly tallest plant in both location at 3 to 5 weeks after sowing (WAS) followed by 4tons/ha poultry manure and shortest plant was recorded in control plot. At 7 WAS plant height were significantly taller at both location with application of 4tons/ha poultry manure compare to control. The tallest plant recorded could be attributed to the ability of Aliagra liquid organic fertilizer (hydrate and propagate) and poultry manure to retain water and supply soil organic nutrient and biostimulants more quickly to okra plant which supported its growth, the taller plant observed indicate that okra was able to utilized nutrient element present in the liquid organic fertilizer. This is in conformity with the finding of Nelson *et a*l, (2010) and is in agreement with the study of Martinez-Alcantara *et al* (2016) who reported that either animals or plant based liquid organic fertilizer produced tallest plant than mineral fertilizer.

Table 1. Effect of Aliagra liquid organic fertilizer, N K P fertilizer and poultry manure on plant height (cm) of Okra

Effect of Aliagra liquid organic fertilizer, NPK fertilizer and poultry manure on number of leaves of Okra

Table 2 showed the result of analysis of number of leaves. The result revealed that there was significant ($P<0.05$) different in the number of leaves of okra. At all sampling period (3, 5 and 7) in both locations, 40L/ha hydrate+1L/2ha propagate stage 1-4 and 4tons/ha poultry manure produced statistically highest similar number of leaves compared to other application and the lowest leaves was recorded in control. The increase in leaves production by application of Aliagra liquid organic fertilizer and poultry manure may be attributed to the increase in nutrients uptake in the okra plant leading to improved in cell division and formation hence increased the number of leaves. This is line with the report of Jayansundara *et al*, (2016) and also in agreement with the finding of Abbasi *et al*, (2010) who stated that foliar application of liquid organic fertilizer increased the growth performance of okra plant especially the leaves production.

Effect of Aliagra liquid organic fertilizer, NPK fertilizer and poultry manure on leaves area of Okra.

Table 3 showed the result of leaves area. The result revealed that there was significant ($P<0.05$) different in the leaves area of okra. In both location at all sampling period i.e. from 3,5 and 7 WAS, application of 4tons/ha poultry manure produced significantly widest leaf area compared to other treatment and the smallest leaf was recorded in control. The wider leaf area recorded in poultry manure organic fertilizer indicate that okra plant was able to absorbed and utilized the available nutrients which resulted to wider leaf and attributed to the already soluble nutrients release from poultry manure and was taken up by okra plant resulting to improved cell formation consequently produced widest leaves area. This is similar to the finding of Ramasamy *et al*, (2010) but not in line or agreement with the report of Oluwagbenga *et al* (2016) who state that there was no significant different in the number of leaves using Alpha life liquid bio-fertilizer.

Effect of Aliagra liquid organic fertilizer, NPK fertilizer and poultry manure on the stem girth of okra

Table 4 showed the result of stem girth. The result on the stem girth revealed significant ($P<0.05$) different from 3 to 7 WAS at both locations. Application of 40L/ha hydrate+1L/2ha propagate stage 1-4 and 4tons/ha poultry manure produced statistically similar bigger stem compared to other treatment and smallest stem was recorded in control at all sampling period. The biggest stem recorded in Aliagra liquid organic fertilizer (hydrate+propagate) and poultry manure indicate that liquid organic fertilizer applied in the soil and foliar contain useful and absorbable nutrients needed by okra plant that result in the vigorous growth performance by improved cell formation. therefore, increased the stem girth. This is similar to report of Jayasundara *et al* (2016) when liquid organic fertilizer was compared with poultry manure on growth enhancement of *Abelmoschus esculentus* and *Alternanthera sessilis.r*. and in conformity with the report of thanaporn *et al*, (2019) who stated that liquid organic fertilizer produced after 30 days of fermentation and used at a dilution of 1:100 demonstrated the best growth performance in okra.

Table 2. Effect of Aliagra liquid organic fertilizer, NPK fertilizer and poultry manure on number of leaves of Okra.

Effect of Aliagra liquid organic fertilizer, NPK fertilizer and poultry manure on herbage yield (Biomass) of okra

Table 5 showed the result of analysis of herbage yield. The result revealed that there was significantly ($P<0.05$) difference in the herbage yield of okra. In Lafia 40L/ha hydrate+1L/2ha propagate stage 1-4 Produced significantly heavier herbage compared to other treatment and, the lowest was recorded in control. At Akwanga 40L/ha hydrate+1L/2ha propagate stage 1-4 and 4t/ha poultry manure produced statistically the same heavier herbage compared to control. The increased in the herbage yield recorded in Aliagra liquid organic fertilizer is as a result of vigorous performance observed in the vegetative growth (plant height, number of leaves, leaves area, stem girth) which indicate that the liquid fertilizer contained essential nutrients needed for the growth and yield of okra. This is in line with Chandrakala (2008) who reported that fresh matter and dry matter yield of chilli were increased with combined application of jeevamruth and panchagavya liquid organic fertilizer.

CONCLUSION AND RECOMMENDATION

Used of fertilizer is essential in crop production especially area low soil fertility to increase growth and yield. In this study the use of Aliagra liquid organic fertilizer improves the availability and mobility of plant nutrients. Thus, increasing the nutrients uptake by okra plant roots leading to vigorous growth. I therefore, recommend that further study should be carry out on other crop with this product to confirm the result.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An experiment was carried out during the cropping season of 2023 in the Research and Experimental Field of the Botanical Garden of the Department of Plant Science and Biotechnology of Federal University of Lafia, Nasarawa State to investigate the influence of Alpha spin nanoparticles and different Organic manure on the germination of onion (Allium cepa). The onion seeds were exposed to different levels of Alpha pin Nanoparticles at 20min, 40min and 60min alongside the untreated (control). The land was treated with different organic manures which are Cow dung, Poultry droppings and Rice husk alongside untreated plot (control). The experiment was laid out in a 4^2 factorial experiment in Randomized Complete Block Design (RCBD) with three replications. The result revealed that there was a significant difference ($p < 0.05$) in number of days to germinate while there were no significant differences ($P > 0.05$) in the percentage germination and seedling heights. The earliest number of days to germination was recorded under 60minutes of Alpha Spin nanoparticles (N3) and T3 (rice husk) . The highest germination percentage was recorded under 40minutes (N2) with 0.63 and T3 (rice husk) with 0.68. The highest seedling height was recorded under control and T2 (poultry dropping). The result also showed that the alpha spin® nano particles reduced the number of days to germination, increased percentage germination against the control but it reduced the parameter for seedling height. Therefore, it could be concluded that Alpha spin® nanoparticles had little impact on the germination of onion.
Keywords: *Alpha Spin, Nanoparticles, Organic Manure, Germination, Onion*

INTRODUCTION
Onion (*Allium cepa*) is an important worldwide vegetable crop (Best, 2000) which belongs to the family of Liliaceae. It is divised into three groups: *Allium cepa*, *Allium aggregattum, Allium prolilum,* which are all diploids (2n = 2x = 16) (Boukary *et al*., 2012). The crop is a biennial herb of Central Asian origin (Afghanistan, Iran and Pakistan) and is cultivated all around the world. Onion occupies the 4th world rank of consumed vegetables after tomato, cabbage and watermelon with a global annual production of 25 million tonnes) (Boukary *et al*., 2012) *Allium* is the largest and most important representative genus of the Alliaceae family and comprises of 450 species, widely distributed in the northern hemisphere. Besides, the well-known garlic and onion, several species are widely grown for sculinary use, such as leek (*Allium porrum* L.), shallot *(Allium ascalonicum* Hort.) wild garlic (*Allium ursinum* L.), chive (*Allium schoenoprasum* L.) (Marsili, 2017).
The pungency of onions made them popular among poor people throughout the world who could feely use this inexpensive vegetable to spark up their meal. Today China, India, the United State, Russian and Spain are among the leading producers of onions. Onions have a great therapeutic value. They are stimulants and mild counter-irritants. It has been used as a herbal remedy for centuries in colds, coughs, bronchitis and influenza. Onions are well known for their easily assimilable iron content (Gough, 2016). Recent researches establish that the onion has an effective prevention against heart attacks. It is an effective remedy for cholera also. Onions are highly beneficial in the treatment of the disorders of urinary system. Onions are very effective in bleeding piles. Other uses of this herb are teeth disorders, ear disorders, and tuberculosis (Jones, 2010).
The current challenges of sustainability, food security and climate change are engaging researchers in exploring the field of nanotechnology as new source of key improvement for the agricultural sector. Several technological innovation have been employed in agricultural improvement of plants which have resulted in, hybrid variety, synthetic chemicals. Therefore, it will be of immense importance for researchers to seek in nanotechnology a new source of agricultural improvement (Claudio, *et al*., 2015).

Alpha spin optimizes the natural frequency as it can increase harmony in the body by stimulating vital life energy. Any contact with alpha-spin, the molecular structure will create smaller clusters that will make penetration and absorption easy by full optimizing the body's molecular and cellular functions via resonance and then forming a vortex that results in the expression of a quantum energy field which will exert its effect in the content of an organism's body (Gogos *et al.*, 2012). Its functions include improvement of absorption and increase in hydrations, improve micro circulations. It can also be used to facilitate the flow of energy through reflexology frequency, through which it can improve plant growth, seed germination and extend the shelf life of fruits and vegetables (International, 2017).

Nanotechnology has the potential to advance agricultural productivity through genetic improvement of plants, delivery of genes and drug molecules to specific sites at cellular levels, and nano-array based gene-technologies for gene expressions in plants and animals under stress conditions. The potential is increasing with suitable techniques and sensors being identified for precision agriculture, natural resource management, and early detection of pathogens and contaminants. Nanomaterials in agriculture aims in particular to reduce the amount of sprayed chemical products by smart delivery of active ingredients, minimise nutrient losses in fertilisation and increase yields through optimised water and nutrient management (Gogos *et al.*, 2012). The study investigates the effect of Alpha spin nanoparticles and organic manure on the germination of onion.

MATERIALS AND METHODS

This research was carried out in the Botany Garden of Federal University of Lafia, Nasarawa State, located on latitude 8^0 35'N, longitude $8^0$32'E altitude 181.53m above sea level with a mean temperature of 34^0c , relative humidity 0f 40-80 % and average day light of 9-12. It is located in the southern Guinea Savannah Region of North-central Nigeria. In the year 2022. Onion seeds (variety (ies)) were obtained from Nasarawa Agricultural Development Program (NADP).

The treatments comprises of three levels of organic manure (cow dung (T1), poultry drop (T2) and rice husk (T3) and three levels of Alpha Spin nanoparticles at 20min (N1), 30mins (N2) and 60mins (N3) before planting while the untreated seeds were planted alongside the treated seeds and used as control. The experiment was laid out in a 4^2 factorial experiment in a Randomized Complete Block Design (RCBD) with three replications.

Data were collected on the Number of Days to Germination, Number of Germinated Seeds, and Seedling Height (cm).

The data were subjected to Two-Way analysis of variance (ANOVA) using GENSTAT version 17.0 software. Means were separated using least significant difference (LSD) at $p \leq 0.05$.

RESULTS AND DISCUSSION

Number of Days to Germination

The result shows that the differences in the number of days to germination among the plants exposed to alpha spin treatments are significant (Table 1). The number of days to germination of the control and N1 treatment do not significantly differ from each other whereas the N3 treatment was observed to have lowest (6.08) number of days to germination. Also as for the organic manure treatment, the differences in the number of days to germination are significant among the treatments with control having the highest (7.67) while T3 had the lowest (6.33) as indicated in Table 1. What is the implications of this findings / (results presented).

Percentage Germination of Seeds

The effects of the organic manure treatments and alpha spin treatments on the percentage germination are not significant (Table 2). Although the plant exposed to N2 alpha spin treatment had the highest percentage germination (0.63) but not significantly different from that of the control, and other treatments. Similarly, the plants exposed to T3 organic manure treatment was observed to have the highest percentage germination which is not significantly different from the others as indicated in Table 2. You only presented the results but no discussion

Seedling Height

The effects of the organic manure treatments and alpha spin treatments on the seedling height are not significant (Table 3). The control plant had the highest seedling height but not significantly different from those of other alpha spin treatments. Similarly, the plants exposed to T2 organic manure treatment was observed to have the highest seedling height which is not significantly different from the control and others in Table 3. You only presented the results but no discussion.

Table 1: Number of days to germination of plant under Alpha spin and organic manure treatments

Alpha spin Treatments	Organic manure Treatments				Mean
	T0	T1	T2	T3	
N0	9.00	7.67	7.67	6.00	7.58^c
N1	8.00	7.67	7.00	7.00	7.42^c
N2	7.33	6.67	6.67	6.33	6.75^b
N3	6.33	6.00	6.00	6.00	6.08^a

Mean	7.67^{c}	7.00^{b}	6.83^{b}	6.33^{a}
LSD_{OM} = 0.45				

Values with same superscript across same column or same row are not significantly different (P > 0.05)

Table 2: percentage germination of plant under alpha spin and organic manure treatments

Alpha spin Treatments	Organic manure Treatments				**Mean**
	T0	T1	T2	T3	
N0	0.48	0.72	0.52	0.57	0.57^{b}
N1	0.52	0.24	0.54	0.53	0.46^{b}
N2	0.74	0.63	0.61	0.55	0.63^{b}
N3	0.49	0.61	0.45	0.68	0.56^{b}
Mean	0.56^{d}	0.55^{d}	0.53^{d}	0.59^{d}	
	LSD_{OM} = 0.20				

Values with same superscript across same column or same row are not significantly different (P > 0.05)

Table 3: seedling height of plant under alpha spin and organic manure treatments

Alpha spin Treatments	Organic manure Treatments				**Mean**
	T0	T1	T2	T3	
N0	8.43	8.50	11.23	9.30	9.37^{d}
N1	8.63	8.43	8.43	6.73	8.06^{d}
N2	8.67	8.17	8.13	7.93	8.23^{d}
N3	8.20	7.23	6.30	8.77	7.63^{d}
Mean	8.48^{e}	8.08^{e}	8.53^{e}	8.18^{e}	
	LSD_{OM} = 2.12				

Values with same superscript across same column or same row are not significantly different (P > 0.05).

Where:

Alpha Spin®	Organic Manure
N0= Control	T0= Control
N1= 20 Minutes	T1= Cowdung
N2= 40 Minutes	T2= Poultry Dropping
N3= 60 Minutes	T3= Rice Husk

CONCLUSION AND RECOMMENDATIONS

From the findings of this study, it could be concluded that Alpha spin nanoparticles and organic manure have impact on the number of days to germination of onion, percentage germination and seedling height because there were significant differences between the exposed times in the number of days to germinations although there were no significant differences in the percentage germination and seedling heights respectively. Specifically, 60mins (N3) and Rice Husk (T3) treatments reduced the number of days to germination of the plant. This present study recommended that for better seedling height, percentage germination and number of days to germination, onion seeds should be treated with Alpha spin nanoparticles at a longer period of time and organic manure such poultry droppings and rice husk should be used because the lowest number of days to germination, the highest percentage germination and the highest seedling heights were observed in the rice husk and poultry droppings treatments in combination with Alpha spin nanoparticles at 60minutes time of exposure.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study aimed to investigate the impact of different drying methods, namely shade drying, vacuum oven drying, and freeze drying, on the concentration of bioactive compounds, specifically epicatechin, kaempferol, and syringic acid, in ginger (Zingiber officinale). The concentrations of the compounds were measured in milligram per gram (mg/g) in triplicate measurements using high performance liquid chromatography and statistically evaluated for significant differences. For Epicatechin, Vacuum oven drying showed the greatest concentration (0.384± 0.026), followed by freeze drying (0.338± 0.024) and shade drying (0.308± 0.022). Fresh samples, on the other hand, had the lowest Epicatechin content of (0.204± 0.030). Kaempferol concentrations followed a different pattern, with freeze drying producing the greatest concentration (1.201± 0.092), Vacuum oven drying (1.099± 0.065), shade drying (0.926± 0.045), and fresh samples (0.061± 0.053).Furthermore, freeze-dried samples showed the greatest Syringic acid contents (0.221± 0.012), followed by vacuum oven drying (0.191± 0.010), shade drying (0.113± 0.006), and it was not detected in the fresh samples. The results revealed substantial variations in the concentrations of these compounds across the drying methods, shedding light on the optimal preservation method for each of the ginger's bioactive constituents.

INTRODUCTION

Ginger (Zingiber officinale) is widely recognized for its potential health benefits attributed to its diverse array of bioactive compounds, including epicatechin, kaempferol, and syringic acid. These compounds possess antioxidant (Nile and Park, 2015), anti-inflammatory (Zhang et al; 2016), anti-bacterial and potential therapeutic properties (citronberg et al; 2013). Preservation of ginger is crucial to maintaining its nutritional and medicinal value. Various drying methods are employed for this purpose, each potentially influencing the phytochemical profile differently. This study aimed to assess the impact of three common drying methods on the concentration of epicatechin, kaempferol, and syringic acid in ginger.

Experimental

MATERIALS

Methanol
Vacuum oven
Freezer
Whatman filter paper
Rotary vacuum evaporator
Ginger (*Zingiber officinale*)

METHODS

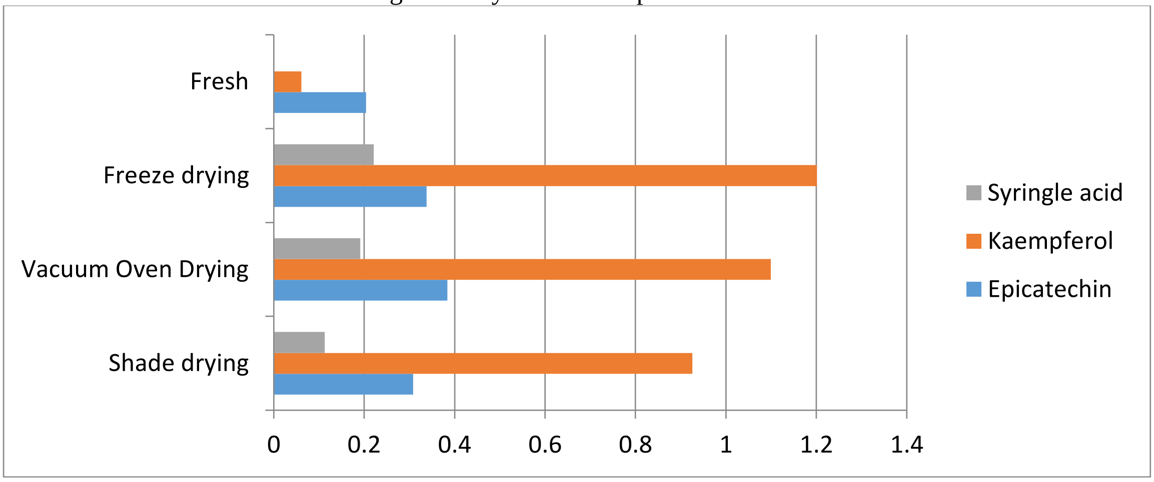
Collection and Preparation of Samples: The sample for this investigation was carefully chosen. For each drying step, the sample was cleaned, weighed, and divided into four equal pieces. Drying methods: Four different drying methods were used: shade drying, freeze drying, vacuum oven drying, and a fresh un-dried control group. Extraction and Analysis of Compounds: Methanol was used as a solvent to extract the dried and fresh ginger samples. 5g weighed and refluxed in a water bath for 15 minutes with methanol (100ml) before filtering using whatman filter paper (No.41). The leftover residue was filtered after being refluxed three times for 15 minutes with 70ml of methanol. The solvent was then evaporated using a rotary vacuum evaporator. This was done on all of the samples. The extract was examined, using high performance liquid chromatography. Statistical Analysis: ANOVA was used to investigate the significance of variations in the means of the various drying procedures.

RESULTS AND DISCUSSION

The results presented in the table below indicated significant variations in the concentrations of Epicatechin, Kaempferol and syringic acid based on the drying method employed.

Drying Method	Epicatechin (mg/g)	Kaempferol (mg/g)	Syringic acid (mg/g)
Shade drying	0.308± 0.022 ^{c}	0.926± 0.045^{c}	0.113± 0.006^{c}
Vacuum Oven drying	0.384± 0.026^{a}	1.099± 0.065^{b}	0.191± 0.010^{b}
Freeze drying	0.338± 0.024 ^{b}	1.201± 0.092^{a}	0.221± 0.012^{a}
Fresh	0.204± 0.030 ^{d}	0.061± 0.053^{d}	ND

The Data represents means of triplicate measurements. The means that are not sharing a common letter in each column for each measurement are significantly different at p<0.05. N D   Not detectable



Among the three compounds studied, kaempferol exhibited the highest sensitivity to drying methods, with freeze drying (1.201 ± 0.092 mg/g) showing the highest concentration (1.099 ± 0.065 mg/g), followed by Vacuum oven drying (1.099 ± 0.065 mg/g), and shade drying (0.926 ± 0.045 mg/g). Epicatechin concentration was highest in vacuum oven dried samples (0.384 ± 0.026 mg/g), while freeze drying resulted in the highest concentration of syringic acid (0.221 ± 0.012 mg/g).

Shade drying exhibited the lowest concentration for all three compounds, likely due to prolonged exposure to light and heat, which can lead to degradation. Vacuum oven drying, characterized by controlled heat and reduced pressure, appeared to be a preferable method for preserving epicatechin. Freeze drying, involving rapid freezing and sublimation, retained higher concentrations of syringic acid and kaempferol.

CONCLUSION

This study highlights the impact of different drying methods on the concentrations of epicatechin, kaempferol, and syringic acid in ginger. The results underscore the need for careful consideration of drying methods when aiming to preserve the bioactive content of ginger. Vacuum-oven drying demonstrated superior preservation of epicatechin, while freeze drying was more effective for syringic acid and kaempferol. These findings provide valuable insights for optimizing the drying process to retain the beneficial bioactive compounds present in ginger.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Seven Turmeric landraces were collected from the Genetic Resources Unit of the National Root Crops Research Institute, Umudike, Abia State and characterized in 2022 planting season at Umudike. The seven landraces were laid out in randomized complete block design (RCBD) using three replications. The list of the landracesused were; Ajo (Igbaraodo), Turmeric Uromi, Atale (Yakooyo), kadi – Odo, Atale (Temidire), Red ginger and Ege Apana . Morphological character analysis was based on the "mathematics of information Theory" which allows simultaneous analysis of both quantitative and qualitative data. Principal component analysis have proved to be effective methods in grouping turmeric accession according to their morphological characteristics and better understanding of the existing variability that will facilitate genotypic selection for crop improvement.

Keywords*: Turmeric, Landraces, "mathematics of information Theory, Characterization*

INTRODUCTION

Turmeric (*Curcuma longa* Linn) is a shallow-rooted crop and an herbaceous plant with thick and fleshy rhizomes (Olojede *et al.*, 2009). It is a tropical perennial monocotyledonous herb belonging to the family Zingiberaceae and consists of many species (Jilani *et al*, 2012). Its origin has been traced to south and southern Asia and it has been used in India for at least 2,500 years. *C. longa* Linn is the highest yielding turmeric of commercial value. It is valued for its underground rhizome which contains a yellow coloured phenolic pigment called curcumin which is used as natural colouring agent for food, cosmetics, dye and as an active ingredient in some medicine (Olojede *et al*, 2015). Characterization of germplasm is essential to provide information on the traits of accessions assuring the maximum utilization of the germplasm collection to the final users (Singletary, 2010)). Morphological characterization is an important tool even in the era of molecular characterization because of its reliability and easy identification with less resources for certain stable characters unaltered by environmental interactions. The study was to characterize seven turmeric genotypes for different morphological characters based on Distictiveness, Uniformity and Stability (DUS) guidelines. Therefore, two objectives of this study were to determine the morphological diversity among the seven turmeric landraces and to determine duplication of cultivars within the turmeric landraces.

MATERIALS AND METHODS

The turmeric landraces used for this study were collected from the Genetic Resources Unit of the National Root Crops Research Institute, Umudike, Abia State. The seven landraces were laid out in RCBD using three replications. The list of the genotypes used were; Ajo (Igbaraodo), Turmeric Uromi, Atale (Yakooyo),kadi – Odo , Atale (Temidire),Red ginger and Ege Apana. The plot size was 6m^2 (2m x 3m) using raised beds, while seedling rate was 1 rhizome/stand. The plants were spaced 50cm x 30cm apart between and within rows, respectively. Fertilizer application was at the rate of 400kg per hectare of NPK (15:15:15). First weeding was carried out at between 4 weeks after planting, and roguing was carried out at 10 weeks after planting. Three plants of uniform size and vigor were selected for recording observations.landraceswere evaluated for 19 DUS traits viz., Plant: pseudostem habit, plant height (cm), number of shoots, number of leaves on main stem, Plant leafs: leaf disposition, petiole length (cm), leaf lamina length (cm), leaf lamina width (cm), dorsal leaf colour, ventral leaf colour, leaf venation pattern, leaf margin, vigor. Rhizome: Rhizome habit, rhizome shape, rhizome internode pattern, status of tertiary rhizome, primary rhizome length, number of mother rhizome were recorded at harvest. The assessment of characters was done at 5 months when the plant growth and its morphological characters were optimal. Harvesting was done when the leaves were dried. Morphological character analysis was based on the "mathematics of information Theory" (Nwankwo 2014) which allows simultaneous analysis of both quantitative and qualitative data. Any character or state that is not in alliance with the column characters is discriminatory.

RESULTS AND DISCUSSION

Morphological characters are predominantly used for easy differentiation of genotypes because the characters are expressed genetically involving one or more genes. Among the 7 landraces studied, considerable variation was recorded for all the important characters (Table 1).Based on the mathematics theory that rank all the morphological traits, it was observed (Table 1) that all the seven landraces were related eight out of nineteen characters measured namely: rhizome shape, the same number of leaves on main stem, Plant leaf disposition, petiole length (cm), ventral leaf colour, leaf margin, rhizome internode pattern and primary rhizome length. The eight related characters shows that they are from the same family but distinct and different in eleven traits which indicated they are different and distinct landraces However since none of the landraces are uniform in all the characters ranked showed that there was no duplication of the genotypes Table 1 below

Table 1: Morphological variation among turmeric landraces (Using DUS descriptor)

	Pseudo stem habit	Plant height(cm)	No of shoots	No of leaves on main shoot	Leaf disposition	leaf petiole length(cm)	Lamina length	Lamina width(cm)	Venation pattern	Leaf margin	Leaf color on the ventral side	Leaf color on dorsal side	Vigor
Ajo (Igbaraodo)	9	3	1	5	5	3	3	3	5	5	5	3	1
Turmeric Uromi	9	3	3	5	5	3	5	3	5	5	5	5	1
Atale (Yakooyo)	9	5	3	5	5	3	3	5	5	5	5	3	1
Kadi – Odo	9	3	3	5	5	3	5	5	5	5	5	3	1
Atale (Temidire)	9	3	5	5	5	3	5	3	3	5	5	5	1
Red ginger	9	3	3	5	5	3	3	5	5	5	5	3	1
Ege Apana	9	5	5	7	5	3	3	5	5	5	5	3	1

Note: Each column is a character and the rows respective state or genotype represents status of each genotype for each character

Coded List Of Genotype States.

Explanation of the status of each character expressed by the genotypes

1. Pseudo stem habit: Even= 3, Wavy =5
2. Plant height (cm): Short (<85) = 3, Medium (85-100) = 5
3. Number of shoots: Few (>5) =1, Medium (3-5) =3, Many (>5) = 3
4. Number of leaves on main stem: Intermediate (5-10) = 5, Many (>10) = 7
5. Leaf disposition; Erect (<45°) = 3, Semi-erect (45°-85°) = 5, Horizontal= (>85°) = 7
6. Plant petiole length (cm): Short (<15) = 3, Intermediate (15-25) =5, Long (>25) = 7
7. Leaf lamina length (cm): Short (<30) =3, Medium (30-40) =5, Long (>40) =7
8. Leaf lamina width (cm): Narrow (<10) = 3, Medium (10-15) =5, Broad (>15) =7
9. Leaf colour on dorsal side: Light green =3, Green =5
10. Leaf colour on the ventral side: Dark green= 7, Green =5
11. Leaf venation pattern: Close =3, Distance= 5
12. Vigor: Low vigor= 1, moderately vigorous= 2
13. Leaf margin; Compact = 1, Open = 9
14. .Rhizome habit: Compact= 3, Intermediate=5, Loose= 7
15. Rhizome shape: Straight= 3, Curved=5
16. Rhizome internode pattern: Close (<1) = 3, Distant (>1) =5
17. Status of tertiary rhizome: Absent= 1, Present= 9
18. Primary rhizome length: Short (<5 cm) =3, Medium (5-10 cm) =5, Long (>10 cm) =7
19. Number of mother rhizome: One= 1, Two =3, More than 3=5
20. Internode pattern: Close (<1) = 3, Distance= (>1)

CONCLUSION

Findings show that out of the nineteen descriptor traits used for this experiment, Venation pattern, number of leaves on the main shoot, rhizome habit, lamina length, leaf color on the dorsal side, number of mother rhizome and status of tertiary rhizome are good discriminant descriptor traits for characterizing turmeric landraces. The eight related characters showed that they are from the same family but distinct and different in eleven traits which indicated they are different and distinct landraces However since none of the landraces are uniform in all the characters ranked showed that there was no duplication of the genotypes The variations analyzed using DUS characters offer a bright scope for selection based on desirable morphological traits which can be used in future breeding purposes.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Twenty genotypes of Dioscorea rotundata was collected from yam programme of the National Root Crops Research Institute, Umudike, Abia State and was characterized in 2022 planting season at Umudike for enhancing further selection for breeding purpose. The field was marked out into three replications and each replicate was divided in to 20 plots measuring 4m x5m (20m²). The spacing between each replicate was 1m and the spacing between each plot was 0.5m. The sett size was 100g of 20 different genotypes of white yam were the experimental treatments. The experiment was a Randomized Complete Block Design (RCBD) with three replications. Morphological character analysis was based on the "mathematics of information Theory" (Nwankwo 2014) which allows simultaneous analysis of both quantitative and qualitative data have proved to be effective methods in grouping yam genotypes according to their morphological characteristics and better understanding of the existing variability that will facilitate genotypic selection for crop improvement, number of tuber per stand, corm size in relation to tuber size, tuber shape and hairiness of surface are good discriminant descriptor traits for characterizing yam tubers
Keywords: *Morphological Diversity, Genotypes, Mathematics of information Theory*

INTRODUCTION
Yam belongs to the genus Dioscorea in the family Dioscoreacea and is one of the most important staple foods in the world, especially some parts of Tropics and Subtropics (Okigbo and Ogbonnaya, 2006). The edible varieties of yam are important food crops and serve as an important carbohydrate staple for millions of people in both the Tropical and Subtropical countries in West Africa, the Carribeans, the Northerrn and Central part of South East Asia including parts of China, Malaysia, Japan and Oceania (Mignouna *et al*., 2003). The FAO (1989) estimated that the world production is around 20 million ton per year. Nigeria alone produces three quarter of the world total output of yams. Okigbo (2004).The tuber is the edible portion of yam and has high carbohydrate content, serving as a major source of energy but, low in fat and protein. Yam is consumed as boiled yam, pounded yam and fried yam or processed into flour. Morphological characterization is an important tool even in the era of molecular characterization because of its reliability and easy identification with less resources for certain stable characters unaltered by environmental interactions. Therefore the objectives of this study was to characterize 20 white yam genotypes based on morphological diversity in Umudike south eastern Nigeria.

MATERIALS AND METHODS
The field trial was conducted at the farm of the National Root Crops Research Institute (NRCRI), Umudike, South Eastern Nigeria in 2022. The field was prepared by slashing, ploughed and harrowed. The field was marked out into three replications and each replicate was divided in to 20 plots measuring 4m x5m (20m²). The spacing between each replicate was 1m and the spacing between each plot was 0.5m. The sett size was 100g of 20 different genotypes of white yam were the experimental treatments. The experiment was a Randomized Complete Block Design (RCBD) with three replications. Data were collected on 12 morphological characters from at least three healthy plants. Traits measurement and data collection procedure used was based on those presented in the International Plant Genetic Resources Institute's descriptor list for yam (IPGRI/ IITA, 1997) with slight modifications. Only those descriptors or traits that discriminated between genotypes were used in this study. Data were the average of at least three different healthy plants per genotype. Morphological character analysis was based on the "mathematics of information Theory" (Nwankwo 2014) which allows simultaneous analysis of both quantitative and qualitative data. Any character or state that is not in alliance with the column characters is discriminatory

RESULT AND DISCUSSION

The tubers of the twenty advanced yam genotypes were characterized for their morphological variability (Table 1). List of morphological characteristics and character states were based on yam descriptor manual code character, while morphological character analysis was based on the mathematics of information theory which allows simultaneous analysis of both quantitative and qualitative data (Nwankwo 2014). This method simultaneously group tubers that have corresponding biological similarity together in ranks. Any character or state that is not in alliance with the column character is discriminatory. At a glance in the table, duplicate genotypes can easily be detected out (Table 1). The result of the twelve principal characteristics namely flesh colour, number of tubers per plant, relationship of tubers, corm size, tuber length, texture of skin, hairiness of surface tuber, tuber spines, maturity of tuber and tuber habit were analyzed using the mathematics of information theory. The twenty white yam genotypes are uniform in relationship of tubers i.e. they are completely separate not fused, the flesh colour is white, Under tuber length, the twenty yam genotypes were uniform in that character. Their tuber lengths were from 20 to 100cm. As regard their tuber maturity and tuber habit, all the yam genotypes indicated that they were early maturing (7 months or less) and annual plants (that is can be harvested the same year). Other characters in the other six columns are discriminatory. Each column is a character while each row is a state (or genotype). All the 20 advanced white yam genotypes have the same four characteristics namely relationship of tubers, tuber length, maturity of tubers and tuber habit but there were remarkable variation in number of tubers per stand, corm size, texture of tuber skin, tuber shape ,hairiness of surface tuber, and spines. Each genotype differs from the other as they appear in their rows. Based on the result of Table 1, the morphological characterization using yam manual descriptor indicated that there is variation among the yam genotypes

Based on these morphological variations, the 20 genotypes are characterized into the following groups:

Group 1. Out of the 20 genotypes of white yam used,18 genotypes exhibit variation for number of tubers as normal one TDR 1439018, TDR 000021, TDR 090061, TDR 1414005,TDR 1440035,TDR 1436015, TDR 11/00585,TDR 1417015 ,TDR 000078, TDR 11/00396, TDR 89/02665,TDR 09/00082,TDR 1430007,TDR1429027,TDR 1439027,TDR OBIATURUGO, TDR 0000360, TDR 1428017),while 2 genotypes (TDR 1401593,TDR 100003) exhibits variation for few number tubers per stand.(Table 1)

Group 2. Out of the 20 genotypes of white yam used, there is morphological diversity in corm size,9 genotypes TDR 1436015,TDR 11/00585,TDR 1417015,TDR 09/00082,TDR 1430007,TDR 1429027,TDR 1439027,TDR OBIATURUGO,TDR 1428017 exhibits small corm size ,9 genotypes TDR 1439018, TDR 000021, TDR 090061, TDR 1414005, TDR 1440035, TDR 100003 TDR 000078, TDR 89/02665, TDR 0000360 exhibits medium corm size while only 2 genotypes TDR 1401593, TDR 11/00396 exhibits large corm size (Table 1)

Group 3. Out of the 20 genotypes of white yam used, there is variation in tuber length ranging from 6-20cm(2) to 21-100(3),5 genotypes TDR 1439027,TDR 1439018, TDR 100003, TDR 1430007, TDR 1429027 has tuber length of 6-20cm while 15 genotypes TDR 000021, TDR 090061, TDR 1414005, TDR 1440035, TDR 000078, TDR 89/02665, TDR 0000360,TDR 1436015,TDR 11/00585,TDR 1417015 ,TDR 09/00082, TDR OBIATURUGO, TDR 1428017,TDR 1401593, TDR 11/00396 has tuber length ranges from 21 to 100cm) Table 1

Group 4.Out of the 20 genotypes of white yam used, variation in texture of Tuber skin among the genotypes ranges from smooth to rough.18 genotypes TDR 1430007, TDR 1429027,TDR 000021, TDR 090061, TDR 1414005, TDR 1440035,TDR 89/02665, TDR 0000360,TDR 1436015,TDR 11/00585,TDR 1417015 ,TDR 09/00082, TDR OBIATURUGO, TDR 1428017,TDR 1401593, TDR 11/00396, TDR 1439027,TDR 1439018,are smooth(1) while only 2 genotypes TDR 100003, TDR 000078 are rough in texture of tuber skin.

Group 5. Out of the 20 genotypes of white yam used, variation in hairiness of surface ranges from absent, few and profuse, 5 genotypes TDR 100003, TDR 000078, TDR 89/02665, TDR 09/00082, TDR 1429027 has no hair on their surface,11 genotypes TDR 000021, TDR 090061, TDR 1414005, TDR 1440035, TDR 0000360, TDR 11/00585,TDR 1417015 , TDR OBIATURUGO, TDR 1428017,TDR 1401593, TDR 11/00396, has few hair on their surface while 4 genotypes TDR 1439018, TDR 1436015, TDR 1430007, TDR 1439027, has profuse hairiness on their surface.

Group 6. Out of the 20 genotypes of white yam used, there is diversity in spines on the yam tubers,15 genotypes TDR 09/00082, TDR 1429027,TDR 000021, TDR 090061, , TDR 1440035, TDR 0000360, TDR 11/00585,TDR 1417015 , TDR OBIATURUGO, TDR 1428017 , TDR 11/00396, TDR 1439018, TDR 1436015, TDR 1430007, TDR 1439027, has no spine on their surface,3 genotypes TDR 1414005, TDR 000078, TDR 1401593 has some spines on their surface while 2 genotypes TDR 100003, TDR 89/02665 has profuse spines on their surface.

Group 6. Out of the 20 genotypes of white yam used, their is diversity in tuber shape among the genotypes used,4 genotypes TDR 1439018, TDR 090061, TDR 1414005, TDR 000078 are oval long in shape,7 genotypes TDR 1401593, TDR 1440035 ,TDR 11/00396, TDR 11/00585, TDR 89/02665, TDR 1439027 ,TDR OBIATURUGO are oval in shape while 9 genotypes TDR 100003, TDR 09/00082, TDR 1429027,TDR 000021, TDR 0000360,TDR 1417015 , TDR 1428017 , TDR 1436015, TDR 1430007 are round in shape.

Table 1: Morphological Variations of Advanced white yam genotypes (tubers)

NAMES	Tuber Flesh Colour	No of Tubers Per Stand	Relationship of Tubers	Corm Size	Tuber Length	Texture of Tuber Skin	Hairness of Surface	Spineness	Maturity of Tuber	Tuber Habit	Tuber Shape	Skin Colour
TDR 1439018	1	1	1	2	2	1	1	1	2	1	4	4
TDR 000021	1	1	1	2	3	1	2	1	2	1	2	4

TDR 0000360	1	1	1	2	3	1	2	1	2	1	2	4
TDR 1428017	1	1	1	1	3	1	2	1	2	1	2	4
TDR 1401593	1	2	1	3	3	1	2	2	2	1	3	4

Note: Each column is a character and the rows respective state or genotype

Coded List of Genotype States

(1).Flesh colour:1 = white, 2 = cream, 3 = yellow
(2) Hairiness of surface: 1 absent, 2 few, 3 profuse
(3).Number of tubers per stand: 1 = normal one, 2 = few (2-5), 3 = several (>5)
(4) Spineness: 1= none, 2= some, 3 = profuse
(5).Relationship of tubers: 1 = completely separate and Distant, 2= completely separate in close cluster, 3 = fused
(6). Maturity of tuber: 1= Early maturing: (7 months or less), 2 = Medium maturity more than 7 less than 10m, 3. Late maturity (more than 10 months)
(7).Corm size in relation to tuber size: 1 = small, 2 = medium, 3 = large
(8).Tuber habit: 1=annual, 2= perennial
(9).Tuber length: 1 = 1-5cm, 2 = 6-20cm, 3 = 21-100cm, 4 = >100cm
(10).Texture of tuber skin: 1= smooth, 2= rough
(11).Tuber Shape2=Round, 3=Oval,4=Oval long
(12).Skin colour, 1=greyish, 2= maroon,3=black,4=Brown

CONCLUSION

Findings shows that out of the twelve principal characteristics used, there is varuation among the 20 genotypes used, number of tuber per stand, corm size in relation to tuber size, tuber shape and hairiness of surface are good discriminant descriptor traits for characterizing yam tubers .This is because descriptors correspond to characteristics or attributes whose expressions are easily detected by the naked eye, be recorded, have high heritability, high taxonomic and agronomic value, easy to measure or evaluate (Hildago, 2003). Morphological characterization of plants is vitally imperative for the detection of desirable peculiar traits, identification of duplication, accessions and structuring of population for conservation (Manamela, 2009) The variations analyzed using "mathematics of information Theory" offer a bright scope for selection based on desirable morphological traits which can be used in future breeding purposes.

23rd – 27th Oct., 2023

ABSTRACT

Castor (Ricinus communis L.) expresses a wide-range of plasticity to changing in environment, hindering effective ranking of genotypes by mean performance. In the present trial assessment of performance and stability of some promising large seeded castor genotypes at eight locations in Nigeria. The trial was laid out on randomized complete block design with three replications. Results showed significant effects of genotypes, locations as well as genotype by locations interaction for seed yield, height at maturity, spike per plant and seed oil content. Pool means showed a range between 781.16 kg/ha and 1263.53 kg/ha among the genotypes. The GGE Biplots revealed that the eight locations could be grouped into two clusters. The genotype Acc001 (Gen3) out yielded others at five out of the eight locations. Genotype Acc001 and Genotype Acc045 showed better performance and stability among the evaluated castor genotypes.

Keynote: *Yield performance, Stability, Castor, GGE Biplot*

INTRODUCTION

Castor has a wide-range of variability for characteristics such as seed size (Wiess, 2000). The small seeded castor is commonly chosen if the interest is on the seed oil while the large seeded ones are preferred if the interest is on the product derived from seed endosperm (Salihu *et al.*, 2015). In Nigeria and some other parts of West Africa, the large seeded castors are used to produce '*Ogiri'* - a local condiment (Gana, 2015). The small seeded are not used for the condiment due to the drudgery involved in the removal of the seed coat and low endosperm yield. The condiment is a highly proteinous fermented food supplement traditionally consume by about 20% of the Nigerian population (Okeke *et al.*, 2009). The castor condiment has been reported to have 5.70 and 2.57-times higher protein content than pumpkin and snail respectively (Okeke *et al.*, 2009). The seed may also contain up to 60% oil content. The castor oil has a unique fatty acid composition which provide expanding utilization in many industries.

Despite the economic potential, castor improvement programme in Nigeria has not been receiving much attention, resulting in lack of improved production practices to the farmers (Amosun *et al.*, 2013). Low yield is a major limitation of production in Nigeria (Gana, 2015). Against average yield of 1,200 – 3,000kg/ha obtainable in other countries like India, China and Brazil; the average yield among farmers in Nigeria ranges between 300 kg/ha and 600kg/ha (Amosun *et al.*, 2013). Another major limitation in the country is poor and unorganized castor market (Salihu *et al.*, 2015). The major off take of castor seed in Nigeria presently are the local condiment producers and some cottage oil industries; thus, farmers have preference for the large seeded castor because of the available market. Therefore, the objectives of this research were to assess the yield performance as well as stability of some promising large seeded castor genotypes across eight locations in Nigeria.

MATERIALS AND METHODS

Eight (8) large seeded genotypes (including a check) were evaluated in 2016 and 2017 rainyseasons. The trials were arranged in a Randomised Complete Block Design (RCBD) with three replications. The genotypes were evaluated on plot size of 5m x 6m with a plant spacing of 1.00m by 0.75m. Two seeds were sown and later thinned to one stand per hill. Fertilizer at 60:30:30 kg/ha of N:P:K respectively was applied. Weeding was carried out at 3, 7 and 11 weeks after planting. The locations used were Badeggi, Minna, Zuru, Mokwa, Bacita, Riyom, Ibadan and Amakama. Yield Performances and Stability Analysis (GGE Biplot) for the multi-locational data was done following the procedure of a statistical package PBTools 1.3 version.

RESULTS AND DISCUSSION

A Significant contribution of genotypes to the variation in seed yield was recorded in all the locations (Table 1). Also, the pool ANOVA showed that there were significant differences in the seed yield and all other traits considered among the genotypes (Table 1). Significant effects of environments as well as genotype by environment were observed for seed yield and height at maturity (Table 1). Pool means showed a range between 781.16 kg/ha and 1263.53 kg/ha among the genotypes. The genotype Acc001 recorded the highest average seed yield of 1263.53 kg/ha while the least mean was recorded by the local check (i.e popular farmers' accession – not standard check). The significant effects of locations as well as G × E interactions observed for the seed yield and height at maturity have also been reported by Solanki and Joshi (2003) and Aher *et al.* (2015).

According to the GGE Biplots, a total of 84.3% (PC1 - 61.1% + PC2 - 23.3%) variation was attributed to the Principal Component Axis 1 and 2 (Figures 1, 2, 3). Ibadan and Mokwa locations showed the highest discriminating ability among the locations in the two clusters respectively (Figure 1). In terms of representativeness (location spread), Zuru (E8) Bacita with least angle to the average environmental axis (AEA) are the most representative of the two groups (1). The genotype Acc001 (Gen3) showed good stability and falls within the concentric cycle of ideal genotype, representing the most ideal genotype among the entries (Figure 2). The which-won-where biplot for the entries is presented in Figure 3. The genotype Acc001 (Gen3) out yielded others in Amakama (E1), Bacita (E2), Mokwa (E6), Riyon (E7) and Zuru (E8). Genotype Acco040 (Gen6) out yielded all others at Badeggi (E3) and Ibadan (E4). From the results of the performance and stability assessments, it is logical to recommend both Acc001 and Acc045 for on farm trials in both identified clusters of environments so as to exploit the opportunity of both broad adaptation and specific adaptation to the environments if any.

CONCLUSION

The results revealed wide range of yield performance means among the genotypes evaluated. Out of the 8 genotypes evaluated, genotype Acc001 and Acc045 were two best performing genotypes (for what)?? and could be recommended for farmers' adoption following multilocational On Farm Adaptive Research studies.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Castor (Ricinus communis L.) is an important oil-crop, considered very critical for many industrial applications. In the present study, the genetic diversity in the available castor breeding lines at the National Cereals Research Institute Badeggi was assessed. The lines were evaluated on a replicated progeny row plots arranged in a randomized complete block design. The results showed variation for all the 8 agronomic traits studied among the entries. Days to First Raceme Maturity varied from 80 days to 118 days with average mean of 103.95 days. The length of the spike was between 15.40cm and 49.20cm among the lines. Height to First Raceme between 44.20cm and 135.4cm were recorded among the lines. The seed yield per plant among the lines was between 0.08 and 0.48 (kg/plant). Six cluster groups, with 2 to 20 members, were generated. Cluster III comprises of two early maturing lines (Line9 and Line43) with a range between 96 to 97 days. Populations with high seed yields could be constituted from the cluster I and IV. The cophenetic coefficient of 0.812 was obtained among the clusters. The results revealed optimum genetic distance among the breeding lines evaluated; therefore, they could serve as good parental materials for castor breeding in Nigeria.
Keywords: *Castor, Breeding lines, Genetic diversity, Nigeria*

INTRODUCTION
Castor oil plant (*Ricinus communis* L.) is an oil-crop considered very critical for many industrial applications because of its ability to form many important derivatives (Ogunniyi, 2006). The oil, which is extracted from the seed, is used in more than 700 applications, including the applications in pharmaceutical industries, rubber/plastic industries, and lubricants/biodiesel industries (Mutlu and Meier, 2010). In the southern part of Nigeria, a food condiment (*Ogiri*) among the Igbo tribe is produced from castor seeds (Salihu *et al*., 2014). The residual meal of castor seed, after detoxified by boiling, could be used as supplement feed in preparation of broiler finishing diets without any harmful effects (Ani and Okorie, 2009). Also, the meal (autoclaved) could be used in place of the soybean meal in sheep rations (Pompeu, 2009). Organic fertilizer produced from castor meal was reported to have advantage of high nitrogen content, fast mineralization and anti-nematode effects (Lima *et al*., 2011). The leaves, seeds and capsules of castor are used for traditional medicines (Gana, 2015). Concoctions prepared from the leaves and roots are used in the treatment of after birth weakness in baby.

Despite the huge economic benefits of castor, it's genetic improvement in Nigeria has not been receiving much attention. Consequently, the seed yield among Nigerian castor farmers is low in comparison with the average yields in other countries (Salihu *et al*., 2019). Therefore, there is the need for active castor research in Nigeria if the country is to exploit the potential of the crop for economic growth. With the availability of castor germplasm in some research centres like National Cereals Research Institute Badeggi, there are opportunities to increase the yield level of castor in Nigeria. However, for any successful genetic improvement programme, identification of appropriate parents is very crucial (Shivanna, 2008). Information on genetic diversity of available breeding lines is of high priority. Under these ideas, the present research was to assess the genetic diversity in the available castor breeding lines at the National Cereals Research Institute Badeggi, Nigeria.

MATERIALS AND METHODS
Seventy four selected improved breeding lines, sourced from the National Cereals Research Institute (NCRI) Badeggi, were evaluated at NCRI Castor Experimental Field Badeggi during 2020 raining season. The lines were evaluated on a replicated progeny row plots arranged in a randomized complete block design. Three replicated

plot size of 1m x 7m was used and plant spacing of 75cm and 1m for intra-row and inter-row respectively were adopted. Data were taken on Days to First Raceme Maturity, Number of Nodes, Number of leaf lobes, Leaf Length (cm), Leaf Petiole Length (cm), Spike Length (cm), Height to 1st Raceme (cm) and Yield/Ha (kg/ha). The genetic diversity among the lines was assessed through cluster analysis procedure of Statistical Package for Agricultural Research (STAR 4.0.1).

RESULTS AND DISCUSSION

The results revealed variations for all the studied traits among the entries. Days to First Raceme Maturity varied from 80 days to 118 days with average mean of 103.95 days. Number of internodes to First Raceme ranged between 11 and 21. The length of the spike was between 15.40cm and 49.20cm among the lines. Height of 44.20cm to 135.4cm was recorded among the lines for Height to First Raceme (cm). The seed yield per plant recorded among the lines was between 0.08 and 0.48 (kg/plant). Agglomerative cluster dendrogram constructed from morphological data among the lines is presented in Figure 1. The summary statistics for the agronomic performances of the cluster groups is shown in the Table 2. Six cluster groups, with 2 to 20 members, were generated (Figure 1 and Table 1). The cophenetic coefficient was 0.812, signifying optimum genetic distance among the lines. Cluster I was the largest groups with 20 cluster members. Cluster III comprises of two early maturing lines (Line9 and Line43) with a range between 96 to 97 days; however extra-early maturing lines of about 80 to 84 days could be sourced from the cluster V, IV and VI (Table 1). Short height to first raceme could be found among the members of the cluster V and VI. Parent with long spike could be sourced within the members of the cluster III. Populations with high seed yields could be constituted from the cluster group I and IV.

Genetic improvement in any crop can be accomplished only if there is optimum diversity in the breeding populations. The findings from the present study indicate adequate variability for the traits studied. Golakia *et al.* (2015) also documented variability for most of characters reported in this study. Assessments of castor genetic diversity and phenotypic variability through several methodologies have been reported by several authors (Allan *et al*., 2008; Rao *et al.,* 2006 and Zheng *et al.*, 2010). Anjani and Reddy (2003) reported high divergence among twenty-one castor genotypes for yield and yield attributes. In a study on genetic diversity among nine castor accessions, Costa and Pereira (2006) distinguished two clusters and said that the prominent variability to the diversity among the accessions were contributed by days to flowering, raceme length, plant height and seed oil content. Zhang-Xishun and Yang-Jian (2006) considered forty-six castor germplasm and distinguished four clusters with no geographic clustering pattern.

CONCLUSION

From the findings of the study, it is shown that the breeding lines evaluated are divergent in nature and they could serve as good parental materials for castor breeding in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cassava is crucial for food security which has great potential to contribute to African development and is increasing its income-earning potential for small-scale farmers and related value chains on the continent. This study was conducted at National Root Crops Research Institute, Umudike to evaluate genetic analysis of selected yellow root cassava genotypes at advanced yield trial in a randomized complete block design with three replications. The analysis of variance shows significant difference among genotypes for cassava mosaic disease (CMD), harvest index (HI), fresh root yield (FRY) and dry root yield (DRY). In terms of fresh root yield, genotypes NR170199 (21.13t/ha), NR170065 (21.60t/ha), NR170190 (21.66t/ha), NR170164 (23.00t/ha), NR170166 NR170007 (29.13t/ha), and NR170166 (32.53t/ha) performed better while genotypes NR170183 (30.02%) NR170207 (30.77%), and NR170146 (31.16%) had dry matter content better than the two check varieties (TME419&TMS070539). Six genotypes had total carotene content (TCC) better than the mean while NR170005 (9.23 µg/g) and NR170065 (9.54 µg/g) performed better than the checks UMUCASS46 (9.20 µg/g) and TME 419(1.44 µg/g). Also, all the genotypes were susceptible to cassava bacterial blight (CBB) and cassava anthracnose disease (CAD). A significant positive correlation was observed between harvest index and fresh root yield (r = 0.65374), but negatively correlated to total carotene content (r = -0.37469); FRY was negatively correlated to dry matter content (r = -0.14163) and TCC (r = -0.26025) while DMC was also negatively correlated to TCC (r = -0.00501).

Keywords: *Agronomic parameters, yellow root, location, disease, design*

INTRODUCTION
The increase in demand by fast expanding feed and starch markets as well as other cassava based industries across the globe and rising prices of close substitutes like rice and maize are rapidly re-ordering the dynamics of cassava market in the tropics of Africa, Asia and Latin America (Market Research Future, 2020; Ikuemonisan *et al*., 2020). A highly tolerant cassava crop known for its wide ecological adaptability will always perform relatively well where other crops may not be able to produce reasonable yield (Otekunrin and Sawicka, 2019). This attribute confers on cassava a reliable food security for farming households in the tropics (Ikuemonisan *et al*., 2020) in addition to providing dietary energy for close to a billion people and livelihood for millions of farmers/processors traders worldwide (FAO, 2018; Ikuemonisan *et al*., 2020). According to FAO (2018), cassava is a choice crop for rural development, poverty alleviation, economic growth and ultimately, food security. It is in view of the above that critical stakeholders have continued to contribute immensely to shaping the development of cassava sub-sector in Nigeria. The objectives of the study were to determine: (i) the influence of genotypes on fresh root yield (FRY), dry root yield (DRY), dry matter (DM), cassava mosaic disease (CMD), cassava bacterial blight (CBB), cassava anthracnose disease (CAD),cassava greenmite (CGM) and total carotene content.

MATERIALS AND METHOD
Selected twenty yellow genotypes selected from the preliminary stage and two checks (TME419 and UMUCASS46). Cassava planting stakes of 20-30 cm in length were planted on July 2020 laid out in Complete Randomized Block Design with a plot size 4m × 7m. The experiment was replicated two times. A planting distance of 1 m x 1 m was maintained making 28 stands per plot. Pre and post-emergence herbicide was used after planting. Weeding of the farm was done manually. The plants were scored for resistance to major cassava disease and pests

1,3,6,9 and 12 MAP. Determination of dry matter, fresh root yield, dry matter content, and dry root yield of the cassava genotypes were carried out at harvesting using specific gravity method.

Statistical analysis

The data collected were subjected to analysis of variance (ANOVA) using General Linear Model (GLM) procedure in SAS software, 2002 to test for the treatment of effect and significant interaction of the variables considered.

RESULTS

The analysis of variance shows significant difference among genotypes for cassava mosaic disease (CMD), harvest index (HI), fresh root yield (FRY) and dry root yield (DRY) (Table 1). Nine genotypes had fresh root yield better than the checks and genotype means (19.50t/ha). Genotype NR170166 shows the highest FRY of 32.53t/ha while NR170183 revealed the least value of 11.40t/ha. Genotype NR170146 had the highest dry matter content (31.16) while NR170168 had the least valve (26.64%)(Table 2). However, three genotypes had DMC as from 30.00% above; and perform well better than TME419 and TMS070539 and the genotype mean (28.30%) (Table 2). Nine genotypes were not infected with cassava mosaic disease while seven genotypes were susceptible; all the genotypes were susceptible to cassava bacteria blight (CBB) and cassava anthracnose disease (CAD) (Table 2) .Total carotene content ranged from 5.25µg/g to9.54 µg/g with NR170065 recording the highest value of 9.54 µg/g and NR170009 with the least value of 5.25µg/g. Six genotypes had TCC better than the mean while NR170005 (9.23 µg/g) and NR170065 (9.54 µg/g) performed better than the checks UMUCASS46 (9.20 µg/g) and TME 419(1.44 µg/g) (Table 2) .A significant positive correlation was observed between harvest index and fresh root yield (r = 0.65374***), but negatively correlated to total carotene content (r = -0.37469); FRY was negatively correlated to dry matter content (r = -0.14163) and TCC (r = -0.26025) while DMC was also negatively correlated to TCC (r = -0.00501) Table 3.

CONCLUSION

The results showed that all the genotypes were susceptible to cassava bacterial blight (CBB) and cassava anthracnose disease (CAD). In terms of fresh root yield, genotypes NR170007 (29.13t/ha), NR170009 (19.60t/ha), NR170207 (19.60t/ha), NR170174 (19.66t/ha), NR170164 (23.00t/ha), NR170199 (21.13t/ha), NR170065 (21.60t/ha), NR170166 (32.53t/ha), NR170190 (21.66t/ha) and NR170151 (18.73t/ha) perform better while genotypes NR170183 (30.02%) NR170207 (30.77%), and NR170146 (31.16%) had dry matter content better than the two check varieties (TME419&UMUCASS46).Genotypes NR170005 (9.23µg/g) and NR170065 (9.54µg/) had total carotene content better than the checks

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A preliminary experiment was carried out to analyse the growth performance of *Pleurotus ostreatus* mushroom *cultures using chemosynthetic media. The objective of the study aimed to differentiate media such as Potato Dextrose Agar (PDA), Malt Extract Agar (MEA), Corn Meal Agar (CMA) and Czapex Dos Agar(CDA) on the growth of Pleurotus ostreatus mycelia. The study revealed that all the media had a significant growth from day 2 –day 8 at different growth level. There is equally a growth different between all the growth media as the incubation days increases. Malt Extract Agar had the highest mycelial density of 5+ and (5.7mm per day) with CMA being the least for mycelial density of 1+ growth rate with 5.0mm per day. At Day 6, PDA had 34.00mm radial growth of mycelial, MEA had 35.00mm, CDA with 30.00mm while CMA had mycelial growth of 26.00mm. The best out of the four growing media used is MEA (40mm), followed by PDA (39mm) while the least is CMA (35mm) (MEA>PDA>DOX>CMA). All the used media excluding CMA had averagely a good mycelia density growth (2+ -5+) and can support the growth of Pleurotus ostreatus mycelia in the Laboratory depending on their availability. This information would be important for researchers that needs to maintain mushroom in the laboratory for further study and equally for starter culture for farmers before using media derived from agro-residue to increase the productivity of mushroom mycelia for commercial purposes.*

Keyword: *Pleurotus ostreatus, mushroom,Malt extract agar media*

INTRODUCTION

Mushroom, a macro fungus with a distinctive fruiting body, is a unique biota which assembles its food by secreting degrading enzymes. Oyster mushroom grows wild on logs and stumps of trees in forests that fell or cut down. It belongs to the class Basidiomycetes subclass Hollobasidiomycetes, order Agricales and family Pleurotaceae (Alexopolous and Mims, 1996) and comprises about 40 species (Chang, et al., 1998). They are widely used as delicacies in different parts of the world because of their excellent flavor and taste (Jonathan and Esho, 2010). Mushroom growth is highly influenced by several factors such as spawn, growing media, pH, temperature, moisture content and light intensity (Kadiri and Kehinde, 1999). Storage and maintenance of mushroom species in a pure, viable and stable condition is essential for their use as reference strain, both in research and industrial scales (Bhatt et al., 2010). The identification of suitable agar media, substrate and incubation temperature is essential to obtain high yield and quality of mushroom.(Hasan et al., 2015). Mushrooms are good sources of sugars, fiber, protein and minerals (Senadore, 1990), with comparable amino acid with animal protein (Yang, et al., 2002). Mushroom cultivation is an eco-friendly method of solid waste management. It is evident that mushroom cultivation helps in the biological degradation of natural resources and are eco-friendly, protein rich food and the recent developments in the scientific understanding of mushroom cultivation has aided in improvement of its cultivation technology (Puri, 2011). Shiitake mushroom species are the edible mushroom which have originated from East Asia and cultivated and consumed in numerous Asian nations. Shiitakes give good amounts of protein (18%), potassium, niacin and B vitamins, calcium, magnesium and phosphorus. Furthermore, mushrooms contain a great quantity of dietary fiber and given their chemical structure, they show immunostimulatory and anticancer activity (Cheung 2013). The availability of the agro-residues after crop harvest like straws of various crops as that of wheat, sorghum and rice has been used as a basal substrate for the cultivation of shiitake in recent times. *Lentinula edodes* is a white rot fungus that secretes a class of ligno-cellulolytic enzymes, which permit it to grow on ligno-cellulosic substrates rich in lignin (Barros, et al., 2006). The use of locally available agro-residues provide a way to minimise the cost of cultivation and also helps to reduce the environmental pollution that occurs due to burning of various agro-residues in the field after the harvest. The growth of Shiitake was found faster on agro-residues compared to the natural log cultivation but with drawback of contamination of mycelia (Puri, 2011).Malt extract agar, Potato dextrose agar and Czepa dox agar are media with growth chemical requirements for fungi growth. With this background the present study is undertaken to evaluate the effect of different synthetic media on growth of (*Pleurotus ostreatus*) shiitake mushroom for mycelial growth.

MATERIALS AND METHODS

The present investigation was carried out at Plant Pathology Laboratory, National Root Crops Research Institute, Umudike, Abia State, Nigeria. The pure culture (mycelia) of *Pleurotus ostreatus* used for the present investigation was obtained from Plant Science and Biotechnology Department, Michael Okpara University of Agriculture, Umudike and was subsequently evaluated for the growth of its mycelial.

Sterilization of medium: The flasks having media were sterilized in the autoclave at 121^0c for 15 minutes and then poured in 90 mm Petri dishes under the laminar flow hood to avoid contamination. Media were cooled to 47ºC. The cork borers used for inoculation were sterilized through the flame of Bunsen burner. The experiment was repeated for 3 times.

Media preparation

All the media used – Malt extract agar, Potato dextrose agar, Corn meal agar and Czapek dox agar are produced aseptically according to the manufacturers instruction by dispensing the proper amount of media into one liter of distilled water and sterilized in an Autoclave at 121^0C for 15 minutes.
