Determination of Quality Parameters of Eggs

The quality parameters were determined using AOAC (2012). Moisture content was determined by drying in hot air oven at 100-102^{0}C for 16-18 hours. Crude protein was estimated by multiplying 6.25 by the nitrogen content obtained through Kjeldal method. Ether extract and ash were analysed by Soxhlet extraction and 550^{0}C furnace respectively.

Data Analysis

The data collected were subjected to analysis of variance and significantly different means were separated using least significant difference with the aid of statistical package (SPSS, 2015).

RESULTS AND DISCUSSION

Effects of Different Storage Methods on the Proximate Composition of Quail Eggs

The effects of different storage methods on the proximate composition of Japanese quail eggs is presented in Table 1. All the values for the different storage methods were significantly different ($p<0.05$), the values did not follow any definite trend, values for moisture ranged from 2.00 to 3.00%. This result was similar to that reported by Dudusola (2009) in Japanese quail eggs.

The parameters for determining quality of eggs are at maximum when the eggs are freshly laid and decrease with increase in storage time (Panigraphi *et al.*, 1989) . Storage conditions are chosen with regard to the retention of these quality characteristics. Temperature, relative humidity and air flow or moisture are considered as the main factors in determining the technological conditions for egg storage (Orji *et al*., 1981). The low weight loss of oiled eggs may be due to blockage of the shell pores by thin film of oil thus preventing water and gaseous escape (Dudusola, 2009).

Table 1: Effects of Different Storage Methods on the Proximate Composition of Quail Eggs

Storage Method	Proximate Values (%)			
	Moisture	Ash	Crude Protein	Ether Extracts
Oiling	3.20^{a}	32.80^{a}	29.80^{a}	13.30^{a}
Room temperature	2.00^{b}	28.60^{b}	20.80^{a}	10.40^{b}
Clay pot	2.90^{a}	32.30^{a}	28.40^{a}	12.80^{a}
Covered with leaves	2.30^{b}	32.50^{a}	22.00^{b}	11.50^{b}
SEM	0.65	1.51	1.61	1.02

a,b, Treatment Means with Different Superscripts along the columns are Significantly ($P <0.05$) Different, SEM Standard Error of Means

Effect of Storage Duration on Proximate Composition of Quail Eggs

The effects of storage duration on the proximate composition of Japanese quail eggs is presented in Table 2
The proximate values for all the storage durations showed significant difference ($P<0.05$). The values for crude protein ranged from 27.00 - 35.00%. The values showed that the longer the storage duration the more the deterioration of the eggs. This was in agreement with the report of Dudusola, (2009) with Japanese (Quail eggs). With increase in storage length egg weights decreased as a result of increase in weight losses. The losses may be due to loss of carbon dioxide, ammonia, nitrogen, hydrogen sulphide, gas and water from the eggs (Haugh, 1993).

Table 2: Effect of Storage Duration on Proximate Composition of Quail Eggs

Storage Duration (Days)	Proximate Values (%)			
	Moisture	Ash	Crude Protein	Ether Extracts
0	15.50^{a}	3.40^{a}	35.00^{a}	32.00^{a}
7	12.90^{b}	2.70^{b}	30.50^{b}	25.30^{b}
14	5.00^{c}	2.00^{c}	28.30^{c}	22.10^{c}
21	4.60^{d}	1.80^{d}	27.20^{c}	20.20^{d}
SEM	1.21	0.75	1.05	1.01

a,b,c,d Treatment Means with Different Superscripts along the columns are Significantly ($P <0.05$) Different; SEM Standard Error of Means

Effects of Different Storage Methods and Storage Duration on Quality Parameters of Quail Eggs

Effects of Different Storage Methods and Storage Duration on Quality Parameters of Japanese Quail Eggs is presented in Table 3. All the values for the quality parameters viz-a-viz the storage methods and storage duration were significantly different ($p<0.05$) except the Haugh unit in oiling, clay pot and covering leaves treatments. The values generally showed lower quality parameters with longer storage days. Haugh unit values for clay pot storage ranged from 56.00 to 58.20%, while yolk index values for oiling method ranged from 0.20 – 0.40. Oiling method provided the best preservation method of all the 4 methods determined. Dudusola (2009) reported that refrigeration and oiling were the best eggs storage methods.
Haugh unit and yolk indices are generally considered as good indicators to evaluate egg quality (Chang *et al*., 2000)). The higher the yolk index (Ayorinde, 1987)) and the Haugh unit (Haugh, 1993) the more desirable the egg quality. The variations observed in eggs stored under different methods and different storage durations indicates chemical degradation and favourable environment for bacterial activity. Haugh units are 75% and above for excellent quality eggs and 50% and below for stale eggs. The Haugh unit of 56.60 – 58-30 % were far below 75% and above for excellent eggs. These values were also lower than 58.60 - 62.10% reported by Dudusola (2009).

Table 3: Effect of Different Storage Methods and Storage Duration on Quality Parameters of Japanese Quail Eggs

Quality Parameters/ Storage Methods	Storage duration 0	7	14	21	SEM

a,b,c,d Treatment means with Different Superscripts across the rows are Significantly ($P<0.05$) Different; SEM Standard Error of Means

CONCLUSION AND RECOMMENDATIONS.

Conclusion

This study showed that oiling was seemingly the best method to preserve Japanese quail eggs.
The shelf life of Japanese quail eggs is short, just like other eggs, no matter the storage method deterioration will set in,

RECOMMENDATIONS

Japanese quail eggs may not be stored for more than 21 days but oiling method may be recommended for storage and preservation of Japanese quail eggs

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was conducted to evaluate mistletoe as a feed resource for ruminant animals in Jigawa State. Proximate and mineral composition of the plant suggested its potentials to meet some of the nutritional requirements for utilization as livestock feed. Sixteen (16) samples were allotted into (4) treatment and (4) four replication in a Completely Randomized Designed (CRD) dry matter (DM),17.39% crude protein (CP), 25.85% crude fibre (CF), 3.65% this indicate higher protein % moderate dry matter and low crude fibre. While macro mineral was significantly (P>0.05) higher in phosphorus (P) 226.52ppm with low in potassium (K) 3.12 ppm. Micro mineral was significantly (P>0.05) higher iron (Fe) 9.72ppm and low in manganese (Mn) 0.04ppm. Therefore, mistletoe of Adonosonia digitata (Tapinanthus globiferus) contained some adequate nutrients and alternative minerals for ruminant feeding especially in dry season.

Keywords: *Ruminant animals, mistletoe, Adonosonia digitata (Tapinanthus globiferus), livestock feed.*

INTRODUCTION

Nutrition is the single most important factor militating against livestock production in Nigeria (Bishir *et al.*, 2021). Thus, there is need to search for alternative feedstuffs that are locally available and cheap. Feed tends to be the most considered amongst factors influencing livestock production (Tunde and Agustine, 2016; Devendra and Leng, 2011). At critical dry season, available feed for grazing by animals are almost bare ground with poor vegetation cover and low biomass (Muhammad and Kallah, 2013). The main problem confronting ruminant livestock producers in Nigeria today is the seasonal fluctuation in the availability of forages for ruminants (Bukola *et al.*, 2022). Browse plants comprised of annual or perennial trees, shrubs and woody vines that are either legumes or non-legumes. They have a great value in the extensive system of animal production in the arid and semi-arid region (Amodu and Otaru, 2004). The use of protein-rich leguminous trees and shrubs appears to be one sustainable solution for dry season ruminant supplementation in the tropics (Saleh *et al.*, 2015). The use of leaves from trees that retain their leaves during the long dry season, to feed ruminants during the difficult period is very important (Bukola *et al.*, 2022). Mistletoe is a general term for woody shoot parasites in several plant families, especially in *Loranthaceae* and *Viscaceae* families (Ogunmefun *et al.*, 2013; Begho *et al.*, 2007). It is popularly called "*Kauchi*" and "*ewe afomon*" among the Hausa/Fulani and Yoruba speaking people of Nigeria, respectively (Saleh *et al.*, 2015). It is an obligate semi-parasitic evergreen tropical plant, normally found growing on a variety of trees, including palm fruit, mahogany and other tropical plants (Saleh *et al.*, 2015). Mistletoes as part of an ecosystem, attracts avian frugivores and exotic animals (Garnett *et al*., 2016; De Buen and Ornelas, 2001). According to Godschalk (1983), mistletoe provide birds for nourishment (protein 6%; lipids 44% and sugars 12%)

as well as hiding and nesting sites for birds and other reptiles (Parks *et al.*, 1999). Therefore, the study aimed to evaluate the proximate and mineral composition of mistletoe (*Viscum album*).

MATERIALS

Mistletoe plant
Milling machine

METHODS

Research Design

A completely randomized design (CRD) was used, as outlined by Steel and Torrie (1980). The mistletoe plant meal (MTPM) was used as four samples representing four (4) different local government areas (Miga, Garki, Kaugama and Maigatari local governments, respectively). The samples were randomly allotted to four (4) treatment groups with four (4) replicates.

Data obtained from the experiment were subjected to analysis of variance (ANOVA) procedure of Statistical Analysis System (SAS, 2003). Software package version (16) were significant differences observed between the treatments, the means were separated using Duncan multiple range test at 5% level of probability (Duncan, 1995).

Sample Preparation and Treatment

Jigawa State is located in the semi-arid region of Nigeria and lies between coordinates 12.2280°N; 9.5616°E. The annual rainfall distribution ranges from 42.97mm (1.69 inches) of precipitation and has about 60.55% rainy days (16.59% of the time) annually. https://tcktcktck.org. Rainfall normally last for an average of five (5) months, while, the rest of the year is dominated by dry season. The mean annual temperature in the area can be as high as 38.94^{0}C and could be as low as 24.93^{0}C. https://tcktcktck.org. The soil type of the area is sandy loam, with little organic matter. The natural vegetation of the area is Sudan savannah type, which consisted of moderately tall grasses such as *Andropogon gayanus, Panicum maximum, Pennicetum pedicellatum* etc, and scattered browse species like *Acacia spp*, *Balanite agiptica, Zizipus* spp, *and Pilliostigma thoningii.* The area supports good Agricultural activities with Sorghum, millet, cowpea, groundnut and sesame being the major crops cultivated (Danladi *et al*., 2015).

Mistletoe of *Adonsonia digitata* (*Tapinanthus globiferus*) was randomly obtained as four samples from four different local government areas of Jigawa State, and air-dried under the shed daily for about seven (7) days until they became crispy, while retaining the greenish coloration. The air-dried samples were milled into coarse texture, using machine to produce mistletoe plant meal (MTPM). For proximate and mineral analysis.

RESULTS AND DISCUSSION

The mistletoe of the MPTS (*Adonsonia digitata*) had less anti-nutritional factors and was more abundant in the study area. Therefore, it was selected for proximate analysis. The results of chemical composition of mistletoe of *Adonsonia digitata (Tapinanthus globiferus)* were presented in Table 4.7. Mistletoe of *Adonsonia digitata* contains 87.88% dry matter (DM),17.39% crude protein (CP), 25.85% crude fibre (CF), 3.65% ether extract (EE),10.35%, ash, 42.76% nitrogen free extract (NFE), 31.70% neutral detergent fibre (NDF), 18.45% acid detergent fibre (ADF), 5.23% acid detergent lignin (ADL), 13.22% cellulose and 13.25% hemicellulose.

Table 1. Chemical composition (%) of the Mistletoe of *Adonsonia digitata (Tapinanthu globiferus*)

Parameters	Values
Dry matter	87.88
Crude protein	17.39
Crude fibre	25.85
Ether extracts	3.65
Ash	10.35
Nitrogen free extracts	42.76
Neutral detergent fibre	31.70
Acid detergent fibre	18.45
Acid detergent lignin	5.23
Cellulose	13.22
Hemicellulose	13.25

The results of mineral analysis of mistletoe of *Adonsonia digitata (Tapinanthus globiferus)* were presented in Table 1. The results showed that, the mistletoe had mean, calcium content of 13.83ppm, magnesium 18.10ppm, potassium 3.12ppm, sodium 24.87ppm and phosphorus 226.52ppm. Similarly, the mistletoe had 0.32ppm zinc, 0.04ppm manganese, 0.29ppm copper, and 9.72ppm iron.

Table 2. Mineral Composition (ppm) of mistletoe of *Adonsonia digitata (Tapinanthus globiferus)*

Parameters	Values
Macro minerals	
Calcium (Ca)	13.83
Magnesium (Mg)	18.10
Potassium (K)	3.12
Sodium (Na)	24.87
Phosphorus (P)	226.52
Micro minerals	
Zinc (Zn)	0.32
Manganese (Mn)	0.04
Copper (Cu)	0.29
Iron (Fe)	9.72

From Table 2 above, the factors causing variation in the chemical composition of browses and forages include soil types, climate, plant part (leaf, stem and fruit), age and season. The dry matter (DM) values of mistletoe of *Adonsonia digitata (Tapinanthus globiferus*) obtained in this study were similar to 92.30% reported by Anthony *et al*. (2017), for mistletoe (*Viscum album)* leaf meal as feed additive for broilers. This implied that, mistletoe species are high in dry matter. And hence high energy value. The crude protein (CP) value of mistletoe obtained in this study was higher than the value (12.50%) reported by Franklin *et al*. (2017), when mistletoe of *Phragmanthera capitate,* (a mistletoe growing on rubber trees) was evaluated for proximate composition. However, the slight differences might have occurred as a result of studying other parts of the plant as test materials, not leaves alone. Crude fibre (CF) values obtained in this study were lower than CF value (28.19%) reported by Saleh *et al.* (2015), for Mistletoe of *Parkia biglobosa*. The value of ether extract (EE) in the present study were lower to those (4.13%) reported by Saleh *et al*. (2015), for Mistletoe of *Parkia biglobosa*. Nitrogen free extract (NFE) values in this study were similar to the values reported by the same author for mistletoe of *Feildherbia albida*. The ash content of the test plant was higher than 5.16% reported by Saleh *et al*. (2015) for the chemical composition of mistletoe of *Vitallaria paradoxa*. The similarities could be as a result of using plants of the same Genus – *Tapinanthus*.

Fibre is the predominant fraction of the plant cell wall and primarily comprised of carbohydrates. The primary components of fibre are cellulose, hemicellulose and lignin. However, the neutral detergent fibre (NDF) value obtained in this study was lower than the value 48.50% reported by Kubkomawa *et al*. (2017) of mistletoe *Balanite aegyptica*. Acid detergent fibre (ADF), acid detergent lignin (ADL) values obtained in this study, were similar to reported values of (19.60%) and (5.61%), respectively (Kubkomawa *et al*., 2017). Cellulose and hemicellulose values reported in this research were similar to those values 12.47% and 12.50%, respectively, recorded by Kubkomawa *et al*. (2017). This considering the chemical composition of mistletoe, it implies that it could be a good feed ingredient for ruminant animals.

Mistletoe plant is an excellent source of alternative minerals for ruminant animals Madibela *et al*. (2000). The mineral values of mistletoe of *Adonsonia digitata (Tapinanthus globiferus)* obtained in this study were lower than the values 622.58. Ca, 361.15. Mg, 1047.83. K, 115.40. P, 19.23. Na, 2.49. Zn, 1.81. Cu, 27.57. Mn, and 105.15. Fe, (Mg/100g) reported by Franklin *et al*. (2017). The values were obtained for mineral analysis of *Phragmanthera capitate,* a mistletoe growing on rubber trees. However, the variation could be as a result of differences in tree plants, test materials, time of sampling and climatic condition of the environment on which they grow. Franklin *et al*. (2017) reported that, the body of animals need macro minerals in moderate proportion and micro in very small amounts. According to Duyff (2002), some minerals are structural components (calcium and phosphorus) while others are haemostats (sodium and magnesium) and yet others are component of organic bimolecular (all trace elements such as zinc, iron). Mgbemena and Obodo (2016), reported higher values of Ca, Mg, K, Na, and P as 2.61- 4.22, 1.094 -1.64, 0.625 - 0.850, 0.300 - 0.825 and 0.249 – 0.758 %, respectively, for *Moringa oleifera* roots, leaves and seeds. However, all the values obtained for the mineral contents showed that, mistletoe could be a very good source of minerals for ruminants feeding. Minerals are essential elements in animal nutrition as they fulfil multiple functions in the physiology of all systems (Jerson, 2021). Macro minerals are the group of mineral elements most needed by animals in their diet to fulfill a numerous of physiological functions, deficiencies of these elements cause various pathologies or dysfunctions that must be promptly corrected. Moreover, depending on the animal species (poultry, swine, or ruminant), the signs and effects may vary (Jerson, 2021). Micro minerals are elements that are found in smaller quantities compared to macro minerals. However, they also fulfill many functions in the physiology of animals. The functions of micro minerals are the same for animals as they constitute basic processes for animal life (Jerson, 2021).

CONCLUSION AND RECOMMENDATION

Mistletoe of *Adonosonia digitata (Tapinanthus globiferus)* contained some adequate nutrients and alternative minerals for ruminant feeding especially in dry season. Used of mistletoe as animal feed resources could improve growth performance, nutrient intake and digestibility of animal especially in the dry season.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Ziziphus species are drought-tolerant plants found in warm-temperate, tropical, and subtropical regions of the world. They include a variety of plants, from shrubs, small to medium-sized trees, and they have a wide range of canopy morphology, including spreading, semi-upright, and erect. However, they are highly significant for their nutritional value and their numerous roles in dry zone agroforestry systems, including soil cover, wind protection. Ziziphus mauritiana grows naturally, it is widely recognized as a cultivated fruit tree that has sub-spontaneously spread in several tropical and sub-tropical regions of the world. It is a great top feed species that produces nutrient-rich leaves that are used as source of fodder for desert animals like sheep, goats, camels, and cattle. ***Ziziphus fruit has a pleasant aroma and chemically, it is a nutrient powerhouse, containing high levels of protein, fiber, and vitamin A, B, C, flavonoids, tannins, lipids, alkaloids, steroids, carbohydrates, calcium, potassium, sodium, phosphorus, copper, iron, and zinc.*** *Z. mauritiana inclusion at 8 to 10% (DM) dry matter was reported to boost feed intake, milk yield, milk quality in nursing cows while also improving feed nutrient utilization., this also allow dairy cows to maintain a normal rumen environment and enhanced the feed's flavor, nutrient digestibility, and lactation efficiency. Z. mauritiana is palatable and is high in energy, protein as well as minerals contents, rich in vitamins and has antidiarrheal, antibacterial, immune promoting, and antioxidant properties. Optimal feeding level recommendations and processing technology should be improved. In addition, attention should be paid to the feeding safety of microbial populations, mycotoxins and heavy metals in Z. mauritiana by-products.*

INTRODUCTION
Researchers and developers are paying greater attention to the use of functional feed additives as a result of the strict regulations for the use of antibiotics in animal feed as well as the rising standards for the quality and safety of foods derived from animals (Xu *et al*., 2022). *Ziziphus* species are found in South Asia, Africa, and the warm subtropics and tropics regions of the world. The pulp from the fruits, which is consumed fresh or dry and can also be turned into a juice, is the major product of these species. Additionally, leaves are utilized as fodder and for medicine. Bark, roots, and leaves are also used as feed, whereas, the wood is utilized for handles, cooking utensils, firewood, and charcoal (Kalinganire and Koné, 2011). *Ziziphus* species are drought-tolerant Rhamanaceae plants found in warm-temperate, tropical, and subtropical regions of the world. They include a variety of plants, from shrubs, small to medium-sized trees, and they have a wide range of canopy morphology, including spreading, semi-upright, and erect. *Ziziphus species* are significant not only for their nutritional value but also for their numerous roles in dry zone agroforestry systems, including soil cover, wind protection (Macwan *et al*., 2012; Riaz *et al*., 2021; Singh and Meghwal, 2020). It is commonly called Indian jujube, Indian plum, Chinese date, Chinee apple, ber and dunks (Morton, 1987).

Ziziphus mauritiana trees are used as food, fodder, and medicine; they produce effectively and tolerate in high temperatures and short rainfall. However, cultivation of these trees could be a solution to the problem of food insecurity and a source of income for households in arid and semi-arid areas as a result of the current impact of climate change (Muhammad *et al*., 2022). Fruits like *Ziziphus mauritiana* are high in energy and have anti-inflammatory, antibacterial, and anti-diarrheal effects (Maaiden *et al*., 2020; Xu *et al.*, 2022). *Z. mauritiana* by-products are widely produced due to the growing territories under *Z. mauritiana* tree cultivation and the heavy processing of jujube throughout Arid and Semi-arid areas of the world. These byproducts are frequently used into animal feed for pigs, fowl, cattle, goats, and fish because they support healthy digestion, increase growth performance, and improve the quality of animal products (Singh and Meghwal, 2020; Xu *et al*., 2022). *Z. mauritiana* is a plant that grows naturally or is widely recognized as a cultivated fruit tree that has sub-spontaneously spread in several tropical and sub-tropical regions of the world *(*Macwan *et al., 2012;* Riaz *et al.*, 2021; Uddin *et al*., 2019; Yahia *et al*., 2020). It is a small, spiny tree or shrub that can grow to a height of 10 m. It has a trunk that is at least 30 cm in diameter, a spreading crown, numerous spines, and a number of drooping branches. The bark is markedly dark gray or dull black with irregular fissures (Uddin *et al*., 2019). It is a great top feed species that produces nutrient-rich leaves that are used as a wonderful source of fodder for desert animals like sheep, goats, camels, and cattle (Singh and Meghwal, 2020).

Cattle, sheep, pigs, goats, and other farm animals are considered livestock. They serve a variety of purposes, including providing food (meat and milk) and other benefits like security, drought power, manure production (dung and urine), biofuel production, social values, and recreation. However, some of these animals, like ruminants (cattle, sheep, and goats), are herbivorous in nature, which means that the majority of their nourishment comes from grazing on natural pasture, fallow ground, and cropland (Lamidi and Ologbose, 2014).

BOTANICAL DESCRIPTION OF *Ziziphus mauritiana*

Ziziphus mauritiana is a tiny, heavily branched tree or frequently a large bushy shrub with short stipular spines, a corky stem, a powerful root structure, and the ability to be evergreen or go leafless for a brief period of time during hot summers (Singh and Meghwal, 2020; Tripathi and Preeti, 2014). It can grow in a variety of ways, from an upright branching habit to a drooping and spreading type. The leaf apex was sharp or obtuse, and the leaves were elliptical, elliptic to ovate, or oblong. The ventral surfaces of the leaves were smooth to rough to mentose with reticulate venations, whilst the dorsal surface was smooth (Tripathi and Preeti, 2014; Yassine *et al.*, 2020). In August and September of the current growing season, tiny, greenish-yellow flowers on a short stalk bloom in the axils of the leaves. The fruits are drupes that range in size and form from round to rectangular, oval, and obovate. As the fruit ripens, the smooth skin turns from light green to yellow. A single, tough, rough, oval or oblate center stone houses two elliptical, brown seeds (Singh and Meghwal, 2020).

SCIENTIFIC CLASSIFICATION OF *Ziziphus mauritiana*

Kingdom	Plantae
Division	Magnoliophyta
Subdivision	Angiosprm
Class	Magnoliopsida
Order	Rosales
Family	Rhamnaceae
Genus	*Ziziphus*
Species	*Mauritiana*

Sources: (Macwan *et al*., 2012; Parmar *et al*., 2012; Tripathi and Preeti, 2014)**.**

Chemical Composition of *Ziziphus mauritiana* Fodder Fractions

As a browse plant, *Z. mauritiana* meets the majority of the nutritional needs of goats and camels while also supplementing the diets of cattle and sheep with the protein, vitamins, and minerals that bush straw lacks during the dry season (Yahaya *et al*., 2021). Yerima and Adamu (2011) reported the highest crude protein (36.10%) in *Z. mauritiana* seeds, while Keta (2017) reported the lowest crude protein (6.18%) in *Z.mauritiana* fruits pulp. This was higher than the suggested %CP requirement for maintaining sheep and goats, which was reported by NRC (2007) as 9.4 and 7.93%CP, respectively.

According to Abdurrahaman *et al*. (2021), the high levels of fiber content were among the reasons that led to the low concentration of protein. For the moisture (5.16%; 4.21%) and ash (6.16%; 2.79%) levels in the pulp and seeds of *Z. mauritiana* fruits, respectively, Keta (2017); Yerima and Adamu (2011) found lower values. *Ziziphus mauritiana* leaves had the highest neutral detergent fiber content (NDF) of 575.40 g/kg and the highest acid detergent fiber content (ADF) of 228.30 g/kg (Njidda and Olatunji,2012).

***Ziziphus* fruit has a pleasant aroma and it includes high levels of protein, fiber, and vitamin A, B, C, flavonoids, tannins, lipids, alkaloids, steroids, carbohydrates, calcium, potassium, sodium, phosphorus, copper, iron, and zinc** (Maaiden *et al*.**,** 2020; Rabie *et al.*, 2019; Riaz *et al*.**,** 2021**;** Tripathi and Preeti**,** 2014**).** ***Ziziphus* species extracts and fractions of the leaves, fruits, and seeds have demonstrated antiviral, antifungal, and antibacterial activity and have been used in medicine to treat a variety of illnesses, including diarrhea and conditions of the digestive tract. (Maaiden *et al*., 2020; Rabie *et al*., (2019).** Analysis of the chemicals constituents on a dry weight basis indicates that the leaves contain 15.4% crude protein, 15.8% crude fibre, 6.7% total minerals, and 16.8% starch (Orwa et al., 2009). **Ground seeds on extraction with petroleum ether gave 33% of bright yellowish oil. Fatty acid composition of the oil contains oleic acid- 71.7%, Linoleic acid- 15%, while the fruits are very rich in vitamins C and B1 and B2 (Tripathi and Preeti, 2014).**

Uses of *Ziziphus mauritiana* in Livestock Feed

Cattle, camels, goats, and other animals eat the leaves of the *Ziziphus mauritiana* plant, which provides them with nutrients good for their health such as carbohydrate, proteins, minerals, and vitamins (Parmar *et al*., 2012). *Z. mauritiana* is a desirable ingredient for animal feed due to its abundance, affordability, and health benefits. It is currently available as dried powder, pellets, fermented powder, and complete feed. However, these products have been studied for use in animal feed on a global scale. Many studies on the impact of *Z. mauritiana* on ruminant milk production have been published. Industrial by-product of *Z. mauritiana* was added to diets to boost feed intake, milk output, and milk quality in nursing cows as well as improving feed nutrient utilization. The ideal amount of *Z. mauritiana* residue to add to a meal was 8 to 10% dry matter; this allowed dairy cows to maintain a normal rumen environment and enhanced the feed's aroma, nutrient digestibility, and dairy productivity (Xu *et al*., 2022). Badakaya *et al.* (2021) and Abdu *et al*. (2012) reported higher weight gain in growing Rabbits fed diet containing 45% and 10% *Z. mauritiana* leaves respectively. In broilers and laying hens, the effects of supplementing the diet with *Z. mauritiana* leaves powder have been studied. *Z. mauritiana* powder replaced 10 - 15% of the maize in the feed of Taihang hens, which reduced stress, boosted protein synthesis, raised serum globulin levels, encouraged the growth and development of immunological organs, increased pathogen resistance, and increased survival rates (Xu *et al*., 2022). Khan *et al*. (2009) reported the results of an experiment with Beetle goats supplemented with *Z. mauritiana* leaves, which resulted in a final body weight gain of (56 kg). The average body weight gain, organic matter, crude protein, and acid detergent fiber were all enhanced by replacing maize with 5 to 20% *Z. mauritiana* powder, which also raised the net meat output and dressing percentage in Jinlan Cashmere goats (Xu *et al*., 2022). The *Longissimus dorsi* muscle's pH and crude fat content fell when *Z. mauritiana* powder was added to the meal, while the meat's protein and amino acid content, as well as the amounts of Ca, K, Mg, Na, Mn, Fe, and Zn, increased the composition of fatty acids was unaffected. Therefore, 15% jujube was suggested as the best amount for goats since it improved meat quality and increased growth performance (Xu *et al.*, 2022). In a study on fattening lambs, Xu. (2022) reported that jujube consumption decreased blood concentrations of urea nitrogen, total cholesterol, and triglycerides without changing blood glucose or insulin levels.

Other Uses of *Ziziphus mauritiana* Fodder Fractions

Various plant components can be used medicinally to cure a range of local health issues (Maaiden *et al*., 2020; Singh and Meghwal, 2020); the roots are used as a decoction to treat fever and the powder from the roots is applied to ulcers and old wounds, the bark is used to treat diarrhea, the leaves are used to treat wounds as poultices and are beneficial for liver problems, asthma, stomatitis, gum bleeding, and fever, the fruits have laxative, energizing, burning-sensation-removal, thirst-relieving, vomiting-control, and blood-disorder-controlling properties. *Z. mauritiana* has been used for thousands of years in traditional medicine to treat fever, diabetes, and skin conditions because of its antipyretic, antinociceptive, antioxidant, antibacterial, and insecticidal characteristics (Muhammad *et al*., 2022). The fruits are used as a liver tonic, as an antioxidant, hepatoprotective, protective effect, weight gain, increases stamina, and reported to have anticancer effects, while the leaves are used for hypoglycemic effects, reduction of sweetness judgments, as diuretic, emollient, expectorant, to promote hair growth, anticancer, sedative, blood purifier, and in the treatment of diarrhea (Tripathi and Preeti, 2014). Buttermilk and the calming properties of the seeds can ease pregnancy-related nausea, vomiting, and pain in the abdomen. Locals use the astringent seed to quench their thirst (Singh and Meghwal, 2020). A total of 431 chemical compounds (including those found in the fruits, roots, leaves, and stems) have been found in the *Ziziphus* species, according to Muhammad *et al.* (2022), of which polyphenols were isolated using a variety of extraction techniques and demonstrated a wide range of biological activities.

CONCLUSION

Ziziphus mauritiana is palatable and has high in energy, protein as well as minerals contents. Its vitamins and has antidiarrheal, antibacterial, immune promoting, and antioxidant properties. The inclusion of *Z. mauritiana* as a supplement or as a replacement can increase feed palatability, feed intake, and nutrient digestibility, and thereby improve the quality of animal products. Given its ability to improve immunity, and, thereby, to reduce the use of antibiotics, *Z. mauritiana* fruits and leaves has broad potentials uses in animal feed as a growth promoter, antioxidant, and flavoring agent. Finally, the recommended feeding levels as inclusion or supplement and processing technology should be improved by researchers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted at the Poultry Unit of the Teaching and Research Farm of the Department of Animal Health and Production, Binyaminu Usman Polytechnic, Hadejia, Jigawa State. The research focused on ascertaining the effects of varying energy regime on the growth performance and primal cuts characteristics of noiler birds. To arrive at the presented results, a total of seventy-two (72), day-old noiler chicks were procured and used for the eight weeks experiment. The chicks were randomly divided into three treatments with 24 chicks per treatment in a completely randomized design (CRD). Each treatment has four (4) replicates of six (6) birds per replication. Three (3) different experimental diets containing varying energy regimes of 2600MEkcal/kg, 2800MEkcal/kg and 3000MEkcal/kg were formulated and fed to T_1, T_2 and T_3 respectively. Water and the compounded feed were made available ad-libitum. The results showed that there were significant differences in average body weight gain, average final body weight and feed conversion ratio ($P<0.05$). However, no significant difference ($P>0.05$) was observed in all primal characteristics of the experimental birds across all the dietary treatments. It is concluded that, birds fed T2 diet (2800MEkcal/kg) has higher final body weight and feed conversion ratio with no distinctive feed intake. Moreover, varying energy regime has no effect on noiler birds primal cut parts. Hence, it is recommended for consideration while formulating noiler diet.
Keywords: *Energy, Noiler, Primal Cuts, Regime, Growth, Performance.*

INTRODUCTION
Poultry production is one of the best means for production of high biological value animal protein in terms of eggs and meat (Yakubu *et al*., 2007). The poultry sector contributes about 25% of the agricultural domestic products of the Nigerian economy (FAO, 2010). Nigeria presently produces above 550,000 mt of poultry meat per annum and 770,000 mt of eggs (FAO, 2010). The energy requirements of poultry and the energy content of feedstuffs are expressed in kilocalories i.e 1kcal equals 4.1868 kilojoules. Poultry like other farm animals consume feed primarily to satisfy their energy requirements (Oluyemi and Robert, 2007).

The feeding component of poultry farming is clearly a burden for farmer (Shiferaw *et al.*, 2013; Marangoni, *et al.*, 2015). This is due to the fact that poultry and humans have similar nutrition requirements, and that grains (such as corn) used in poultry diets are also consumed by humans. Besides, grains are also in competition with various industries as they are used as industrial raw material. In addition, the level of production of these important grains is not sufficient to meet the increasing demand of the poultry industry. Therefore, it is essential that scientific knowledge be improved on the utilization of low-cost and locally available materials in varying amounts and or proportion in poultry feed. This will help reduce the feed cost and increase profitability (Sissoko *et al.*, 2011). Body weight and a number of primal cut parts such as breast, shank, back, thigh, drumstick e.t.c have been applauded to be good indicators of body growth and value in noiler. Despite the Nigerian local chickens, not much information exist is comparing them with noiler which is an improved local breed. Thus, this research was embarked upon to evaluate the effects of varying energy regimes on growth performance and primal cut parts characteristics of noiler chicken.

MATERIALS AND METHODS

This research was conducted at the Poultry Unit of the Teaching and Research Farm of the Department of Animal Health and Production, Binyaminu Usman Polytechnic, Hadejia, Jigawa State (coordinates of 12º28'N /10º01'E).

Experimental Birds Management and Experimental Diets

Seventy-two (72), day-old noiler chicks were used in the experiment. The chicks were randomly divided into three (3) groups with twenty-four (24) chicks per treatment in a completely randomized design. Each treatment has four (4) replicates of six (6) chicks in each. The experimental diets were formulated with varying energy regimes (i.e. 2600MEkcal/kg, 2800MEkcal/kg and 3000MEkcal/kg) and the experimental diets were designated as T_1-600MEkcal/kg, T_2-2800MEkcal/kg and T_3-3000MEkcal/kg. The birds were fed with Ultima broiler starter feed in the first two weeks before placing them on the formulated experimental diets. The chickens were reared for 8 weeks. The birds were reared on a deep litter system, given Feed and water ad libitum and stricted bio-security measures were kept in place. All birds were vaccinated against Newcastle and Gumboro diseases. Coccidiostat, antibiotics and vitamins were also administered to birds.

Table 1: Composition of experimental diet (2-4weeks)

Ingredients	T_1(2600mekcal/kg)	T_2(2800mekcal/kg)	T_3(3000mekcal/kg)
Maize(kg)	42	50	60
Wheat offal(kg)	20	17	8
Soya beans meal(kg)	35	30	29
Limestone(kg)	0.7	0.7	0.7
Bone meal (kg)	1.30	1.30	1.30
Common salt (kg)	0.35	0.35	0.35
Vitamin premix (kg)	0.25	0.25	0.25
Lysine(kg)	0.20	0.20	0.20

Data Collection

Average Daily Feed Intake: Feed given and the left over were weighed, the difference between the quantity of feed given and the left over, gave the daily feed intake for the previous day.

Average Body Weight: Initial body weights of each of the birds were taken before assigning them to the various treatments. Weekly measurement of body weight was also taken using a digital weighing scale.

Average weight gain: This was taken as the difference between the initial body weights and the final body weights of the birds. This measurement was carried out on weekly basis.

Feed conversion ratio: The quantity of feed consumed per unit increase in live weight. It is the reciprocal of feed efficiency and is estimated as:

FCR=feed consumed (g)/weight gain (g)

Primal cuts Characteristics: The head, neck, wing, breast, back, thigh, drumstick and feet were carefully dissected and their weights were obtained using sensitive electric weighing scale.

Data Analysis

The data generated were subjected to analysis of variance (ANOVA) in completely randomized design (CRD) of GENSTAT (2014), where significant differences between means were separated using Duncan Multiple Range Test.

RESULTS AND DISCUSSIONS

Growth performance of noiler chicken fed diets containing varying energy regime was presented in Table 3. The results revealed that there were no significant differences (P>0.05) in initial body weight and average feed intake among all the birds across the dietary treatments, however there were distinctive differences in final body weight, body weight gain and feed conversion ratio (P<0.05). Birds fed diet T1 reported in this research was found to be statistically better in final body weight and feed conversion ratio compared to the other treatments, this indicated that chicken reared on a moderate-level energy regime (2800MEkcal/kg) consume feed reasonably and convert it optimally. The present results are in contrast with the finding of Sheriff *et al.*, (1981) who obtained higher feed consumption in broiler fed 2950 kcal ME/kg ration. but agreed with the findings of Tooci *et al.* (2009) who compared concentrate diets (3010, 3150 and 3200 kcal/kg ME respectively for starter, grower and finisher phases) versus diluted diets (2800 kcal/kg ME) and reported that feed intake of broiler chickens was not influenced by energy content in diets, but concentrate diets improved weight gain and feed conversion.

Result of final body weight equally showed significant (p<0.05) difference where T2 appears to be the best among the treatments, the result obtained might be due to the fact that excess energy (glucose) in the diet is the major source utilized for storage as glycogen in animals Sheriff *et al.*, (1981). The body weight gain indicated that ration containing moderate energy, gained maximum growth. The higher level of energy was found to induce poor performance on body weight gain. The results are in agreement with Verma and Pal (2001) findings as moderate energy, and high protein had a positive effect on growth rate and was also reported by Bamgbose (1999). However, chicks fed diet with 3000 kcal ME/kg utilized feed more efficiently than the lower level of energy in the diet. As reported by Haunshi *et al.* (2012) that different ME levels had a significant effect on body weight gain, feed intake, and FCR.

Result of AFI obtained in this study showed no significant (p>0.05) difference, despite that there is numerical variation among the treatments, this finding also is at variance with the finding of Farrell *et al.* (1973) who concluded that the feed intake was inversely related to energy concentration in the diet.

Table 3: growth performance of noiler chicken fed diets containing varying energy regime

Parameters	Treatments			
	T_1 (2600MEkcal/kg)	T_2 (2800MEkcal/kg)	T3 (3000MEkcal/kg)	Pr<F
AIBW	318.8	329.0	329.8	0.55
AFBW	962.2^{ab}	1031.2^{b}	893.2^{a}	0.087
ABWG	644.0^{ab}	702.2^{b}	563.5^{a}	0.097
AFI	2022.0	2052.0	2102.0	0.33
FCR	3.20^{ab}	2.94^{a}	3.80^{b}	0.088

^{a,b,c}, Means with different superscript along the same rows are significantly (P<0.05)

ABWG= Average Initial Body Weight Gain, AFBW= Average Final Body Weight, AFI= Average Feed Intake,
Table 4 shows the effect of varying energy regimes on primal cut characteristics of noiler chicken. The result showed no significant (P>0.05) difference across the treatment groups in all the parameters (i.e., head, neck, wing drumsticks, thigh, breast and back) measured despite the slight numerical variations. This implied that varying energy regime has no any significant effect on primal cut value (Sese *et al*., 2013). While improvement in carcass was also recorded in noiler chickens fed by Kana *et al.* (2017). It is expected that the dietary energy levels would improve carcass yield as a result of better dietary amino acid digestion, which would favor muscle deposition, this agreed with Windisch *et al.* (2008) report that phytobiotics increased stabilization of intestinal health, animals are less exposed to microbial toxins and other undesired microbial metabolites such as ammonia and biogenic amines. As a result, animals are relatively relieved from immune defense stress during critical situations and there is increased availability of essential nutrients for absorption, thereby helping the animals to grow better within the framework of their genetic potential.

Table 4: Primal Cut Characteristics of noiler Birds Fed Diets Containing Varying Energy Regimes

Parameters	Treatments			
	T1	T2	T3	F pr.
Head	38.75	36.75	34.50	0.79
Neck	54.25	56.50	52.50	0.29
Wings	83.75	85.00	81.50	0.86
Breast	113.0	120.0	115.0	0.42
Back	10.25	116.0	98.00	0.87
Thigh	102.75	98.01	97.75	0.46
Drumsticks	87.50	87.75	82.25	0.44
Legs	49.25	47.75	43.25	0.54

$^{a, b, c, d}$ Means with different superscripts along columns differ significantly at (P < 0.05).

CONCLUSION AND RECOMMENDATION

It is concluded that, birds fed T2 diet (2800MEkcal/kg) has higher final body weight and feed conversion ratio with no distinctive feed intake, moreover, varying energy regime was found to have no effect on noiler birds primal cut parts. Hence, it is recommended for consideration while formulating noiler diet.

PREVALENCE OF TICK INFESTATION IN SMALL RUMINANTS BROUGHT FOR SLAUGHTER AT THE KAZAURE ABATTOIR SLAUGHTER STAGE (CASE STUDY OF KAZAURE ABATTOIR)

***A.L. Kazaure, Abunabo M.M, M. Dahiru, N. Salisu, B. Babandi, A. Abdulaziz**

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The research was conducted at Kazaure abattoir to determine the prevalence of tick infestation in small ruminants at pre-slaughter stage. For this purpose, a total of one hundred and thirty-four (134) small ruminants were examined in a systematic random sampling, were an average of twenty (20) small ruminants were randomly selected and examined every Saturday for a period of seven weeks, starting from 1st April, to 20th May, 2023.The prevalence of tick was determined by dividing the number of positive samples by the total sample size, and was expressed as percentages. The result revealed a prevalence 61.94% among the small ruminants brought in to the abattoir for slaughter. Regarding species, sheep were found to have higher prevalence (66.67%) than goats (59.04%); higher prevalence was recorded in female (68.57%) than male (56.04%). On the age side, adults were confirmed to have higher prevalence (75.34%) than young and old (47.83% and 44.74% respectively). Animals examined with poor body condition score has the highest prevalence (87.50%) compared to those with medium and good (68.57% and 46.27% respectively) body condition scores. The highest total prevalence (87.50%) confirmed among small ruminants with poor body condition brought to the abattoir seems to be as a result of poor tick control by the small ruminants rearers or salvaging decision taken by the rearers instead of controlling the condition. It was recommended that Extension workers should shed light to small ruminants rearers on treating ticks infested animals instead of salvaging, slaughtering of ticks infested animals should be discouraged to avoid transmission of zoonotic ticks borne diseases to meat consumers and good veterinary services should be provided in the study area.

INTRODUCTION

The arthropods contain over 80% of all known animal species and occupy almost every known habitat, as well as a plethora of small and little-known groups. As a result of their activity, arthropod ectoparasites may have a variety of direct and indirect effects on their hosts (Wall and Shearer, 2001). Ectoparasites, particularly ticks, are important parasites because of their voracious blood-feeding activity and as vectors for various agents of diseases in both man and livestock (Cumming, 1998). In Nigeria parasites constitute a major constrain to livestock production (Fabiyi, 2007). This is particularly of cattle, sheep and goat. Ticks are ectoparasites of ruminants and other domestics and wild animals living by haematophagy on blood, causing skin irritation and anemia (Wilson, 1990).

Ticks are among the most difficult ectoparasites of domestic animals to control (Walker *et al.*, 2007). Ticks are also one of the major vectors of pathogens, such as Bebesiosis, Theileriosis, Anaplasmosis,Dermatophilosis etc to animals in the world (Soulsby, 1982; Morel, 1989). Severe irritations caused by their bites especially when numerous can result to severe emaciation as animals do not settle down to feed well. The large volume of blood they suck when they occur in large number can lead to anemia which in turn results in weakened stock. Their bites cause serious damage to hides and skins which are valuable export products in Nigeria (Fabiyi, 2007). The productivity of ruminant animals depends on the health status of the animals (Lamorde, 1981). Good herd health can only be achieved by adequate control of vectors of the diseases and this is one of the costly operations in the livestock industry. Effective control of vectors could be possible if farmers have the idea of infestation (Hassan, 1997). It is important to know the prevalence of the ticks species involved in the transmission as well as their geographical distribution for the control of ticks borne diseases (Gholan *et al.*, 2007).

All ticks are obligate temporary parasites of vertebrate animals in which they cannot survive without blood. Larvae, nymphs and adults, both males and females need to suck blood and are characterized by a complex developmental cycle. Ticks thus can become integrated into the epidemiological chain of pathogen transmission, by means of the so-called trans-stadia (stage-to-stage, also called horizontal) or transovarial (female-to-egg, also called vertical) passages (Kahl *et al.*, 2002). Ticks feed on concentrate blood meal by removing the excess water. This helps to accommodate the large blood intake (several milliliters) in the relatively small body. The engorgement and blood sucking habit, longevity, high reproductive potential, relative freedom from natural enemies and highly sclerotized bodies that protect them from environmental stress contributed to their successful life (Estrada-Peña *et al*., 2013).

Ticks may have multi-year life cycles, long starvation tolerance and various stages may survive over winter. Slow intracellular digestion of blood allows for pathogens to escape digestive process in the ticks' gut and protects pathogens in an intracellular location. An early painless bite, saliva containing pharmacologically active compounds mediating the host immune response and anticoagulant compounds allowing continued blood flow into feeding lesions all contribute to effective tick parasitism (Gary and Lance, 2009). The objectives of the study therefore were to investigate the prevalence of ticks on small ruminants brought for slaughtering at the Kazaure abattoir with respect to species, sex, age and body condition and to understudy the most susceptible small ruminants to ticks.

The Study Area

The research was conducted in Kazaure Abbatoir, in Kazaure town, Kazaure Local Government Area of Jigawa State, Nigeria. Its headquarters is in the ancient city of Kazaure, it is also an Emirate Which Comprises Kazaure, Roni, Gwiwa And Yankwashi Local Governments.

Sampling Procedure

A total of one hundred and thirty-four (134) small ruminants were examined in a systematic random sampling during the course of this research, an average of twenty (20) small ruminants were randomly selected and examined every Saturday for a period of seven weeks, starting from 20th April to 2nd June, 2023.

Data Collection

The Data was obtained by physical examination of the animals kept in the pens of Kazaure abattoir for the presence of tick. Species, sex and body condition scores (BCS) of the small ruminants were determined at the time of collecting the data. Ticks were checked on different parts of the body including the neck/dewlap, eyes, ear, udder and external genitalia, inner thighs, under the tail/perineum and legs /inter digital spaces by using forceps and gloved hands. The age of the animals were categorized as young (0 up to 1 years), adult (2 up to 4 years) and old (above 4 years old) according to the classification method used by Gatenby (2002). Those small ruminants on which tick were seen were marked as positive.

Data Analysis

The data obtained were analyzed using simple descriptive statistics such as means and percentages. The prevalence of tick was determined by dividing the number of positive samples by the total sample size, and was expressed as percentages.

RESULTS AND DISCUSSION

A total of 134 small ruminants (51 sheep and 83 goats) were examined to determine the prevalence of tick infestation in small ruminants at the Kazaure abattoir. Of these 83(61.94%) of the examined small ruminants brought to the abattoir for slaughter were infested by tick. Based on species, sheep were found to have higher prevalence (66.67%) than goats (59.04%),higher prevalence was recorded in female (68.57%) than male (56.04%).On the age side, adults were confirmed to have higher prevalence (75.34%) than young and old (47.83% and 44.74% respectively). Animals examined with poor body condition (i.e. itching, scratching and visible red or inflamed irritations on the skin) score has the highest prevalence (87.50%) compared to those with medium and good (68.57% and 46.27% respectively) body condition scores. The highest total prevalence (87.50%) confirmed among small ruminants with poor body condition brought to the abattoir seems to be as a result of poor tick control by the small ruminants rearers or salvaging decision taken by the rearers instead of controlling the condition.

Table 1: Prevalence of tick infestation in small ruminants at the Kazaure abattoir with respect to species, sex, age and body condition scores

Variable	Categories	No.of animals examined	No.of infested animals	Prevalence
Species	Sheep	51	34	66.67
	Goats	83	49	59.04
Sex	Male	64	36	56.25
	Female	70	47	68.57
Age	Young	23	11	47.83
	Adult	73	55	75.34
	Old	38	17	44.74
	Poor	32	28	87.50

BSC	Medium	35	24	68.57
	Good	67	31	46.27

BCS=Body Condition Scores

DISCUSSION

The current study revealed that tick infestation is widespread and amongst the most significant external Parasites of small ruminants in the study area. The result of this study revealed a relatively low prevalence (61.94%) of tick infestation on small ruminants compared to the reports of Ahmed *et al.* (2017) who investigated the prevalence of ticks on small ruminants in Beadle district, Oromia Region, of Ethiopia. In the report, tick prevalence as high as 76.50% was reported in small ruminants. However, tick prevalence of 66.12% (goats) and 80.30% (sheep) was recorded in Bedelle district, Oromia Region, Ethiopia by Abunna *et al*. (2009). The higher prevalence recorded in female (68.57%), than that of male (56.04%) in this study agrees with the findings of Ahmed *et al*. (2017) who reported 59.34% in female and 70.47 in females. The animals examined with poor body condition score in this study has the highest prevalence (87.50%) compared to those with medium and good (68.57% and 46.27%, respectively) body condition scores, this agrees with report by Ahmed *et al*. (2017) and (Aminu, 2015). Some ticks species have preference for the host species (host specific) while some species can affect all species of livestock (McCoy *et al*., 2013). Attention should be given to the prevention and control of ticks since they served as vectors to livestock diseases and caused damage to the skin of animals.

CONCLUSION

The results obtained revealed a moderate overall prevalence of 61.94%, and amongst the variables. Higher prevalence (87.50) was observed among small ruminants with poor body condition score among the animals brought to the abattoir for slaughter.

RECOMMENDATIONS

i. Extension workers should shed light to small ruminant's rearers on treating ticks infested animals instead of salvaging.
ii. Slaughtering of ticks infested animals should be discouraged to avoid transmission of zoonotic ticks borne diseases to meat consumers.
iii. Good veterinary services should be provided in the study area.
iv. The farmers should be encourage to go for veterinary services.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analysed the factors affecting poultry egg production efficiency in Etim Ekpo Local Government Area. The objectives of the study were to describe the socio-economic characteristics of poultry egg producers and factors affecting Poultry egg production efficiency in the study Area. Multistage sampling procedure was adopted to collect primary data from seventy-five (75) poultry egg producers using a well-structured questionnaire. Percentage, frequency count, average and ordinary least square regression were employed to analysed the data in the study area. The result of the findings revealed that, majority about 71% of the poultry egg farmers in the study area were male. The average age of the respondents in the study stood at 41 years, The study revealed that, the respondents in the study area had one form of education or the other. It was also discovered that most of the farmers were married about 83%. The means household size stood at 4 persons per household. 76% of the respondents were members of cooperative society. The mean income of the respondents stood at ₦70,800 per month. The result also revealed that majority, about 99% of the respondent had farming as their major source of income. From the findings of the study, it was concluded that there was a significant relationship between input and output in poultry egg enterprise. The study recommends, the integration of poultry egg production programmes to geared towards empowerment, better management practices, subsidy on poultry equipment and credit facilities and encouragement of farm records keeping for high production efficiency attainment.
Keywords: *Analysis, Factors, Poultry, Egg Production, Efficiency*

INTRODUCTION
The poultry industry is significant to the Nigerian economy at large and the rural economy in particular because it provides a good source of meat and eggs which supplies animal protein to the human diet. Proteins play key roles in the formation of a balanced human diet that is essential for better health, vigor, and productive capacity of the people. It builds and repairs body tissues; a low intake or deficiency of protein reduces the skillfulness of the young, hinders the development of the brain, retards rate of growth and increases rate of susceptibility to infections by animals. Ijah, Ishola, Ayodele, Yahaya, and Olukotun, (2020).
The poultry sector is one of the most organized and vibrant segments of the agriculture industry in Nigeria, which strives harder towards the provision of much protein human diet. This sector generates direct and indirect employment and income for many people not leaving out the generation of revenue to the overall economy. Ijah *et al.,* (2020). Tijani *et.al.* (2012) reported that eggs have many uses apart from domestic consumption in households; eggs are used in confectionery, bakery products, ice cream, and cosmetics. Egg shell is a good source of calcium for the formation of strong bones and teeth. Nutritionally, eating an egg per day is a good way of putting proteins, fats, vitamins and minerals in human diet. According to Mere, Ater, and Ezihe, (2017), a medium sized egg supplies about 80 calories of energy to our body. They further asserted that egg contains not only a trace of carbohydrate, but it was also adjudged to be a replacement for meat as it contains all essential amino-acids in adequate proportion required by the body for general growth and repair.
Efficiency of poultry egg production is defined as the ability of a poultry egg producer to achieve the highest possible quantity of egg, return and profit given the prices and levels of all input factors as well as the prevailing technology which will enable the farmer to operate along the production possibility frontier. Research carried out on the Efficiency of Poultry Egg Production in some areas revealed impressive results as follows: Hassan *et al.,*

(2016) examined the input-output relationship and cost and return in egg production in Kaduna state using descriptive statistics, multiple regression, cost and return analysis. The result revealed that, the total cost of production was N206, 610. 44 per 100 layers and net farm income was N208, 079. 75. The return per Naira invested was N1.01. Feed cost accounted for 69% of the total cost of egg production. The regression result revealed that all the parameters estimated except labour (-0.742) carry positive sign. Which implied that flock size (1.287), feed (0.911) and medication cost (0.305) have direct relationship with the farmer's egg output. The t-ratios showed that flock size, and feed were significant at 5% and 10% level of significance respectively.

Ayinde *et al.*, (2012) examined the economics value of poultry egg production under different management systems in Odeda Local Government Area of Ogun State in 2008 using a combination of descriptive statistics, budgetary techniques, profitability ratios and multiple regression analysis. The study results showed that the Gross Margin under battery cage system per bird / year was N8, 089.56, while the Net Farm Income per bird / year was N1, 773. 17. Under deep litter system, the Gross Margin per bird / year was N1, 404.09, while the Net Farm Income per bird / year was N1,029.43. The regression result showed that educational qualification (α0.10), total feed used (α0.05), total labour used (α0.05), and the stock size (α0.01), were significant determinants affecting the quantity of egg produced.

The study of technical efficiency in small and medium scale poultry, egg production in Ogun State, Nigeria was reported by Akerele *et al*. (2019). The results on age showed that the mean age of the producers is 43 years with higher percentage of the farmers being relatively young and in their active age of production. The implication is that younger farmers are likely to adopt innovations faster than the older ones. The result on farming experience revealed a mean experience of 9.8 years, with majority (67.7%) having 10 and below years of experience. The mean flock size of chicken table egg farmers in the study area was found to be 1040 birds. Analyses of household size of the producers showed a mean household size of 7 persons with a modal household size of ranges of between 6 and 10 persons. The high mean household size means that there is high availability of family labour to the enterprises in the study area. The result on marital status showed that majority (78.5%) of the sampled producers were married. This shows that the producers are responsible according to the societal standard and therefore are likely to have some experience of life challenges which instills some level of discipline in making decision. On educational status of the producers, the result shows that majority (69.2%) of the producers had tertiary education indicating that they are highly educated. The result on occupational status showed that most of the respondents (53.8%) in the enterprise were engaged in the eggs production venture as their secondary occupation.

The estimation of the efficiency of poultry-egg farmers in Ondo State was reported by Oluyemi *et al*. (2020). The findings showed that 81.7% of the farmers were male and the mean age was 46.2. Most of the respondents constituting about 90.4% were married and majority (84.3%) had tertiary education. 68.7% of the respondents had access to credit facility. The profitability analysis showed that feed constituted the highest variable cost item. Small scale enterprise spent 83.80% on feed, medium scale spent 85.18% while large scale incurred 76.41% on feed. The technical efficiency result showed that 40.9% of the respondents were most efficient. The mean technical efficiency of the farmers was 83.1% while the minimum and maximum efficiencies were 13% and 97% respectively. About 3.5% of the respondents were below 50% economic efficiency and the mean economic efficiency was 0.771. The allocative efficiency analysis revealed that farmers were at least 50% efficient and the mean allocative efficiency was 0.948. Inefficiency result showed that feed and stock had significant influence on egg production at (P=0.1). High cost of input was rated the major constraint and inadequate storage facilities was rated as the least constraint.

Apart from poultry industry being so significant to the Nigerian economy, it also provides a good source of meat and eggs supplies of animal protein to the human diet. The proteins play key function in the formation of a balanced human diet that is essential for better health, vigor, and productive capacity of the people as well as building and repairing of body tissues. While low intake or deficiency of protein reduces the skillfulness of the young ones, hinders the development of the brain, retards rate of growth and increases rate of susceptibility to infections (Ijah *et al.,* (2020)). It is on this ground that this research study is necessary to analysed the factors affecting poultry egg production efficiency in Etim Ekpo Local Government Area. The specific objectives are to; assess the socioeconomic characteristics of poultry egg producers and ascertain the factors affecting poultry egg production efficiency in the study area.

RESEARCH METHODOLOGY

This study was conducted in Etim Ekpo L.G.A of Akwa-Ibom State, coordinate is $5^0$1'N $7^0$37'E. The L.G.A was created out of the former Abak division, Etim Ekpo is one of the Annang-speaking natives. The seat of the local government council is in Utu Etim Ekpo a community in Etim Ekpo. The inhabitants of this town are estimated to be 108,418, according to 2006 population census. This figure was projected to 112,660 people in 2021. Etim Ekpo local government area is made up of four districts of seventy-four communities and villages. The people of this locality are predominantly subsistence farmers, traders and craftsmen. Natural resources in Etim Ekpo local government area are sharp sand, gravel, timber and oil-palm. The people of Etim Ekpo are mainly farmers, but the educated indigenes work as civil servants within and outside the local government area. In the area of education, there are many public and private secondary schools. The local government area is the home of one private university, the Obong University, located at Obong Ntak. The people of Etim Ekpo are vast in knowledge and every other creative activity (Wikipedia, 2021). A multistage sampling technique was adopted in this research. The first stage was a purposive selection of five (5) clans in Etim Ekpo Local Government Area. The second stage, was a simple random selection of five (5) villages from each clan. The third stage was a simple random selection of three (3) poultry farmers in each of the five villages. The total respondents for the research were 75 poultry farmers. Both descriptive and inferential statistics were used in the analysis. Descriptive statistics such as percentages, frequency counts, arithmetic means and tables were employed in analysing the socioeconomic characteristics of the farmers. While, OLS regression was used to analysed the factors affecting poultry egg production efficiency in the study area.

RESULTS AND DISCUSSION

Socioeconomic Characteristics of Poultry Egg Farmers in the Study Area

The Result in Table 1 below shows that majority about 71% of the poultry egg farmers in the study area were male while minority about 29% were females. This indicated that the males were more involved in poultry egg production in the study area than their female counterparts. This finding is in line with the finding of Ijah *et al.*, (2020) and Oluyemi *et al.* (2020) who discovered that the poultry egg producers were predominately male in their study areas as expected because of the energy demanding nature of the poultry enterprise.

Age is an indication of the stage of life of the respondents as well as how active a respondent could be especially in poultry egg farming activities. Table 1 also reveal that 29 farmers fell within the age range of 25-36 years representing about 38% of the total respondents, 31 farmers fell within the age range of 37 – 48 years representing about 41% of the total respondents and 15 farmers fell within the age range of 49-60 years representing about 20% of the total respondents. While the average age of the respondents in the study was 41 years. This is an indication that the farmers as at the time of this research were at their prime and active stage of their life existence, as such being able to cope with the tediousness involved in the poultry egg production as well as adaptation of new techniques for production. This age status will enhance their rate of production efficiency which will lead to increase in income to enhance more profit. This is confirming Akerele *et al.* (2019) that, the mean age of the producers is 43 years with higher percentage of the farmers being relatively young and in their active ages of production which, implied that the younger farmers are likely to adopt innovations faster than the older ones.

On the aspect of educational attainment, Table 1 further revealed that, about 11% of the respondents had First School Leaving Certificate (FSLC), majority representing about 39% of the respondents had West African Examination Certificate/ West African Senior Secondary Certificate Examination (WAEC/WASSCE), 16% acquired Ordinary National Diploma (OND), about 13% of the farmers had the National Certificate in Education (NCE), 20% had higher National Diploma (HND) while only about 1% had either Bachelor of Art or Bachelor of Science (BA/B.Sc.), respectively. The figure depicts that, the respondents in the study area had one form of education or the other. This implied that their educational status has significantly contributed to the increase in poultry egg production efficiency in the study area whereby enhanced high-income generation. This is in line with Akerele *et al*. (2019) findings that, the level of education of the producers will contribute significantly to their decision making.

The findings further revealed that most of the farmers were married about 83%, while about 17% were single. This is in line with Akerele *et al*. (2019) who revealed that, majority (78.5%) of the sampled producers were married with implication that the producers are responsible according to the societal standard and therefore are likely to have some experience of life challenges which instills some level of discipline in making decision. The study depicts that majority, about 75% of the respondents had household size that ranged between 3 – 4 persons, followed by about 21% of the respondents fell within 5-6 persons and 4% had 1-2 persons in their household. While the means household size stood at 4 persons per household, indicating that the household size is small within the African context.

Results on cooperative society membership revealed that, majority (76%) of the respondents do not belong to any cooperative society while only 24% of the respondents belong to one cooperative society or the other. This may be the reason why some of them were unable to accessed loans to increased their production capacity. Majority, about 69% of the poultry egg farmers in the study area acquired monthly farm income ranges from ₦20,000 – ₦80,000. This was followed by about 27% of the respondents who got income ranges from ₦81,000 –₦140,000 per month. Only 4% of the respondents acquired the ranges of income between ₦140,000 – ₦200,000 per month. While, the mean income stood at ₦70,800 per month, this level of income may be as the result of the high cost of production inputs. The result also revealed that majority, about 99% of the respondents had farming as their major source of income while only 1% of the respondents had income from civil Service work as well as farm work. This result may not be far from the average age status of 41 years, being young and active to perform farm work as well as their literate levels which will enable them to adopt innovation faster. Another reason for the respondents to take farming as their major source of income may be due to lack of white-collar jobs for the teeming youths' population that make them to resort to farming as their last option.

Table 1: Distribution of Egg Producers Based on Socio-economic Characteristics

Item	Variables	Frequency (n = 75)	Percent	Mean
1	**Sex**			
	Male	53	70.7	
	Female	22	29.3	
2	**Age**			
	25 – 36	29	38.7	
	37 – 48	31	41.3	41
	49 – 60	15	20.0	
3	**Educational Level**

The Factors Affecting Poultry Egg Production Efficiency in the Study Area

This subsection analyzed factors affecting egg production in the study area as shown in table 2. The result revealed that out of the four functional forms tried, exponential production form was chosen as the lead equation for the analysis based on conformity with a priori expectation of signs, magnitude of coefficients, overall significance of the functional form (F-statistics) as well as the explanatory power of the variables (adjusted R^2) included in the model. The F –value is statistically significant at 10% level which implies that the independent variables (X_1 to X_{12}) included in the model best explained the dependent variable (Y), value of egg production. The R^2 was 0.267 which implied that the regression model gives a good fit. It means that 26.7% of the total variations in value of egg production was explained by the independent variables (Xi) included in the model.

The results also show that factors such as cost of feeds, and membership in cooperative were the major factors that affected the value of egg production because they have shown a statistically significant effect at 5% and 1% levels respectively. The implication is that 5% reduction in feed cost will lead to about 37% increase in output while 1% increase in the membership cooperative, can increase value of egg production by 28% in the study. This may be due to the fact that cooperative members can easily access loans from financial institutions as well as obtaining firsthand information agricultural production activities. This is in line with the a priori expectation that the higher the exposure to social capital, knowledge, and economics of cooperate entrepreneurship involvement, the higher the returns from egg investment opportunities. The coefficients of other variables even though were not statistically significant were ether positively or negatively related to the poultry egg production efficiency in the study area.

CONCLUSION AND RECOMMENDATIONS

Based on the findings from the study, it was concluded that there is a significant relationship between input and output in poultry egg enterprise as well as poultry farming being a profitable venture in the study area. With the continues rise in demand for poultry egg in the study area, investment in poultry egg production is a viable enterprise for income generation, job creation especially, poverty alleviation and enhancement of food security in line with the poultry value chain transformation action plan of the on-going agricultural transformation agenda of Nigeria.

In the light of the research findings, the following recommendations are hereby proffered: Adequate measures aimed at reducing the cost of poultry egg production through research in the study area, especially the cost of feeds which constituted the largest proportion of the total cost of commercial poultry egg production, that will help in increasing egg production efficiency of the commercial poultry farmers in the study area and the nation at large. Poultry egg production should be integrated as a vital component in government programs geared towards empowerment especially for the teeming unemployed youths in the state as well as the nation due to its profitability. To increase the rate of production efficiency, better management practices should be implemented, feed should be formulated locally to reduce feed cost. Importers and manufacturers of poultry equipment should be given subsidy and credit facility respectively to reduce their importation and production cost, thereby enhance high rate of production efficiency. Poultry egg producers should be encouraged to keep records of sales, purchase in order to determine their productive performance which will eventually lead to production efficiency

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The research was conducted to evaluate the growth performance characteristics of Uda rams fed diets containing graded levels of millet stalk meal (MSM) as a replacement for cowpea husk. Twelve (12) entire Uda rams were used in this experiment, the animals were housed in 2m x 1m pen and randomly allotted into three experimental diets designated as; T1(control diet), T2 and T3 containing 0 %, 50 and 100 % respectively of MSM as a replacement for cowpea husk. Each treatment was replicated four times with one ram per replicate in a completely randomized design (CRD). Data were collected on feed intake, body weight gain, feed conversion ratio (FCR). The experiment lasted for 12 weeks. All the parameters measured indicated a slight decreased in values as the level of levels of MSM increases in the diet. The results of feeding graded level of MSM to Uda rams showed a comparable performance in terms of feed intake, body weight with those on the control diets. The highest feed intake (846.79g/d) and final body weight (32.05kg) were recorded in treatment 1. However, there was no significant (p>0.05) differences in the dry matter intake and dry matter intake as percentage body weight. The optimum weight gain and efficient utilization of the diet was achieved in treatment 2 (6.78kg) at 50% inclusion level of MSM when compared with treatment 3 (3.95kg). The highest feed cost (₦57.96k) was recorded in the control diet while the least (₦52.96k) was obtained in treatment 3 This study indicated that millet stalk meal could be incorporated into the diet of growing Uda rams up to 50 % replacement with cowpea husk at a reduced cost is recommended for intensive feeding of Uda rams without any deleterious effect on their growth performance.
Key words: *Growth performance, Uda rams, Millet Stalk Meal*

INTRODUCTION
Inadequate availability of feeds and forages due to reduction in area and deterioration of grazing lands poses a serious threat to sheep production in the Nigeria, it is one of the major problems facing the stock owners especially during the long dry season which is experienced in the northern part of Nigeria (Williams *et al*., 1997). Large scale production and utilization of crop residues is most common in the northern savannah environment which has the advantage to reduce the cost of feeding ruminants especially during the dry season period (Onwuka *et at*., 1997).

Crop residues of cereal origin are generally of poor quality due to high fiber content, low protein and low digestibility. They are poorly utilized when fed alone to ruminants but can be highly utilized when fed along with other conventional ingredients (Heuze and Tran, 2013). Therefore, the present study was carried out to evaluate the potential of millet stalk meal at graded levels on the growth response of Uda rams.

MATERIALS AND METHODS
Experimental site
The study was conducted at the Livestock Teaching and Research Farm (LTRF) of Kebbi State University of Science and Technology, Aliero. The Farm is located within the campus of the University around Zoological Garden. Aliero Local Government Area lies at latitude 12°16′44″N and Longitude 4°27′6E. The annual temperature varies considerable but usually between 26°and 38°C while the mean annual rain fall is about 500mm. The town has the largest onion market in Northwest Nigeria. The predominant ethnic group of the area is Hausa (KARDA, 2012).

Experimental animals and their management
Twelve (12) entire male Uda rams of ±24.45kg average weight, were purchased from a local market in Kebbi State for the fattening. The animals were group fed with cowpea hay and wheat offal for a period of two weeks before the commencement of the study. The rams were balanced for weight before being allotted to treatments

and were dewormed with anthelmintic (Ivomec) at the rate of 1ml/10kg body weight. They were Sprayed against ecto-parasites with Triact and treated with oxytetracycline HCL (a broad-spectrum antibiotic). Experimental animals were house in an individual pen measuring 2m ×1m. The pens were clean and disinfected with Izal solution. Prior to the commencement of the experiment, the animals were managed intensively and group-fed with cowpea hay and wheat offal.

Experimental diets preparations and formulation

The test ingredient (millet stalk) was, purchased from local farmers at Aliero local government area. The millet stalk was grinded using crushing machine. Other feed ingredients that were used in the preparation of the experimental diets including groundnut cake, cowpea husk, salt, rice bran and maize, salt and other feed ingredients were purchased from Aliero Market.

Three complete experimental diets were formulated using varying levels of millet stalk to replace cowpea husk at 0, 50, and 100 % levels of inclusion and were designated as diets 1, 2, and 3 in the experiment. Variation in composition of some feed ingredients was made in order to balance up the crude protein and energy.

Table 1: Ingredients Composition (g/kg DM) of the Experimental Diets

	Treatments		
Parameters (%)	1 (0%)	2 (50%)	3 (100%)
Maize	13	14	14
Wheat Offal	17	12	19
Rice Bran	29	25	23
GNC	18	20	21
Cowpea husk	22	11	0
Millet stalk	0	11	22
Salt	1	1	1
Total	**100**	**100**	**100**
Calculated value			
Cp (%)	13.91	13.21	12.16
ME (Kcal/kg)	2169.8	2153.5	2140.1
Feed cost (₦/kg)	57.96	55.74	52.19

Experimental design and feeding procedure

A Complete Randomized Design (CRD) as outline by Gomez (1984) was used in this experiment. Four (4) rams were allotted as replicates to three experimental diets as treatment in the feeding trials. Each ram was individually house in a pen. Each group of four animals were assigned to one experimental diet and fed at 3% of its body weight for 12 weeks. The animals were weight weekly between 8:00am and 9:00am for the period of the experiment. Daily records of feed intake were taken for twelve weeks of feeding trial by measuring the feed offered and that of the Left over. The basal diet was served and water was offered ad libitum to each animal for 12 weeks.

Data Collection

The animals were weighed before the commencement of the experiment and every week on the same day of the week between 8.00 and 9.00am after feed withdrawal for 14-16 hours to avoid error due to gut fill. Daily record of feed intake and weekly body weight gain were taken throughout the 12 weeks of the feeding trials.

Data Analysis

The data generated on the performance characteristics which include feed intake and live weight changes and were subjected to Analysis of Variance using the Statistical Package for the Social Sciences SPSS (2007) 16.0 software. Tukey`s-b Test was used to separate the treatment means.

RESULTS AND DISCUSSION

The results of the calculated feed cost obtained (Table 1) indicated that the cost of feed per kg decreased as the MSM increases in the diet with the control diet having the highest value (₦57.96k) while the least value was recorded in treatment 3 (₦52.19k). The decreased in cost is an indication of MSM potential in the diet of Uda rams. This is in line with the findings of Maigandi *et al*. (2002). The results in Table2 Indicates the performance measurement of the Uda rams fed diets containing millet stalk meal. The final body weights showed a non-significant (P>0.05) difference across the treatments with treatment 1 having the highest value (32.05kg) while treatment 2 (31.03kg) was higher than treatment 3 (28.38kg). The highest value was recorded in treatment 1 (7.825kg) and the least value was obtained in treatment 3 (3.950kg). The value obtained were statistically significantly different (P<0.05) across the treatments.

The results of the daily feed intake were similar (p>0.05) for treatment 1 (846.79g) and treatment 2 (822.92g). However, both had values which were significantly different (P<005) from treatment 3 (735.27g). The results of this experiment indicate a decreased in feed intake and weight gain with increased levels of millet stalk meal in the diets. The decrease in feed intake with increasing levels of millet stalk meal in the diet, could be due to the fact that millet stalk meal is characterized as low quality roughage which tends to be eaten less by animals to satisfy their needs for energy and other nutrients (McDonald *et al*., 1995).

The feed conversion ratio was significantly ($p<0.05$) affected across the treatments. The values (0.11, 0.09 and 0.07) obtained for feed conversion ratio were lower than the values reported by Ochepo *et al.* (2012) when goats were fed complete diet containing sugar cane peels. These results agreed with the report of Abubakar (2016). Who reported that feeding rams with crop residues alone could lead to an apparent loss of weight. The dry matter (DM) intake recorded for both treatments were not significantly ($p>0.05$) different across the treatment. The highest DM intake recorded were statistically the same across the treatments. However, treatment 3 had the highest value (92.25) while the least was obtained in the control diet. The DM intake increase as the level of MSM inclusion in the diets increases. This present finding is in agreement with Abdul *et al*. (2008) in their study on the effects of supplementing sorghum stover with poultry litter on the performance of Wadara cattle where they reported that supplementation with poultry litter significantly ($P<0.05$) increased dry matter intake (DMI). The dry matter as percentage body weight gain was not significantly ($p>0.05$) different across the treatments. The DM intake as percentage of body weight increases as the inclusion level of MSM in the diets increases. Treatment 3 had the highest value of 325.97% while the treatment 1 had the least value of 287.58%

Table 2: Performance characteristics of Uda rams fed experimental diets

Parameters (%)	Treatment 1(0%)	2(50)	3(100)	SEM
Initial body Wt. (kg)	24.23	24.45	24.43	1.49
Final body Wt. (kg)	32.05	31.13	28.38	2.13
Feed intake (g/day)	846.79^{a}	822.92^{a}	735.27^{b}	13.98
Av.Feed intake (kg)	72.04^{a}	68.76^{ab}	57.04^{b}	4.29
Feed conversion ratio	0.11^{a}	0.09^{ab}	0.07^{b}	0.012
Dry matter intake	90.00	92.00	92.25	0.68
Dry Matter intake as % body weight	287.58	299.87	325.97	21.01

abc: means in the same row followed by the same superscripts were not significantly ($p>0.05$) different

CONCLUSION

This study indicated that millet stalk meal could be incorporated into the diet of growing Uda rams up to 50% replacement with cowpea husk at a reduced cost as compared to the control diet is here by recommended for intensive feeding of Uda rams without any deleterious effect on their growth performance.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A 28 day feeding trial was conducted at the Teaching and Research farm of the Department of Agriculture, Alex Ekwueme Federal University Ndufu Alike Ikwo Ebonyi state, to evaluate the growth performance of finisher broilers placed on graded levels of vegetable rejects as dietary supplement. Five (5) treatment diets were formulated such that the homogenized vegetable rejects (VR) was incorporated into the treatment rations at graded levels notably T_1 (VR_0), T_2 ($VR_{1.0}$), T_3 ($VR_{1.5}$), T_4 ($VR_{2.0}$), and T_5 ($VR_{2.5}$) respectively. The birds were divided into 5 groups of 18 birds per treatment, replicated 3 times with 6 birds per replicate. The treatment diets were randomly assigned to experimental stocks in a Completely Randomized Design (CRD). The results obtained from this study indicated that VR had a significant effect ($P<0.05$) on growth, average daily feed intake and cost per kilogramme weight gain of finisher broilers. It was established from the study that VR should be included as a supplement at 1.0% level for optimum performance so as to make animal protein available at a reduced cost and maximized profit.

INTRODUCTION
Poultry industry in Nigeria contributes about 25% of the Agricultural Gross Domestic Product of the economy and employs over 25 million Nigerians directly and indirectly (Nigerian Tribune, 2023). Poultry production as an enterprise is now attractive and popular among small, medium as well as large scale livestock farmers. The industry has become a diverse industry with a variety of business interests including egg production, broiler production, hatchery and poultry equipment businesses (Rao, 2015). The consumption of chicken has no religious bindings as compared to the case of beef (Hindus) and pork (Muslims) and has an overall acceptable nutritional profile and taste.

The most effective ways to reduce feed costs is to explore alternatives that can reduce feed costs without compromising the nutritional requirements of livestock. Thus, in the course of world clamour for sustained food and nutrition security through organic farming enhancement, the combination of fluted pumpkin (Telfairia occidentalis), bitterleaf (Vernonia amygdalina) and Oha leaf (pterocarpus soyauxii) leaves could be a very good substitute in poultry diets production. Vegetable refuse by definition are those vegetable leftovers either discarded in homesteads or in the market which if allowed to decompose will constitute environmental nuisance and enhances climate change carbon foot print. Often times, VR are thrown out in land-fills were they breakdown anaerobically and produce methane. Methane is about 21 times more potent than carbon dioxide as greenhouse gas.

Vegetable refuse if harnessed properly yields nutrients and energy, vitamins, minerals like phosphorus, calcium, iron, magnesium, zinc and easily digestible fibre (Homestead, 2022). From positive indicators of results from past studies on vegetables wastes, this experiment is therefore aimed to evaluate the performance of finisher broilers placed on graded levels of vegetable wastes as dietary supplement,

MATERIALS AND METHODS
Location of study
This study was conducted at the Poultry unit of the Teaching and Research farm of the Department of agriculture, Alex Ekwueme Federal University Ndufu-Alike Ikwo, Ebonyi State which lies between latitude $06^{0}5'$N and longitude $08^{0}5'$E of the Greenwich meridian and Altitude of 55m. The annual rainfall is between 1000-1500mm.

The vegetation of the area is predominantly derived Savannah and mean annual temperature is about 24^{0}C while relative humidity is between 60-80% (Ogbodo, 2013).

Experimental birds and design

A total of Ninety (90), 4-week old Anak broilers used for the study were obtained from a hatchery farm at Ogun State certified to be of good health and physical stability. They were acclimatized for four (4) days and fed on controlled diet. The birds were raised in a deep litter system whose floor was covered with wood shavings and feed was provided throughout the experimental period. Standard management practices were strictly observed. Thereafter, birds were randomly allocated to five (5) dietary treatments and were replicated three (3) times with each replicate having six (6) birds in a completely randomized design (CRD). Feed and clean drinking water were supplied *ad-libitum* while other routine management practices were observed.

Experimental diets and ration Formulation

The vegetables wastes used for the experiment notably Pumpkin, bitter leaf and Pterocarpus were collected from Ikwo and its environs, dried, crushed in a hammer mill and homogenized before mixing with other basic ingredients. Five (5) treatment diets were formulated such that the homogenized vegetable rejects (VR) was incorporated into the treatment rations at graded levels notably T_1 (VR_0), T_2 ($VR_{1.0}$), T_3 ($VR_{1.5}$), T_4 ($VR_{2.0}$), and T_5 ($VR_{2.5}$) accordingly. The control diet (VR_0) did not contain homogenized vegetable rejects so as to examine the performance of the finisher broilers with respect to the experimental diets. The test ingredient (homogenized vegetable rejects) was subjected to proximate analysis (AOAC, 2006). The broiler birds were weighed at the beginning of the experiment and body weight changes taken thereafter on weekly basis for 28 days. Daily feed intake was determined by obtaining the difference between the quantity of feed given and the quantity leftover. Feed conversion ratio and feed cost/kg live weight were computed accordingly.

Table 1 Ingredients composition of experimental diets fed to broiler birds

Ingredients	VR_0	$VR_{1.0}$	$VR_{1.5}$	$VR_{2.0}$	$VR_{2.5}$
Maize	55	55	55	55	55

Energy Value (Kcal/Kg)	2213.30

ME= Metabolizable energy calculated; ME (Kcal/kg) =37 × %CP+81 × %E.E+35 × %NFE (Pauzenga, 1985).

Statistical Analysis

Data obtained from the study were subjected to one-way analysis of variance (ANOVA) (Snedecor and Cochran, 1980) using general linear model of SPSS version (SPSS, 2015), while mean value variance showing ($P<0.05$) difference were separated using Duncan's Multiple Range Test as outlined by Onu and Igwemma (2000).

RESULTS AND DISCUSSION

The results shows that there were significant differences (P<0.05) among the treatment means in final body weight, body weight change and average daily weight gain of the birds, however, there were no significant differences (p>0.05) in initial body weight and feed conversion ratio among the treatments (table 3).

Table 3: Performance characteristics of finisher broilers on varying dietary levels of sun-dried vegetable refuse supplementation

a,b,c,d = Means on the same row with different superscripts are significantly (P<0.05) different. SEM= Standard Error of means.

In the present study, initial body weight (28 days of age) was not significantly different among treatments (Table 3) indicating that birds presented uniform body weight at the start of experiment. The highest final body weight of (2784g) was recorded in T_4 ($VR_{2.0}$) while the least body weight of (2680g) was recorded by finisher broilers in $T_{1,}$ while T_2, T_3 and T_5 recorded (2720, 2735 and 2780)g respectively. T_2 and T_3 are statistically similar (P>0.05) while significant differences (P<0.05) existed between T_1 and T_2, T_3, T_4 and T_5 in terms of final body weights respectfully. T_2 recorded the highest daily weight gain (50.71g) followed by T_5, T_3, T_4 and T_1 in that order. Daily weight gain was marginally affected by dietary treatments although the result didn't follow any definite trend. Okerulu et al. (2017) reported that indigenous vegetables like Pterocarpus contain many mineral elements, vitamins, and bioactive compounds which catalyze the growth of animals. Inclusion of vegetable rejects at higher levels reduced weight gain as recorded in T_3, T_4 and T_5 respectively. According to Hossian *et al*. (2013) inclusion of vegetable waste to broiler birds slows down their growth rate but improved meat quality ie aids to maintain broilers requirements. Mustafa & Baurhoo (2017) stated that high vegetable waste inclusion levels in broiler diets resulted to lower nutrient intake and retarded growth. . In addition, high fiber dietary content also causes poor feed efficiency due to nutrient dilution and impairment of absorption and assimilation (Thacker & Petri, 2009).

Average daily feed intake was also marginally influenced (P<0.05) by the dietary VR. Highest feed intake (108g/bird/day) was recorded by T_3 followed by T_4 (107g), T_5 (106g), T_1 (105g) and T_2 (102g) in that order. Feed intake in this study was inversely related to weight gain as T_2 ($VR_{1.0}$) that recorded the highest weight gain didn't follow the same trend in feed intake. The variability in daily feed intake (Table 3) recorded in this study may not be attributed to metabolizable energy content of the treatment diets since the energy contents of all the diets are the same (2887kcal/kg) ie isocaloric but rather attributed to the nutritional variation of the diets (Raza *et al*., 2018). Feed conversion which is a function of nutrient absorption was highest in T_2 (2.01) followed by T_5 (2.09), T_3 (2.15), T_4 (2.16) and T_1 (2.17) in that order. However, no significant difference (P>0.05) existed between the treatment means. From the nutritional view point and convertibility, their exists some inter-relationship between feed conversion ratio and weight gain as finisher birds in T_2 recorded the highest weight gain of 50.71g hence, efficient nutrient absorption promotes increase in weight gain (NRC, 2012). According to Leeson and Summers, (2006) a feed conversion ratio of 2 to 4 is ideal in broiler chicken performance. Feed conversion ratio in this study aligns to the values reported by Adeyemo *et al.*, (2013). Hence birds on VR based diets had better feed utilization than those on control.

The results of the present study are consistent with those reported by Westendorf & Myer (2009), who also observed slow broiler growth rate when vegetable waste was added to the diet. In a similar study, Oghenebrorhie & Oghenesuvwe (2016) obtained comparable final body weight (p>0.05) but worse feed efficiency when 10% of a conventional feed was replaced with vegetable sources. Bhuiyan et al. (2012a, b) fed broilers with diets supplemented with vegetable sources, but did not observe any significant differences in the growth performance. On the economy of production, T_5 promoted the least (N404) followed by T_3 (N406.20), T_4 (N406.75) and T_1 (N407.75) respectively. Cost of feed per kg weight gain was highest in the control diet T_1 (N880.05) and least in T_5 (N848) and statistically different (P<0.05) across the treatment means. Profitability emphasizes the resources used to produce the profit and with least input dissipation, higher rate of return is achieved. Hence, the cost per kilogramme of chicken influences tremendously the cost of the final product.

CONCLUSION AND RECOMMENDATION

The results obtained from this study indicated that VR had a significant effect ($P<0.05$) on growth, average daily feed intake and cost per kilogramme weight gain of finisher broilers. T_2 (1.0 % inclusion) performed better than other levels of inclusion. In view of the above result, VR should be included in the ration of finisher broilers as a supplement at 1.0% level for optimum performance so as to make animal protein available at a reduced cost and maximized profit.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The effects of feeding grower rabbits with graded levels of soybean cheese waste to determine the growth response and haematology was evaluated in a 42 days feeding trial. A total of 30, composite 10week old rabbits were randomly allotted to the experimental diets in a completely randomized design (CRD) and replicated 3 times having 2 rabbits per replicate. Rabbits were reared in an open-sided mesh hutches and fed with weighed amount of experimental diets and watered at all time. Other standard routine management practices were strictly observed. The diets were formulated to be isocaloric (2700kcal/kg) and isonitrogenous (18% crude protein) with five (5) levels inclusion of soybean cheese waste 0%, 25%, 50%, 75%, and 100% representing T1, T2, T3, T4 and T5 respectively. The result showed significant ($P<0.05$) improvement in the total weight gain (380g/rabbits), average feed intake (63.66g/rabbits) for 75% and 25% SCW inclusion compared with 0% (356.67 and 49.87g/rabbits). Similarly, packed cell volume (41.00%), haemoglobin (13.05g/dL), red blood cell count (6.15 $x10^{12}$) were improved by 50% SCW than 0% SCW (30.50%, 8.70 g/dL and 4.25 $x10^{12}$). White blood cell count increased at 25, 75 and 0% SCW inclusions (9.00, 8.35 and 8.25 x 10^{12}) than rabbits fed diets containing 50% SCW with lower RBC (5.45). Based on the result obtained, up to 100% SCW is recommended for grower rabbit's production without any effect in the performance and physiological responses.
Keywords: *Growth, Haematology, Rabbits, Soybean cheese waste*

INTRODUCTION
Soybean cheese waste (SCW) is an agro-industrial by-product that is found in every part of Nigeria. This is due to the increase in the production of soybeans which has resulted in a concomitant increase in the consumption of soybeans and its products such as soy milk, soy flour, and soy cheese. Soybean cheese waste (residue) is a by-product of soy cheese production (Inuwa *et al.* 2020). It is used in feeding animals such as cattle, sheep, goats, pigs etc. and its readily available and cheap in towns and villages where the cheese is widely produced and consumed. It has the potential for reducing cost of concentrate intake in livestock due to its high nutrient values of soybean and its products (Duwa *et al.*, 2014).

Feeding by-products of crops and food processing waste to livestock has two important advantages; these being to limit dependency of livestock on grains that can be consumed by humans and to eliminate the need for costly waste management programs which has become very important in recent years as the world human population increased, particularly in developed countries (USDA, 2013). Thus, the need for utilizing alternative feed ingredients removed from human and industrial uses have been stressed by several researchers (Fanimo *et al.*, 2007; Nsa *et al.*, 2007).

MATERIALS AND METHODS
Experimental site
This experiment was conducted at the Teaching and Research Farm of Animal Science Department of the Faculty of Agriculture, Nasarawa State University Keffi, Shabu -Lafia Campus.

Source of feed ingredients
The soybean cheese waste (SCW) was sourced from local soybean processors into cheese known as awara within Mangu Local Government Area of Plateau State. The cheese waste (residue) was collected, sun dried for 2-3 days

to reduce the moisture content and also to avoid the growth of mold and rancidity. Other feed ingredients were purchased from feed suppliers in Lafia town, Nasarawa State.

Experimental rabbits and management

Thirty (30) weaned rabbits of the same age and similar live weight were purchased from a reputable rabbits farm in Jos Plateau State and reared in an open- sided mesh rabbit hutches at the rabbits unit of the research and teaching farm of the Nasarawa state university Keffi. They were randomly assigned to a 5 dietary treatments with 3 replicates in each and 2 rabbits per replicate in a Completely Randomized Design (CRD). Each hutch was equipped with feeders and drinkers. Rabbit were fed with weighed amount of the experimental diets and drinking water was supply *ad-libitum* and Other routine management practices were observed.

Proximate analysis of soybean cheese waste

Proximate composition of the experimental test ingredient were determined using the procedure outlined by (1) and the results were presented in Table 1.

Table 1: Proximate Composition of Soybean Cheese Waste (SCW)

Parameters	Values (%)
Dry matter	91.51

Experimental diets and composition

Five (5) experimental diets were formulated to provide approximately 2500 kcal/kg and 15% CP for all the experimental groups for the grower rabbits with five (5) levels of inclusion of soybean cheese waste 0%, 25%, 50%, 75%, and 100% representing T1, T2, T3, T4 and T5 respectively. T1 contain 0% SCW and it served as control. Presented in Table 2.

Table 2: Gross composition of experimental grower rabbit's diets/100kg

Ingredients (%)	T1 (0%SCW)	T2 (25%SCW)	T3 (50%SCW)	T4 (75%SCW)	T5 (100%SCW)

SCW* Soya cheese waste inclusion levels. The vitamin- mineral premix supplied the following per 100kg of diet: vitamin A15,000 I.U, vitamin D3 300,000 I.U. vitamin E 3,000 I.U., vitamin K 2.50mg, vitamin B_1 (thiamin) 200mg, Riboflavin (B_2) 600mg, pyridoxine (B_6), Niacin 40.0mg, vitamin B_{12} 2mg, Pantothenic acid 10.0mg, folic acid 100mg, Biotin 8mg, choline chloride 50mg, anti-oxidant 12.5mg, manganese 96mg, zinc 6mg, Iron 24mg, Copper 0.6mg, Iodine 0.14mg, Selenium 24mg, cobalt 214mg. Using Feedwin software version 1.01

Growth parameters

The growth performance included body weight gain which was computed as the difference between the final weight and the initial weight of the rabbits, feed intake determined as the difference between the amount of feed fed and the leftover. Feed conversion ratio was calculated as the rate of feed intake to live weight gain/day from the data obtained.

Haematological parameters

At the end of the experiment, sample bottles were used to collect blood samples from two rabbits per treatment through the ear veins. The blood samples were collected in bottles containing Ethylene Diaminetetra-acetic Acid (EDTA) as an anti-coagulant for analysis of hematological indices: Packed Cell Volume (PCV). Hemoglobin Concentration (Hb), Red Blood Cell (RBC), White Blood Cell (WBC). Mean corpuscular haemoglobin (MCH), Mean corpuscular haemoglobin concentration (MCHC), MCV = Mean corpuscular volume.

Statistical analysis

Data collected were subjected to one way analysis of variance (ANOVA) using (SPSS) Model 22. Significantly different means were separated using Duncan's Multiple Range Test.

RESULTS AND DISCUSSION

Table 3 shows significant ($P<0.05$) improvement in the total weight gain (380g/rabbits), average feed intake (63.66g/rabbits) for 75% and 25% SCW inclusion compared with 0% (356.67 and 49.87g/rabbits) but statistically similar for T1, T4 and T5 respectively. Feed conversion ratio (12.73 and 11.67) were significantly ($P<0.05$) higher for 25 and 50% SCW. This indicated poor conversion of feed to flesh. However, 0, 75 and 100% had lower FCR which indicate better conversion of feed to flesh. In the same vain, packed cell volume (41.00%), haemoglobin (13.05g/dL), red blood cell (6.15 $x10^{12}$) were improved by 50% SCW compared with 0% SCW (30.50%, 8.70 g/dL and 4.25 $x10^{12}$). Similarly, white blood cell increased at 25, 75 and 0% SCW inclusions (9.00, 8.35 and 8.25 $x\ 10^{12}$) but did not show difference with 100% included SCW (T5). Rabbits fed diets containing 50% SCW had lower RBC (5.45) but did not cause any signs of diseases throughout the period of the experiment. The improvement in the total body weight in this study agreed with Iyeghe-Erakpotobor *et al.* (2006) who fed soybean cheese waste/maize and brachiaria hay to weaner rabbits and observed significant increase in body weight gain, average body weight gain and lower feed conversion ratio. The increase in the level of packed cell volume, haemoglobin, and red blood cell for rabbits fed 50% soybean cheese waste. Generally, the soybean cheese waste-based diets had better values for these parameters compared to the control. The red blood cells values indicates that rabbits have normocytic and normochromic red cells (Aderemi and Wuraola, 2010), thus, explaining that feeding soybean cheese waste up to 100% inclusion does not affect the utilization of iron. The lower value of white blood cells in 50% indicates a fall in the production of defensive mechanism to combat infection when it occurs. Madubuike and Ekenyem (2006) indicated that haematological characteristics of livestock suggest their physiological disposition to the plane of nutrition. Since all the haematological parameters fall within the normal ranges for rabbits, it then implies that the different treatment diets fed the rabbits were balanced in their formation to promote their performance and maintained the normal physiological profile of the rabbits.

CONCLUSION AND RECOMMENDATION

Inclusion of soya bean cheese waste in the diet of grower rabbits had improved growth performance by 75% and also increases most of the haematological indices up to 100%. It is therefore recommended for the grower rabbit's production without any deleterious effect.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study aimed to determine the effects of antibiotics inclution in corn meal on haematological and growth performance of Wister rats. Thirty (30) Male Wistar strain of albino rats, divided into five groups (A-E) of six (6) each arranged in a Complete Randomised Design. Rats were managed on a deep litter system for 6 weeks. Data on body weight, feed intake, feed conversion ratio and blood parameters were collected. On weight gained, there was no significant difference (P = 0.05) in groups A, B and E which were significantly (P<0.05) higher compared to groups C and D rats. For feed intake, sample A, D and E were similar no significant different compared to B and C. In protein intake, groups A, C and E were similar with no significant different compared to B and D that were significantly different. In NPR, groups A, C and D were similar in which there were no significant different in them compared to groups B and E. In PER, sample A, B, C and D were similar in which there were no significant different in them compared while sample E was significant different only. In FER, sample B, C, D and E were similar in which there were no significant different in them compared to group A only. In SGR, sample B, D and E were similar in which there were no significant different in them compared to sample A and C. In PR, sample A, B, D and E were similar in which there was no significant different in them compared to group C only. The PCV of the rats were similar in which sample A, C and D were no significant different in them compared to sample B and E that were significantly different. The PCV values fell within the normal range of 25% – 45%. In hemoglobin, sample A, B and D were similar in which there was no significant different in them compared to groups C and E that were significantly different. However, the total RBC count of the rats was similar in which there was no significant different in sample A, D and E compared to sample B and C that were significantly different. the total WBC count of the rats were similar in which there was no significant different in sample B, C, D and E compared to sample A that was significantly different (P = 0.05). The platelet count of the rats were similar in which there was no significant different in all the samples. It can be concluded that supplementation of corn powder with different antibiotics improved growth performance and haematological characters in wister rats.

Keywords: *Corn meal, weight gained, blood parameter, blood serum, biochemical indices*

INTRODUCTION

Nutrition has been recognized as a major constraint to livestock production in Nigeria and elsewhere (Okai and Boateng, 2007 and Yusuf *et al*., 2008). Research has shown that feed cost accounts for 70-80% of total production (Sola-Ojo *et al*., 2011) and protein is likely to be the first limiting factor in poultry diets at the level of small scale farmers. The feed cost in Nigeria, just as any other developing countries of the world, is quite expensive, and often beyond the reach of ordinary farmer. The end of the 20th century was marked by drastic increase in the incidence of protein energy malnutrition, chemical hazards and other safety issues (Moterjemi and Lelieveld, 2013).
The use of laboratory rats (*Rattus norvegicus*) in research has increased steadily as they are preferred because of their short life cycles, inexpensive cost to purchase, easy maintenance in limited space (Neg, 2008) and availablity of a large database of their characteristics that are useful in interpreting relevant animal data for humans. The rats particularly the inbred strains are now more widely used as laboratory model in the understanding and studying of diseases (Ihedioha and Okafor, 2004; and Smith *et al*., 2004). In this research, abnormal treatment-related values could represent changes pertaining to the effects of the treatments such as the toxicity's effects, which could be detected by alterations in a series of in vivo analysed parameters (Ihedioha and Okafor, 2004). Among these parameters are haematology data and are of great importance in determining such effects. This is because

blood plays a major role in the body's transport system and excretion of substances of almost all the body's metabolic processes, and any deviations from normal are detectable in the blood profile (Ihedioha and Okafor, 2004) One way of evaluating the haematologic profile is by Full Blood Count (FBC) otherwise called Complete Blood Count (CBC).

It also provides information about the immune system through the evaluation of the WBC counts especially along with differential counts (George-Gay and Parker, 2003). Thus, CBC is one of the most frequently requested tests in clinical medicine with multiple indications such as anaemia, cancer, infection as well as monitoring for side effects of drugs causing blood dyscrasias (George-Gay and Parker, 2003; Graham, 2003) of all the rat models, Sprague Dawley (SD) rats are the most widely used research models in all aspects of biomedical (Ihedioha and Okafor, 2004). In evaluating the biological effect of some food on rat organs (small intestine, pancreas, liver and heart), Smith *et al*., 2004 observed no significant difference in the organ weight of the rats fed the test diets as compared with cerelac- a commercial weaning diet. Rats fed on extruded weaning foods based on peanut, maize and soybean were observed by Smith *et al*., 2004 to have between 60-100-fold increases in mean weight gain over the control. It was also reported that haemotological data of test animals showed normal values for white blood cell count, red blood cell count, haemoglobin level and packed cell volume for all the weaning food studied except the control.

MATERIALS AND METHODS

Description of Study Area

The study was carried out in Ibarapa central local government area, which has its head quarters in the town of Igboora, covers about 440km^2 of savannah zone to the west of Ibadan, the Ogun and Oyan rivers from eastern and western boundaries respectively. It is between latitude 7'53^0 and longitude 3'08^0 with the population of 102,979 according to 2006 census (Sanusi, 2011).

Experimental animals

Thirty (30) Male Wistar strain of albino rats, divided into five groups (A-E) of six (6) rats each per group were used for the studies. The average weights of the rats were between 150 to 200g. The rats were housed individually in stainless-steel metabolic cages. The rats were allowed to acclimatize with the environment and feeding trial was done for four weeks with each group receiving graded levels of corn meal and bone meal mixed with antibiotics.

The antibiotics used include, Penicillins, Cephalosporins, Cloraphenicol and Gentamycine.

Experimental diets and Treatment

Rats were divided into five (5) groups and labeled as follows, A with Penicillins, B with Cephalosporins, C with Cloraphenicol, D with Gentamycine and Control = E with no antibiotics. The rats were fed for 30 days

Growth performance

At the onset of the experiment, initial body weights of the rats were recorded. Feed intake (FI) and body weight (BW) were measured weekly. Mortality was recorded as it occurred. Weight gain, average daily weight gain, and feed conversion ratio were calculated. The weight gain was calculated as the difference between the final weights and the initial weights. FI was determined as the difference between the amount of feed offered and refusals. Feed conversion ratio (kg feed/kg gain) was calculated by dividing FI by BW gain.

The growth performance was evaluated in terms of feed intake (FI), weight gain (%), specific growth rate (SGR) and feed efficiency ratio (FER).

Weight gain (%) = (final weight - initial weight) /initial weight ×100

SGR = 100 (loge average final weight x loge average initial weight) /number of days z

FER = weight gain (g)/feed intake (g)

Haematological parameters

Blood collection was carried out at the end of the experiment (6th week). Five (5) rats were selected at random from each of the treatments and bled via the vein using sterile needles and syringes. Two (2.0) ml of blood was collected into each sterilised bottles containing EDTA as anticoagulant for haematological analysis. The packed cell volume (PCV), red blood cell (RBC) count, white blood cell (WBC) count, Platelet and haemoglobin (Hb) concentrations were measured using Mindray BC 2800, an automated system for the determination of haematological parameters.

Statistical analysis

The data were analyzed using one way ANOVA and expressed as mean ± SEM. The significant differences between means were determined using Duncan's multiple range comparison tests. The level of significance was set at 5%. All analyses were performed using statistical software package SPSS version 16.

RESULTS AND DISCUSSION

Weight gained, food intake, protein intake and feed conversion ratio

The results of effects of treatment on growth performance of Wister rats were presented in Table 1. In weight gained, there was no significant difference ($P = 0.05$) in between groups A, B and E which were significantly ($p<0.05$) higher compared to groups C and D. In feed intake, groups A, D and E were similar with no significant different compared to groups B and C. In protein intake, groups A, C and E were not significant compared to groups B and D that were significantly different. In NPR, groups A, C and D were not significant compared to groups B and E. In PER, groups A, B, C and D were not significant while group E was significant. In FER, sample B, C, D and E were not significant compared to sample A. In SGR, groups B, D and E were not significant compared to group A and C. In PR, groups A, B, D and E were similar and significantly higher compared to group C. The results obtained were similar to the work of Tokofai *et al*., (2020) in which there was variation in weight gained, food intake, protein intake and feed conversion ratio.

Table 1. Effect of corn meal on the performance of the wister rats

Parameters	Sample				
	A	B	C	D	E
Weight Gained (g)	51.73 ± 2.15^{a}	55.21 ± 1.26^{a}	49.97 ± 2.33^{b}	49.65 ± 1.95^{b}	53.07 ± 2.03^{a}

PR	45.24^{b}	43.14^{b}	41.22^{a}	43.57^{b}	49.63^{b}

^{abc} Means with different superscripts on the same row differ significantly ($P < 0.05$) while a, b and c with the same superscripts on the same row are not differ significantly ($P < 0.05$).

NPR = Net protein utilization, PER = Protein efficiency ratio, FER = Feed efficacy ratio, SGR = Specific growth rate, PR = Protein ratio, Weight gained % = final weight - Initial weight/ initial weight X 100, Specific growth rate (SGR) = 100(Log_eaverage final weight X Log_eaverage initial weight) /number of days, FER = Weight gained (g) / feed intake (g)
A = bone meal combined with Penicillins., B = bone meal combined with Cephalosporins.
C = bone meal combined with Cloraphenicol., D = bone meal combined with Gentamycine.
E = control group animals and given normal rat cerelac only.
Table 2 shows the haematological characters of the various treatments. The PCV of the rats were similar and samples A, C and D were not significant compared to sample B and E that were significantly different. The PCV values fell within the normal range of 25% – 45%. In hemoglobin, samples A, B and D were not significant compared to samples C and E that were significantly different. However, the total RBC count of the rats was similar and was not significant samples A, D and E compared to samples B and C that were significantly different. The total WBC count of the rats were not significant in samples B, C, D and E compared to sample A that was significantly different ($P = 0.05$). The platelet count of the rats was not significant different in all the samples.

Table 2. Haematology repormance of corn meal on blood characters of wister rat

Parameters	Samples				
	A	B	C	D	E
PCV (%)	34.9^{a}	33.5^{b}	32.4^{a}	35.7^{a}	35.3^{b}

^{abc}Means with different superscripts on the same row differ significantly ($P < 0.05$). PCV = Packed cell volume, RBC = Red blood cell, WBC = White blood cell

DISCUSSION

Body weight, feed intake and feed conversion ratio

From this study, it could be clearly shown that incorporation of corn meal with different antibiotics in the wister rat diet had affected the growth performance and haematological and characteristics of the blood. The performance of the rats in the present study shows that the final weight gain and feed conversion ratio of the rats were significantly different. The rats fed with corn meal had better weight gain and feed conversion ratio. The result is in line with the findings of (Yusuf *et al*., 2008) who reported improved growth performance of rats fed with bitter leaf. The improvement in weight gain observed in the treated group resulted in a lower FCR. (Olobatoke and Oloniruha, 2009) reported that inclusion of corn meal powder in rat diets significantly improved FCR.

Haematological variable

In the study, there was no influence of the dietary treatment on haematological indices among the treatments, except for PCV and WBC. On the other side, there was a marginal increase in RBC levels of rats fed corn meal and this shows that corn meal powder may have a possible potential to stimulate erythropoietin release from the kidneys, which is the humoral regulator of RBC production. According to Maxwell *et al*., (1990), blood parameters are important in assessing the quality and suitability of feed ingredients for farm animals. It's also reported that blood parameters are the major indices of the physiological, pathological, and, when compared to normal values, nutritional status of an organism. Changes in the constituent compounds of blood could be used to interpret the metabolic stage of an animal as well as the quality of the feed (Attia *et al*., 2017; Attia *et al*., 2018; Attia *et al*., 2019). The higher PCV and WBCs in rats offered corn meal are in agreement with earlier findings of Owen and Amakiri (2011) who showed that, with the exception of WBC, all other haematological indices measured were influenced by increasing levels of corn powder. The numerical differences observed in the PCV, Hb, RBC, and WBC of rats fed suggest that the feed were better utilised and assimilated into the blood stream of the rats (Onu, 2010).

CONCLUSION

Considering the effects of different levels of corn meal on weight gain, food intake and feed gain ratio of the rats, it appears that the corn meal showed optimum effect on the improvement of growth performance and physiological responses in rats. It can therefore be recommended for wister rat as meal for growth performance, although further experiments are recommended for further findings.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Growth in animal is determined by a complex variety of factors which can be reduced to three main factors – the animal's gene pool, the nutrients with which it is supplied, and its environment. This 10-week feeding trial was carried out to evaluate the effect of genotype, dietary energy, and protein inclusion on growth (body weight) of local and improved Nigerian indigenous guinea fowl keets. A total of two hundred and sixteen (216) brooded unsexed guinea fowls: 108 locals and 108 crossbreds were assigned to nine (9) experimental diets (T1, T2, T3, T4, T5, T6, T7, T8 and T9). A 2x3x3 factorial layout (genotype: local and improved; crude protein: 26, 24 and 22% CP and metabolizable energy ME: 2650, 2750 and 2850.00 Kcal/kg) fitted in a completely randomized design was adopted for the study. Data obtained were subjected to GLM procedure to determine the fixed and interaction effects on growth performanc. The improved keets showed superior growth performance (P<0.05) compared to their local counterparts. Variations in growth performance (P<0.01) were also observed due to crude protein and energy. Keets fed diet containing 2,650 and 2,750 Kcal/kg showed similarity in performance and had higher body weights. With respect to protein, inclusion at 24% CP had the best performance. For interaction, keets fed 24% CP with 2,650 Kcal/kg performed best. Therefore, it is recommended that 24% CP and 2,650 Kcal/kg inclusion levels could lead to good growth of keets.
Keywords: *Dietary, Energy, Protein, performance, guinea fowl*

INTRODUCTION
Guinea fowl production in Nigeria is gradually gaining prominence (Obike, 2014). This witnessed popularity is because of their relished meat and egg, scavenging ability, and resistance to common chicken diseases (Naandam & Issah, 2012) as well as their ability to utilize marginal areas. The popularity may however be limited or short lived if deliberate efforts are not directed towards understanding their optimum nutritional requirements, eggs, and growth performance. In communities where guinea fowls are fondly raised, they are allowed to scavenge freely; this practice will not reveal the true worth of the birds neither will it promote commercialization. However, like with chicken production, growth and nutritional development will accelerate production and commercialization of guinea fowls. Protein and energy play critical roles in the development of animals. They are needed to maintain health, growth, and production (Ihiwe et al., 2018). While energy controls feed consumption, protein serves as building blocks for cells and aid repairs and maintenance of body cells and tissues. The utilization of commercial feed on performance of guinea fowls have been investigated, however, there is a dearth of

information on formulated feed that utilized locally accessed ingredients. This study, therefore, evaluated the performance of local and improved guinea fowl keets fed formulated diet with three levels of proteins and energy.

MATERIALS AND METHODS

The experiment was carried out at the Guinea Fowl Improvement Unit of the Teaching and Research Farm, Landmark University, Omu-Aran, Kwara State, Nigeria. The Unit is co-managed by the Federal University of Agriculture, Abeokuta, Landmark University and Nasarawa State University, Keffi, Shabu-Lafia Campus to facilitate the implementation of the 2019 TETFUND National Research Grant for guinea fowl improvement in Nigeria. The farm lies on latitude 8.9ºN and longitude 50.61ºE within the guinea savannah zone of North Central Nigeria. A total of two hundred and sixteen (216) brooded unsexed guinea fowls: 108 locals and 108 crossbreds (Local x Exotic) were assigned to nine (9) experimental diets (T1, T2, T3, T4, T5, T6, T7, T8, T9). A 2x3x3 factorial layout (genotype: local and improved; crude protein: 26, 24 and 22% CP and metabolizable energy ME: 2650, 2750 and 2850.00 Kcal/kg) fitted in a completely randomized design was adopted for the study. Body weight (grams) and feed intake were observed throughout the study period using sensitive weighing scales. Data obtained were subjected to general linear model (GLM) procedure to determine fixed and interaction effects using IBM-SPSS (2020). Significant differences were separated using the least significant difference (LSD) method.

RESULTS AND DISCUSSION

Table 1 shows the composition of the feed for the keep phase.

Table 1: Feed Composition for Keet Phase

Ingredients	T1	T2	T3	T4	T5	T6	T7	T8	T9

Table 2 shows the effect of genotype on the growth performance of keets. From the result obtained, the growth performance of the local and crossbred keets significantly differed (P<0.05) with higher values recorded for the latter. The overall or combined records also showed significant (P<0.05) improvement in growth performance from week 1 to week 10.

Table 2: Effect of Genotype on weekly body weight of Crossed and Local Guinea Fowls

Week	Crossed	Local	Overall
1	63.64 ± 0.77^a	57.23 ± 0.77^b	60.44 ± 0.54^q

$^{a\,b}$ Means bearing different superscripts in a row differ significantly at P<0.05

$^{q,\,r,\,s,\,t,\,u,\,v,\,w,\,x,\,y,\,z}$ Means with different superscripts in a column differ significantly at P<0.05

Growth in animals represents increased in size and or mass. It is influenced by the genetic makeup and the environment of the animal (Pell, 1994). The observed superiority of the improved keets to their local counterparts could be attributed to the influence of better genetic traits acquired from the crossing of their parents with an exotic breed. This is consistent with the findings of Kgwatalala et al. (2020) where crossbreeding was found to be effective in improving the growth performance of guinea fowl.

The effect of varying protein on growth performance of guinea fowls keets is presented in Table 3. The result showed significant (P<0.01) effect on growth rate. Superior growth was recorded in keets fed diet containing 24% CP.

Table 3: Effect of Protein on Growth rate of Crossed and Local Guinea Fowls

Week	P1 (26)	P2 (24)	P3 (22)
1	62.00 ± 0.94^{b}	64.83 ± 0.94^{a}	54.47 ± 0.94^{b}
2	122.07 ± 0.94^{b}	126.68 ± 0.94^{a}	121.99 ± 0.94^{b}
3	180.14 ± 0.94^{b}	182.08 ± 0.94^{a}	175.71 ± 0.94^{b}
4	239.99 ± 0.94^{b}	246.24 ± 0.94^{a}	238.22 ± 0.94^{b}
5	306.56 ± 0.94^{b}	311.72 ± 0.94^{a}	309.21 ± 0.94^{b}
6	377.50 ± 0.94^{b}	385.65 ± 0.94^{a}	385.51 ± 0.94^{b}
7	460.69 ± 0.94^{b}	477.08 ± 0.94^{a}	471.83 ± 0.94^{b}
8	550.61 ± 0.94^{b}	568.14 ± 0.94^{a}	654.04 ± 0.94^{b}
9	625.04 ± 0.94^{b}	630.49 ± 0.94^{a}	627.11 ± 0.94^{b}
10	676.04 ± 0.94^{b}	681.78 ± 0.94^{a}	679.86 ± 0.94^{b}
Overall	**360.06 ± 0.29^{b}**	**367.47 ± 0.29^{a}**	**362.79 ± 0.29^{b}**

[a b] Means bearing different superscripts in a row differ significantly at P<0.01).

Feed intake decreased as protein inclusion increased from 24% CP to 26% CP. The observed decrease in feed intake as protein inclusion increases shows that the keets had satisfied their protein requirement at 24% CP inclusion level. Inclusion at 26% CP represents waste of nitrogen and ammonia (Liu et al., 2021) as well as financial resources, which is related to the findings of Batkowska et al. (2021). The present observation agrees with the report of Amoah et al. (2018) whose recommended 24% CP as optimum protein inclusion level in Ghanian guinea fowl. Similarly, an earlier study by Nahashon et al. (2005) reported that semi domesticated guinea fowl keets were found to perform best on 20-24% CP diet. However, this could be reduced to 18% by eight weeks of life.

Table 4 presents the effect of varying energy on the growth rate of guinea fowls keets. Keets fed diet containing E1 (2,650) and E2 (2,750) had higher body weight for week 1, 2, 3 and 4 than E3 (2850) respectively. Similarly, Week 6, followed the same trend with week 1, 2, 3 and 4 respectively. At week 7, keets fed E2 (2750) had higher growth compared E1 and E3 which were similar. At week 8, growth rate improved consistently as the energy inclusion increased in the diet. At week 9 and 10, keets fed E1 (2,650) had higher growth rate than those on E2 and E3. E2 had a lower growth rate compared with E3. The overall growth rate was higher for keets fed E1 and E2 compared with E3. The improved growth rate of keets fed diet E1 (2,650) and E2 (2750) is contrary to Amoah et al. (2018) who reported high 12.5 MJ ME /kg (2,985.63 kcal/kg ME).

Table 4: Effect of Energy (Kcal/kg ME) on Growth Performance of Crossed and Local Guinea Fowls

Week	E1 (2,650)	E2 (2,750)	E3 (2,850)
1	61.47 ± 0.94^{a}	61.04 ± 0.94^{a}	58.79 ± 0.94^{b}
2	123.89 ± 0.94^{a}	124.64 ± 0.94^{a}	122.21 ± 0.94^{b}
3	179.27 ± 0.94^{a}	180.73 ± 0.94^{a}	177.92 ± 0.94^{b}
4	241.64 ± 0.94^{a}	242.57 ± 0.94^{a}	240.24 ± 0.94^{b}
5	308.65 ± 0.94^{b}	310.36 ± 0.94^{a}	308.47 ± 0.94^{b}
6	382.97 ± 0.94^{a}	383.99 ± 0.94^{a}	381.71 ± 0.94^{b}
7	468.71 ± 0.94^{b}	471.17 ± 0.94^{a}	469.73 ± 0.94^{b}
8	559.39 ± 0.94^{b}	560.96 ± 0.94^{b}	562.44 ± 0.94^{a}
9	630.36 ± 0.94^{a}	625.19 ± 0.94^{c}	627.08 ± 0.94^{b}
10	681.47 ± 0.94^{a}	677.21 ± 0.94^{c}	679.00 ± 0.94^{b}
Overall	**363.78 ± 0.29^{a}**	**363.79 ± 0.29^{a}**	**362.76 ± 0.29^{b}**

[abc] Means bearing different superscripts in a row differ significantly at P<0.0

Superior average body weight of 372.89±0.51g was recorded for keets fed the energy and protein levels combination of P2 (24% CP) and E1 (2,650 kcal/kg) (Table 5). However, the least body weight of 358.37±0.51g was recorded against the energy and protein levels combination of P1 (22% CP) and E1 (2,650 kcal/kgME. These are in consonance with those of Nahashon et al. (2006) and Odukwe et al. (2017) who reported decrease in feed intake with increase in energy inclusion, which could affect growth performance. Generally, animals feed to meet their ME requirement. The rate of feed consumption decreases when birds are fed a high energy diet due to heat increment, which does not encourage high feed intake but rather encourage high water intake.

Table 5: Effect of Protein (and Energy Interaction on Growth Performance of Crossed and Local Guinea Fowls

Protein (%)	Energy (Kcal/kg ME)	Body weight (Average for ten weeks)
P1 (22)	E1 (2,650)	358.37±0.51^{b}
	E2 (2,750)	362.12±0.51^{a}
	E3 (2,850)	359.71±0.51^{ab}
P2 (24)	E1 (2,650)	372.89±0.51^{a}
	E2 (2,750)	366.48±0.51^{b}
	E3 (2,850)	363.05±0.51^{c}
P3 (26)	E1 (2,650)	360.11±0.51^{c}
	E2 (2,750)	362.77±0.51^{b}
	E3 (2,850)	365.53±0.51^{a}

^{abc} Means bearing different superscripts in a column differ significantly at $P<0.05$

CONCLUSION

Genotype, variation of crude protein and energy in the diet of guinea fowl keets significantly affected their growth performance. Result of interaction showed that, inclusion at P2 (24% CP) with E1 (2650) had superior performance. Hence, 24% CP with up to 2750kcal/kg ME is recommended for better growth performance.

ABSTRACT
This study assessed the effects of farmers-herders conflicts on arable crops production in Oke-Ogun area of Oyo State, Nigeria. Farmers and herders which are the largest agricultural land-users need land to carry out their activities. However, the conflicts between the two major agricultural land users over the use of existing land is not a new thing but it is an age long issue that has been existing in different parts of Nigeria. Multistage sampling procedure was used to select 160 respondents for the study. Data were collected using interview guide to elicit information on Socio-economic characteristics, causes of conflict sand the effects of the conflicts on the arable crop production. The results showed that poisoning of animals (88.13%) and tribalism (84.38%) were the major causes of the conflicts in the area. The study concluded that the effects of famers-herders conflicts was unfavorable on their crop production in the study area. Based on the findings, it was recommended that government should provide drinkable water for the populace, so as to reduce competition for water between the farmers and the Fulani cattle, since scarcity of water was indicated as one of the causes of the conflicts in study area.
Keywords: *Herders, Arable crops, Conflicts.*

INTRODUCTION
All human activities whether in urban or rural area are dependent on land. However, agricultural land must be rich in nutrient and water which makes it suitable for agricultural production activities. Farmers and herders which are the largest agricultural land-user needs land to carry out their activities. However, the conflicts between the two major agricultural land users over the use of existing land is not a new thing but it's an age long thing that has been existing in different parts of Nigeria. Due to the economic importance of land to the group, it is therefore not surprising that unhealthy competition will exist between the two groups on the use, control, ownership and acquisition of land. Nigeria which is one of the African countries is not immune to these conflicts. Although the two of them have co-existed for over a long period of time, the crisis between farmers and herders over competition on who owns and control economically viable lands in the country is taking a more drastic dimension. This is because more sophisticated arms are used by herders leading to the death of many farmers, the perceived lack of political will on the part of the government at the federal level to manage this conflict, destruction of properties and the crisis is gradually taking an ethnic dimension against the Fulani's who are generally seen as herders (Cotula, *et.al*,2004). Farmers-herders conflict in the 21st century in the use of agricultural land are becoming intense because of a number of factors such as climatic change which is pushing herders southward in search of water and grasses, increased human population (Fasona and Omojola,2005). Many researchers had workedon farmers-herdsmen conflicts but this study will work on how farmers-herdsmen conflicts have affected the arable crops production in the study area. Moreover, this aspect has not been given adequate attentions in the existing literature. The specific objectives of the study were to: identify the socio-economic characteristics of the respondents in the study area, identify the causes of farmers-herders' conflicts and asses the effects of farmers-herdsmen conflict on arable crops production.

METHODOLOGY
The study area is Oke Ogun area of Oyo state. Okeogun is one of the materially richest parts of Oyo state. It lies within latitude $7^0$70'N and longitude $2^0$60' EThe target population comprised of all the arable crop farmers in Oke Ogun Area of Oyo State. Multistage Sampling procedure was used to select 160 respondents for the study;. According to Oyo State Agricultural Development Programme (OYSADEP) administrative System, there are 24 functional Cells in the chosen Local governments, 20% of the cells was randomly chosen to give 5 cells. There

are 1605 arable crops farmers in the Extension agents register covering the 5 cells. 10% of the registered farmers were randomly chosen to give 160 respondents for the study.

RESULTS AND DISCUSSION

Socioeconomic characteristics of arable crop farmers

The result of the Socio-economic characteristics of the respondents is presented in Table 1. The results show the mean age of the respondents was 47 years. This implies that majority of the respondents were in their productive age. This is in line with Brown *et. al.*, (2019) that age may influence land use decisions. Majority (65.63%) of the respondents were married while 33.37% of them were single. The educational distribution of the respondents revealed that 21.88% of the respondents had no formal education while 60.00%, 15.63% and 2.50% of the them had primary education, secondary education and tertiary education respectively. This implies that majority of the respondents had one form of education or the other.

Table 1: Socio-economic characteristics of arable crop farmers in the study area

Socio-economic characteristics	Frequency	Percentage	Mean
Age (years):			
Less than 30	16	10.00	
30 – 40	44	27.50	
40 - 50	54	33.75	47
Above 50	46	28.75	
Marital Status:			
Single	7	4.38	
Married	105	65.63	
Divorced/Separated/Widowed	48	30.00	
Educational qualification:			
No Formal	35	21.88	
Primary	96	60.00	
Secondary	25	15.63	
Tertiary	4	2.50

Causes of conflicts in the Study Area

The percentage distribution of the respondents based on the causes of conflicts in the study area was presented in Table 2. In term of causes of conflicts in the study area as stated by the respondents, 89.38%, 84.38%, 77.50% and 63.75% of the respondents reported that religion intolerance, tribalism, selfish interest from both parties involved and communal values/norms respectively were the factors that caused conflicts between arable crop farmers and herders in the study area respectively, This implies that the peaceful co-existence between arable crop farmers and herders is had been threatened by the factors mentioned above, local leaders andreligous leaders in the area must pay due attention to the factors causing conflicts between arable crop farmers and herders in the study area.

Table 2: Distribution of the respondents based on causes of conflicts in the study area

S/N	Causes of conflicts	Always	Occasionally	Never
		Freq. (%)	Freq. (%)	Freq. (%)
1	Religion intolerance	143 (89.38)	4 (2.50)	13 (8.130
2	Tribalism	135 (84.38)	14 (8.75)	11 (6.88)
3	Illiteracy	12 (7.50)	137 (85.63)	11 (6.88)
4	Selfish interest	124 (77.50)	30 (18.75)	6 (3.75)
5	No interest in funding animals by herders	20 (12.50)	128 (80.00)	12 (7.50)
6	Ammunitions in the custody of herders	94 (58.75)	42 (26.25)	24 (15.00)
7	Government bias ethnical policies	25 (15.63)	49 (30.63)	86 (53.75)
8	Land ownership dispute	18 (11.25)	116 (72.50)	26 (16.25)
9	Climate variabilities	94 (58.75)	12 (7.50)	54 (33.75)

10	Values and norms	102 (63.75)	16 (10.00)	42 (26.25)
11	Poisonings of animals	141 (88.13)	8 (5.00)	11 (6.88)

Effects of farmers – headers conflict on Arable crop production
Table 4 showed that majority (92.5%) of the respondents agreed that there had been low productivity in Arable crop production due to the effects of farmers- headers conflicts. The table further revealed that timely operations are difficult to follow (86.25%), reduction in size of farmland (83.75%), increase in price of the produce (78.13%) and harvesting of immature crops (68.13) were also the effects of farmers-herders' conflicts in the area. Among these effects, tree crops planting had replaced arable crops and scarcity of the arable crops were ranked 1st with the weighted WMS of 2.26. Ranked least were reduction in size of farm land and harvesting of immature crop with the WMS of 2.09. This implies that farmers – herders conflicts had affected the arable crop farmers negatively and they will need more tolerance and perseverance in order to remain on the farm.

Table 4. Effects of farmers-herders' conflicts on arable crop production

S/N	Statements	Agreed	Undecided	Disagreed	WMS	Rank
1	Timely operations are difficult to fellow	138(86.25)	02(1.25)	20(12.50)	2.20	5th
2	Reduction in size of farmland	134(83.75)		26(16.25)	2.09	11th
3	Wastage of crops on the farm	112(70.00)		48(30.00)	2.18	6th
4	Low productivity	148(92.5)	02(1.25)	10(6.25)	2.27	3rd
5	Tree crops planting had been replacing arable crops	45(28.13)		115(72.37)	2.36	1st
6	High cost of production	56(35.00)	04(2.5)	110(68.75)	2.17	7th
7	Arable crop production is becoming more tedious	95(59.38)	15(9.38)	50(31.25)	2.26	4th
8	Increase in price of the produces	125(78.13)	08(5.00)	27(17.34)	2.16	9th
9	Non-farm activities had been replacing arable crops production	(35.00)56	04(2.5)	110(68.75)	2.17	7th
10	Scarcity of the crops	45(28.13)		115(72.37)	2.36	1st
11	Harvesting of immature	109(68.13)	09(5.62)	42(26.3)	2.09	11th
12	Poor quality at marketing	102(63.75)	18 (11.25)	40. (2500)	2.14	10th

Percentages are in Parentheses
Field Survey, 2023

CONCLUSION AND RECOMMENDATIONS

It can be concluded from the study that the major causes of conflicts in the area were religion intolerance, tribalism, illeteracy and land ownership dispute. Based on the findings of this study, it was recommended that government should provide potable water for the populace, so as to reduce competition for water between the farmers and the cattle of the herders.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The present study aimed at determining age effect on body weight and cumulative egg production of Lohmann Brown layers reared in Lafia, Nasarawa State. A total of forty (40) Lohmann Brown layers in cage system at the Faculty of Agriculture Livestock Farm were utilized in the study. The birds were randomly arranged in a completely randomized design. The performance parameters considered were weekly body weight (BW), (g), determined weekly and cumulative egg number (CEN) per week. The effect of age (27, 28, 29 and 30 weeks old) on weekly BW and CEN was determined using one-way analysis of variance (ANOVA) with repeated measures. Significant ($P<0.05$) means were separated with Greenhouse-Geisser correction. Logistic 3P, 4P, 5P and Gompertz 3P models were employed to predict body weight from the age of the birds. However, the relationship between cumulative egg production and age was established using linear, quadratic, and cubic regression models including the artificial neural network (ANN). Age significantly affected the weekly body weight and cumulative egg production of Lohmann Brown layers. The Gompertz 3P model offered the best fit for body weight parameters over logistic 3P, 4P and 5P models. With regard to cumulative egg production, the ANN performed better than the quadratic, linear and cubic models. In all the models, body weight and cumulative egg production were optimized at 28.5 weeks of age. This optimal value obtained, however, could change with a longer duration of study.

INTRODUCTION

Poultry farming is fast becoming an attractive business and a sub-sector which generates employment opportunities for both skilled and unskilled labor. This is due to its short gestation period and generation interval, prolificacy and lack of taboos to its production coupled with an increasing demand for its production by a large segment of the populace especially during religious and other local and national festivals. In order to meet this increasing demand, however, there is an urgent task of developing or procuring the fastest growing strain for new entrant and long-time poultry farmers considering the environmental sensitivity of every genotype (Jesuyon & Oseni, 2015).

There is strong evidence that there are genetic differences in growth rate between strains or breeds of chicken (Yakubu
& Aguda, 2020). Certain studies have shown that there are significant differences between body weight, weight gain and egg production characteristics at different ages of chicken (Yakubu et al., 2018). There is no doubt about the fact that the bird's live weight at times of commencement of egg laying determines its age at first egg production and its peak production as well as the overall performance of the hen. A hen that reaches sexual maturity earlier will produce more eggs than the one that reaches its sexual maturity later. The objective of the study was to evaluate the effect of age on bodyweight and cumulative egg number of Lohmann Brown hens kept in Battery cages in Nasarawa State, Nigeria.

MATERIALS AND METHODS

The experiment was carried out at the Livestock Section of the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University, Keffi, Shabu-Lafia Campus, Lafia, Nigeria. A total of forty Lohmann Brown layers on cage system were utilized in the study. The birds were randomly arranged in a completely randomized design. There were four replicates each comprising ten birds. They were fed conventional commercial feed. There was appropriate vaccination and medication of the birds in line with established standards and procedures. Other routine management practices were strictly carried out. From week 27-30 of age, the performance parameters considered were weekly body weight (BW), (g), and cumulative egg number (CEN) per week. The effect of age (27, 28, 29 and 30 weeks old) on weekly BW and CEN was determined using one-way analysis of variance (ANOVA) with repeated measures. Significant means were separated at 95% confidence with Greenhouse-Geisser correction (IBM-SPSS, 2020). Logistic 3P, 4P, 5P and Gompertz 3P models wer used to predict body weight from the age of the birds. However, the relationship between cumulative egg production and age was established using linear, quadratic, and cubic regression models including the artificial neural network (ANN) (JMP, 2022).

RESULTS

There was significant ($P<0.05$) increase in body weight of Lohmann Brown birds at 30 weeks of age (2.02 g) when compared to 27 weeks old birds (1.80 g). Mean cumulative egg production was also higher ($P<0.05$) at 30 weeks of age (6.73) compared to 27 weeks of age (5.28). The Gompertz model had the best fit for modeling the growth curve of the birds, according to AIC and BIC followed by Logistics 3P, Logistics 4P and Logistics 5P (Table 1 and Figure 1). Coefficient of determination ranged from 0.643 and 0.645 for the models, indicating good fit and high ability to predict weight during the laying periods. The age at inflection point was 28.5 weeks for all the models while the body weights at inflection point were 1.903, 1.903, 1.896 and 1.896 for Gompertz, Logistics 3P, Logistics 4P and Logistics 5P. The neural network had the best fit for modeling the cumulative egg production of the birds, with a coefficient of determination of 0.756 (Table 2). It was followed by the cubic, linear and quadratic models, respectively. The neural network also had the highest number of eggs (6.01) at inflection point compared to 6.0 obtained in others. However, the age at inflection point was 28.5 weeks for all the models.

Table 1. Estimated growth curve parameters for body weight in Lohmann Brown layers

Model	A	b	C	d	e	Age and weight at inflection point	AIC	BIC	RMSE	R^2
Gompertz 3P	0.005	442.27		2474.26		28.5; 1.903	-469.086	-457.044	0.0550	0.643
Logistic 3P	0.034	304.53		24812.39		28.5; 1.903	-469.160	-457.117	0.0549	0.643
Logistic 4P	0.203	78.41	1.58	7573.31		28.5; 1.896	-468.096	-453.110	0.0549	0.645
Logistic 5P	-0.202	122.07	1.58	438892.92	114.82	28.5; 1.896	-465.936	-448.035	0.0551	0.645

AIC = Akaike information criterion; BIC = Bayesian information criterion; RMSE = Root mean square error; R^2 = Coefficient of determination; a = maturity index; b = scale parameter; c = asymptotic weight; d = upper asymptote; e = power or asymmetry parameter

Table 2. Estimated cumulative egg production curve parameters in Lohmann Brown layers

Model	b_o	b_1	b_2	b_3	Age and egg number at inflection point	AIC	BIC	RMSE	R^2
Linear	-6.40	0.44			28.5; 6.00	128.739	137.810	0.357	0.653
Quadratic	-6.40	0.44	-4.971e-9		28.5; 6.00	130.843	142.886	0.358	0.653
Cubic	-5586.65	588.82	-20.66	0.24	28.5; 6.00	95.536	110.522	0.320	0.725
Neural network					28.5; 6.01			0.313	0.756

AIC = Akaike information criterion; BIC = Bayesian information criterion; RMSE = Root mean square error; R^2 = Coefficient of determination; b_0 = intercept; b_1, b_2 and b_3 = regression coefficients

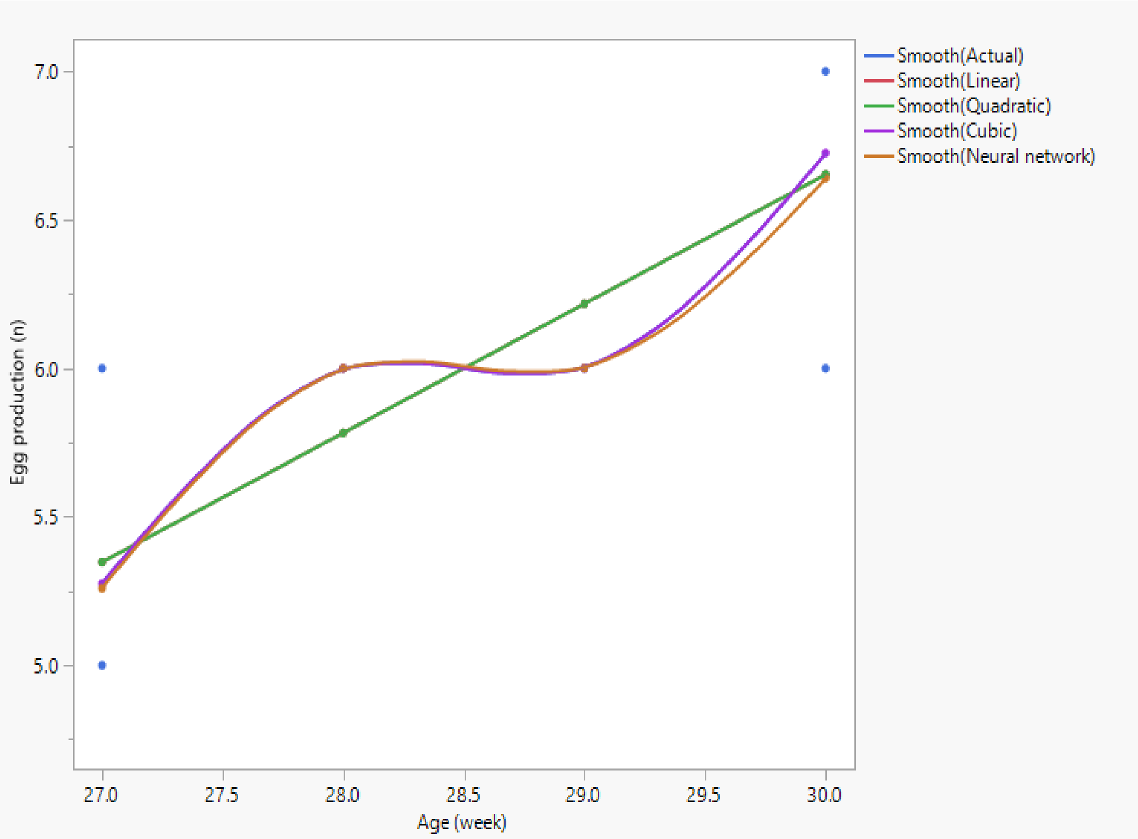

Figure 2. Actual and predicted cumulative egg number of Lohmann Brown layers.

DISCUSSION

Body weight and cumulative egg production was highly influenced by age in the current study. This is consistent with the findings of Tůmová & Gous (2012) and Şekeroğlu et al. (2014). The lowest egg production and small egg size recorded at week 27 could be due to the fact the birds had just got into laying. According to Johnston & Guos (2007), the age of hens is a very vital factor that influences egg production and egg size. They further stated that the rate of egg production increased as the age of the bird increased, and at a particular age of about 70 weeks, egg production began to decline gradually. It has been reported that older birds of about 70 weeks and above have a larger preovulatory follicle and oviduct compared to younger birds. Modelling production parameters of laying hens permits a good understanding of the production cycle. This might be exploited in decision making especially where there is an unexpected decline in production at a particular phase. To validate a regression function or estimate, the R^2 is taken often (Olaniyan et al., 2017). The current observation is not consistent with the submission of Yakubu & Madaki (2017) where the prediction of body weight from age (weeks) using the quadratic model gave R^2 and adjusted R^2 values of 0.852 and 0.852, respectively. Also, the current optimal body weight at 28.5 weeks is lesser than the 47.5 weeks of age reported by Yakubu & Madaki (2017). The differences could be due to genetic factor, plane of nutrition, management and the length of egg collection.

Several authors have adopted different models in the layer–type birds to predict performance characteristics (Narinc et al., 2014; Selvaggi et al., 2015; Okoro et al., 2017; Safari−Aliqiarloo et al., 2018). In poultry farms, optimum production time estimation is very important as regards economic production. The determination of the best performance of birds at appropriate ages may be exploited in the improvement of farm output. The set of values obtained in the present study could guide management decisions on the use of resources to reduce wastage and losses while maximizing economic gains in the poultry farms.

CONCLUSION

Age significantly affected the weekly body weight and cumulative egg production of Lohmann Brown layers. The Gompertz 3P model offered the best fit for body weight parameters over logistic 3P, 4P and 5P models. With regard to cumulative egg production, the neural network performed better than the quadratic, linear and cubic models. In all the models body weight and cumulative egg production were optimized at 28.5 weeks of age. This could however change when the period of study is elongated.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23^{rd} – 27^{th} Oct., 2023

ABSTRACT
A 4-week study was conducted using 120 unsexed Anak strain broilers to determine the carcass and internal organs characteristics of finishing broilers fed unpeeled and peeled fermented pro-vitamin A cassava meal as total replacement for maize. Fresh bio-fortified pro-vitamin A cassava was harvested and divided into two batches. The first batch was peeled and the second batch was unpeeled. Both were soaked separately in a plastic vat containing clean water and allowed to ferment for 72 hours. Thereafter, they were washed with clean water, sundried and milled to produce i. peeled fermented pro-vitamin A cassava tuber meal (PFPC). ii. Unpeeled fermented pro-vitamin A cassava tuber meal (UFPC). The broilers were divided into three groups and fed diets containing 100% maize T_1 (control) as the source of energy, while T_2 and T_3 contained 100% unpeeled and peeled fermented pro-vitamin A cassava as the source of energy respectively. Each group was replicated four times with 10 birds per replicate in a completely Randomized Design. Feed and water were provided ad libitum for the period. Result showed that final body weight, daily weight gain and breast weight of the control were significantly ($p<0.05$) higher than UFPC and PFPC groups. The treatment had no significant ($p>0.05$) effect on the internal organs of the birds. Abdominal fat of the PFPC group was significantly ($p<0.05$) higher than the control and UFPC. The results of this study revealed that unpeeled and peeled fermented pro-vitamin A cassava meal may completely replace maize in the diets of finishing broilers.
Keywords: *Broiler, pro-vitamin A cassava*

INTRODUCTION
Provision of feed is the most important consideration in poultry enterprise. Feed alone has been reported to account for 60-80% of the total cost of poultry production in developing countries (Igboeli, 2000; Esonu, *et al*., 2001). Maize contribute 55% of the total cost of poultry diets. Limitations imposed by scarcity and high cost of maize due to its consumption by humans, has forced many farmers into employing other readily available alternative source of energy such as cassava.

Cassava is one of the alternative energy sources that can replace a considerably proportion of maize in livestock feed industry (Bokanga1995). Its products have been in use for a long time in place of cereal grains for livestock (Eruvbetine *et al.*, 2014). In order to reduce the high level of toxic cyanogens, increase in shelf-life and vitamin A content in cassava, provitamin A also known as UMUCASS 36 bio-fortified cassava was introduced by plant breeders who conducted series of crosses among selected parents and also evaluate their promising progenies for over 10 years (Khajarern,1997).

Research on the potentials of pro-vitamins A cassava has not been fully explored as animal feed stuff, therefore, the aim of this research was to assess the potentials of pro-vitamin A cassava as a source of energy on the carcass and internal organs of finishing broilers.

MATERIALS AND METHODS
Experimental Site
The experiment was carried out at the Poultry Unit, Teaching and Research Unit of Michael Opara University of Agriculture, Umudike in Abia State. The area lies within the latitude 5^0 29' North and longitude 7^0 32΄΄East, the altitude is 122m above sea level with relative humidity of about 50-95%, temperature range of about 22-36^{0}C

Source of pro-vitamin A variety of cassava and Processing Method
The fresh pro-vitamin A variety of cassava (UMUCASS 36) tubers were obtained from National Root Crops Research Institute Umudike, Abia State. The tubers were divided into two batches. One batch was peeled and the

other was left unpeeled. The peeled and the unpeeled tubers were washed and later soaked in separate plastic Vat containing clean water and allowed to ferment for 72 hours. Thereafter, the fermented tubers were washed, sundried for 3-4 days and run through a hammer mill using 2mm sieve to homogenized it thereby producing; i) unpeeled fermented pro-vitamin A cassava tuber meal (UFPC) and ii) Peeled fermented pro-vitamin A cassava tuber meal (PFPC)

Experimental Diets

Three experimental diets T_1, T_2 and T_3 were formulated such that T_1 (control) had maize as source of energy, T_2 and T_3 contained 100% UFPC and PFPC respectively; completely replacing maize in the diet. Other ingredients were adjusted such that the diet met nutrient requirement of finishing broilers. The ingredients composition of the experimental diets is shown in table 1.

Experimental Birds and Design

One hundred and twenty broiler chickens of mixed sexes (Anak Strain) obtained from a local hatchery were used for the experiment. The broilers were brooded for 3 weeks and fed with normal feed while the test ingredient were used for the experiment proper. At 35- day of age, the birds were divided into 3 groups of 40 birds each and each group were randomly assigned one of the three experimental diets using Completely Randomized Design . Each group was further replicated 4 times and with 10 birds per replicate. Feed and water were provided *ad-libitum*. All necessary prophylactic medications and vaccinations were also provided.

Carcass and Internal Organ Evaluation

At day- 63 four birds were randomly selected from each treatment, starved of feed overnight but provided with water, weighed and sacrificed by cutting their jugular vein. The carcasses were scalded in hot water of about 80ºC for a minute and the feathers were plucked manually. The carcasses were eviscerated by cutting through the vent and the viscera were removed. Weights were obtained for edible carcass parts; drumstick, thigh, shank, back, wings and breast. Weights of internal organs were also determined (gizzard, liver, kidney and heart). The dressed carcasses weights were expressed as percentage of live weight.

Data Analysis

Data generated were subjected to analysis of variance in a statistical analysis System package (Delapenha and Jhanelle, 2020) The means were compared using Duncan New Multiple Range Test (DNMRT) as outlined by (Obi 1990).

RESULTS AND DISCUSSION

Table 1 shows the carcass, cut-up parts and internal organs evaluation of finishing broiler chicken fed pro-vitamin A variety of cassava tubers. The live weight, dressed weight and dressing percentages of birds in the control were higher than the UFPC and PFPC groups. The cut-up parts; thigh, drumstick, back, wing and neck were not significantly ($p>0.05$) affected by the diet except breast. The value for breast in the control was significantly ($p<0.05$) higher than the UFPC and PFPC groups.

The dietary treatment had no significant effect ($p>0.05$) on the internal organs of the birds. The group of PFPC diet developed significantly ($p<0.05$) more abdominal fat than the control and UFPC group. Similar observations had been made by Adedokun *et al.* (2017) and Udedibie *et al.* (2008).

Table 1: Carcass, Cut-up parts and Internal Organs Evaluation of finishing broiler Chicken fed pro-vitamin A variety of cassava tubers

Parameter	T_1control	T_2 UFPC	T_3 PFPC	SEM
Live weight (kg)	2.53^a	2.37^b	2.39^b	1.12

Kidney	0.25	0.20	0.24	0.01

ab – means within rows with different superscripts are significantly ($p<0.05$) different

Cassava has been widely used to replaced maize in poultry diets but the results in terms of its feeding value, nutritional problems encountered, biological responses and productive performances of chickens fed cassava products has always exhibited wide variability (Khajarern, 1997). This is because of the presence of toxic cyanogenic glycoside but with the introduction of bio-fortified cassava (pro- vitamin A (UMUCASS 36) which was used in this study that contain insignificant level of HCN and fermentation method which is regarded as the best method for detoxification of tuberous crops (Adedokun *et al.*2017). This method was also used in this study to process the cassava thus would have helped to reduce the effect of HCN toxicity on the birds, however the higher body weight gain recorded by the control over the UFPC and PFPC group could be attributed to the level of protein content of the feed ingredients (maize and cassava). The protein content in maize is higher and of a better quality than cassava (Oker, 2011) reported that feed quality affects the growth performance of chickens. The liver, kidney, heart and gizzard of the birds were not affected by the diet. There was no observed abnormality on the internal organs. The liver, kidney and heart weights indicated that both UFPC and PFPC diets did not apparently inflict them with toxicity. The non significant ($p>0.05$) effect of the gizzard showed that the control, UFPC and PFPC diets were finely ground; there were no structural components such as hulls, cereal particles and wood shaving in diets.

CONCLUSION

The information presented in this study herein has strongly shown that feeding broiler birds with unpeeled and peeled fermented pro-vitamin A cassava (UMUCASS 36) as a reference diet to maize may improve the carcass characteristics with little or no adverse effect. It is therefore suggested that pro-vitamin A cassava could be used in poultry diets as total replacement for maize but the diet should be formulated in a way to balance the disparity inherent in crude protein content of cassava and maize, respectively.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This experiment was conducted to determine the effect of feeding varying levels of tigernut meal on nutrient digestibility of female weaner rabbits at graded levels of inclusion (0%=T_1, 10%=T_2, 20%=T_3 and 30%=T_4). Twenty-four (24) clinically, healthy female weaner rabbits were used in the experiment to evaluate the effect of feeding varying levels of tigernut meal diet which was randomly divided into 4 groups of 6 animals per treatment with 2 animals per replicate giving 3 replicate per treatment, in a completely randomized design (CRD). Water and feed were given ad libitum. The experiment lasted for 120 days. Simple Descriptive Statistics and Analysis of Variance (ANOVA) were used to analyze the data while the New Duncan's Multiple Range Test was employed to compare treatment means. The dry matter (DM) and crude protein (CP) digestibility values were improved ($P<0.05$) by dietary treatments. This study revealed that tigernut meal is rich in carbohydrate, it also showed that the tigernut meal could be used as a partial or total replacement for maize at upto 30% level of inclusion without any adverse effect on the growth and reproductive performance of the female weaner rabbits.

INTRODUCTION

The high cost of maize as the main energy source for livestock and rabbit feeds and a staple food for Nigerians and Agro-allied companies including brewing industries cannot be over- emphasized. The resultant effect is high cost of animal protein hence inability of the populace to meet the minimum dietary protein intake of 56g per person per day as recommended by the. Food and Agricultural Organization of the United Nation (Fasuyi, 2005). Many attempts have been made to solve this problem through the use of some non-conventional energy sources in poultry such as maize offal (Vantsawa *et al.*, 2008), palm oil sludge (Esonu *et al*., 2006), cassava (Udedibie *et al*., 2009) and in rabbit nutrition, wild variegated cocoyam (Agbabiaka *et al.*, 2006), cocoyam corm (Omorege *et al*., 2009, Aderolu and Sogbesan, 2010). These tuber crops have been found to be of good potential but with limited crude protein content which is often below 3%. Tigernut (*Cyperus esculentus* L.) has been reported to be rich in energy while its oil content (about 25%) is resistant to peroxidation (Belewu and Belewu, 2007).

Tiger nut is a tuber rich in energy content (starch, fat, sugar), minerals (mainly phosphorus and potassium), and vitamins E and C thus making the tuber also suitable for diabetic patients to take (Ekeanyanwu and Ononogbu, 2010).

MATERIALS AND METHODS

The experiments were carried out at the Rabbitary Unit of the Teaching and Research Farm of Abia State University, Umuahia Location. The Campus is located within the Southeastern Nigeria and lies between Longitude 07º 33ꞌ E and Latitude 05º 29ꞌ N at about 8km East of the Umuahia-Ikot Ekpene road. It is 140 km North of Port Harcourt International Airport, 135 km South of Enugu Airport and 80 km East of Owerri Airport. The experiment lasted for 120 days. The tiger nut seeds were purchased from "Ama Hausa" in Umuahia in Abia State, Nigeria. The milling was done at Feed Mill Unit of National Root Crops Research Institute, Umudike. Twenty-four (24) female weaner rabbits were used for the experiment and were assigned to the four treatment diets following the Completely Randomized Design (CRD). where each treatment had six rabbits which was further replicated 3times with 2 rabbits per replicate and the breed used for the studies was New Zealand White with an average weight of 980g and 6-8 weeks of age. The rabbits were purchased from the rabbit unit of National Root Crops Research Institute, Umudike.

The rabbits were housed in galvanized metal hutches measuring 100×60×80cm^3. The hutches were placed in an open sided house with corrugated roofing sheets, the side walls built up to 1meter high and the remaining part of the sides covered with wire mesh.Four treatment diets containing 0%, 10%, 20% and 30% tigernut meal were compounded.

RESULTS AND DISCUSSION

Nutrient digestibility

The digestibility result is presented in Table 1. The result showed that the values of rabbits fed 0% (77.21%) and that of 10% (72.15%) diet were same statistically. They also indicated that rabbits fed 10% diet had no problem in digesting the dry matter in the diets contrary to those fed 30% diets. It therefore showed that rabbits fed 10% tigernut meal had better and superior dry matter digestibility than treatments 3 and 4.

Crude protein digestibility showed no significant difference (P>0.05) between rabbits fed 0 and 10% tigernut meal diets but differed significantly (P<0.05) from rabbits fed 20%(52) and 30% (51.06) diets which were statistically similar (P>0.05). In this study it was observed that rabbits fed tigernut meal were able to digest crude protein at a decreasing rate as the level of inclusion increased. The reason for the poor digestibility at 30% maybe attributed to higher concentrations of tannins, phytate, etc. These observations agreed with the findings of Sathe and Salunke, (1981).

Ether extract digestibility was highest in rabbits under treatment 1 (63.45%) followed by T_2 (61.31%), T_3 (53.35%) and T_4 (48.35%) respectively. Rabbits on T_1 and T_2 had similar (P>0.05) digestibility but they differed significantly from rabbits on 20 and 30% levels of inclusion. Rabbits on 20% level of inclusion differed significantly (P<0.05) from those on 30% (T_4) level of inclusion.

Nitrogen free extract digestibility had significant difference (P<0.05) between treatments 4 and 3, but had higher non-significant difference between treatments 2 and 1.

Crude fibre digestibility was significantly different among the treatments. The values were 53.25, 55.45, 61.18 and 62.33% for T_1, T_2, T_3 and T_4 respectively. The difference in digestibility between rabbits on T_1 and T_2 was not significant (P>0.05) but they differed significantly (P<0.05) from rabbits on T_3 and T_4 which were statistically similar (P<0.05). The observed trend in nutrient digestibility was that the digestibility of DM, CP, EE and NFE declined as the level of tigernut meal increased in the diet. However, CF digestibility increased as the level of tigernut meal in the diet increased. This may be due to the fact that tigernut meal contains about 12.4% CF (Ladeji *et al.*, 2003).

Table 1. Effect of Tigernut meal on Nutrient Digestibility of various diets in female rabbits

	Treatments of dietary levels of tigernut meal (%)				
Parameters	**T_1 (0%)**	**T_2 (10%)**	**T_3 (20%)**	**T_4 (30%)**	**SEM**
Dry matter (%)	77.21^a	72.15^a	56.00^b	53.00^b	5.95
Crude protein (%)	70.25^a	63.50^a	52.00^b	51.06^b	4.64
Ether extract (%)	63.45^a	61.31^a	55.34^b	52.30^b	2.58
Nitrogen free extract (%)	84.21^a	77.30^a	53.35^b	48.35^c	8.81
Crude fibre (%)	53.25^a	55.45^b	61.18^a	62.33^a	2.20

a, b, c: Means with different superscript on the same row differ significantly (P<0.05).

The proximate composition of the experimental diet

The results in the Table 2 of this study established that tubers of *C. esculentus* diet compared favourably with the control that had no tigernut. The results showed that the proximate composition of the diet in dry matter and crude fibre indicated no significant (P>0.05) differences among 0%, 10%,20% and 30% levels of inclusion of tigernut meal. In crude protein there were no significant difference (P>0.05) between T_2, T_3 and T_4 respectively but differed (P<0.05) slightly from T_1. In Ash there were significant difference (P<0.05) between T_1, T_2, T_3 and T_4 respectively while T_2 and T_4 had no significant difference (P>0.05). In ether extract there were no significant between (P>0.05) T_1 and T_2 but differed significantly (P<0.05) from T_3 and T_4. Nitrogen free extract showed no difference (P>0.05) between T_1 and T_2 but differed significantly (P<0.05) with T_3 and T_4 as T_3 and T_4 had no significant difference (P>0.05) between them. In metabolisable energy the result showed no difference (P>0.05) between T_1 and T_2 but differed significantly (P<0.05) with T_3 and T_4 as T_3 and T_4 had no significant difference (P>0.05) between them. The proximate composition of the experimental diet offered the normal nutrition required for maximum performance.

Table 2. Proximate Composition of the Experimental Diet (%DM)

	Concentration (%)			
Parameters	**T_1 (0%)**	**T_2 (10%)**	**T_3 (20%)**	**T_4 (30%)**

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analysed farmers and pastoralists willingness to used Alternative Dispute Resolution (ADR) strategies in conflict resolution in Nasarawa State, Nigeria. Three-stages sampling techniques was used to select one hundred and sixty farmers and fifty-one pastoralists. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected were analysed using frequency percentage, mean and Kendall Coefficient of Concordance. Result of the farmers willingness to used ADR elucidated that ADR is restorative ($\bar{X}$ =4.13), ADR is easily accessible to the poor and vulnerable ($\bar{X}$ =4.05), panellists involved in ADR are highly experienced ($\bar{X}$ =4.01) and ADR focus on understanding issues better ($\bar{X}$ =4.01). The pastoralists indicated that ADR provide a model for quick dispute resolution ($\bar{X}$ =4.29), ADR provides flexible means of resolving conflict ($\bar{X}$ =4.23) and ADR focus is on understanding issues better ($\bar{X}$ =4.18). Farmers reported that dialogue/convening a meeting ($\bar{X}$=15.43), mediation by `elders ($\bar{X}$=14.58), tendering apology ($\bar{X}$=14.16) were the most strategies used for improving relationship with pastoralists while pastoralists reported that compensation and punishment ($\bar{X}$=17.22), tendering apology/use of negotiation ($\bar{X}$=13.76), dialogue/conveying meeting ($\bar{X}$=12.69) were the most strategies used for improving relationship with farmers. It is recommended that curfew should be proactively used in curbing conflict. Sanction should be apportioned to the offenders in order to correct abnormities. Lastly, democratic approaches should be used by agents in conflict resolution.
Keywords*: Farmers-Pastoralists, Willingness, ADR, Conflict Resolution*

INTRODUCTION
Farmers and pastoralists conflict have been a dwindling issue affecting many countries Nigeria inclusive. The country has witnessed the re-occurrence of farmers and pastoralists' disputes in the past, which has not only deteriorated farmers and pastoralists relationshipsbut also resulted in losses of lives and properties. The occurrence of conflict is always associated with the struggle for inadequate resources and egocentricity. Also, conflict creates an avenue for dispute resolution, and dispute resolution can reduce or eliminate causes of underlying conflictwith the agreement of both parties involved (Mwajaide *et al.*, 2015). Alternative Dispute Resolution (ADR) is one of the solution to re-concurrent farmers-pastoralists conflicts in Nigeria. ADR encompasses all legally permitted processes of dispute resolution other than litigation (Ibrahim, 2014). It is also seen as an umbrella term that refers to general, alternatives to court adjudication of disputes such as negotiation, mediation, arbitration, minitrial and summary trial (Nformi *et al.,* 2014). ADR has been useful in restoring farmers and pastoralists relationships in the past with other traditional means of dispute resolution. On the effectiveness of the strategies employed for improved farmer-pastoralist relationship Olaleye *et al.* (2010) identified the following strategies to include; intervention by traditional leaders, payment of compensation to victims, court verdicts, dialogue between parties involved, the intervention of Miyetti Allah cattle breeders association, local community crop farmers/herders intervention and establishment of grazing routes, educating farmers and herders by person or bodies responsible

for conflict resolution. The objectives of the study were; to determine the willingness of farmers and pastoralists to use ADR and examine the ADR strategies used in improving farmers-pastoralists relationship

METHODOLOGY

The study was conducted in Nasarawa State. The State is located between Latitudes 7 º and 9' N and Longitudes 7 º and 10' E. Nasarawa State has a land area of 28,735 square kilometers and is divided into thirteen (13) Local Government Areas (LGAs). The 2006 population census pegs the state's population at 1,863,275million, the projected population as of 2018 using a 2.5% growth rate is 2,456,955 million (Nasarawa State Agricultural Development Programme [NSADP], 2016). The major crops produced are cassava, yam, rice, maize, guinea corn, cowpea, soya bean, acha, melon and millet. However, animals such as Goat, Sheep, Cattle, and Pig were reared in the State (NSADP, 2016). Three-stage sampling technique was used to select respondents from the study area. The first stage involved the purposive selection of three (3) Local Government Areas' agricultural zones, namely: Akwanga, Awe and Karu making a total of three (3) Local Government Areas. The second stage involved random selection of three (3) villages from each of the Local Government Areas selected making a total of nine (9) villages. The third stage involved the use of proportional sampling to select 10% of the farmers as presented in Table1. Snowball sampling method was used for the pastoralists through the help of their umbrella body Miyetti Allah Cattle Breeders Association of Nigeria (MACBAN) in each State. The leadership assisted the researcher to select one pastoralist who assisted in locating other pastoralists due to their nature of settlement (*Rugage*). A total of fifty-one (51) herdsmen were targeted.

Table 1: Sample distribution of the farmers in the study area

State	Zones	LGAs	Villages	Sampling frame	Sample size (10%)
Nassarawa State	Central	Akwanga	Nunku	210	21

Primary data was used for this research. Data were collected by researchers assisted by trained enumerators using structure questionnaires and interview schedules.

Analytical Techniques

Willingness to use ADR: This was achieved using 5 points Likert scale of strongly agreed =5, agree=4, undecided=3, disagree=2 and strongly disagree=1. These were summed together that is 5+4+3+2+1 and be divided by 5 to arrive at a mean value of 3. The decision: <3=not willingness to use ADR=0, $\geq$3 = willingness to use ADR.

Kendall's coefficient of concordance

To examine alternative dispute resolution strategies being used in improving farmers-pastoralists relationship was achieved using Kendall's coefficient of concordance (*W*) described by Mattson was used to rank the problems. A lower mean rank indicates the problem is severe and vice versa. The Kendall's *W* was computed as shown below.

$$W = \frac{12\sum R^{-2} i - 3N(N-1)^2}{N(N-1)}$$

Where:

W = Kendall's value, *N* = total sample size, *R* = mean of the rank. Kendall's coefficient of concordance (*W*) is a measure of the extent of agreement or disagreement among farmers of the rankings obtained. The value of *W* is positive and ranges from zero to one where one denotes perfect agreement among farmers of the rankings and zero denotes maximum disagreement.

RESULT AND DISCUSSION

Willingness of Farmers and Pastoralists to use ADR

Table 1 indicated that farmers were willing to use ADR because ADR is restorative ($\bar{X}$ =4.13), ADR are easily accessible to the poor and vulnerable ($\bar{X}$ =4.05), the panellists involved in ADR are highly experienced ($\bar{X}$ =4.01), ADR focus on understanding issues better ($\bar{X}$ =4.01), ADR provide flexible means of resolving conflict ($\bar{X}$ =3.84), ADR is expected to provide a model for quick dispute resolution and ADR is a cheaper means of resolving conflict($\bar{X}$ =3.8), ADR provides strict confidentiality ($\bar{X}$ =3.68) and parties have equal control over the outcome ($\bar{X}$ =3.65). Table 1 indicated that pastoralists are willing to use because; ADR provide a model for quick dispute resolution ($\bar{X}$ =4.29), ADR provide flexible means of resolving conflict ($\bar{X}$ =4.23), ADR focus is on understanding issues better ($\bar{X}$ =4.18), ADR preserve relationship ($\bar{X}$ =4.16), ADR is easily accessible to the poor and vulnerable ($\bar{X}$ =4.09), the panelists involved in ADR are highly experienced ($\bar{X}$ =4.04), ADR maintains a cooperative approach($\bar{X}$ =3.98) and ADR is a cheaper means of resolving conflict($\bar{X}$ =3.94). This finding denotes that ADR restore relationship, by ensuring farmers and pastoralists have equal right to judgment. Also, the outcome is always communicated in the common language understand by the pastoralists and the strategies allows both farmers and pastoralist involved to contribute their inputs without partiality, favoritism, sentimentalism and other vices that could disrupt peace in the study area (Uwazie, 2011).

Table 2: Distribution of respondents according to willingness to use ADR

Variables	Farmers (n=160) Mean ($\bar{x}$)	R `	Pastoralists (n=51) Mean ($\bar{x}$)	R
ADR provide a model for quick dispute resolution	3.83	6th	4.29	1st
ADR provide flexible means of resolving conflict	3.84	5th	4.23	2nd
ADR is a cheaper means ofresolving conflict	3.83	6th	3.94	8th
ADR are easily accessible to the poor and vulnerable	4.05	2nd	4.09	5th
ADR is restorative	4.13	1st	3.92	9th
ADR maintains a cooperative approach	3.16	16th	3.98	7th

ADR Strategies used in Improving Farmers-Pastoralists Relationship

Table 3 elucidates the distribution of ADR strategies used in improving farmers-pastoralists relationship.The finding according to farmers indicated Kendall's coefficient of concordance of 19.6% level of probability while that of pastoralists was 19.7%. The finding elucidated a weak agreement among the strategies. The low Kendall value recorded might be due to error term or low agreement by farmers on the outcome among the variables included in the model. Farmers in the study area Elucidated that dialogue/convening a meeting ($\bar{X}$=15.43), mediation by `elders ($\bar{X}$=14.58), tendering apology ($\bar{X}$=14.16), reconciling both parties ($\bar{X}$=14.16), inter-faith dialogue ($\bar{X}$=13.99), effective communication($\bar{X}$=12.80), informal settlement ($\bar{X}$=12.47), use of agents to monitor conflict ($\bar{X}$=12.47), check and balances ($\bar{X}$=12.30), setting of the judicial committee ($\bar{X}$=11.96), compensation and punishment ($\bar{X}$=11.70), peace education/teaching ($\bar{X}$ =11.37), and traditional oath-taking ($\bar{X}$ =11.20) were the ADR strategies used in improving farmers-pastoralists relationship. The pastoralists reported that compensation and punishment ($\bar{X}$=17.22), tendering apology/use of negotiation ($\bar{X}$=13.76), dialogue/conveying meeting ($\bar{X}$=12.69), use of agents to monitor conflict occurrence ($\bar{X}$=12.47), mediation by elders ($\bar{X}$=12.04), reconciling both parties ($\bar{X}$=12.04), effective communication ($\bar{X}$=11.82), informal settlement ($\bar{X}$=11.61), interfaith dialogue ($\bar{X}$=11.39) and use of marriage ($\bar{X}$=11.39) were the strategies used in improving farmers-pastoralists relationship.

ADR Strategies used in Improving Farmers-Pastoralists Relationship

Table 3 elucidates the distribution of ADR strategies used in improving farmers-pastoralists relationship.The finding according to farmers indicated Kendall's coefficient of concordance of 19.6% level of probability while that of pastoralists was 19.7%. The finding Elucidated a weak agreement among the strategies. The low Kendall value recorded might be due to error term or low agreement by farmers on the outcome among the variables included in the model. Farmers in the study area Elucidated that dialogue/convening a meeting ($\bar{X}$=15.43), mediation by `elders ($\bar{X}$=14.58), tendering apology ($\bar{X}$=14.16), reconciling both parties ($\bar{X}$=14.16), inter-faith dialogue ($\bar{X}$=13.99), effective communication($\bar{X}$=12.80), informal settlement ($\bar{X}$=12.47), use of agents to monitor conflict ($\bar{X}$=12.47), check and balances ($\bar{X}$=12.30), setting of the judicial committee ($\bar{X}$=11.96), compensation and punishment ($\bar{X}$=11.70), peace education/teaching ($\bar{X}$ =11.37), and traditional oath-taking ($\bar{X}$ =11.20) were the ADR strategies used in improving farmers-pastoralists relationship. The pastoralists reported that compensation and punishment ($\bar{X}$=17.22), tendering apology/use of negotiation ($\bar{X}$=13.76), dialogue/conveying meeting ($\bar{X}$=12.69), use of agents to monitor conflict occurrence ($\bar{X}$=12.47), mediation by elders ($\bar{X}$=12.04), reconciling both parties ($\bar{X}$=12.04), effective communication ($\bar{X}$=11.82), informal settlement ($\bar{X}$=11.61), interfaith dialogue ($\bar{X}$=11.39) and use of marriage ($\bar{X}$=11.39) were the strategies used in improving farmers-pastoralists relationship.

CONCLUSION AND RECOMMENDATIONS

Based on this study it can be concluded that ADR is restorative, ADR is easily accessible to the poor and vulnerables. The panellists involved in ADR are highly experienced and that is the reasons behind farmers' willingness to use ADR. Pastoralists were willing to use ADR and it provides a model for quick dispute resolution, ADR provides flexible means of resolving conflict and focuses on understanding issues better. Farmers reported that dialogue/convening a meeting, mediation by elders and Reconciling both parties were used in improving relationship with pastoralist while the pastoralists reported that compensation and punishment, mediation by elders and tendering apology were effectively used in improving relationship with farmers. It is recommended that curfew should be proactively used in curbing conflict in the study area. Sanction should be apportioned to the offenders in order to correct abnormities. Lastly, democratic approaches should be used in conflict resolution in the study area.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABTRACT

The study investigated the effects of farmer-Pastoralist conflict on agricultural extension service delivery in the study area. Data were collected primarily by administering questionnaires to 50 respondents. Data were analyzed using descriptive statistics. Results of the study shows that average age and years spent in school were 35 years and 10years while the major perceived causes of conflicts include increased pressure on land ($\bar{X}$ =4.56), Search for water and pastures ($\bar{X}$ =4.10) and population growth. More so, results from the study also showed that the effects of farmer-Pastoralist make extension work difficult ($\bar{X}$ =4.42, delay in completion of extension work ($\bar{X}$ =4.38) and monitoring farmers progress becomes difficult ($\bar{X}$ =3.32). Constraints faced by extension agent were bad road ($\bar{X}$ =4.34), Re-occurrences of farmers-Pastoralist conflicts ($\bar{X}$ =4.1) high cost of transportation ($\bar{X}$ =3.86) and inadequate cooperation from community leaders ($\bar{X}$ =3.22). The study recommends that government should adopt policies that would tackle the causes of farmer-pastoralist conflict in the study area especially in the case of land control measures, provision of basic infrastructural facilities such as roads, water points and ranches in the study area in other to facilitate effective communication, implementation and functioning of extension workers. There is also need to set up reconciliation committees in the communities.

INTRODUCTION

Agricultural extension is a science of social change with the basic purpose of increasing farmer's productivity through efficient production. It therefore emphasized among other things like the use of fertilizer, improved seed and chemicals. Agricultural extension services assist farm people through educational procedures, improving farming methods and technique increasing production, efficiency and income satisfying their levels of living and lifting the social and educational standard of living a rural life. Pastoralism often has mobile aspects but can take many forms and be at different scales. The increase in pressure resulting from resource degradation and scarcity natural resources has aggravate the situation of competition between farmers and pastoralists. In the area where the two-production system interacts, both communities are increasingly considering the option of expansion to each other's holding. As a result, conflicts are getting recurrent and intensified in many parts of the country, this is supported by Blench (2003) that farmer pastoralist conflicts are increasing both in terms of recurrent and intensity. The farmer- Pastoralist conflict is one of the most complex social problems affecting Nigeria's survival as it has direct impact on the survival of those involved who the country depends heavily on, in terms of provision food and raw materials for industry and export in order to meet ever-growing demands.

Table 1: Socio-economic characteristics of respondents

Variables	Frequency	Percentage (%)	Mean

Source; Field survey, 2019.

Socio-economic characteristics of respondents

The mean age was 35years.This agrees with the findings of Ezeh (2013) who reported that age range of extension agents is between 40-60 years. Table 1 further revealed that, male respondents accounted for 72% and 28% were female. The involvement of more male as extension workers may probably be due to the cultural and religious belief of the rural people (especially in Northern Nigeria) which tends to restrict women to household domestic chores. The findings also shows that 58% of respondents had attained tertiary level education, 20% had attained secondary level education, while 16% attained non-formal and very few 6% attained primary level education. The level of education of extension agents agrees with the findings of Ezeh (2013) who found out that the majority of extension agents completed post-secondary education.

Table 2: Extension service rendered by the respondent

Extension services rendered	**SA**	**A**	**UD**	**DA**	**SD**	**WS**	**WM**	**Position**
Educating the farmer	33(165)	15(60)	2(6)	0(0)	0(0)	231	4.62	1st

Respondent perceived causes of conflicts

The farmer- Pastoralist conflict is one of the most complex social problems affecting Nigeria's survival as it has direct impact on the survival of those involved who the country depend heavily on, in terms of provision food and raw materials for industry and export in order to meet ever-growing demands In the study area, the causes of conflicts are increased pressure on land ($\bar{X}$= 4.56), Search for water and pastures ($\bar{X}$=*4.1*), Population growth ($\bar{X}$=*3.96*). Audu (2013) who opined that about half of the land conflicts are over boundaries that occur mainly with neighbors or relatives who live close by, decrease in water availability as a result of changes in global climatic conditions and migration of herdsmen. In the past five years, it appears that there are more conflicts related to land sales. As the value of land increases due to population pressure, agricultural commercialization, and urbanization, it is expected that the land sales market will develop over time. However, if property rights are not clearly defined, there could be more cases of land conflicts related to land sales.

Table 4: Effect of farmer-pastoralist conflict on Extension service delivery

Effects of conflicts	SA	A	UD	DA	SD	WS	WM	Rank
Extension work becomes difficult	26(130)	21(84)	2(6)	0(0)	1(1)	221	4.42	1st
Completion of extension work are delayed	23(115)	26 (104)	1(3)	0(0)	0(0)	219	4.38	2nd
Monitoring farmers progress becomes difficult	21(105)	27(108)	0(0)	1(2)	1(1)	216	4.32	3rd
Destruction of mutual trust between farmer and pastoralist	29(145)	15(60)	2(6)	3(6)	1(1)	212	4.24	4th
Programme evaluation becomes difficult	17(85)	30(120)	0(0)	2(4)	1(1)	210	4.2	5th
Reduces turnover of extension work	13(65)	32(128)	4(12)	0(0)	1(1)	206	4.06	6th

Source; Field survey, 2019. Note SA= Strongly Agree, A=Agree, UD=Undecided, DA= Disagree SD=Strongly Disagree WS= Weighted Sum WM= Weighted Mean Cut-off mean=3.0

The Effects of Conflicts on Extension Services Delivery

Table 4 shows that conflicts affect extension services delivery ($\bar{X}$=4.42), causes delay in completion of extension work ($\bar{X}$=4.38), difficulty in monitoring farmer ($\bar{X}$=4.32), destruction of mutual trust between farmer and pastoralist ($\bar{X}$=4.24), Programme evaluation becomes difficult($\bar{X}$=4.2), reduce turn-over of extension worker ($\bar{X}$=*4.06*), extension agent abandon work ($\bar{X}$=*3.98*), and hampers cooperative activities(mean=3.96),

Table 5: Socioeconomic loses among respondents as a result of conflict

Variables	Frequency*	Percentages (%)
Loss of lives	20	14.59
Loss of animals	33	24.08
Loss of properties	33	24.08
Migration	13	10.21
Reduction in crop production	37	27.00

Source; Field survey, 2019 *Multiple Responses Recorded

Socioeconomic loses among respondents as a result of conflict

The result shows that 14.49% of the respondents agreed that there was loss of lives during conflict, while 24.08% accepted that there was loss of animals and properties during the conflict. Finding of this study is in line with the studies of Aliyu (2015): Burton (2016). who reported that loss of lives and properties are some of the characteristic features of farmer-herders conflict. Also, Adeoye, (2017) reported that herders-farmers clashes over cattle destruction of crops; farmers' encroachment on grazing reserves and indiscriminate bush burning by nomads usually leads to loss of crops

Table 6: Constraint face by the respondent in delivering extension service in the study area

Constraints	SA	A	UD	DA	SD	WS	WM	Rank
Bad road	23(115)	23(92)	2(6)	2(4)	0(0)	217	4.34	1st
Reoccurrences of conflicts	27(135)	9(36)	8(24)	4(8)	2(2)	205	4.1	2nd
High cost of transportation	14(70)	24(96)	5(15)	5(10)	2(2)	193	3.86	3rd
Inadequate cooperation from community leaders	10(50)	25(100)	2(6)	2(4)	1(1)	161	3.22	4th
Migration and displacement of farmer	0(0)	11(44)	17(51)	2(4)	14(14)	113	2.26	5th

Source; Field survey, 2019. Note SA= Strongly Agree, A=Agree, UD=Undecided, DA= Disagree SD=Strongly Disagree WS= Weighted Sum WM= Weighted Mean Cut-off mean=3.0

RECOMMENDATIONS

- it is recommended that land reforms and laws should be ratified and enforced by key government authorities such as the Parliament, government, judiciary, and local government to ensure peace and prosperity.
- The study recommends that capacity building should be provided to both the farmers and pastoralists by the government officials and NGOs to build relevant infrastructures for rainwater harvesting so that they can use for various purposes (livestock, domestic, irrigation and pasture production).
- Farmers and pastoralists should be given input subsidies in order to use land resources economically.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
*The study was conducted to determine the effect of sire on body linear measurement of Japanese quails. Six sires were randomly mated with 4 dams each to generate the quail chicks. The chicks were raised following standard procedure until maturity and data were collected on body weight, breast girth, body, wing and shank lengths. The data collected were subjected to one-way analysis of variance and correlation procedure of the SPSS statistical package. The results obtained indicated that sire had significant effects on shank length and breast girth. Sires 1, 4 and 6 had significantly higher shank length while sire 4 had significantly breast girth compared to other sire groups. The highest coefficient of variability (CV) value was noted in breast girth followed by body length and shank length while the wing length had the lowest CV value. The phenotypic correlation between body weight and body linear measurement were all positive, generally high and significant. Body weight vs shank length demonstrated the strongest (0.861**) relationship. Correlation between wing length and all other body linear parameters were all very low and not significant. From the findings of this study, it was recommended that selection of Japanese quails should be based on individual selection due to significant effect of sire on body linear parameters. Also, the strongest correlation between body weight and shank length couple with high value of coefficient of variability indicated that shank length is the best linear parameters to be used for selection if meaningful progress must be made.*
Keywords: *body linear measurements, Japanese quails, sire, coefficient of variation, phenotypic correlation, Tropical environment.*

INTRODUCTION
Poultry industry is one of the growing industries globally; many people have developed interest and realized the benefits of investing in this area of production (Abdel-Azeem, 2005, Ojo *et al.,* 2011). Globally, due to the continued preference of white meat to red meat, consumption of poultry has increased from 68.5 million tons in 2000 to 103.5 million tons in 2012 which is a 51 per cent increase. This has led to increased animal protein consumption 11.1g per day to 13.6g per day (Abdel-Fatah *et al.*, 2006). In Africa, per person average animal protein consumption is as low as 6g per day. This is far below the Food and Agriculture Organization recommended of 26 g per person per day (Gambo, *et al.,* 2013). The potential of poultry production has not been fully exploited because most farmers have restricted themselves to chicken production as compared to other birds such as quails which are equally of economic, social and nutritional benefits. In spite of intensive research, however, much still remains to be discovered and verified with regard to why there is slow uptake of quail farming by farmers. Quails have several advantages which includes: they mature early, are excellent layers, low feed consumption, require small floor space, have high immunity against diseases, meat low in fat and their eggs are claimed to have high nutritive and medicinal value (Ali *et al.,* 2002; Gambo *et al.,* 2013). Quail rearing at small-scale household level has still potential to open another avenue to provide an alternative source of animal protein and to offer the poor families as an income generation source by rearing a small unit of quails. The general objective of this study is to assess effect of sire on body weight and body linear measurements of Japanese quails.

MATERIALS AND METHODS

The experiment was carried out at the Livestock Teaching and Research Farm of the Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University, Keffi, Nasarawa State. Nasarawa State falls within the Southern Guinea Savannah Zone of Nigeria. Lafia lies between latitude 7^0 and 9^0 North and Longitude 7^0 and 10^0 East. It has a climate typical of the tropical zone because of its location. It has a temperature ranging from 20 ^{0}c in October to 36 ^{0}c in March while rainfall varies from 13.73 cm in some places to 14.00 cm in others. The area is characterized by farmers with backyard animal (chicken) rearing (Faculty Weather Station, 2022).

Experimental Birds and Their Management

The total of 30 hens and 12 cocks at three weeks of age were purchased from the poultry unit of the National Veterinary Research Institute, Vom, Plateau State and used as the base population. This base population were housed in the same pen for two weeks for the purpose of acclimatization. At the 6th week of age, they were randomized into 6 breeding cages in the rearing house. A mating ratio of 1:4 (i.e. 1 cock to 4 hens) were used. Each breeding cage had a dimension of 47(length) x 40(width) x 36(height) cm. The hens in each breeding cage were allowed to freely mate the respective cock as from 6 weeks of age. However, fertile eggs for hatching were collected when the birds were 9 weeks of age for higher rates of fertility and hatchability. Eggs were collected and accumulated for five days. The birds were fed standard feed as recommended by Dafwang (2006). Feed and water were provided *ad-libitum.* Eggs were collected twice a day and accumulated for 5 days during which they were held in egg crates under room temperature with good ventilation. The eggs were labeled according to sire. At the end of 5 days of egg collection, the eggs were transported to Zanwa Hatchery, Lafia for hatching. After successful four batches of hatching, a total of 184 chicks were obtained from the base population. The birds were managed using standard procedure until maturity and data collected.

Data collection

Linear Body Measurement: The linear body measurements such as body length, shank length, wing lengths and breast girth were measured at weekly interval for the first 6 weeks using measuring tape.

Experimental Design and Data Analysis

The design of the experiment was a nested or hierarchical design. In other word, random samples of dams were nested within random sample of sire. The data collected were analyzed using descriptive statistics, correlation and analysis of variance procedure of the SPSS software. Were statistical differences exist, Duncan multiple range test was used to separate the means at 5 percent probability using the same software.

RESULTS

The effect of Sire on body weight and body linear measurements of Japanese quails is presented in table 1. Sire had significant ($P<0.05$) effects on shank length and breast girth. Sires 1, 4 and 6 had significantly higher shank length compared to sires 2, 3 and 5. Similarly, Sire 4 had significantly ($P<0.05$) breast girth compared to other sire group. Sire however did not have significant ($P>0.05$) effect on body length, body weight and wing length.

Table 2 present the descriptive statistics of body weight and body linear measurements of Japanese quails. The result showed various degree of variability. The highest coefficient of variability (CV) value was noted in breast girth with the value of 12.82%. This was followed by body length (12.44%) followed by shank length while the wing length had the lowest (9.86%) CV value.

Phenotypic correlation (Table 3) between body weight and body linear measurement were all positive, generally high and significant. Body weight vs shank length demonstrated the strongest (0.861^{**}) relationship. This was followed by body length vs shank length (0.685^{**}). Correlation between wing length and all other parameters were all very low and not significant.

Table 1: Effect of Sire on body weight and body linear measurements of Japanese quails

Breast girth (BG)	0.313**	0.279**	0.321**	0.011	1

DISCUSSION

The significant effect of sire on body weight and body linear measurements of Japanese quails as observed in this study strongly agree with the report of Adeogun and Adeoye (2004) and Oyetade *et al.* (2011). Values obtained for body weight and body measurements in this study were similar to the report of Adeogun and Adeoye (2004). The varying degree of variability reported in this study agrees with the report of Gambo *et al.*, (2013). The highest coefficient of variability (CV) value was noted in breast girth. This result is in centrally with the report of Adeogun and Adeoye (2004) who reported that, shank length has the highest value of coefficient of variation in Japanese quails. The generally significant, all positive and high correlation coefficient as observed in this study agrees with the findings of Abdel-Fattah *et al.* (2006) and Saatci *et al.* (2002). The mostly significant correlation obtain in this study is similar to the report of Tawefeuk (2001) and Ali *et al.* (2002). Similarly, the positive phenotypic correlation between body weight and shank length strongly agreed with the findings of Adeogun and Adeoye (2004) who reported that, phenotypic correlations of body weight and shank length are positive at all age from 1-6 weeks of age in Japanese quails. Also, the all positive and generally significant relationships between body weight and body linear parameters agree with Adeogun and Adeoye (2004) and Oyetade (2011) who reported all positively and mostly significant ($P<0.05$) relationship between body weight and all linear body measurement at various ages in Japanese quail. This all positive and mostly significant relationships between body weight and body linear parameters indicate that an improvement in body weight could lead to a concomitant improvement in the body linear measurements. Thus any selection programme aimed at improving body weight will lead to corresponding improvement in linear body measurements of the birds.

CONCLUSION

Sire had significant effects on shank length and breast girth. Sires 1, 4 and 6 had significantly higher shank length while sire 4 had significantly breast girth compared to other sire group. The highest coefficient of variability (CV) value was noted in breast girth followed by body length and shank length while the wing length had the lowest CV value. The phenotypic correlation between body weight and body linear measurement were all positive, generally high and significant. Body weight vs shank length demonstrated the strongest (0.861**) relationship. Correlation between wing length and all other body linear parameters were all very low and not significant. From the findings of this study, it was recommended that, selection of Japanese quails should be based on individual selection due to significant effect of sire on body linear parameters. The strongest correlation between body weight and shank length couple with high value of coefficient of variability indicated that shank length is the best linear parameters to be used for selection in Japanese quail.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Study on the effect of batch of hatch on hatch weight and weekly body weight of Fulani chicken ecotype was undertaken to investigate genetic diversity within the populations. A total of 55 chickens at maturity were purchased and used as the base population. The birds were mated at a ratio of 1 cock to 10 hens and eggs were collected for hatching. After successful four batches of hatching, 184 chicks were generated. The birds were raised according to their batches. Data were collected on hatch weight and body weights. The data collected were subjected to one-way analysis of variance using SPSS statistical software version 21. The results indicate that batch of hatch had significant ($P<0.05$) effect on hatch weight and weekly body weight. Batch 2 had significantly ($P<0.05$) higher hatch weight and body weights at weeks 1 and 2 respectively while at weeks 3, 5, 6 and 10 weeks, birds in batches 3 and 4 had significantly ($P<0.05$) higher body weights compared to those in batches 1 and 2. At weeks 4, 8, 9 and 12, birds in batch 4 had significantly ($P<0.05$) higher body weights compared to batches 1, 2 and 3 while at weeks 7 and 20, birds in batch 3 had significantly ($P<0.05$) higher body weight with values of 209.46±6.71g and 1093.09±34.75g respectively. From this study, it was recommended that the genetic diversity across batch of hatch observed in this study should be exploited through selection and subsequent crossing between birds from different batch of hatch to take advantage of heterosis.

Keyword: *Brooding, day-old-chicks, deep litter, hatching, incubation.*

INTRODUCTION
Genetic diversity is the product of interaction between environment and genetic effects. Quantifying the structure of genetic diversity in chicken populations is of significance in optimizing genetic improvement, conservation and utilization strategies. The unique values of the Fulani chickens' genes for egg and meat production, disease resistance, hardiness and adaptation to local environment would in future be needed to broaden the genetic resource base for breeding of improved commercial birds. Nigerian local chickens have been described based on phenotypic traits by several researchers (Mancha, 2004; Momoh *et al.*, 2007; Desha *et al.*, 2016; Gambo *et al.*, 2023). Such information if complemented with findings obtained using batch of hatch could be useful in formulating long term plans of breeding for genetic improvement programs. The objective of the study was to determine the effect of batch of hatch on growth performance of Fulani chicken ecotype of Nigeria.

MATERIALS AND METHODS
The experiment was carried out at the Livestock Teaching and Research Farm of the Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University, Keffi, Nasarawa State. Nasarawa State falls within the Southern Guinea Savannah Zone of Nigeria. Lafia lies between latitude 7^0 and 9^0 North and Longitude 7^0 and 10^0 East. It has a climate typical of the tropical zone because of its location. It has a temperature ranging from 20 ^{0}c in October to 36 ^{0}c in March while rainfall varies from 13.73 cm in some places to 14.00 cm in others. The area is characterized by farmers with backyard animal (chicken) rearing (Faculty weather Station, 2022).

Experimental Procedure
A total of 55 Fulani chicken ecotype comprising 50 hens and 5 cocks were purchases from Fulani settlement and used as the base population to generate the foundation birds. The birds were housed according for two weeks for

quarantining and acclimatization. The birds were randomly assigned into identified five breeding pens in the rearing house. A mating ratio of 1:10 (i.e. 1 cock to 10 hens) was used. The cock in each breeding pen was allowed to freely mate their respective hens. Fertile eggs for hatching were collected when the birds had laid for four weeks. This was aimed at obtaining higher fertility and hatchability. The birds were fed standard feed as recommended by Dafwang (2006). Feed and water were provided *ad-libitum.* Eggs were collected twice a day and accumulated for 5 days during which they were held in egg crates under room temperature with good ventilation. At the end of 5 days of egg collection, the eggs were transported to Phenab Agro Venture, beside fire service, Bukuru express way, Angul-D Jos for hatching. The eggs were set for hatching in an automatic electric incubator at weekly interval for four consecutive weeks (four batches). After successful four batches of hatching, a total 184 chicks were obtained from the base population. The birds were managed using standard procedure until maturity and data collected.

Parameters Measured

Hatch weight and weekly body weight: Live body weights were measured at hatch using sensitive electronic scale and then at weekly interval until 12 weeks of age. Thereafter, body weights were taken at week 16 and week 20.

Experimental Design Data Analysis

The design of the experiment was Completely Randomized Design (CRD). Data collected were analyzed using one-way Analysis of Variance (ANOVA) of the SPSS statistical software (2011) to test the effect of batch of hatch on hatch weight and weekly body weight. The following statistical model was entertained:

$Y_{ij} = \mu + E_i + e_{ij}$

Y_{ijk} = The j^{th} observation on the i^{th} batch of hatch

μ = Overall mean

E_i = Fixed effect of the i^{th} batch of hatch (j = 1, 2, 3 and 4)

e_{ij} = Random residual error ~ (0, 1)

RESULTS

Batch of hatch had significant (P<0.05) effect on hatch weight and weekly body weight of fulani local chickens except on body weight at week 16 which was not significant. Batch 2 had significantly (P<0.05) higher hatch weight and body weights (26.62±0.40 g, 38.80±0.74g and 48.00±1.28 g) at weeks 1 and 2 respectively. At 3, 5, 6 and 10 weeks, birds in batches 3 and 4 had significantly (P<0.05) higher body weights compared to those in batches 1 and 2. Batch 4 had significantly (P<0.05) higher body weights at weeks 4, 8, 9 and 12 compared to batches 1, 2 and 3. At weeks 7 and 20, birds in batch 3 had significantly (P<0.05) higher body weight with values of 209.46±6.71 g and 1093.09±34.75 g, respectively. Birds in batches 2, 3 and 4 had significantly (P>0.05) higher body weight compared to batch 1.

DISCUSION

The significant effect of batch of hatch on hatch weight and weekly body weight obtained in this study strongly agrees with the report Gambo *et al.,* (2023) who reported that batch of hatch had significant effect on growth parameters of Nigerian Tiv chicken ecotype. The results also agree with the report of Mancha (2004) and Momoh *et al.* (2007) who observed that, differences in live weight in local chicken could varies due to locations, batches, environment, crossbreeding and family level preference, isolation and selection. Also, this result agrees with the report of Desha *et al.* (2016) who reported that batch of hatch had significant effects on body weight of Bangladesh local chicken. The mean body weights across batches of hatch from weeks 1- 8 were lower than the values reported by Gwaza *et al.* (2015). The mean body weight obtained at hatch across batches in this study strongly corroborated with the value of 23±1.60 g reported by Adedokun and Sonaiya (2001) and fall within the range of 22.22g to 43.00g reported by Anang *et al.* (2001) for some local chicken in Nigeria. Momoh (2005) reported 24.27±0.05g and 30.23±0.06g for the Nigerian light and heavy chicken ecotypes. Halima (2007) reported a slightly higher value of 27.30 g as body weight at hatch. Woanski *et al.* (2006) reported that hatch weight is a function of egg weight (size) prior to incubation. These authors opined that, heavier eggs contain more nutrients than small or medium sized eggs and as a result, chicken from heavier eggs tend to have more yolk attachment at hatching. This is expected since there is strong correlation between egg weight and chick hatch weight (Ndofor-Foleng *et al*., 2015). At week 4, the mean body weight in all batches is far lesser than 92±2.10g, 104±14.50g and 157.16±0.45g reported by Momoh (2005) for Nigerian local chicken. However, at week 8, mean body weight obtained in this study across batches of hatch are similar to 262±4.8 and 289±2.2 g reported by Adedokun and Sonaiya (2001) but lower than 349.88±3.01 g reported by Momoh (2005) for Nigerian heavy chicken ecotype. These observed differences could be due to environment, season, management practice, strain and selection among others. The body weight at week 12 is far less than 589±4.4 and 605±67.5 reported by Adedokun and Sonaiya (2001). The body weight at week 16 acros batches is fairly similar to the value of 744±0.01 and 765±103.4 reported by Adedokun and Sonaiya (2001). Body weight at week 20 considered to be matured weights in all batches fall within the range of 980 to 1,420g and 870-1,900g reported by Essien and Joy (2003), respectively for Nigerian local chicken. Mancha (2004) observed 1.38±0.05 kg as matured body weight of local chickens in Jos, Plateau State. At maturity, live weight changes with natural processes, production status, management practices and seasonal changes. Mancha (2004) stated that under similar management and seasons, body weight difference could be due to variation in additive genetic variance. The author also opined that body size differences could occur between populations due to environment, cross breeding and development through progressively family-level selection especially when such populations are isolated. The result of effect of batch of hatch on hatch weight and subsequent weekly body weight demonstrated that weekly hatches in not more than three consecutive hatches can be taken as the same age group. This implies that in rural settings where large numbers of eggs can not be hatched at once due to small flock sizes, chicks from two to three consecutive hatches can be managed together to achieve uniform growth and development. Also, several batches of hatch have revealed several genetic characteristics within the birds which could be utilized for genetic improvement through selection.

CONCLUSION

Batch of hatch had significant (P<0.05) effect on weekly body weight, body weight gain and growth rate at day old and at subsequent weeks until maturity in Fulani ecotypes. However, birds in batch 1 had significantly (P<0.05) higher weekly body weight, body weight gain and growth rate at hatch, weeks 1, and 3 while birds in batches 3 and 4 had significantly (P<0.05) higher body weight from weeks 4-20. In the Tiv ecotype, batches 3 and 4 significantly (P<0.05) differed from batches 1 and 2 at weeks 2-3, 3-4 and 5-6.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The present study was conducted to assess the characteristics of Fulani chicken production in Nasarawa South agro-ecological zone of Nasarawa State. A total of 200 female Fulani ecotype chicken farmers (40 per LGA) were randomly sampled in Lafia, Doma, Obi, Keana and Awe. Well-structured questionnaires were administered on the farmers. The questionnaires contained information on the socio-economic characteristics of the respondents, breeding objectives and flock reproductive performance. The categorical variables were compared using Chi square (χ^2) statistics. Descriptive statistics were computed for the continuous variables. The result obtained indicated there were more of married women (95.0%) than single women (5.0%). Most of the farmers had secondary education (37.0%) while 62.0% of the women had no access to financial credit. The mean age of the farmers was 43.29 years while the mean household size was 8.54. The primary reasons why the women keep Fulani chickens were for income. 71.5 % of the respondent said they kept Fulani chickens for income. This was followed by the consumption of eggs (17.0%) and meat (11.5%). The mean clutch number was 5.57 while the number of eggs in a clutch was 11.08. The length (days) of natural incubation per clutch was 21.2 while the mean number of eggs that hatched in a clutch was 8.44. There is a need to boost Fulani chicken production in the study areas through modern breeding practices and interventions from the governments and other donor agencies.
Keywords: *Smallholder, chicken, performance, breeding, Nasarawa State*

INTRODUCTION

The main challenge of developing countries is to ensure food sufficiency and safety for the relatively poor population. These countries have therefore focused their development programmes of food safety and security on livestock production in general and short-cycle species in particular including the traditional poultry breeding systems. Although local chickens are generally less productive when compared to the exotic species, native chickens play an important role as a household food supply in the rural areas of Nigeria (Ogunshola et al., 2012; Yakubu & Ari, 2018; Terfa et al., 2019). They serve as a rapid means of bridging protein deficiency and providing an additional income to the generally resource-poor farmers, thereby helping to alleviate poverty.

The Fulani ecotype is native to the harsh parts of the country, and its purity has been preserved by the isolated family group lifestyle of the Fulani keepers, which hinders its interbreeding with other native chickens (Fayeye et al., 2005). However, they are of small size and lay lesser eggs compared to their exotic counterparts. There is therefore a need to improve these birds. Such improvement effort will be more imperative if it adopts the bottom-top approach while considering farmers' production objectives. This is central to the formulation of livestock breeding policies aimed at improving the livelihoods of smallholder chicken farmers (Yakubu et al., 2020), who raise their chickens mainly in scavenging and semi-intensive systems (Ngogo et al., 2023). In Nasarawa State, north central Nigeria, there is dearth of information on the traditional breeding practices and performance of Fulani ecotype chicken farmers. The objective of this study therefore was to assess the breeding practices and reproductive performance of Fulani ecotype chickens reared by female farmers in Nasarawa South agro-ecological zone of Nasarawa State.

MATERIALS AND METHODS

The study was conducted at Lafia, Doma, Obi, Keana and Awe Local Government Areas (LGAs) of Nasarawa State. The five LGAs fall within Nasarawa South agro-ecological zone of the State. Qualitative-quantitative research design (survey only) was applied in the study. A total of 200 female Fulani ecotype chicken farmers (40 per LGA) were randomly sampled in two villages of Lafia (Wakwa and Gimare), Doma (Dogon Kurmi and Alwaza), Obi (Daddare and Angwan atashi), Keana (Giza and Kadarko) and Awe (Azara and Ribi) local government areas. Well-structured questionnaires were administered on the farmers. The questionnaires contained information on the socio-economic characteristics of the respondents, breeding objectives and reproductive performance of the flock. Female Fulani ecotype chicken' farmers were asked separately to list the reasons why they are into the rearing of Fulani birds in order to assess their production objectives. The categorical variables were compared using Chi square (χ^2) statistics. Descriptive statistics were computed for the continuous variables. IBM-SPSS (2020) statistical package was employed in the analyses.

RESULTS

The socio-economic characteristics of the female farmers rearing Fulani chickens in Nasarawa South are presented in Table 1. There were more of married women (95.0%) than single women (5.0%). Most of the farmers had secondary education (37.0%) while 62.0% of the women had no access to financial credit. The mean age of the farmers was 43.29 years while the mean household size was 8.54.

Table 1. Socio-economic characteristics of the female farmers rearing Fulani chickens in Nasarawa South

Parameters	**Frequency/(%)**	**Chi-square**	**P-value**
Categorical variables			
Marital Status			
Single	10 (5.0)	162.00**	0.01
Married	190 (95.0)		
Educational level			
None	34 (17.0)	27.52**	0.01
Primary	62 (31.0)		
Secondary	74 (37.0)		
Tertiary	30 (15.0)		
Access to credit			
Yes	76 (38.0)	11.52**	0.01
No	124 (62.0)		
Quantitative variables			
Parameters	**Mean**	**Standard Deviation**	
Age (years)	43.29	7.41	
Household size	8.54	5.41	
Market experience (years)	19.75	10.62	

The primary reasons why the women keep Fulani chickens are presented in Table 2. Most of the respondents (71.5%) said they kept Fulani chickens for income. This was followed by the consumption of eggs (17.0%) and meat (11.5%).

Table 2. Reasons for keeping Fulani chickens

Parameters	**Frequency/(%)**	**Chi-square**	**P-value**
Meat	23 (11.5)	132.01**	0.01
Eggs	34 (17.0)		
Income	143 (71.5)		

The productivity indices of Fulani chickens in Nasarawa South are presented in Table 3. The mean clutch number was 5.57 while the number of eggs in a clutch was 11.08. The length (days) of broodiness per clutch was 21.2 while the mean number of eggs that hatched in a clutch was 8.44. The percentage hatchability therefore was 76.2%.

Table 3. Productivity characteristics of Fulani chickens in Nasarawa South

Parameters	Minimum	Maximum	Mean	Standard error
No of clutch of eggs laid in a year	2	7	5.57	0.11
No of eggs in a clutch	3	18	11.08	0.25
Length (days) of broodiness per clutch	19	23	21.21	0.08
No of eggs that hatched in a clutch	2	15	8.44	0.21

DISCUSSION

The characterization of chicken farmers is imperative in order to understand the production environment and performance of the birds. In the present study, the population of married women was more than single. The mean household size of 8.54 also appears high. This is an indication that there will be more hands to assist in the care of the birds. The level of understanding of farmers and the implementation of new technologies requires the analysis of the role of household members and gender in village chicken production (Mujyambere et al., 2022). On the average, the female farmers of this study appear to be literate. The implication of this is that they will be more disposed to adopting better management practices and innovations to boost production. Poor access to financial credit could hamper the production level of the farmers. The mean age (43.29 years) of the farmers implies that they are still very active. Income was found as the primary reason for keeping chicken in the study area. This is not surprising considering the importance of money in meeting the financial needs of the households. According to Alabi et al. (2007), family poultry husbandry has the potential to influence women income. The present findings are also consistent with the submissions of Yakubu et al. (2020) and Ogunwale et al. (2021). In terms of productivity indices, the average values observed for Fulani chickens with regard to mean clutch number, the number of eggs in a clutch, the length (days) of broodiness and the mean number of eggs that hatched appear to be within the limits expected of traditionally managed birds in Nigeria (Sola-Ojo et al., 2011). The hatchability rate of 76.2% obtained in the current study is close to the range of 78.6-85.8% reported by Mengesha et al. (2022) in Ethiopian indigenous chickens. Notwithstanding, the performance of the Fulani birds,they may be improved when crossed with other certified dual-purpose tropically adapted birds. The genetic superiority of improved tropically adapted birds over the locals has been reported in earlier studies (Ajayi et al., 2020; Akinsola et al., 2021). Also, crossbred chickens have been found to exhibit hybrid vigour in terms of egg production under free range and semi-intensive systems under tropical conditions (Ochora *et al.,* 2023).

CONCLUSION

In the present study, the population of married women was more than those that were single. The mean household size appears high while the female farmers were within the active growth age, which implies that there will be enough labour to assist in the care of the birds. A good number of the farmers were literate which could assist in better management decisions and adoption of innovative techniques to boost production. Majority of the farmers did not have access to financial credit. The primary reason for keeping the Fulani birds was to generate income. The average values observed as regards mean clutch number, the number of eggs in a clutch, the length (days) of broodiness and the mean number of eggs that hatched are pointers to the fact the rearing Fulani chickens could be profitable. However, future studies are advocated to evaluate performance when Fulani chickens are crossed with superior tropically adapted birds.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study on the analysis of profitability of broiler production was carried out in Jos North Local Government Area of Plateau State, Nigeria. The specific objectives were to: describe socio-economic characteristics and determine the costs and returns of broiler farmers in the study area. Primary data were collected from broiler farmers using structured questionnaire and the study was carried out between July and October 2022. A multi-stage sampling technique was employed to select 107 farmers from which input-output data were collected. Descriptive statistics and net farm income model were employed for data analysis. Descriptive statistics result revealed that about 60% of the respondents fall within the age range of 31 to 50 years with mean age of 39 years, majority of the farmers (90.7%) had formal education. Results also indicated that majority of the farmers (about 71%) had farming experience ranges from 11 to 20 years with mean of 15.83 years. Findings further revealed that the average rate of return on investment (return per naira invested) was ₦1.69 indicating that for every one naira invested in broiler production in the study area, a profit of ₦1.69 was made. It therefore implies that broiler production in the study area was economically viable.

Keywords: *Profitability, Broiler, Plateau State*

INTRODUCTION

Broilers are simply chicken raised for meat and it production is the process of rearing broiler birds for meat, a key measure of performance being the feed conversion ratio (FCR) (Ettah *et al.,* (2021). According to Mgbakor and Nzeadachie (2013) broiler production of the poultry enterprise has great potentials for increasing protein supply in Nigeria, because of their fast growth rates and prolificacy, which can be adapted under a wide range of marginal climatic conditions and can generally be combined conveniently with other farm enterprises and/or occupation, with mutual benefits to the farmer.

MATERIAL AND METHODS

Study Area

The study was carried out in Jos North Local Government Area of Plateau State. Jos North is one of the 17 Local Government Areas in Plateau State. The L. G. A. is situated in the tropical zone lying between latitude 9^0 5 and 11^0 15^1N of the equator and longitude 8^0 5 53' and 90 45^1E of the Greenwich meridian. It is bordered in the northeast by Toro L.G.A. in Bauchi State, the South by Fabur and Shere districts of Jos East L.G.A., on the south by Du and Gyel districts and west by Pengana Irigwe and Rukuba chiefdoms in Bassa L.G.A. of Plateau State, Nigeria (Bitti *et al*., 2020). It has total land area of about 291km^2 with a population of 429,300 National Population Commission (NPC), (2006), with a projected population of 643,200 as at 2022.

Sampling Procedure

A multistage sampling technique was used to select respondent for the study. In the first stage, Jos North Local Government Area was purposively selected due to the prevalence of poultry farmers in the area. Jos north has a total number of 22 villages, and10 villages was selected randomly from the 22 villages. The Final stage involved a proportional sampling of broiler farmers from the 10 villages selected. Sixty-one percent (61%) of the sample frame (176) was used as sample size. A total of 107 farmers were proportionally selected.

Table 1: Sample frame and sample size of broiler farmers in the study area

Villages	Sampling Frame (SF)	Sample size (61% of SF)
T/wada	11	7
Laranto	15	9
Babale	16	10
Naraguta B	17	10
Naraguta A	50	31
Jos Jarawa	10	6
Nassarawa	26	16
Rusau	13	8
Gwash	10	6
Zakaliyo	8	8
Total	176	107

Source: Field Survey: 2022

Data Collection and Analysis

Primary data were used for this study. These were collected with the aid of structured questionnaire, using interview method. The information was collected on farmers' socio-economic characteristics and inputs used like feed, medication, day-old-chicks, and labour. Information was also collected on the output from broiler production. The data were analyzed by means of descriptive statistics which involved the use of percentages and means and Net Farm Income (NFI). The formular for net farm income is stated as follows:

NFI = TR – TC

Where, NFI = net farm income (₦) per 200 birds

TR = total revenue (₦)

TC = total cost of production (₦)

TC = TVC + TFC

TVC = total variable cost

TFC = total fixed cost.

The fixed inputs are not normally used up in a production cycle. They were depreciated using the straight-line method given by:

$D = \frac{P-s}{N}$

Where:

D = Depreciation (₦)

P = purchase value (₦)

S = salvage value (₦)

N = life span of asset (years)

Return per naira invested (RNI) was obtained by dividing the total revenue (TR) over the total cost (TC).

Therefore, $RNI = \frac{TR}{TC}$

Where, RNI = return per naira investment

TR = total revenue

TC = total cost

Decision Rule:

RNI > 1, it implies there is profit in production.

RNI = 1, the farmer is at breakeven

RNI < 1, the farmer is at loss.

RESULTS AND DISCUSSION

Socioeconomic characteristics of poultry farmers

Summary statistics of the findings reported in Table 1 indicate mean age of 39 years for broiler farmers in the study area. This implies that majority of farmers were middle aged and there is likelihood of increased efficiency in broiler production. Also, farmers within the age category of 31-50 constituted most broiler farmers with about 60% indicating that broiler farming in the study area was dominated by an agile workforce that could handle the stress involve in broiler production to increase their efficiency. The findings agreed with Ogheneruemu and Dominic, (2020). Also, about 91% of the broiler farmers had one form of education or the other while about 10% had no formal education. Education could affect their chances of using improved breeds which can boost broiler output. About 71% of the farmers in the study area had farming experience of 11-20 years with mean of 15.83 years. Years of farming experience according to Oladimeji & Abdulsalam, (2013) is a factor that enhances agricultural productivity among farming households in Nigeria.

Table 2: socio-economic characteristics of the respondents

Variables	Frequency	Percentage
Age of broiler farmers (years)		
21-30	24	22.43
31-40	39	36.45
41-50	25	23.36
>50	19	17.75
Total	107	100
Mean = 39		
Educational level		
No formal education	10	9.35
Primary education	12	11.21
Secondary education	45	42.06
Tertiary education	40	37.38
Total	107	100
Farming experience (years)		
1-5	15	14.02
6-10	17	15.89
11-15	29	27.10
16-20	46	42.99
Total	107	100
Mean = 16		

Source: Field Survey, 2022

Average costs and Returns in Broiler Production

Results presented in table 3 shows that the total revenue realized from broiler production in one production season was ₦792,000.94. The result from total variable and fixed costs was ₦411,607.75 and ₦57,940.53 respectively. This implied that broiler business made a net farm income of ₦322,452.26. It therefore means that broiler farmers in the study area made profit. The return per naira invested was 1.69, indicating that for every ₦1 invested in broiler production, a profit of ₦1.69 was made. Thus, it could be concluded that broiler production in the study area was economically viable. This finding is the same with Ettah *et al*., (2021) who observed that broiler production is profitable by returning 1.67 to every ₦1.00 spent.

Table 3: Average Cost and Returns of Broiler Production Per Production Period of 8 weeks (Production Size of 200 Broilers)

Parameters	**Amount (₦)**	**% Contribution**
Fixed Cost		
Building or cage	49,420.33	10.53
Equipment	8,520.20	1.81
Total fixed cost (TFC)	**57,940.53**	
Variable cost		
Day old chicks	92,000.53	19.59
Feeds	280,000.22	59.63

Drugs/vaccines	22,100.11	4.71
Labour	14,316.23	3.05
Electricity/charcoal	2,240.41	0.48
Wood shaving	950.25	0.20
Total variable cost (TVC)	**411,607.75**	
Total cost (TC)	**469,548.28**	
Revenue		
Sales of broiler	780,000.71	
Manure	12,000.23	
Total revenue	792,000.94	
NFI (TR-TC)	322,452.26	
Return per naira invested (TR/TC)	**1.69**	**100**

RECOMMENDATIONS

The results from the study revealed that broiler production in the study area is profitable. Therefore, more youth should be advised to go into broiler production which will provide more job opportunities for the teeming population that are unemployed as well as bridge the gap of protein shortage in Nigeria.

CONCLUSION

Based on the findings of this study, it can be concluded that broiler production in the study area is profitable by returning ₦1.69k to every ₦1.00 invested. Given that broiler is an important source of protein in Plateau state, and Nigeria in general any attempt to increase its productivity would be a right step towards the resolution of food crisis and would also increase the country's Gross Domestic Product (GDP).

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study examined the purchasing behavior of rice consumers in Minna Metropolis of Niger state, Nigeria. Data were collected from 114 rice consumers across markets within the metropolis and this was done to understand the consumer preferences for rice variety for desired attributes. The study used descriptive statistics such as mean, frequency, percentages and Kendall coefficient of concordance. The result shows that a significant proportion 36.84% had their tertiary education and 10.14% had no formal education. A sizeable proportion of the respondents however had secondary and post-secondary education. It was also shown that larger proportions (78.95%) of the sampled heads of households were civil servants and this is not unconnected to the high educational attainment of majority of the household heads. The results of the study show that majority (55.3%) of the respondents consumed rice 2 to 4 times a week whiles 36.6% consumed rice every day and 8.1% of the respondents consumed rice at least once in a week. It also shows that (35%) of the respondents preferred combination of both imported and local rice, whiles 34.1% of the respondents preferred local and 30.9% preferred imported rice. A total of 68.4% of the respondents preferred to purchase rice from the open market, 26.3% (supermarket and 5.3% (shop/store). It was also shown that rice impurities (present of other materials) was the highest ranked constraint by consumers in the study area with the mean rank of 3.42 and followed by high cost of local rice with the mean of 3.90. Inferior taste and poor cohesion were ranked least constraints associated with local rice consumption in the study area with the mean rank of 6.04 and 6.84 respectively. It was concluded that private sector should invest in modern processing facilities for local rice as this would place the commodity in a better position when compared with imported rice. Therefore, it is recommended that knowing what is important about attributes affecting retail outlet selection, marketers should ensure that they meet their customers' expectations concerning those features, and help them gain a competitive advantage.

Keywords: *Assessment, Purchasing Behavior, Rice consumers Niger state and Nigeria*

INTRODUCTION

Rice is an important food crop and major normal food for up to half of the world's population (Dauda *et al*. 2019). It is also the staple food in most African countries, providing dietary energy to the rapid increasing population (Dauda *et al*. 2019). In Africa, rice provides 715 kcal, 27% of nutritional supply of energy, 20% of nutritional protein and 3% of nutritional fat (Dauda *et al*. 2019). Rice occupied fifth major source of energy in diet for mankind, providing 9% of caloric usage (FAO, 2012). Rice is a source of raw material for industries and offers job opportunity for the growing Nigerian population of different forms, from the onset of rice cultivation,

processing, wholesales and sales to final consumers (Marlia *et al*. 2011). Local rice is all rice, regardless of improved or unimproved varieties that are produced within Nigeria.
Consumers often express their preferences for product quality by paying a premium for the product with the desired characteristics. These premiums give producers an incentive to improve product quality and quantity consequently enhancing the welfare of the consumer and the producer. Consumers face tradeoffs in their purchasing decisions since income is limiting and choices are numerous (Lawal *et al,* 2016). The objectives of the study were to describe the socio-economic characteristics of rice consumers; describe purchasing behavior of consumers and describe the constraints associated with the consumption of local rice.

METHODOLOGY

Study Area

The study was undertaken in Minna Metropolis of Niger State, Nigeria. Niger State is located between Latitudes 80 22/N and 110 30/N and Longitudes 30 30/ E and 70 20/ E. The State is bordered by Zamfara and Kebbi States in the North and North-west respectively, currently, the State covers a total land area of 74.244 sq.km, which is about 8% of Nigeria's total land area. This makes the State the largest in the Country (www.nigerstate.gov.ng). The population of the State is about 3,950,249, comprising 2,082,725 males and 1,867,524 females (National Population Commission (NPC, 2006). The projected population of the State as at 2016 was 5,556,200 (United Nations Population Fund (UNFPA), 2016).

Sampling Procedure

A multi-stage sampling technique was used. The first stage was purposive selection of Niger state from North-central zones of Northern Nigeria, and the selection was based on the high concentration and intensity of rice production, processing and marketing within the State. The second stage was purposive selection of three different retail market outlets within the metropolis, selected markets were Kure ultra-model market, Gwari market and Gwadabe market.
In the third stage, based on the reconnaissance survey conducted from all the markets, a total number of 127 rice retailers were identified across the three markets within the metropolis and 40% of the retailers from each market were randomly selected. Estimated average daily number of consumers per retailer was given out by the respective retailers from which 20% were randomly selected. The random selection was systematic so as the researcher selected each 3rd consumer met at retail outlet until reaching the total desired sample size of 114 across the markets within the metropolis.

Method of Data Collection

Primary data was used for the study. The data was collected using a well-structured questionnaire administered to the respondents by the researcher through multi stage sampling techniques. Information on the socio-economic characteristics of the consumers such as age, gender, marital status, farm size, level of education, average income per month, purchasing behavior of consumers and the constraints associated with the consumption of local rice in the study area were collected.

Analytical Techniques

The analytical tools used were descriptive statistics such as mean, frequency, percentages and Kendall coefficient of concordance

RESULTS AND DISCUSSION

Socioeconomic Characteristic of Consumers in the Study Area

The descriptive statistics of socio-economic characteristics such as age, household size, monthly income, gender, marital status, educational level and occupation of household head as shown in Table 1

Table 1: Distribution of rice consumers according to their socio-economic variables (Quantitative)

Variable	Frequency	Percentages (%)
Age		
25-32	6	5.3
33-40	46	40.4
41-48	46	40.4
49- 56	16	14
57-64	-	
Minimum	25	
Maximum	58	

Mean	42	
Standard Deviation	7	
Household size		
1-3	26	22.8
4-7	76	66.7
8-11	9	7.9
12-15	3	2.6
16-19	-	
Minimum	2	
Maximum	18	
Mean	6	
Standard Deviation	3	
Monthly Income (₦)		
15,000-55,000	1	9
56,000-97,000	14	12.3
98,000139,000	37	32.5
140,000-181,000	20	17.5
182,000 -250,000	42	36.8
Minimum	15,000	
Maximum	250,000	
Mean	77,059	
Standard Deviation	42,113	

Source: Field Study, 2022.

Results from table 1 shows the average age of the respondents indicates 42 years with minimum of 25 years and maximum of 58years, which means that most of the respondents ware within the working age group and they are likely to have some disposable income for household expenditure. This indicates that they are young and within the middle age range, capable of making their own decisions on the rice brands they consume. The results of the study revealed that the mean household size as indicated in table 1 was 6 persons per household with the minimum household member of 2 and the maximum household members of 18 persons. Income dictates to a large extent the consumers choice of goods. A rational consumer will make a right choice of superior and high-quality goods as income increases. The result also shows that average monthly household income was estimated to be ₦77, 059 with the minimum ₦15, 000 and maximum of ₦250,000.

Table 2: Distribution of rice consumers according to their socio-economic variables (Qualitative)

Variable	Frequency	Percentages (%)
Gender

Trading	8	7.02
Civil servant	90	78.95
Artisan	11	9.65
Total	114	100

Source: Field Study, 2022

The result in Table 2 shows that the sampled consumers in the study areas are largely male headed households with 89.47% while 10.53% are female. This finding corroborates the finding of Erhabor and Ojogho (2011), who also found out in a similar study that rice consuming households are largely male headed with 89.3% of the household heads being males. Gender of household head could influence food consumption pattern of households and this was shown by Agbola (2003), who noted that gender was one of the socioeconomic characteristics that was significant in influencing grains, dairy products and vegetables demand in a study on estimation of food demand pattern in South Africa. The distribution of consumers based on marital status as indicated in the table shows that 97.37% ware married, 1.75% ware single and 0.88% ware widow. The level of education of household head has a serious implication for the types and quality of food consumed by the household. The result shows that a significant proportion (36.84%) had their tertiary education and 10.14% had no formal education. A sizeable proportion of the respondents however had secondary and post-secondary education. Educational status of household heads could influence rice demand as well as the preference for imported or local rice types. As noted by Chiwuzulum *et al*.(2010), rice demand was significantly influenced by educational level of households heads on household food demand. The mean years of schooling of the household heads was reported to be 13 years and this is higher than the national mean years of schooling of 5 years for Nigeria (UNDP, 2012).
It was also shown that larger proportion (78.95%) of the sampled heads of households were civil servants and this is not unconnected to the high educational attainment of majority of the household heads. This result suggests that there is a greater tendency for the households to rely on purchasing rice for household consumption rather than own production. This finding is in line with that of Kassali *et al*. (2010), who reported that majority (55 %) of the household heads were civil servants in a study of demand for rice in Osun state.

Purchasing behavior of rice consumers in the study area

Table 3 shows the purchasing behavior of rice consumers in the study area. he results show that majority (55.3%) of the respondents consumed rice 2 to 4 times in a week whiles 36.6% consumed rice every day and 8.1% of the respondents consumed rice at least once in a week. It also shows that 35% of the respondents preferred combination of both imported and local rice, whiles 34.1% of the respondents preferred local and 30.9% preferred imported rice. In a similar study Diako *et al.*, (2010) reported that consumers who patronize domestic rice do so out of preference, perceived good nutritional qualities and relatively low price. A total of 68.4% of the respondents preferred to purchase rice from the open market, (26.3%) supermarket and shop/store (5.3%).

Table 3: Purchasing behavior of rice consumers in the study Area

Variable	Frequency (114)	Percent (%)
Frequency of eating rice		
Once a week	5	4.4
2-4 times a week	63	55.3
Everyday	46	40.4
Type of rice		
Imported rice	8	7.0
Local rice	76	66.7
Both import& local rice	30	26.3
Type of markets		
Open market	78	68.4
Super market	30	26.3
Shop or stores	6	5.3
Total	**114**	**100**

Constraints Associated with *Low Consumption of Local Rice in Minna Metropolis*

*T*he results of *K*endall's *W* are presented in *t*able 4, *where* value of *W* (0.166) was highly significant at 1% significance level, and implies a high level of agreement among the respondents in ranking the constraints associated with local rice consumption in the area.

Results shows that rice impurities (present of other materials) was the highest ranked constraint by consumers in the study area with the mean rank of 3.42 followed by high cost of local rice with the mean of 3.90. Inferior taste and poor cohesion were ranked least constraints associated with local rice consumption in the study area with the mean rank of 6.04 and 6.84 respectively .

Table 4: Constraints associated with local rice consumption in Minna

Constraints associated with local rice consumption	Mean score	Rank
Impurities	3.42	1st
High cost of local rice	3.90	2nd
Poor aroma	4.08	3rd
Less available	4.87	4th
Low swelling capacity	4.89	5th
Broken grains	5.00	6th
Poor packaging	5.96	7th
Inferior taste	6.04	8th
Poor cohesion	6.84	9th

N=114, Kendall's W=0.166, Chi-Square=151.730, Sig. <0.001

CONCLUSION AND RECOMMENDATIONS

The objectives of the study were to describe the socio-economic characteristics of rice consumers; describe purchasing behavior of consumers and describe the constraints associated with the consumption of local rice". The study therefore, recommends that efforts should be made by the government to formulate price control policy on local rice for its affordability by the consumers. Also, farmers should be encouraged to produce more local rice through the provision of incentives and credit facilities for its availability of all year round to the consumers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The experiment was conducted to evaluate blood parameters and economics of production of broiler chickens fed local white sorghum (farfara) as a replacement for white maize. A total of two hundred and forty day old chicks were used for this study. Five diets for both starter and finisher phase were formulated and were designated as D1, D2, D3, D4 and D5 in which local white sorghum (farfara) replaced white maize at 0%, 25%, 50%, 75% and 100% respectively. Each diet was replicated four (4) times with 12 birds per replicate in a completely randomized design. Feed and water were supplied ad libitum and the experiment lasted for 7 weeks. The result revealed no significant difference in all the parameters measured. It was concluded that local white sorghum (farfara) can replace white maize in broiler chicken diets without adverse effect on performance, blood parameter and economics of production.
Keywords: *Blood Parameters, Replacement, White Sorghum, Economics of Production, Broiler*

INTRODUCTION
Traditionally, maize is used as an energy source in poultry feeds (Rajaesh, 2021). The major challenge in poultry feed production is the shortage of energy feedstuff (maize). It is therefore essential to identify alternative energy feedstuff for profitable and sustainable poultry production. There are various sources of energy in poultry diets in the tropics but maize has remained the chief energy source in compounded diet and constitutes about 50% of poultry ration (Ragab, 2001 and Ajaj *et al.,* 2005). The use of sorghum for human consumption is relatively low compared to maize and is a good alternative source of energy in livestock feeding (Olomu, 2011). According to Atteh *et al.* (1993) such alternatives should have comparative nutritive value but cheaper than maize. They should also be available in large quantities. According to Gebeyew *et al.* (2015), it is important to assess the feeding and replacement value of sorghum for maize as alternative cheap and easily available feedstuffs in broiler ration. Sorghum has a similar energy value to maize therefore sorghum can be used as an energy source in broiler feed (Hidayat *et al.,* 2022). This research was conducted to evaluate blood parameters and economics of production of broiler chickens fed local white sorghum (f*arfar*a) as a replacement for white maize.

MATERIALS AND METHODS
Study Area
The experiment was conducted at the Poultry Units of Teaching and Research Farm of Animal Production Department in Abubakar Tafawa Balewa University Bauchi, Bauchi State. The research began on 15th May, 2022 and ended on 7th July, 2022. Bauchi lies between longitude 10 $^{0}10^{1}$to 30^{1}N and latitude 9041 and 10^{0} 31^{1}E at an altitude of 6902 meters above sea level (BSADP, 1994).

Sources of Experimental Ingredients
White maize, white sorghum, soybean meal and other feed ingredients such as premix, fish meal, lysine, methionine, limestone were purchased from local market in Bauchi metropolis, Bauchi local Government Area - Bauchi State.

Experimental Birds and their Management
A total of 240 unsexed day-old broiler chicks were used for the study. Prior to the arrival of the chicks the brooding room was thoroughly cleaned and disinfected. The floor of the poultry pen was well insulated with a thick layer

of wood shavings and papers were laid to prevent the broiler chicks from swallowing particles of the wood shavings and blinded by dust. On arrival, the broiler chicks were immediately taken into the brooding room which was heated with charcoal to provide warmth for brooding. They were immediately served water containing glucose as anti – stress. Feeds and clean water were supplied *ad libitum*. The chicks were brooded and fed commercial broiler starter for a period of one week. At the end of one week of brooding, the birds were weighed and randomly allotted to five diets which were formulated and designated as diets 1, 2, 3, 4, and 5. Diet 1 was the control (0 % white sorghum), while diets 2, 3, 4 and 5 contain white sorghum as replacement for white maize at 25, 50, 70 and 100% level of inclusion respectively. The formulated diets contained 23% and 20% crude protein in starter and finisher phases respectively. The fixed ingredients included fish meal, bone meal, salt, premix, lysine, methionine, wheat offal and soybean meal (Tables 1 and 2). Each treatment was replicated four times with 12 birds per replicate in a completely randomized design . Feed and water were served *ad libitum*.
All necessary routine management practices such as vaccinations were adhered to throughout the study period. The experiment lasted for a period of 56days (7day brooding, 28days starter and 21 days finisher). Vaccination routine was carried out at 2nd week (Lasota 1st dose), 3rd week (Gumboro) and 5th week (Lasota 2nd dose).

Table 1: Composition of Experimental Diets at Starter phase (2- 5 weeks)

Ingredients	D1 (0%)	D2 (25%)	D3 (50%)	D4 (75%)	D5 (100%)

Blood Sample Collection for Biochemical and Haematological Parameter

Samples were taken from two birds per replicate through the wing vein with the aid of needle and syringe. Blood sample for haematological parameters were collected into tubes containing EDTA (Ethylenediaminetetraacetic acid) as anti-coagulant. Blood samples for biochemical measurements were collected into sterilized EDTA – free sample bottles to allow the blood to clot for serum separation.

Economic Analysis

The economy of broiler chicken production fed experimental diets was calculated based on the price of the ingredients as at the time of the experiment. The total feed intake (kg) per bird during the 7 weeks of the experimental period was determined by multiplying the overall daily feed intake by number of days the experiment lasted and divided by 1000.

$$\text{Total feed intake} = \frac{DFI_O \times 49 \text{ days}}{1000}$$

Where DFIo is daily feed intake overall; The costs of feeding one bird per treatment for 7 weeks were determined by multiplying the price of each ingredient with the quantity (kg) of that ingredient for the different experimental diets and divided by 25kg. The total weight gain (kg) was determined by multiplying the overall daily weight gain by the number of days the experiment lasted.

$$\text{Total weight gain} = \frac{DWGo \times 49day}{1000}$$

Where DWGo is daily weight gain overall. The total feed cost (₦) was determined by total feed intake (kg) multiply by feed cost (₦). The feed cost per kg weight gain (₦) was determined by dividing total feed cost (₦) with total weight gain (kg).

RESULTS AND DISCUSSION

Serum Biochemical and Haematology Parameters of Broiler Chickens Fed Different levels of White Sorghum (*farfara*) as Replacement for White Maize

Serum biochemistry and haematology of broiler chickens fed graded levels white sorghum (*farfara*) as replacement for white maize. The results of this study elucidated that there was no significant differences (P>0.05) among all the haematological parameters and serum biochemistry (Tables 3 and 4).

Table 3: Serum biochemical parameters of broiler chickens fed graded levels of white sorghum (*farfara*) as a replacement for white maize.

The serum biochemistry indices observed included total protein which ranged from 6.63-7.18g/dl, these values were higher than 2.00– 3.5 g/dL reported by Banerjee (2018) and Medugu *et al.* (2010) obtained a higher (16.00-34.00g/dL) total protein value. Albumin ranged from 3.16-3.40g/dL to 4.30-5.83mmol/L. The value of albumin from this study was lower (4.30-5.83mmol/L.) than what was reported by Medegu *et al*. (2010) and Lakurbe *et al*. (2020). The non-significant in the values of total protein and albumin elucidates the adequacy of protein in the experimental diets and were efficiently utilized by the birds. It also elucidates that the birds were of good health condition because total protein and albumin are used to measure the biosynthetic function of the liver as it is the primary site for the synthesis of plasma proteins (Hoferberge and Block 1996). Packed cell volume (PCV) ranged from 29.83-33.15%. These values were higher than 20.00-31.67% reported by Medugu *et al*. (2010) but lower than 32.15 – 39.88% as reported by Lakurbe *et al.* (2020). The PCV gotten from this study were within the normal range of 25.00-45.00% as reported by Opoola *et al*. (2013) indicating that the birds were nourished, not anaemic and absence of toxic in white sorghum. Haemoglobin values ranged from 9.93 -10.78g/dl. These values were higher than 4.07-6.83g/dL reported by Medugu *et al*. (2010) comparable with 10.20- 10.90g/dL as reported by Lakurbe *et al.* (2020). Haemoglobin values obtained from this study are within the normal range of 7.00 – 13g/dL for Haemoglobin concentration in broiler chickens as reported by Opoola *et al.* (2013) indicating no obvious detrimental effect of white sorghum on broiler chickens. The values of haemoglobin obtained in this study were similar to 9.90-11.50g/dL obtained by Onabanjo *et al*. (2021). Mean corpuscular volume (MCV) ranged from 141.32-148-98fl. This values are higher than 97.13-119.20fl reported by Medugu *et al.* (2010) but comparable with 148.55-159.75fl obtained by Lakurbe *et al.*(2020). Mean corpuscular haemoglobin concentration (MCHC) values ranged from 40.08-137.05. Lakurbe *et al.* (2020) obtained a higher value of 29.70-31.75g/dl. A high MCHC above the normal range may be an indication of a type of anaemia-Autoimmune haemolytic anaemia which may be due to medications. Dehydration may result in high MCHC (Lynne 2022) since birds were starved of feed and water before slaughter. MCH values ranged from 63.73-67.78pg. This values were higher than 18.06-22.76pg reported by Medugu *et al.* (2010) and 46.25- 48.30pg as reported by Lakurbe *et al.* (2020).

The Economic of Production of Broiler Chickens fed Diet Containing Different Levels of Local White Sorghum as replacement for White Maize is shown in table 5 below

Table 5 presents the economics of production of broiler chickens fed white sorghum (*Farfara*) as replacement for white maize. The study revealed that the total feed intake ranged from 3.84 g - 4.22g. The highest cost per kg feed (₦319.68) was in diet 3 and the lowest in diet 5 (₦305.61). Total feed cost (₦) was highest in diet 5 (₦1289.66). This contradicts the report of Ibitoye *et al.* (2012); Etuka *et al.* (2012); Adamu *et al.* (2013); Aladeen *et al*. (2013) reported a significant reduction of cost of production when sorghum completely replaced maize in broiler chicken diets. The total weight gain (1.36kg) was highest in diet 2 and lowest (1.28kg) in diet 4. Feed cost per weight (kg) gain was lowest (₦923.38) in diet 1 and highest (₦969.67) in diet 5. This result agreed with findings of Ibe *et al.* (2013) who reported that broiler chickens fed 100% replacement of maize with white sorghum had the highest cost of feed per kg weight gain. This can be attributed to the nutrient contents of grain especially energy. Yasin (2022) stated that the major energy source used in poultry feed formulation is maize (Yasin, 2022). According to the report, sorghum contains nutritive value similar to those of maize. According to Olomu (1995) the metabolisable energy and crude protein of sorghum are 3270kcal/kg and 95% respectively is comparable with 3319kcal/kg and 10.1% of crude protein respectively of maize. Yasin (2022) reported that energy level of the feed was the major factor influencing feed intake as birds will eat to satisfy their energy needs. This explains the highest feed intake, total feed cost and feed cost per kilogram weight gain recorded in diet 5.

Table 5: Economic of production of broiler chickens fed white sorghum (*Farfara*) as replacement for white maize (2-7weeks).

Parameters	Diets				
	1	2	3	4	5
Total feed intake (kg)	3.98	4.08	3.84	3.89	4.22
Feed cost (₦/kg)	310.89	309.78	319.68	306.97	305.61
Total feed (₦)	1237.34	1263.90	1227.57	1194.11	1289.66
Total weight gain (kg)	1.34	1.36	1.27	1.28	1.33
Feed cost per kg gain (₦)	923.38	929.34	951.60	932.90	969.67

CONCLUSION

Based on the results, it can be concluded that white sorghum can replace white maize up to 75% without adverse effect on performance of broiler chickens. White sorghum may not have adverse effect on blood of broiler chickens. Diet 4 (75% level of replacement) had the lowest total feed cost and therefore can be considered profitable in terms of cost benefit.

RECOMMENDATIONS

It could therefore be recommended that white sorghum (*farfara*) may be included up to 75% level to replace white maize in the diets of broiler chickens. Poultry farmers should be encouraged to explore many techniques used in reducing or removing the tannin content in sorghum. Diet 2 could be recommended for raising broiler chickens.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study aimed to screen and determine the presence of oxytetracycline (OTC) residue in edible tissues of cattle and pigs slaughtered in Kaduna metropolis, Northwest, Nigeria. Microbial inhibition test and high-performance liquid chromatography analysis were used to screen and quantify, the residues of oxytetracycline in liver, kidney and muscle tissues. The results showed that of the samples collected for cattle (150) and pigs (150), 60 (40%) and 40 (26.66%) tested positive for antimicrobial residue in cattle and pigs, respectively, with various levels of zone of inhibition. Out of the positive samples in cattle, 45 (75%) had oxytetracycline residue in excess of acceptable regulating levels with the highest concentration found in the kidney tissue. The study also revealed that 15 (37.55%) of the positive samples had OTC residues in pigs with more occurring in the liver, kidney, and muscle. The mean concentrations of OTC hydrochloride residue across cattle sample tissues were above maximum residue limits of 0.2 µg/g, 0.6 µg/g, and 1.2 µg/g for meat, liver and kidney, respectively, whereas for pigs, the mean concentrations of OTC residue were lower than set residue limits. The obtained OTC levels for pork were relatively safe when compared to that of edible beef tissues. There is an urgent need for stricter regulations and monitoring of antimicrobial drugs usage in the livestock industry to ensure safety of meat products for human consumption.
Keywords: *Oxytetracycline residue, meat, cattle, pigs, Kaduna metropolis*

INTRODUCTION
The use of antibiotics for the treatment of clinically sick animals, disease prevention and promotion of growth is on the increase due to the intensification of farming practices in the developing countries including Nigeria (Adesokan *et al.*, 2013). Oxytetracycline (OTC), a broad spectrum and bacteriostatic antibiotic is widely used to treat gram positive (*Streptococcus* spp.; *staphylococcus* spp.) and gram negative (*Escherichia coli*) bacteria, ricketsiae (*Anaplasma*, *Cowdria*, and *Ehrlichia*s pp.), chlamydiae (*Psittacosis*, *Trachoma*, *lymphogranuloma venereum*) and some protozoa (*Theileria* and *Babesia* spp.) diseases in animals (Aliu *et al.*, 2007; Nonga *et al.*, 2009). The long acting oxytetracycline (LOTC), because of its convenience of administration, wide antibacterial activity and the challenges of accurate bacterial diagnosis under field practice, are widely used to treat a wide range of disease, often indiscriminately. A single injection of LOTC can keep high concentrations in plasma above minimum inhibitory concentration for several days thereby decreasing the number of administrations per treatment (Aliu, 2007). As a result of ready availability of the product at informal markets and lack of restrictions on usage being imposed, OTC has been used indiscriminately by laymen and non-professionals alike in the treatment of various kinds of diseases. Thus, OTC has become a source of concern for residue monitoring authorities around the world.

Consuming meat with high levels of OTC residues could lead to gastrointestinal disturbances, hypersensitivity, bone and teeth problems in children and the development of bacterial resistance (Olatoye and Ehinmowo, 2010). This is because improper dosage of OTC especially at sub therapeutic levels can result in acute or chronic public health problems that could be toxicological, microbiological or immunological (Josiah *et al*., 2018). There is a dearth of data on the levels of OTC residues in cattle and pig carcasses slaughtered within Kaduna metropolis, hence this study. The information from the study can inform regulatory authorities and guide decision making on some edible livestock products.

MATERIALS AND METHODS

This study was conducted to screen for antimicrobial residues and evaluate the levels of OTC residues present in slaughtered cattle carcasses from Kakuri, Kawo and Tudunwada abattoirs and pig carcasses from Barakallahu, Kurminmashi, Narayi and Ungwan Television slaughter slabs, in Kaduna rural and urban metropolis. Kaduna is situated in the Northern guinea savannah zone between latitudes 11^0 and 12^0N and longitudes 7^0 and 8^0E at an elevation of 650 m above sea level. The average annual maximum and minimum temperature are between 31.0±3.2 and 18.0±3.7^{0}C . The average annual rainfall is 1100 mm lasting from May to October with a mean relative humidity of 72%. The dry season lasts from November to April with mean daily temperature ranging from 15^0C - 36^0C and mean relative humidity 20% - 37% (Rekwot *et al*., 1998).

Study design and sample collection

Animals were selected randomly across the abattoirs and slaughter slabs within Kaduna metropolis. Three samples (muscles, liver and kidney) of 100-200 g each were obtained from 10 -15 cows and pigs yielding a total of 30-45 tissue samples each per collection. To increase randomization, samples were collected weekly over a period of five weeks yielding 150 samples each for cattle and pig carcasses. Each collected sample (100 – 200 g) was packaged in a zip-lock polythene bags and stored under ice in a cooler box prior to transportation to the laboratory. The samples were stored in Deep freezer at - 4^0C for approximately a week before analysis.

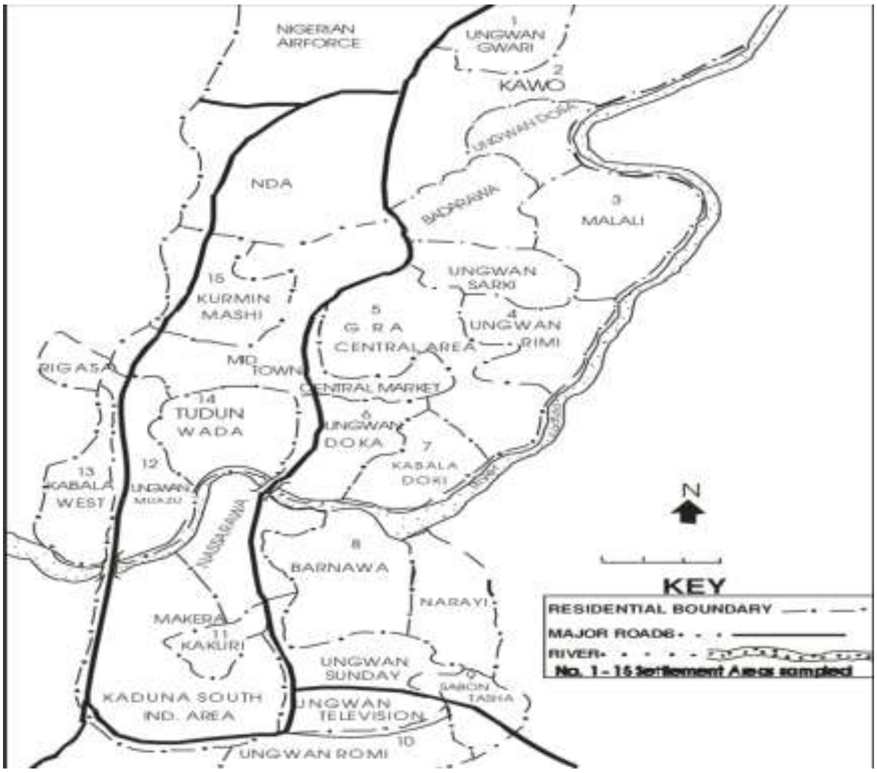

Figure 1. Map showing the location of the study sites (abattoirs/slaughter slabs) within Kaduna metropolis

Sample analysis

Samples were prepared and analyzed at the Department of Public Health Laboratory, Faculty of Veterinary Medicine, Ahmadu Bello University, Zaria. A validated analytical method was used in sample processing and analysis. Samples were removed from the freezer to attain room temperature 19-25^0. An adapted microbial inhibition test was used to screen samples for evidence of antimicrobial drug residue as described by (Ezenduka and Ugwunba, 2012). The presence of antimicrobial agents in each of the samples was confirmed by a complete zone of inhibition of microbial growth in an annular zone not less than 2 mm around the samples. Less than 2 mm inhibitory zone indicate negative result.

Oxytetracycline residue analysis of sample

High performance liquid chromatography (HPLC) standard methods were used for antibiotic residue analysis. The OTC concentrations were determined according to a previously described technique (Kimera *et al*., 2015).

Data Analysis

The data were analysed using graph pad prisim® version 8 for windows, Graphpad software, San Diego, California, USA, www.graphpad.com. Descriptive statistics were used to compute means, standard error of mean and a range. A P-value of less than 0.5 was considered statistically significant. Analysis of variance was used to compare differences in means of continuous variables

RESULTS

A total of 300 samples of edible tissues (kidney, liver and meat) comprising cattle (150) and pig (150) were screened for antimicrobial residues. Out of this number 60 (40%) and 40 (26.67%) tested positive to antimicrobial residues for cattle and pigs, respectively, with various zones of inhibition, while 90 (60%) and 110 (73.33%) tested negative for cattle and pigs, respectively. The mean concentration of oxytetracycline residues in cattle across all tissues was 2,902.5µg/kg ±380.5µg/kg. For the respective tissues types the concentrations were 2,105.6±201.8 µg/kg for muscle, 2,924.5±105.6 µg/kg for livers and 3,012.8±305.1 µg/kg for kidney tissues. Oxytetracycline concentrations were highest in the kidney tissues while lower concentrations of oxytetracycline were found in samples from Kawo abattoir. For pigs, the highest concentration of OTC residue was 470.5µg/kg found in the liver, while the mean concentrations across tissues were 109±7.05 µg/kg, 304± 0.85 µg/kg and 270 ±1.09 µg/kg for muscle, liver and kidney, respectively. The obtained levels in pig samples may not induce adverse effects for consumers. Cattle meat was more likely to be positive for antibiotic residue than pig meat.

Table 1: Proportion of Muscle, Liver and Kidney Samples of Cattle and Pigs for Kaduna Metropolis that contained Antimicrobial Residues

Animal spp	Location (Abattoirs)	Positive Samples (% Positive)	Muscle (% Positive)	Liver (% Positive)	Kidney (% Positive)
Cattle	Kakuri (n = 45)	23 (51.1%)	7/15 (46.67)	8/15 (53.3%)	8/15 (53.3%)
	Kawo (n = 45)	14 (31.11)	3/15 (20.0)	6/15 (40.0)	5/15 (33.3)
	T/Wada (n = 60)	23 (38.33)	7/20 (35.0)	6/20 (50.0)	10/20 (30.0)
Total	150	60	17	20	23
Pigs	Barkallahu (n = 30)	6(20%)	2/10 (20.0)	2/10 (20)	2/10 (20.0)
	KurmiMashi (n=45)	12 (26.7)	3/15 (20.0)	5/15 (33.3)	4/15 (26.7)
	Narayi (n=30)	8 (26.7)	2/10 (20.0)	3/10 (30.0)	3/10 (30.0)
	U/Television (n=45)	14 (31.1)	4/15 (26.7)	5/15 (33.3)	5/15 (33.3)
Total		40	11	15	14

DISCUSSION

Oxytetracycline (OTC) is one of the most commonly used over the counter antibiotics by livestock keepers in African countries, including Nigeria, for the treatment of diseases and other extra label uses (Olatoye and Ehinmowo, 2010). The presence of their residues or metabolites in animal products could have adverse effect on consumer's health. The results of this study indicate the presence of OTC residues in 40% and 26.7% of cattle and pigs samples respectively, with a notable number of samples in cattle and only two samples of pigs being above the acceptable maximum residue of 0.2 µg/g, 0.6 µg/g, and 1.2 µg/g recommended for meat, liver and kidney, respectively (WHO/FAO, 2002). The occurrences of antimicrobial residues in meat, liver and kidney have been reported by several authors (Kabirungi *et al.*, 2022; Mohammed *et al.*, 2022; Adam *et al.*, 2020). However, the OTC levels in this study were lower than that reported in previous studies (Adam *et al.*, 2020; Olufemi and Agboola, 2009; Ezeduka and Ugwumba, 2012) although comparable with 46% in beef reported by Akinwumi *et al.*, 2012 or 41.2% reported by Mmbado, 2004 from Tanzania. The differences in the OTC levels recorded in our study and previous studies could be due to differences in sample size and analytical techniques used for the detection and qualification of OTC residues (Kambirungi *et al.*, 2022). Other factors could be due to differences in climatic factors, age and breed of the cattle slaughtered and the local regulation of antibiotic applications among farmers in different countries (Mohammed *et al.*, 2022).

The relatively low prevalence of antimicrobial residue in this study could probably be due to low doses of antimicrobial usage by livestock traders in order to maximize the number of dosage available (Adesokan *et al.*, 2013). Nomadic herdsmen have been reported to administer chemotherapeutic agents without veterinary prescription, and most likely at incorrect dosage (Olatoye and Ehinmowo, 2010). The prolonged antimicrobial usage at low doses in food animals, could pose a significant risk factor for the development of antimicrobial resistance among bacterial pathogens (Blake *et al.*, 2003; Varga *et al.*, 2009). On comparing the OTC levels in cattle and pigs slaughtered within Kaduna metropolis, this study found out that cattle meat was more likely to be positive for antibiotic residue than pig meat. This has exposed a potentially serious threat for consumers of bovine meat product in Kaduna metropolis.

CONCLUSION

This study indicated that the overall OTC residues positive for cattle samples was 40% distributed as 20%, 44.44% and 35.56% for Kawo, Tudun wada and Kakuri abattoirs respectively. Out of the positive samples, 45/60 (75%)

had OTC in concentration above the recommended maximum residue limits (MRLS). The levels of OTC residues in the cattle tissues followed the order Kidney, liver and muscle. These high concentrations present public and veterinary health threats. Only two samples had concentration above MRLS in pig and mean concentrations were below the acceptable FAO/WHO MRL recommendation. Thus, cattle meats are more likely to contain antimicrobial residues than edible pig products. The enforcement of regulations on indiscriminate use of antibiotics and adherence to withdrawal period of drugs would mitigate antimicrobial resistance threat to public and veterinary health.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Because of the world's rising population, global food security is under threat. As a result, feeding the world's population and ending hunger by 2030 will necessitate deliberate activities such as weed-pasture domestication. This study was conducted to preliminarily assess the preferences for weed pasture grasses for de novo domestication in the southern agricultural zone of Nasarawa State, Nigeria. A multi-stage sampling technique was used to select 45 herders across three Local Government Areas (LGAs) in the zone. The results indicate that urbanization (95.6%) is the major reason for feed scarcity. Majority of the respondents (80%) perceived that displacement of pastures with noxious weeds is one of the reasons for feed scarcity. Moving animals to pre-urban areas (97.8%), exploitation of lowland areas (77.8%), moving cattle to the southern region (73.3%), ranching (68.9%), and exploitation of fresh pastures (64.4%) were the key tactics recognized by herders to cope with feed scarcity. The most preferred grasses were Guinea grass (Panicum maximum), Kyasuwa (P. pedicellatum), and Gamba grass (Andropogon gayanus) because of nutritional content, palatability, and palatability of the grasses.
Keywords: *Denovo, pasture grasses, preference, domestication, herders*

INTRODUCTION
Global food security is under strain due to the world's growing population (Ahmad *et al.,* 2021). Furthermore, increased competition for land, farmer-herder conflicts, as well as climate change and concomitant environmental degradation, are all threatening livestock productivity. According to United Nation's estimate, the global population and food consumption would both increase to 8.5 billion people and 11.6 billion tons by 2030. If current trends continue, the number of hungry people might reach 840 million by 2030 (Ahmad *et al.,* 2021). To avoid this, the United Nations adopted "Zero Hunger" as the second Sustainable Development Goal (SDG2). However, Agriculture's present production is inadequate; feeding the world's population and attaining zero hunger by 2030 will need purposeful actions such as weed-pasture domestication (de novo domestication inclusive) for improved animal production. According to Fernie and Yan (2019) putting wild weed-pasture species under human control might help ease many of these burdens.

Most crop and plant species we have today became popular due to domestication from their wild ancestors during the last 12,000 years (Fernie and Yan, 2019). Ewing (2017) argued that fundamental goal of weed-pasture domestication is to identify species that can fulfil a position in the farming system that is now unfilled by another species. The underlying issue when considering a new venture is: can a modification to the present agricultural system with the addition of a new pasture specie make the system more lucrative; and what important features would the plant require to thrive in that role? Only in the last 50–60 years has science begun to get an understanding of the vast number of plant species that support humanity (Hammer and Khoshbakht, 2014). Globally, the production of livestock is heavily reliant on pasture. Grasses and forage species provide significant value to dairy, beef, wool, lamb, and other products through pasture production (Mitchell *et al.,* 2013). Forage and fodder crops provide forage and fodder to around 97 percent of Nigeria's ruminant livestock (Garba *et al.,* 2020). Feed supplies (including weeds and pasture) vary greatly and are distributed across the country's major agro-ecological zones. There is about 32.42 million hectares of grazing lands in Nigeria (Shiawoya *et al.*, 2011). Unfortunately, extensive areas of the grazing lands are composed of indigenous species, which are of low in yield and quality. Furthermore, forage for cattle grazing is scarce in some parts of the nation during certain times of the year, leading in nomadism and, as a result, farmer-herder clashes.

Because northern Nigeria has a single rainy season, cattle producing operations need a high level of movement in pursuit of fresh pastures in the country's moister areas, particularly during the dry season. These cattle migratory patterns from the arid Sahel and Sudan zones to the wetter Guinea and Rainforest zones include incursions onto farmer crops, which frequently lead to violence. Due to difficulties of land availability and access, there is increasing conflict between nomadic pastoralists and established farmers in most West African nations, especially Nigeria (Usman and Nichol, 2022). This has resulted in an increase in clashes between pastoralists and farmers in most parts of the Nigeria, frequently ending in numerous deaths (Orji, 2021; Nwangwu *et al.*, 2020, Onah *et al.*, 2020, Odoh and Chilaka, 2012). Between 2000 and 2016, about 8000 people died in Nigeria because of pastoral-farmer violence (Institute for Economics and Peace, 2021). Hence, the need to develop or adopt strategies, or technologies that will assist species to cope with and even overcome most of the factors which militate against high availability and productivity of pasture (Shaiwoye *et al.*, 2011), across all ecological zones, always.The objectives of the study are to: identify the causes of feed scarcity and strategies for curtailing feed scarcity; and to assess preference for pasture grasses and the reasons for the preference.

MATERIALS AND METHODS

The preliminary survey was carried out 2022 across the Southern Agricultural zone of Nasarawa state. The field experiments for *De novo* domestication of the most preferred grasses is currently ongoing at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University Keffi, Nasarawa State Nigeria (latitude 08°33N and longitude 08°32E, msl). A multi-stage sampling approach was used to perform a survey on weed-pasture species in the Southern Agricultural Zone of Nasarawa State. Three (3) Local Government Areas (LGAs) were chosen at random in the first stage. The second stage was a purposive selection of three communities. The selection of communities was based on the areas noted for high grazing activities. This was followed by a random sampling of five (5) herders in each community selected making a total of forty-five (45) herders. For quick identification of weed pasture species, Akobundu and Agyakwa's Handbook of West African Weeds, published in 1998, was used. The data collected was subjected to descriptive statistics such as means, frequencies and percentages using Statistical Package for Social Sciences (SPSS) Version 21.

RESULTS AND DISCUSSION

Causes of Feed Scarcity

The general perception of herders on the possible reasons for feed scarcity is presented in Figure 1: The results indicate that urbanization (95.6) is the major reason for feed scarcity. Majority of the respondents (80%) perceived that displacement of pastures with noxious weeds is one of the reasons for feed scarcity. Other possible causes include walking duration, extinction of pasture species, climate change, and herbicides application with 73.3%, 55.6%, 26.7%, and 2.2% respectively. This agrees with Aremu (2022) who posits that climate change and competition between humans and livestock causes feed scarcity. Similarly, Abdulrahman *et al.* (2022) established that erratic rainfall due to climate change, and hoarding of feed increases the cost of feed which by implication leads to feed scarcity.

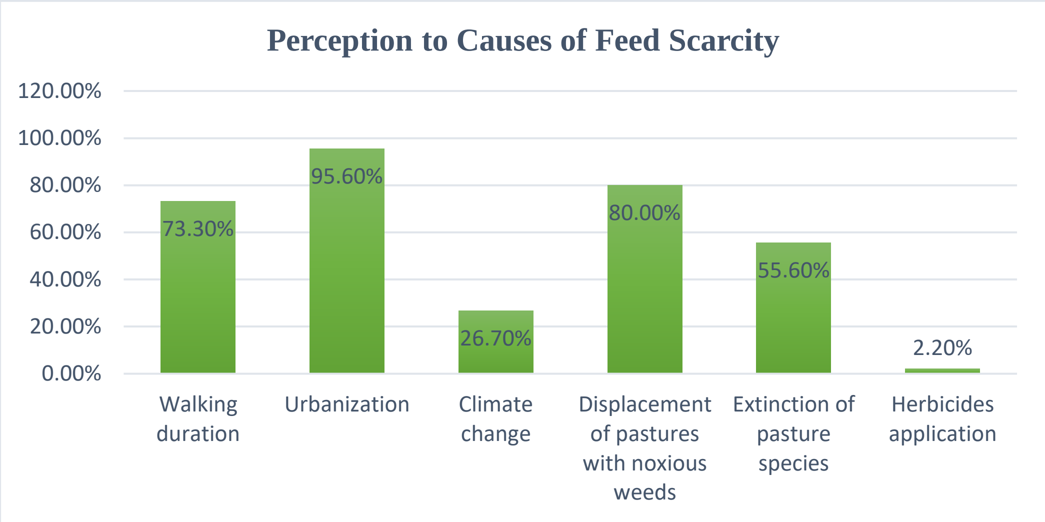

Figure 1: Herders' perception to causes of feed scarcity
Source: Field Survey 2022

Strategies to Curtail Feed Scarcity

Figure 2 depicts herders' perceived techniques for reducing feed scarcity. Moving animals to pre-urban areas (97.8%), exploitation of lowland areas (77.8%), moving cattle to the southern region (73.3%), ranching (68.9%), and exploitation of fresh pastures (64.4%) were the key tactics recognized by herders to cope with feed scarcity. Other techniques include herd division, land ownership, and the use of a semi-intensive cattle production approach. According to Abdulrahman *et al.* (2022) the best coping strategy to feed scarcity especially as a result of high cost feed is the use of alternative feed sources based on availability.

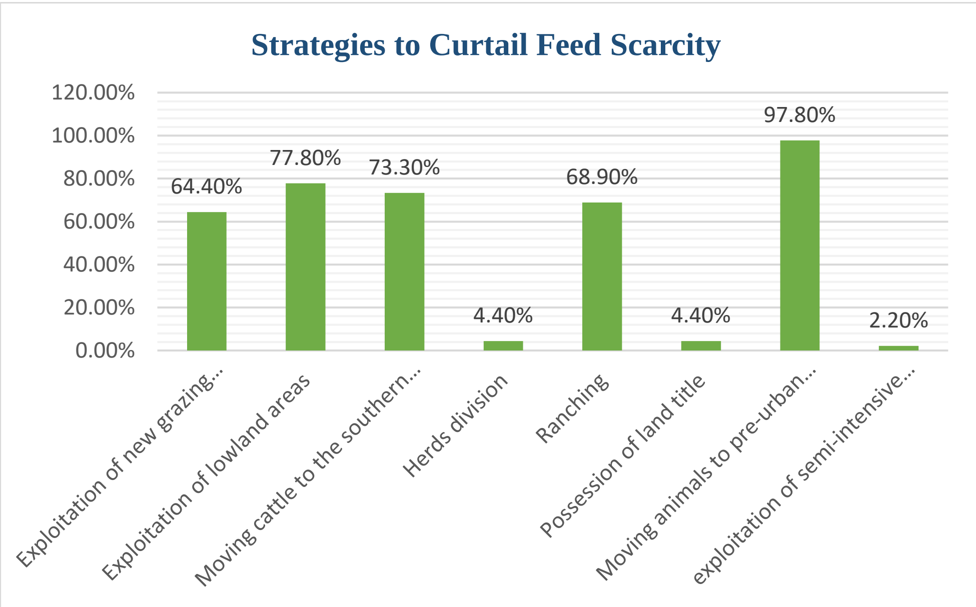

Figure 2: Herders' perception on strategies to curtail feed scarcity
Source: Field survey 2022

Pasture Grass Preference

Table 1 presents the common grasses preferred by cattle as reported by the herders. It was found that the most preferred grasses were Guinea grass (*Panicum maximum*), Kyasuwa (*P. pedicellatum*), and Gamba grass (*Andropogon gayanus*) with 86.7%, 75.6%, and 73.3% respectively. According to Ekwe *et al* (2020), grasses, legumes, and trees are the most preferred forage species while the least preferred forage is *Leucana leucocephala*. Goats show higher preference for grasses especially *Andropogon gayanus, Andropogon tectorum, and Panicum maximum* (Ekwe *et al.*, 2020).

Table 1: Preferences for Pasture Grasses

Grass	Frequency	Percentage
Gamba (*Andropogon gayanus*)	33	73.3
Southern Gamba *(Tectorum)*	5	11.1
Carpet (*Axonopus compressus*)	2	4.4
Imperial (*A. scoparius*)	6	13.3
Signal (*Bracharia documbens*)	5	11.1
Para (*B. mutica*)	6	13.3
Palisade (*B. brizantha*)	4	8.9
Rugu, Congo (*B. ruziziensis*)	18	40.0
Buffel (*Cenchrus ciliaris*)	1	2.2
Rhodes (*Chloris gayana*)	19	42.2
Pangola (*Digitaria documbens*)	2	4.4
Guinea (*Panicum maximum*)	39	86.7
Kyasuwa (*P. pedicellatum*)	34	75.6
Spear (*Imperata cylindrica*)	4	8.9
	178*	

Source: Field survey 2022 ***Multiple responses were allowed**

Reasons for Grass Preference

The common reasons for grass preference reported by the respondents are presented in figure 3. According to the findings, all the respondents (100%) agreed that grasses are preferred because of nutritional content and palatability. Majority of the respondents (88.9%) also agreed that preference for grasses is due to their availability. Only few (8.9%) attributed the reason for preference to cost of grasses. This quite agrees with the findings of Ekwe *et al* (2020) who revealed that accessibility and palatability are important determinants of preference and/or choice of forage species.

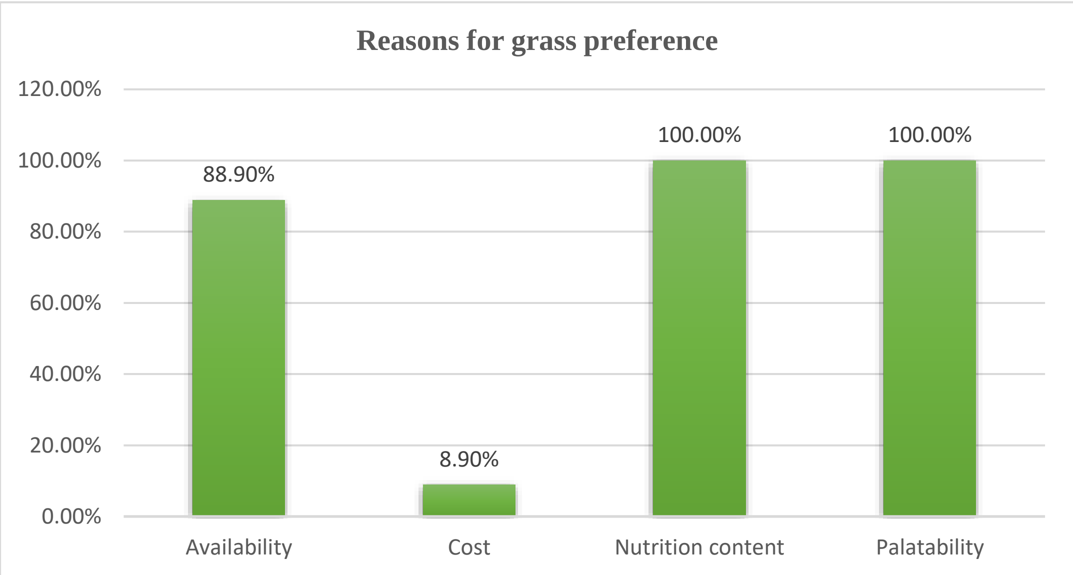

Figure 3: Perceived reasons for grass preference.
Source: Field survey 2022

CONCLUSION

Feed scarcity is caused by urbanization, the substitution of meadows with noxious weeds, and the length of time spent walking. transferring animals to pre-urban areas, utilizing lowland areas, transferring cattle to the southern region, ranching, and utilizing fresh pastures are keyways for dealing with feed scarcity. Guinea grass (*Panicum maximum*), Kyasuwa (*P. pedicellatum*), and Gamba grass (*Andropogon gayanus*) are the most favoured grasses among herders in Nasarawa state due to nutritional content, palatability, and availability.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The effects of probiotics Artichoke (Cynara scolymus) on performance of cockerels fed SWAPSI-based meal diets were studied using 144 day old cockerels in a 3×2 factorial arrangement .The diet is T1 0% probiotics 0% garlic, T2; 0% probiotics 0.05% garlic, T3; 0.05% probiotic A 0%garlic ,T4; 0.05% probiotic A 0.05% garlic, T5; 0.05% probiotic A 0 garlic%,T6; 0.05%probiotic B 0% garlic. Feed and water were provided ad libitum. Parameters measured were final body weight, total weight gain, average daily weight gain, average feed intake, weight gain, feed conversion ratio performance index, protein intake, protein efficiency ratio, energy intake, energy efficiency ratio and survival group fed probiotic A, the results showed significant depression (P<0.05) in the final body weight, average total weight gain, average final weight and performance index compared to the control.

INTRODUCTION
In the face of increased demand for poultry products use of alternative feed stuff as supplementary feed to replace grains and seeds as sources of proteins and energy such as sugar cane waste products (Alu *et al*., 2018). Earlier use of antibiotics in diets of monogastrics (Frost, 1991) as growth promoters became essential worldwide, however, the possibility of developing resistant population of bacteria strain of bacteria including *Salmonella spp,* has residual effects such as allergy in farm animals and humans. These led to the European Union stoppage on their usage as feed additives (Ari *et al*., 2012). Therefore, an intense search for replacements such as probiotics, phytogenics and other feed additives has taken place in the last decade (Ari *et al*., 2012). Agro-byproducts such as sugarcane peels gotten after the processing of sugar from sugarcane are believed to contain high amount of nutrients yet, are often left unutilized and are discarded as unwanted. One of such unwanted products is the solid waste productof sugar industry (SWAPSI) encompassing of the scrapping, peels and baggase of sugar cane. It is alleged to be of nutritional value in terms of energy and other nutrients. The objective of this research was to determine the effects of probiotics on the performance of cockerels fed SWAPSI meal- based diets.

MATERIALS AND METHODS
Experimental Site
The experiment was conducted at the College of Agriculture, Science and Technology Livestock complex Doma Road Tudun-Amba, Lafia, Nasarawa State

Sources and preparation of ingredients
The solid waste product of sugar industry (SWAPSI) were sourced from Dangote sugar processing industry in Numan LGA of Adamawa State, sun-dried for 2 - 3 days. Thereafter, it was ground to produce SWAPSI meal. Other ingredients such as, probiotics were purchased from Global Feed Resources Limited, Abuja. A total of 144 day-old cockerel chicks were obtained from Agric International Technology and Trade (Agrited) hatcheries. The birds were reared in deep litter house partitioned using wire mash. Heat and light were provided throughout the brooding phase using electric bulb. Routine vaccinations (Gomboro and Lasota) were administered and all other routine medications and management practices were adhered to as recommended by Ari *et al.* (2012). Feed were given after weighing and fresh water was provided *ad libitum*. The experiment lasted for a period of 112 days.

Performance response

Performance of grower cockerels feed SWAPSI based-meal diets (table 2) shows that the average final body weight, average total weight, average daily weight gain and performance index were significantly reduced (p< 0.05), in contrast with Karimi *et al.* (2020) who reported no significant differences (p> 0.05) in body weight when birds were fed aqueous extract of *Cynara scolymus*. Tajodini *et al.* (2015) also observed lower body weight as compared to the control. On the effect of probiotic Artichoke (*Cynara scolymus)* on FCR, there was an improvement on the birds during 21-35 days of experiment as reported by Karimi *et al.* (2020).

CONCLUSION AND RECOMMENDATION

The objective of this research was to determine the effect of probiotics Artichoke (*Cynara scolymus)* on performance of cockerels. From the results cockerels fed probiotics Artichoke (*Cynara scolymus*) supplemented diets showed reduced body weight but increased FCR. Therefore it is recommended to cockerels to efficiently convert feed to weight gain.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The experiment was conducted to study the antioxidant effect of taurine on serum biochemistry of mixed sex West Africa Dwarf (WAD) sheep fed taurine supplemented diet. Thirty-two WAD sheep with an average weight of 12kg were used in a completely randomized design involving four dietary treatments (T1, T2, T3 and T4) containing 0, 0.5, 1 and 1.5% levels of inclusion of taurine respectively. Blood sample was collected from each animal and were investigated to determine total protein (TP), albumin, globulin, glucose, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) cholesterol and triglycerides. The TP value was highest in sheep fed T4 (9.00g/dl) which was statistically similar ($p<0.05$) to sheep fed T3 (8.89g/dl) and diet T2 (8.75g/dl) while sheep fed T1 had the least value7.89g/dl Albumin values ranged from 4.31g/dl (T1) to 4.88g/dl (T3). Globulin values varied from 5.18g/dl (T1) to 6.81g/dl (T3). The total glucose recorded varied from 46.25mg/dl (T4) to 62.11(T1). The transaminase enzymes activities (ALT, AST and ALP) were significantly affected by the dietary treatments, there were significant differences ($P<0.05$) in the concentration of cholesterol and triglycerides. There was an extensive variation in the serum biochemical values for sheep fed the control compared to other sheep fed the supplemented diets. It was therefore concluded that taurine may be an anti-oxidant with immense quality which could be incorporated into the diets of sheep for optimal performance.
Keywords: *Antioxidant, Taurine, Serum biochemistry, West African Dwarf, Sheep*

INTRODUCTION
Livestock reared in the tropical region are highly vulnerable to the impact of climate variability and extremity (Mondal and Reddy, 2017). Habeeb *et al*. (2018) reported that small ruminants have a faster breeding or shorter generation interval (about 5 months) and reaching maturity faster than cattle. However, they are susceptible to extreme environmental conditions which lead to stress, characterized with discomfort and subsequently at the extreme to death (Mondal and Reddy, 2017). Antioxidant supplementation provides valuable effects against oxidative stress. Taurine (2-amino-ethanesulfonic acid, $C_2H_7NO_3S$) is a conditional beta-amino acid (De Bertozo *et al*., 2016) involved in a numerous physiological processes like bile acid conjugation, osmo-regulation, neuronal excitability, inflammatory reactions, glucose metabolism, membrane stabilization, lipid metabolism and modification of cholesterol, modulation of cellular calcium flux and regulation of immunity and detoxification (Afsal *et al*., 2018). Haematological and serum biochemical values have been considered useful for the assessment of body condition, nutritional and immune status in animal where other tissue related measurements are not available (Njidda *et al*., 2014).

MATERIALS AND METHODS
Experimental Site
The experiment was carried out at the Small Ruminant Unit of Kogi State Ministry of Agriculture, Kabba located within the Southern Guinea Savannah Zone on latitude $7^{0}5'$N, longitude $6^{0}4'$E and altitude of 640m above sea level. It has an annual rainfall of 1,500mm and rain starts between late April and early May to October. The dry season begins around the middle of November, with cool weather that ends in February. This is followed by relatively hot-dry weather between March and April just before the rain begins. The minimum daily temperature

is from 14^{o}C - 20^{o}C during the cool season while the maximum daily temperature is from 19^{0}C- 40^{0}C during the hot season. The mean relative humidity during dry and wet seasons is 21% and 72%, respectively (Cite).

Experimental Diets

Diets were formulated with graded levels of supplemental taurine at 0, 0.5, 1.0 and 1.5 respectively (Table1) to meet the nutrients requirement of sheep. They were fed at 3% of their body weight. Drinking water was provided daily *ad libitum*.

Table 1: Experimental Diets

Ingredients	Levels of inclusion (%)
Maize offal	78.0
Soya bean cake	6.5
Groundnut cake	8.6
Oil	5.0
Limestone	1.5
Salt	0.4
Metabolizable Energy (Kcal/kg)	2800

Experimental Design and Management of Animals

A total of thirty-two West Africa Dwarf sheep of both sexes were purchased from the open market within Kabba and used for this experiment with an average body weight of 12kg. On arrival, they were given prophylactic treatment and quarantined for two weeks during which they were treated against ecto-parasite using Diasentol and dewormed with Albendazole (2.5% oral suspension) per kg body weight. Experimental diets were fed immediately after acclimatization and were divided into four treatment groups with four replicates in a completely randomized design.

Serum Biochemical Evaluations

Blood samples (2 ml) was collected from the jugular vein from four sheep per treatment at the end of the trial using 2.0 ml syringe into anti-coagulant free plastic tubes, it was allowed to coagulate at room temperature and centrifuged at 3,000 rpm for 5 min. The supernatant serum was stored in a freezer for subsequent biochemical analysis. The serum biochemical parameters that were analyzed included total protein, albumin, globulin glucose, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP). The total protein was determined using Biuret method (Tietz, 1995), while albumin level was determined by the Bromocresol green method (Toro, 1975). The ALT and AST activities were determined according to the methods of (Rej and Hoder, 1983). The ALP activity was determined by the method of (McComb *et al*., 1983). The biochemical analyses were carried out at Veterinary Teaching Hospital, Ahmadu Bello University, Zaria, Kaduna state.

Statistical Analyses

All data obtained were statistically analyzed using the analysis of variance while the significant differences in means were separated using pair wise-difference procedure of SAS (2002)

RESULTS AND DISCUSSION

The effect of taurine on mean serum biochemistry values of WAD sheep investigated in this study is shown in table 2. All the serum biochemistry constituents showed significant differences ($P< 0.05$). The TP value was highest in sheep fed T4 (9.00g/dl) which was statistically similar ($P<0.05$) to sheep fed T3 (8.89g/dl) and diet T2 (8.75g/dl) while sheep fed T1 had the least value (7.89g/dl). This result is similar to the findings of (Zeweil *et al*., 2011) who reported an increase in total protein when taurine was fed to broilers birds. Significant differences ($P < 0.05$) also existed among the means of albumin and globulin. Albumin values ranged from 4.31g/dl (T1) to 4.88g/dl (T3). Globulin values varied from 5.18g/dl (T1) to 6.81g/dl (T3).

Table 2: Effect of Taurine on Serum Biochemistry Values of WAD Sheep

Parameters	T1	T2	T3	T4	SEM
Glucose (mg/dl)	62.11^a	57.84^c	49.63	46.25	0.05
Total protein g/dl	8.11^b	8.75^a	8.89^a	9.00^a	0.13
Albumin (g/dl)	4.31^b	4.41^b	4.88^a	4.47^b	0.15
Globulin (g/dl)	5.68^c	5.83^b	6.81^a	6.31^a	0.22
Aspartate aminotransferase (U/L)	88.53^a	84.51^b	75.25^c	70.88^d	1.13
Alanine aminotransferase (U/L)	33.58^a	29.07^b	24.95^c	24.21^c	0.47
Alkaline phosphatase (U/L)	124.17^a	116.83^b	109.57^c	109.19^s	1.18
Cholesterol (mg/dl)	73.27^a	64.75^b	48.36^c	45.67^d	1.09
Triglycerides (mg/dl)	28.13^a	23.65^b	19.31^c	17.81^c	0.65

The glucose value was significantly affected (P< 0.05) by the dietary treatments. The total glucose recorded varied from 46.25mg/dl (T4) to 62.11mg/dl (T1). However, the glucose concentration decreases with increasing supplementation. This finding is in agreement with Thorstensen *et al.* (2012) who reported a decrease in glucose level of mouse administered with taurine supplemented diet. Taurine control glucose levels improved insulin action. The transaminase enzymes activities (ALT, AST and ALP) were significantly affected (P< 0.\05) by the dietary treatments. values decrease as the inclusion levels of taurine increases in the diet. The decreasing in these enzymes may suggest that there is no liver damage but rather a slowdown of the function of the liver as influenced by the taurine supplementation.

There were significant differences (P< 0.05) in the concentration of cholesterol and triglycerides respectively concentration decreases as the levels of supplementation increases (73.29mg/dl, - 45.67mg/dl and 28.13mg/dl – 17.81mg/dl) respectively. This observation corroborates the findings of (Zeweil *et al*., 2011) who reported that inclusion of dietary taurine decreases plasma total cholesterol and triglycerides on its administration to mice.

CONCLUSION AND RECOMMENDATION

There was an extensive variation in the serum biochemical values for sheep fed the control diet compared to other sheep fed the supplemented diet. The variation can be attributed to the taurine supplemented in the diets. Taurine is an anti- oxidant with immense quality. This study clearly indicates that taurine supplementation has important role in blood constituent of sheep and therefore, can be incorporated in the diet of sheep.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Climate change is a global phenomenon that plays a pivotal role in poultry agriculture. It affects both the broiler chicken and layers in their meat and egg productions respectively. The study was carried out in Kumbotso Local Government Area of Kano State to investigate how poultry farmers perceive climate change. The study also described the socio-economic characteristics of poultry farmers in the study area. A multistage sampling procedure was used to select 120 respondents for the study. Structured questionnaire was used to elicit information from the respondents. Data collected were analyzed using descriptive statistics and Likert scale. The results showed that majority (75.0%) of the respondents were males; mostly were 21-30 years of age (52.5%) and 66.7% had tertiary education. Most of the farmers were married (71.1%). Based on ranking most of the poultry farmers perceived that climate change leads to food shortage for their animals and causes drought; they also perceived that climate change leads to poor performance of animals as well as could cause death of the animals. The study concluded that majority of the farmers were aware that climate change has negative effects on poultry production and understand that the Government is not doing much on mitigation strategies in favour of poultry farmers. Therefore, it was recommended that Government should formulate policies to help farmers mitigate the impact of climate change on their farms. Sensitization on mitigation strategies should be carried out and the awareness should be sustained by extension workers in Kumbotso.
Keywords: *Climate Change, Disease, Management, Perception, Poultry Agriculture*

INTRODUCTION
The need for animal protein is always rising, with meat consumption expected to rise by 76% globally between 2015 and 2050 (WRAP Food Futures, 2015). Livestock farming is a fundamental activity for maintaining the current society. By 2050, the world's population is expected to reach 9.1 billion people. As a result, agricultural activities must grow accordingly in order to sustainably meet this growing food demand (Elverfeldt *et al.*, 2 010). Ruminant livestock, such as cattle, sheep, and goats, are essential for global food security and play a crucial role in agricultural economies worldwide (Beauchemin *et al.*, 2020). Non-ruminant Livestock such as poultry also plays a significant role in agricultural economy. However, one major environmental challenge associated with livestock production is the significant production of potent greenhouse gas (GHG) that contributes to climate change (Knapp *et al.*, 2014). GHG concentrations in the world have increased rapidly since pre-industrial times due to human activities, with negative effects on the climate (Intergovernmental Panel on Climate Change, 2013). Methane emissions from ruminants account for a significant proportion of global GHG emissions, making it crucial to address this issue to reduce the environmental impact of livestock agriculture (Beauchemin *et al*., 2020). Climate change is an indefinite continuous variation in the mean of climate parameters (temperature, rainfall, humidity and soil moisture) due to change in decomposition of atmospheric gases. Krishna (2011) stated that the change in atmospheric composition is attributed to the emission of GHG such as carbon dioxide (CO_2), Methane (NH_4), Nitrogen oxide (N_2O) and other gases. Climate variation is a shift in the average weather that a given area experiences. It occurs over a period of time which may range from several decades to centuries. It has been observed across the globe that there has always been a change in the climate of an area for a period of 30-100 years manifesting in earthquakes, flooding, tsunami, tornadoes, fluctuations in rainfall and temperature.

Intergovernmental panel on climate change (2013) made it certain that climate variation is taking place. Climate change is a global issue because it does not affect the poor and developing countries alone but is also facing the developed world with flooding, earthquakes, cyclones, tornadoes and wild fires. It is clear that climate variation in many parts of the world adversely affect socioeconomic sectors which include water resources, agriculture, forestry, fisheries and animal husbandry. It is a phenomenon that will continue to occur; mitigating it is the only way out. Agriculture is responsible for 14% of global GHG emissions and livestock variation plays a considerable role in climate variation in terms of their contribution to GHG emissions (Steinfeld *et al.,* 2006; Krishna, 2011). The greatest effects of climate variation have however been predicted to be in animal production in sub-Saharan African which include Nigeria (Adesoji and Famuyiwa, 2010). Livestock accounts for 40% of agricultural gross domestic product (GDP) and employs 1.3 billion of people while supporting the live hoods of one billion of the worlds' poor (food and agricultural organization, 2007). Poultry production is a major source of protein which has empowered poultry farmers to secure a means of survival and livelihood. Climate variation affects poultry production by reducing poultry yield and nutritional quality of feeds, increasing disease and disease-spreading pests, reducing water availability and making it difficult for birds to survive (Spore, 2008).
There is the need for the farmer to have understanding of climate change. A farmer having adequate knowledge of climate change and good perception of the effects on his/her poultry production can allow the farmer to take necessary precaution in planning ahead to minimize loss or even to use it for his or her advantage. Many findings had been done on climate change but there is little empirical evidence on the perception of farmers on the effects of climate change on poultry production, hence this study focused on investigating the perceptions of farmers on the effects of climate change on poultry production in Kano state, Nigeria.

MATERIALS AND METHODS

The study was carried out in Kumbotso Local Government Area (LGA) of Kano State. Primary data were obtained by administering structured questionnaire to poultry farmers in the study area by trained enumerators. A total of 120 farmers were involved in the study. Mean, frequency distribution and percentages and five-point Likert scale were employed to analyse the data. Farmers' perceptions on the effect of climate change on poultry production were measured as strongly agree (SA) agree (A), undecided (U), disagree (D) and strongly disagree (SD) which were scored 5, 4, 3, 2, and 1 respectively. Decision rule was based on perception mean that was equal to or greater than three as being a very serious (VS) perception while less than three is considered not serious (NS).

RESULTS AND DISCUSSION

Socio-economic Characteristics of Respondents

Table 1 elucidates that most of the respondents were aged between 21-30 years. This age group makes up about 53% of the total sampled respondents, 33.3% of them were aged between 31-40 years old, 13.3% of the respondents are between the range of 41-50 years while few. 8.0.% of the respondents are between 10-20 years old. These attributes show that the sampled respondents are youths which make them active in poultry production. Taru *et al.* (2008), opined that eligibility of one's performance in certain activities or role including agricultural activities is determined by the age and too young or too old people are generally inactive or of low productivity on the farm. 75% of the respondents were male while 25% of the respondents were female. This implies that majority of the farmers in the study area were male. Furthermore, most of the respondents were educated with 66.7% having attained tertiary education. On marital status, the distribution elucidates that 71.00% of the respondents were married adults and 20.0% are single and 8.00% divorced. This result agrees with the finding of Alade and Ademola (2013) which reported that larger respondents' percentage (73.3) were married. About 73 % of the sampled respondents were on poultry farming full time. The implication of this is that their sole source of income was poultry farming. 10% were civil servants and traders respectively while others were 6.7%. The mean household size for the area was 5, majority (65.0%) of the respondents have household size of about 1-5 persons per family, however 30.00% had between 6-10 household members and about 8% had between 11-15 persons per family. The year of experience of the respondents in poultry farming varies. The largest percentage (68.3%) of the respondents had been in poultry farming for a long period of more than 10 years, implying that the poultry farming has been able to support their livelihood for a long time and they have been through the poultry farming for long so it may be difficult to leave the farming for another new field or trade entirely.

Perception of poultry farmers on climate change

The results in Table 2 showed the perception of poultry farmers on climate change. The results were ranked using the mean of each perception. The statement climate change leads to food shortage for their animals ranked 1st with a means of 4.23. The statement climate change leads to drought ranked 2nd with a means of 3.97. The statement climate change leads to death of animals and the statement climate change leads to poor performance of animals in terms of meat and egg production and climate change leads to death of animals ranked 3rd with a means of 3.77. The statement climate change leads to increase in temperature which increase the heat stress of the animals ranked 5th with a means of 3.76. The statement climate change leads to reduction in the feed intake of the animal ranked 6th with a means of 3.68.

Table 1: Socio-economic variables of respondents

Variables	Frequency	Percentage
Age		
10-20	1	0.9
21-30	63	52.5
31-40	40	33.3
41-50	16	13.3

Table 2: Perception of poultry farmers on climate change in Kumbotso LGA of Kano State

ACTIVITIES	VS	S	UD	LS	NP	N (120)	MS	Rank	Remark
Climate change leads to Government policy in favour of Farmer	6	7	1	20	86	187	1.56	10th	Not Serious
Climate change leads to shortage of food for their animals	66	38	4	5	7	511	4.23	1st	Very Serious
Climate change leads to poor performance of animals	34	56	8	12	10	452	3.77	3rd	Very Serious
Climate change leads to low income for farmers	4	16	18	58	24	278	2.32	8th	Not Serious

Climate change leads to increase in temperature which increase the stress of the animal	5	10	1	79	25	451	3.76	5th	Very Serious
Climate change leads to death of animals	19	76	5	18	2	452	3.77	3rd	Very Serious
Climate change leads to loss of jobs by farmers	5	15	9	45	26	228	1.90	9 th	Not Serious
Climate change leads to outbreak of disease	10	15	18	42	35	283	2.36	7th	Not Serious
Climate change leads to reduction in the feed intake of the animal	45	52	3	15	5	477	3.97	2nd	Very Serious
Climate change lead to drought	42	38	10	20	10	442	3.68	6th	Very Serious

Source: Field survey, 2023

This agrees with Elijah and Adedapo (2006) research in which it was stated that majority of his respondents agreed that high temperature makes birds feed less. The statement climate change leads to outbreak of diseases ranked 7th with a means of 2.36. The statement climate change leads to low income for farmers ranked 8th with a means of 2.32. The statement climate change leads to loss of job by farmers ranked 9th with a means of 1 .9. The statement climate change leads to policy formulation by the government in favour of farmers for mitigation strategies ranked 10th with a means of 1.56. This means that majority of the farmers strongly disagree with the fact that government is doing anything in terms of policy making to help the farmers ameliorate the effect of climate change on their poultry production.

CONCLUSION AND RECOMMENDATION

It was concluded that that the majority of the farmers were aware that climate changes has negative effect on poultry production, and understands that the Government is not doing much on mitigation strategies in favour of poultry farmers It was recommended that more awareness and sensitization on the effect of climate changes on poultry production should created and the engagement of extension workers should be encouraged, the Local Government should also formulate policies to help farmers mitigate the impact of climate change on their farms Also more extension workers should be engaged to train and educate farmers on climate change.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A total of one hundred and twenty (120) day-old Abor Acre strains broiler chickens were used in a feeding trial to determining the effect of feeding composite sweet potato (umuspo 4 or solo gold) meal on the growth performance of broiler chickens. Four roughly isonitrogenous diets containing 2915.50, 2861.73, 2792.70 and 2741.92 Kcal/kg ME were used respectively for the study in a completely randomized design. Feed and water were provided to the chickens ad libitum for eight weeks. The results of the proximate composition of composite sweet potato meal revealed that the crude protein (11.31%), crude fibre (9.71%), Ether extra (1.25%), Ash (8.14%), Moisture content (9.85%) and NFE (59.75%), Total feed intake and average feed intake followed similar trend, with broiler chickens fed diets I, II and III statistically similar but significantly different from broilers fed diet IV. The feed conversion ratio of $diet_{III}$ (1.81) compared favourably with $diet_{I}$ (1.66) but statistically different ($P<0.05$) from $diet_{II}$ (2.04) and $diet_{IV}$ (2.24). Decreasing feed production cost (₦/kg) (380.00, 375.48, 370.96 and 366.44) was observed as inclusion level of composite sweet potato meal increased from 0 to 30%. The carcass /organ weights of broilers fed diets containing varying levels of composite sweet potato meal did not significantly differ among the broiler chickens. Biochemical and haematological indices of broiler chicken fed diets containing varying levels of composite sweet potato meal did not significant vary in packed cell volume, haemoglobin, albumin and alkaline phosphate. Inclusion of composite sweet potato meal up to 20% was apparently better tolerated by the broiler chickens in all the parameters evaluated.

Keywords: *Broiler growth, carcass, organ weight, blood profiles, sweet potato*

INTRODUCTION

Presently poultry/livestock production cannot supply the projected animal protein requirements of the population of Nigeria. The food and agricultural organization (FAO, 2000) report on livestock productivity (i.e. yield in kg/head) showed a drop in the production of animal protein from livestock sources. The production of livestock and livestock products has been declining steadily since 1965, and the percentage decline from year to year has been estimated at over 2% (FAO, 2000). The several challenges facing the poultry industry in the tropics is feed availability and it remains the most pressing (Girma *et al*., 2011). Hence, the need to search for alternative sources to bridge the gap created by the inadequate supply of these expensive conventional protein and energy sources. One possible source of cheap feedstuff is the use of composite sweet potato meal in broiler chickens diet. Sweet potato is a short season plant that can be grown three to four time in a season and the productivity is high if well managed thereby producing the feed needed to rear broiler chickens and/or human needs. Sweet potato leave/vines and the unsalable tuber are common during harvest season and off-season and most common in areas with high potential of producing sweet potato. This study therefore was undertaken to evaluate the proximate composition, best dietary level of inclusion of composite sweet potato meal on carcass/organ weight, haematological and blood chemistry of broiler chickens.

MATERIALS AND METHODS

Experimental Site

The research was conducted at the Poultry Unit of the Teaching and Research Farm of Michael Okpara University of Agriculture, Umudike, Abia State. Umudike lies on latitude 05^0 29'N and longitude 07^0 33'E with an elevation of 122 m above sea level and is located in the tropical rainfall zone of Nigeria. This zone is characterized by annual rainfall of about 2177mm, monthly ambient temperature range of 22^{0}C – 36^{0}C and relative humidity of 50 – 95% depending on the season and location (NRCRI, 2018).

Management of experimental birds

One hundred and twenty day old Abor Acre strains of broiler chickens were assigned in a completely randomized design to four treatment groups with three replicates of ten birds per replicate. The formulated straight broiler diets were used for the period of eight weeks (56 days). Feed and water were provided *ad libitum.* Proper sanitation, routine medication and normal vaccination were maintained to prevent any outbreak of disease.

Processing of composite sweet potato meal

Sweet potato (Umuspo 4 or Solo Gold) tubers and foliage were obtained from NRCRI Umudike used in the research. The test ingredient was made from Umuspo 4 (solo gold) a cultivar of sweet potato. The leaves/vines and tuber were harvested, processed (i.e. cut, chopped, sun dried for four days and hammer milled and combined at a ratio of 1:1:3 to form the composite sweet potato meal.

Proximate compositions and gross energy of the composite sweet potato meal

Samples of the test materials were analyzed for, proximate constituents according to the methods described by AOAC (2005) while the gross energy was determined using Adiabatic Oxygen Bomb Calorimetric technique.

Experimental diets

The composite sweet potato meal was included in the diets at 0, 10, 20 and 30%. Treatment 1 was the control diet having maize as the major energy source. The ingredients and composition of the experimental diets were as shown in Table 1 below: The formulated straight broiler diets were used for the period of eight weeks.

Experimental Design and Statistical Analysis

The experiment layout was completely randomized design using four treatments with three replicates of ten birds each. All data collected were subjected to analysis of variance (Steel and Torrie, 1980), and significant differences between treatments means were separated using Duncan's multiple range test (Duncan, 1955).

Carcass Characteristics and Organ Proportions

The carcass characteristics and organ proportions were determined by slaughtering three birds per treatment at the end of the feeding trial. The birds slaughtered were fasted for 24 hours to empty the digestive tract but drinking water was offered. Slaughtering was done by a clean cut across the jugular Vein and the birds were allowed to bleed for at least three minutes. The birds were de-feathered by dipping into boiling water for one and a half minutes and then the feathers were removed. The carcass was cut into parts and the organs separated according to the procedure described by Ojewola and Longe (1999). All parts (breast, drumstick and thigh) were weighed and expressed as percentage dressed weight. Organs like liver, heart and gizzard were also weighed and expressed as percentage of live weight.

Value of cut-parts and organs expressed as % dressed weight,

$$\text{Cut parts} = \frac{\text{Thigh / drumstick / breast cut/back cut}}{\text{Dressed weight}} \times \frac{100}{1}$$

$$\text{Organs} = \frac{\text{Heart / liver / Intestine / Proventriculus}}{\text{Dressed weight}} \times \frac{100}{1}$$

Blood Examination

At the end of 56 days of experiment, 3 and 4 blood samples were drawn from two birds per replicate through the Jugular vein using a 12 ml gauge (6 cm) needle to draw 10ml of blood. The blood samples were divided into two: first lot (5 ml) was emptied into heparin packs containing about 40 mg of anti coagulant to determine the haematological components. The second lot (5 ml) was collected over anti-coagutant free bottles, and was used to determine blood biochemical components. These samples were used to determine hematological parameters such as packed cell volume (PCV) white blood cells (WBC), WBC differentials and hemoglobin count (Hb).

RESULTS AND DISCUSSION

Table 1 shows the compositions of the study diets. The diets were isonitrogenous and the energy content decreased across the treatments, as composite sweet potato meal increased in the diet. The crude fiber content increased with increase in the inclusion levels of composite sweet potato meal in the diet. The chemical composition of composite sweet potato meal is presented in Table 2, it was as follows crude protein (11.31%), crude fibre (9.71%), ether extract (1.25%), Ash (8.14%), moisture content (9.85%) and NFE (59.75%). Table 3 showed the total feed intake and average feed intake followed similar trend, with broiler chickens fed diets I, II and III statistically similar but significantly different from broilers fed diet IV. This may be due to high fibre level of the diet as represented on the feed composition. More so, birds on diet IV recorded higher crude fibre (CF) many nutritionist have considered that the requirements of broiler for crude fiber (CF) are low and recommended to reduce it in diets for broiler chickens to less than 3.0-4.0% depending on the age (Swennen *et al*., 2010). Janssen and Carrc (1985) indicated that fribrous components of the food had negative effects on growth performance of the broiler chickens. The feed conversion ratio of diet_{III} (1.81) compared favourably with diet_{I} (1.66) but statistically different ($P<0.05$) from diet_{II} (2.04) and diet_{IV} (2.24).

Average Feed Intake (g)	66.53^{ab}	69.37^a	68.54^a	62.70^b	1.55
Feed Conversion Ratio	1.66^b	2.04^a	1.81^b	2.24^a	0.22
Cost/ Kg Feed (₦)	380.00	375.48	370.96	366.44	-

^{abc} Means along the same row with different superscripts are significantly (P<0.05) different.
SEM: Standard error of mean: D_I: $Diet_I$: D_{II} : $Diet_{II}$: D_{III} : $Diet_{III}$ and D_{IV}: $Diet_{IV}$

Decreasing feed production cost (₦/kg) (380.00, 375.48, 370.96 and 366.44 naira) was observed as inclusion level of composite sweet potato meal increased from 0 to 30%. Table 4 reveals the carcass /Organ Weights of Broilers fed diets containing varying levels of composite sweet potato meal. There were no significant differences among the broiler chickens fed the various diets in breast cut, drumstick, thigh cut, back cut and heart. The percentage liver weight and gizard showed significant differences and $diet_{II,}$ $diet_{III,}$ and $diet_{IV}$ were larger than the control $diet_I$ this is in line with the findings of Ukachukwu (2000) who said that the presence of anti-nutritional factors cause the enlargement leading to increase in weight of liver due to detoxifying activities and also the increase in the size of gizzard could be attributed to increase in the quantity of less digestible fibrous materials in the diet (Akinmutimi *et al.*, 2006). In the abdominal fat, broiler chickens fed; $diet_I$ (1.21%) was significantly higher (P<0.05) than broiler chickens fed $diet_{II}$ (0.15%), $diet_{III}$ (0.19%) and $diet_{IV}$ (0.12%). This could be attributed to increase in metabolic activities of the various organ on fibre in the diets which in turn helps to burn down the abdominal fat. Table 5 presents the Biochemical and haematological indices of broiler chicken fed diets containing varying levels of composite sweet potato meal. There were no significant differences in packed cell volume, haemoglobin, albumin and alkaline phosphate. The red blood cells (RBC) count differed significantly ($P < 0.05$), broilers fed diet$_{III}$ was statistically similar to all the broilers fed the various diets. The reduction in the RBC and WBC in broiler chickens fed diet$_{IV}$ can probably be due to the combined effects of anti nutritional factors. Since all the blood parameters were within normal range as reported by Mitruka and Rawnsely (1977), the observed differences in red blood cell, white blood cell and total protein may be due to slight differences in the individual broiler chickens. This trend can be buttressed by the fact that the formed element of blood component cannot be easily altered by nutrition but by disease and genetic makeup of individual animals (Tijani *et al*., 2015).

Table 4 Carcass /Organ Weights of Broilers fed diets containing varying levels of Composite Sweet Potato Meal.

Parameters	D_I	D_{II}	D_{III}	D_{IV}	SEM

CONCLUSION AND RECOMMENDATIONS

The results showed that the best dietary level of inclusion of composite sweet potato meal in broiler chickens is 20%. Therefore, composite sweet potato meal may be utilized in broiler chickens production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was carried out to determine the effect of processed Moringa oleifera leaf meal as a feed additive on growth performance and carcass attributes of broilers. For this purpose, 240 day-old unsexed broiler chicks were randomly allocated to four treatment (iso-caloric and iso-nitrogenous) diets consisting of 0 Moringa oleifera leaf meal (T_1), 250g Moringa oleifera leaf meal (T_2), 500g Moringa oleifera leaf meal (T_3) and 750g Moringa oleifera leaf meal (T_4), each inclusion per 100 kg of diet. The four different graded levels of Moringa oleifera leaf meal were used to formulate poultry feed using soya bean and yellow maize for broiler starter (20% crude protein) and broiler finisher (18% crude protein) using Pearson Square Method. The experiment was carried out in a CRD with the birds distributed into 4 replicates comprising 60 chickens per replicate. Feed consumption, weight gain and feed conversion ratio were recorded to evaluate the growth performance of the birds. At the end of experimental period, the birds were weighed to obtain live body weight, then slaughtered and weighed to get data for carcass quality. The results showed a significant ($p<0.05$) variation in the mean final weight (provide the values), weight gain (provide the values) and feed intake (provide the values) among treatment groups at four weeks of age. However, no significant difference was observed in initial body weight and feed conversion among treatment groups at 28 days. In addition, except for initial body weight, statistically significant variations were observed in all the growth characteristics evaluated in the birds at eight weeks of age. The study indicated that supplementation of diet with moringa leaf meal up to 750g may not have significant influence on growth characteristics of broilers.

INTRODUCTION
The poultry industry contributes significantly in provision of animal proteins in the human diet (Abdulsalam *et al*., 2015). When compared to beef industry, poultry enjoys a relative advantage of ease of management, higher turnover, quick returns to capital investment and wider acceptance of its product for human consumption (Haruna and Hamidu, 2004). Broiler chicken is one of the most important animal protein sources to human diet due to its relatively faster growth rate and shorter life cycle compared with other meat-producing livestock. Numerous studies have shown that the growth of broiler chicken, is dependent on the proper development of its gastro intestinal tract (Dibner and Richards, 2005). The nature of the bird's metabolism and its digestive system has necessitated the addition of appropriate supplements to its feed, to encourage a very high and fast growth and ultimately improve the production performance of the chickens.

Consequently, chemically based feed additives, such as antibiotics and growth promoters, have been widely used in the broiler industries to improve health and productivity of chicken flocks (Murugesan *et al*., 2015). Furthermore, birds raised with these feed additives have been shown to achieve good performance with improved quality products (NOAH, 2001). However, despite the positive impact of these feed additives on growth and development of the birds, there are reports that these feed additives may still remain in the broiler products as residues which may have negative effects on consumer's health (Donoghue, 2003). The use of natural herbs as viable alternatives to antibiotics in poultry production has been reported. For instance, Movahhedkhah *et al*. (2019) reported the growth-promoting roles of dietary inclusion of herbs and their extracts in poultry birds.

Research has shown that *Moringa oleifera* L. is a promising natural herb that could enhance the production performance and health status of birds as an alternative to antibiotics and growth promoters. The *M. oleifera* is a tropical plant native to Asia, belonging to the genus Moringa and family Moringaceae. Moringa is a popular multipurpose tree, naturally cultivated in tropical and subtropical countries, due to its considerable inherent nutritional, antioxidant, and phytochemical benefits, as well as its ability to survive in diverse climatic conditions. It is one of the most promising crops enriched in micronutrients with good antioxidant potential that ultimately strengthen immune system (Yang *et al.*, 2007). It was suggested that *M. oleifera* is a potential plant that could be used to enhance immune response and to improve the intestinal health of broiler chickens (Anwar *et al*., 2007). Along with that, it has high quality protein comprised of significant quantities of all the essential amino acids (Foidl and Paull, 2008). This study was conducted to assess how different levels of supplementary *M. oleifera* leaf meal (MOL) may affect the performance of broilers and to explore the potential benefits of MOL in the diet of broiler chickens.

MATERIALS AND METHODS

The experiment was carried out in an open mesh sided, deep litter poultry house of the Department of Agricultural Technology, Kaduna Polytechnic, Kaduna. The house was cleaned, washed and disinfected using formalin and folic acid. Each pen floor was covered with enough wood shavings with allocation of one tubular feed + trough and one round fountain drinker. Two hundred and forty unsexed day-old Zam strain broiler chicks were purchased from a local hatchery and randomly allotted into 16 pens (four groups) of 15 chicks in a pen, in a completely randomized design. The chickens were allocated to four diets which were formulated with various levels of supplemental *M. oleifera* leaf meal (250, 500 and 750 g per 100 kg diet as treatments 2, 3, and 4, respectively) in addition to a control diet (treatment 1) without *M. oleifera* inclusion.

Fresh mature *M. oleifera* plants was sourced from a local market within Kaduna metropolis. The leaves of the plant were removed from the stems, sorted, cleaned with tap water, and dried under shade for 2 days. Four diets were formulated for both the broiler starter and broiler finisher phases. The experimental diets were made iso-caloric and iso-nitrogenous and formulated to meet the National Research Council requirements of broiler chicks (NRC, 1994). The diets were also formulated to meet all the bird’s dietary nutrient requirements with the starter and finisher diets containing, respectively, table 1. Both diets had a metabolizable energy of 3,200 kcal/kg and 3,100 kcal/kg and crude protein of 20% and 18.79%, respectively and were supplemented with vitamins, minerals and amino acids.

Table 1. Composition and nutrient content of broiler starter and finisher diets (air-dry basis, %)

Enzyme	0.03	0.03
Mobilizing energy (Kcal/kg)	2894.00	2978.07

DM- Dry Matter * Biomix premix supplied per kg of diet

Two hundred- and forty-day-old Zam strain broiler chicks of mixed sexes were sourced from commercial poultry firm and used for the experiment. Sixty chicks were housed for each of the four dietary treatments (with graded levels of *M. oleifera* leaf meal) compared, with three pens per treatment as replicates and fifteen birds in each replicate using completely randomized design. Each pen was provided with aluminum pan feeders (300 mm) and mini plastic drinkers of the same size (300 mm). The broiler chicks used for the study were raised in deep litter and brooded for the first one week in an electrically heated battery brooder cage. Routine management, vaccination and medication were carried out as at when due, and all the possible steps were taken to avoid animal suffering at each stage of the experiment.

The chicks in groups and feeds were weighed weekly according to cage numbers using insert table or sensitive scale. Gain in body weight, feed consumption, average daily gain and feed conversion efficiency of the chicks were recorded at the beginning of each week, starting from placement until slaughter. Then the carcass and liver were weighed. In addition, the proximate analysis for the chemical components of *M. oleifera* leaf meal (dry matter, crude protein, phosphorus, crude fiber, ME, ash and nitrogen free extract) were determined according to

AOAC (2000) and results presented in Table 2. All the data collected were analyzed statistically using one-way analysis of variance according to Steel and Torrie (1981) and means were compared using Duncan's multiple-range test. Statistical significance was determined at P<0.05. The analysis was carried out using statistical analysis system (SAS, 2005) program.

Table 2: Nutrient composition of *Moringa oleifera* leaf meal (dry matter basis)

Parameter	Composition (%)
Dry matter	82.80
Crude protein	27.60
Crude fibre	16.7
Phosphorus	0.80
Ash	3..30
Moisture	7.31

RESULTS AND DISCUSSION

Growth performance (0 to 4 weeks)

The effect of feeding *M. oleifera* leaf meal supplemented diet on growth performance of broiler during grower period (0 to 4 weeks) is presented in table 3. The result showed that there was a statistically significant (p<0.05) variation in growth performance with respect to final body weight (provide the values), weight gain (provide the values) and feed intake (provide the values). The moringa supplemental treatment has an increase in these parameters compared to the control diet without moringa. The positive effects of dietary MOL supplementation on animal performance have been previously observed in broilers and laying hens (Lu *et al*., 2016). In addition, it was found that the differences in initial weight gain (provide the values) and feed conversion (provide the values) were not significant. Contrary to this observation, dietary MOL supplementation was reported to decrease body weight and average daily gain (P<0.01), and increased feed conversion ratio (P < 0.001) in experiment conducted by Cui *et al*. (2018).

The data also indicated that the highest live body weight of 1,012.82 g/bird was recorded in diet containing 500 g *M. oleifera* that was statistically comparable to the control diet and significantly higher than other moringa supplemented feeds. This finding is in line with the work of Khan *et al*. (2017), who recorded higher body weight when moringa leaf powder was used as a dietary supplement at 12% in broilers. Similarly, the chickens fed 500g moringa inclusion per kg broiler feed recorded the highest mean weight gain of 969.61 that was statistically at par with all treatment groups except those fed 750g *M. oleifera* supplemented diet. Previous work conducted by Abdulsalam *et al.* (2015) with moringa leaf meal as a supplement in broilers found significant increase in weight gain and a positive effect on growth performance at finisher period.

It is noteworthy, that the feed consumed by birds fed with no moringa leaf meal supplement (control diet) was found to be statistically at par with the other treatment groups. The highest feed intake of 1,609.54 g/bird was obtained with the supplementation of moringa leaf meal at 500 g which was significantly higher than the least (1,489.69 g/day) observed with moringa supplemented diet at 250 g. Contrary to this finding, no significant difference in feed intake and body weight gain was observed between control diet and 25% level of moringa supplementation of conventional soybean meal in broiler diets in a trial carried out by Gadzirayi *et al*. (2012). Furthermore, the result indicated that there was no significant difference among all the treatment groups in terms of feed conversion ratio. This observation is at variance with the finding of Gakuya *et al*. (2014) who reported that feeding broilers with moringa leaf meal resulted in a lower feed intake and a high FCR attributed to the presence of anti-nutritional factors in moringa leaves.

Table 3. Growth characteristics of broilers at 0 to 4 weeks fed moringa leaf meal as feed additive

Parameters	Different levels of moringa leaf supplement				P-Values	
(Gram/bird)	0	250	500	750	Sign.	SEM
Initial weight	44.44	44.44	44.47	45.12	NS	0.23

Growth performance (4 to 8 weeks)

The influence of *Moringa oleifera* leaf meal on the growth performance of broilers between 4 and 8 weeks is presented in table 4. The data showed that except for the initial body, all the growth performance attributes of the birds differ significantly (P<0.05) probably due to the application of the treatments in the experiment. Previous studies conducted by Briones *et al*. (2017), demonstrated that moringa leaves can be applied as a dietary supplement in layers and broilers for high production performance and improved eggs quality.

This result showed that broilers fed 750 g *Moringa oleifera* leaf supplement per kg had an average final body weight (3,101.82 g) and mean weight gain (2,202.55 g) which were significantly higher than those of the birds fed 500g moringa supplements and at par with the final weight and weight gain of broilers fed 250 g moringa leaf supplements and the control diet without moringa supplement. A 35-day poultry feeding trial conducted by (Ebenebe *et al.*, 2012) observed higher final live weight, average weight gain, and FCR with 10% moringa leaf meal supplemented diets over the control. A similar study carried out on poultry birds found that feeding *M. oleifera* leaf powder improves live weight, body weight gain, dressing percentage, and FCR compared with the control without moringa (David *et al*., 2012).

The control treatment had the highest feed intake of 5,178.55 g/bird that was statistically comparable to feed intake observed in birds fed diets containing 500g and 750g moringa leaf supplements having feed consumption of 5,100.60 g/bird and 5,025.07g/bird, respectively. A similar experiment conducted by Gakuya *et al.* (2014), indicated that feeding broilers with moringa leaf meal as a supplement in diet resulted in a lower feed intake and a high FCR. The result also showed that the chickens receiving 500 g moringa leaf meal treatment had the highest feed conversion ratio (2.81) that was statistically higher than that of the broilers fed 750g moringa leaf supplements (2.58) but significantly (P<0.05) comparable to the feed conversion ratio of the birds in the control group (2.75) and those fed 250g moringa supplement (2.68). It was reported in a previous experiment conducted by Ayssiwede *et al*. (2011) that dietary application of moringa leaf meal up to a level of 24%, had no adverse effects on body weight, average daily weight gain, FCR, mortality, and the weight of organs in broilers compared to the control diet.

As indicated previously, although the growth performance of birds was significantly influenced by supplementing *M. oleifera* leaf meal in the diets, broilers in the treatment groups did not differ statistically with respect to their initial body weight from 4 to 8 weeks. Similar to this finding, Abdulsalam *et al.* (2015) conducted an experiment with moringa leaf meal as a supplement in broilers diets and reported an enhance growth performance at finisher period. Furthermore, inclusion of *M. oleifera* leaves at higher levels (15% and 20%) in broiler diets was observed to result in a higher growth rate and better health status in broilers (Alnidawi *et al*. 2016).

Table 4. Growth characteristics of broilers at 4 to 8 weeks fed moringa leaf meal as feed additive

Parameters	**Different levels of** moringa leaf **supplement**				**P-Values**	
(Gram/bird)	0	250	500	750	Sign.	SEM
Initial weight	898.14	887.84	897.17	870.35	NS	8.02
Final weight	3,077.67^{a}	2,879.53^{bc}	2,813.81^{cd}	3,101.82^{ab}	*	50.57
Weight gain	2,190.97^{a}	2,009.66^{bc}	1,926.92^{cd}	2,202.55^{ab}	*	49.78
Feed intake	5,178.55^{a}	4,982.22^{b}	5,100.60^{ab}	5,025.07^{ab}	*	50.71
Feed conversion ratio	2.75^{a}	2.68^{ab}	2.81^{a}	2.58^{bc}	*	0.06
Mortality rate (%)	0.00	0.00	0.00	0.00	“	“

Means in the same row bearing different subscripts are significantly different (P<0.05): * = Significant; NS = non-significant.

CONCLUSION

This trial has shown the possible use of *Moringa oleifera* leaf meal as an additive in broiler feeds. It could be concluded that supplementation of *Moringa oleifera* leaf meal up to 500 g in the feed may not have effects on growth and productive performance of broilers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The present study was conducted to assess the effect of Moringa oleifera leaf meal as a feed supplement in broiler diets. Two hundred and forty unsexed day-old Zam strain broiler chicks were randomly allotted into 16 pens (four groups) of 15 chicks in a pen, in a completely randomized design. Each group was fed various levels (250g, 500g and 750g as treatments 2, 3, and 4 respectively) of supplemental M. oleifera leaf meal inclusion per 100 kg diet in addition to a control diet (treatment 1) without M. oleifera leaf meal. All rations were designed as iso-nitrogenous and iso-caloric. The broilers were raised for eight weeks. Feed consumption, weight gain and feed conversion ratio were recorded to evaluate the growth performance of the birds. At the end of experimental period, the birds were weighed to obtain live body weight, then slaughtered and weighed to get data for carcass quality (heart, liver and gizzard weight, carcass yield). In addition, blood samples were collected and taken to laboratory for evaluation of hematological attributes. The result showed that with regards to carcass characteristics, the percentages of heart and liver in relation to chicken live body weight did not differ significantly between all the treatment groups. The data further revealed that statistically significant differences (p<0.05) existed between treatments with respect to live body weight, carcass yield and gizzard weight. However, with respect to blood composition, no statistically significant response was observed in all hematological indices of the broilers, except for packed cell volume and white blood cell.
Keywords: *Moringa oleifera, broiler chicks, growth performance, carcass quality, blood samples and hematological attributes*

INTRODUCTION
The poultry sector has seen rapid with constant growth in the previous decades as the global need for food and nutritional security has increased steadily with population growth (Gržinić *et al*., 2023). Intensive poultry farming, which is an optimized production system in high income countries, is fundamental to modern poultry production. However, in low to middle income countries, the poultry system lacks adequate infection prevention measures, veterinary assistance and infrastructure (Kiambi *et al*., 2021; Bamidele *et al*., 2022). One common feature of these two different poultry production systems, is that the producers in such countries often use antibiotics as prophylactics and for growth promotion to increase production and income.
Pharmaceuticals and antibiotics in food have impact on the health of consumers, therefore they are monitored to comply with maximum residue levels, and to ensure that they do not exceed acceptable limits (Chen *et al.*, 2019). The incomplete metabolism of pharmaceuticals in animals, causes them to be detected in many raw meat samples (Davis *et al*., 2018). The presence of antibiotics has been reported at every stage of poultry production, with the drugs detected both in meat samples from slaughter houses and in ready-to-eat products reaching the consumer. Several studies have suggested that despite the ban on the use of antibiotics as growth promoters in European Union countries since 2016, consumers in Europe and other countries are still exposed to pharmaceuticals in chicken meat.
There has been genuine concern regarding the use of antibiotics and growth promoters in the poultry sector. Therefore, greater attention is now directed towards finding alternatives to antibiotics for meat and egg production. Various alternatives to antibiotic growth promoters, such as probiotics and organic acids, are now used

commercially to enhance health status, feed quality and utilization, and production efficiency in poultry (Khan and Naz, 2013; Khan *et al.*, 2016; Abudabos *et al.*, 2017). Research has shown that *M oleifera* is a promising natural herb that could enhance the production performance and health status of birds as an alternative to antibiotics and growth promoters.

Moringa oleifera Lam. (Moringaceae family) popularly referred to as the ‘‘Miracle tree”, is widely cultivated across the world due to its multiple uses and adaptability. The plant has a high nutritive and pharmacological value, while its leaves are a rich source of minerals, vitamins and many health beneficial secondary metabolites with a significant anti-diabetic potential (Zainab *et al*. 2020). The positive effects of dietary *M. oleifera* supplementation on animal performance have been observed in broilers and laying hens (Lu *et al*., 2016). This study was carried out to assess the influence of moringa leaf meal feed as an additive on carcass characteristics and hematological parameters of broilers.

MATERIALS AND METHODS

The experiment was carried out in an open mesh sided, deep litter poultry house of the Department of Agricultural Technology Kaduna Polytechnic, Kaduna. The house was cleaned, washed and disinfected using formalin. Each pen floor was covered with enough wood shavings with allocation of one tubular feed + trough and one round fountain drinker. Two hundred and forty unsexed day-old Zam strain broiler chicks were purchased from a local hatchery and randomly allotted into 16 pens (four groups) of 15 chicks in a pen, in a completely randomized design. The chickens were allocated to four diets which were formulated with various levels of supplemental *M. oleifera* leaf meal (250 g, 500 g and 750 g *M. oleifera* inclusion per 100 kg diet as treatments 2, 3, and 4, respectively) in addition to a control diet (treatment 1) without *M. oleifera*.

Fresh matured *M. oleifera* plants was sourced from a local market within Kaduna metropolis. The leaves of the plant were removed from the stems, sorted, cleaned with tap water, and dried under shade for 1-2 days. Four diets were formulated for both the starter and finisher phases. The experimental diets were made iso-caloric and iso-nitrogenous and formulated to meet the National Research Council, (NRC, 1994) requirements of broiler chicks. The diets were also formulated to meet the crude protein requirements of starter and finisher diets (20% and 18.79 %, respectively), as presented in table 1. Both diets had a metabolizable energy of 3,200 kcal/kg and 3,100 kcal/kg, respectively and supplemented with required vitamins, minerals and amino acids.

Table 1. Composition and nutrient content of broiler starter and finisher diets (air-dry basis, %)

Ingredient	Starter ration (%DM)	Finisher ration (%DM)
Maize	53.45	63.40
Soya bean cake	27.50	17.40
Groundnut cake	10.00	10.00
SOS	5.00	5.00
Limestone	0.50	0.50
Born meal	2.80	2.80
Common Salt	0.23	0.23

Lysine	0.05	0.20
Enzyme	0.03	0.03
Mobilizing energy (Kcal/kg)	2.894.00	2,978.07

DM- Dry Matter * Biomix premix supplied per kg of diet

Two hundred- and forty-day old Zam strain broiler chicks of mixed sexes were sourced from commercial private poultry farm and used for the experiment. Sixty chicks were housed for each of the four dietary treatments (with graded levels of *M oleifera* leaf meal) compared, with three pens per treatment as replicates and fifteen birds in each replicate using completely randomized design. Each pen was provided with an aluminum flooding pan feeder (300 mm) and mini plastic drinkers of the same size (300mm). The broiler chicks used for the study were raised in deep litter and brooded for the first one week in an electrically heated battery brooder cage. Routine management, vaccination and medication were carried out as and at when due, and all the possible steps were taken to avoid animal suffering at each stage of the experiment.

The chicks in groups and feeds were weighed weekly according to cage numbers using a normal scale. Gain in body weight (GBW), feed consumption (FC), average daily gain (ADG) and feed conversion efficiency (FCE) of the chicks were recorded at the beginning of each week, starting from placement until slaughter. At the end of experimental period, all the birds were slaughtered and the trachea, esophagus, crop, intestinal tract, giblet (heart and gizzard), spleen, kidney, oil glands and reproduction organs were removed. Then the carcass and liver were weighed. In addition, blood samples were collected and taken to pathology laboratory for hematological indices determination.

Furthermore, the chemical components of *M oleifera* leaf meal (dry matter, crude protein, phosphorus, crude fiber, ME, ash and nitrogen free extract) were determined according to AOAC (2000) and results presented in table 2.

All the data collected were analyzed statistically using one-way analysis of variance according to Steel and Torie (1981) and means were compared using Duncan's multiple-range test. Statistical significance was determined at $P < 0.05$. The analysis was carried out using statistical analysis system (SAS, 2005) program.

Table 2: Nutrient Composition of *Moringa oleifera* leaf meal (dry matter basis)

Parameter	Composition (%)
Dry matter	82.80
Crude protein	27.60
Crude fibre	16.7
Phosphorus	0.80
Ash	3..30
Moisture	7.31

RESULTS AND DISCUSSION

Carcass characteristics

The result of the influence of *M. oleifera* leaf meal feed inclusion on performance of broilers with respect to carcass characteristics is presented in Table 3. The result showed that percentages of heart and liver in relation to chicken live body weight did not differ significantly between the treatment groups at the end of the experimental period. Although no significant variation was observed in percentages of heart and liver, the potential benefits of dietary MOL inclusion on animal production have been previously reported, such as improving productive performance in broilers and laying hens (Melesse *et al*., 2013), improving carcass quality and meat quality in broilers (Nkukwana *et al*., 2014).

In addition, the data further revealed that statistically significant differences (p<0.05) existed between treatments with respect to the live body weight, carcass yield and gizzard. Abdel Wahab *et al*. (2020) had reported that birds fed MOSP at 0.75% with enzyme had significantly higher body weight (BW) than control with enzyme and other dietary treatments. Similarly, all levels of germinated *M. oleifera* seed (GMOS) was reported to significantly increased BW and BWG at 42 days of age compared to the control group (Mouse *et al*., 2016).

The chickens fed with 500g *M. oleifera* inclusion per kg broiler feed were observed to have the highest mean live weight and carcass yield of 3,044.22 g and 2,448.00 g, respectively that ware statistically comparable to the control treatment but significantly higher than all moringa supplemented diet treatment groups in the experiment. Results obtained herein are in line with Ochi *et al*. (2015) who indicated that the use of *M. oleifera* seed powder (MOSP) at levels of 0.5, 1, and 2% in the diet of the broilers, significantly enhanced ($P < 0.05$) their body weight, weight gain and feed consumption.

With regard to gizzard, the result indicated that an increase in the level of *M. oleifera* leaf meal feed inclusion from 250 g to 500 g had no significant effect on the gizzard, while additional increase in the supplement to 750 g had significant effect on the parameter. The highest percentage value of the gizzard (3.40%) was recorded in the diet of 750g which was significantly (p<0.05) lower than the least (2.30%) obtained in the control treated birds. There was no significant variation in percentage values of the heart and liver in relation to live body. With regards to the carcass indices, it has been reported that dietary manipulation is an important way to improve the meat quality in poultry (Cheng *et al*., 2019). Therefore, Mahfuz *et al*. (2020) has reported that dietary supplementation of antioxidant-enriched moringa leaves would be a potential strategy to improve the meat quality in broilers.

Table 3. Carcass characteristics of broilers fed moringa leaf meal

Parameters (% Live weight)	Different Levels of moringa leaf meal supplement in broiler diet				P-Values	
	0	250	500	750	Sign.	SEM
Live weight (g)	3,010.00$_a$	2,766.56$_b$	3,044.22$_a$	2,782.44$_b$	*	48.44
Heart	0.32	0.45	0.47	0.39	NS	0.6255
Liver	1.67	1.72	1.78	1.85	NS	0.0735
Gizzard	2.30$_c$	2.99$_{ab}$	2.84$_b$	3.40$_a$	*	0.16
Carcass Yield (g)	2,233.30$_{ab}$	1,900.11$_c$	2,448.00$_a$	2,300.00$_b$	*	88.52

Means in the same row bearing different subscripts are significantly different (P<0.05): * = significant (P = 0.05); NS = Non-significant; SEM = Standard Error of Mean

Hematological parameters

The data indicated that except for the packed cell volume (PVC) and white blood cells (WBC) there was no statistically significant response observed in all hematological indices of the broilers due to the application of all the treatments. It is on record that, the hematological parameters of the blood provide information on poultry health and nutritional deficiency, as well as physiological changes in the growth of broilers. Abdel Wahab et al. (2020) observed higher WBC count in birds that received 1% MOSP without enzyme and those of the control diets compared with the other dietary treatments. Previously, Maxwell and Robertson, (1998) reported an increase in the number of heterophils in broilers during mildly or moderately stressful conditions and concluded that the heterophil/lymphocyte ratio in the blood can be used to detect the presence of physiological stress in poultry birds. This study also observed that an increase in the level of *M. oleifera* leaf meal from 0 to 500 g per 100 kg of feed did not significantly increase the PVC and WBC while further increase in level of *M. oleifera* leaf resulted in a significant decline in the PVC and non-significant reduction in WBC as indicated in table 4. In line with this study, Ebenebe *et al*. (2012) examined the roles of *M. oleifera* leaf meal at 10% and 15% level on the hematological parameters in broilers and reported that feeding Moringa leaf meal in broilers resulted in increased red blood cell (RBC), PCV, and hemoglobin (HB) values in both levels of diets. Finally, it was stated that *M. oleifera* leaf meal may be used up to 10% level in broiler diets.

With respect to relationship between moringa plant and blood constituents of broiler it was hypothesized that higher amounts of natural fiber in moringa leaves may have a role in lowering cholesterol level by increasing lipid metabolism in the host body (Mahfuz, 2020). In addition, a study conducted by Alnidawi *et al*. (2016) showed that blood parameters, like hemoglobin percent, total red blood cells number, and total packed cell volume, were found to be higher at 20% supplementation levels of *M. oleifera* than the control diet.

Table 4. Hematological parameters of broilers fed moringa leaf meal

Parameters (%)	Reference Values	**Different levels of** moringa leaf **supplement in broiler diet**				**P-Values**	
		0	250	500	750	Sign.	SEM
PCV	25-45[1]	37.63_a	36.62_a	36.51_a	32.15_b	*	1.15
RBC ($x10^{12}$/L)	2-4[1]	2.58	2.51	2.64	2.20	NS	0.09
Hb conc.	7-13[1]	11.80	11.62	11.46	1008	NS	0.37
WBC ($x10^9$/dL)	9-31[1]	92.51_{ab}	106.53_a	98.01_{ab}	82.73_b	*	5.46
Heterophils (unit)	40-48[3]	1.92	3.11	3.32	3.56	NS	1.01
Lymphocytes (unit)	24-84[2]	60.44	57.19	88.54	87.56	NS	22.47

Means in the same row bearing different subscripts are significantly different (P<0.05): * = significant (P = 0.05); NS = Non-significant; SEM = Standard Error of Mean; PCV = Packed Cell Volume; RBC = Red Blood Cells; HB = Hemoglobin Concentration; WBC = White Blood Cells

CONCLUSION

In conclusion, dietary moringa leaf meal inclusion as a feed additive may have significant influence on the performance of broilers in respects of the carcass characteristics and hematological parameters. These results suggested that MOL could be used as a feed ingredient for broilers to improve the carcass quality and blood hematological indices with little or no adverse effects on growth performance.

ACKNOWLEDGEMENTS

The authors acknowledge with gratitude the financial support of TETfund in execution of this research project.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study assessed macro nutrient content in some selected agro forestry tree species and soil composition status in adjoining agricultural farm. The research was conducted at forest Arboretum of the Department of Forestry and Wildlife Management Federal University Dutsinma, Katsina State Nigeria. Plant materials were collected from five randomly sampled trees; Faidherbia albida, Leuceana leucocephela, Senna siamen, Gliricidia sepium, Albizia lebbeck. A plot of 50×50 m was measured and the trees were counted. Five trees were randomly selected from each selected tree species out of which the leaves were collected. In each of the collected samples was pooled /bulked together while composite samples were also taken. The leafy biomass was air- dried and the sample was grounded and passed through a sieve of 2 mm size. Then, 2.0 g of each sample of the selected species was put into a digestion flask which was washed with distilled water.10 ml of 4 % perchloric acid ($HCLO_4$) was added to the samples under a fume cupboard. The contents was mixed and heated strongly on digestion block under the $HCLO_4$ fume cupboard. The contents were allowed to cool and then 50 ml of distilled water will then be added. The solution was transferred into a 100 ml Pyrex volumetric flask. The soil physical and chemical properties showed that arboretum had 780 g/kg sand, 100 g/kg silt and 120 g/kg clay while chemical properties also showed as folows pH of 6.20, organic carbon 7.00g/kg. It was found that Faidherbia albida, Leuceana leucocephala, Gliricidia sepium and Albizia lebbeck had significantly higher values (0.100.002a, 0.100.001a, 0.100.001a and 0.100.001a) in magnesium. The study concludes that Gliricidia sepium and Albizia lebbeck contained the higher mean concentration of macro nutrients in nitrogen, phosphorus, magnesium and sodium respectively. The study recommends that Gliricidia sepium, Albizia lebbeck and Faidherbia albidashould be considered while selecting species for augmenting soil potential and improving soil fertility for various agroforestry activities.

INTRODUCTION

The perceived rise in global food demand has led to a desire for organic food (Ezeorji *et al*., 2020). Future livelihoods of smallholder farmers around the world, particularly in the tropics, face a major threat from environmental degradation brought on by rising food production demands and related changes in land usage (Kang and Akinnifesi 2000). Due to a combination of high rates of erosion, nutrient leaching, crop residue clearance, and ongoing cultivation of the soil without sufficient fertilization or fallow periods, studies show that soil fertility is rapidly declining (Mugwe *et al*. 2007). Although significant efforts have been made to make inorganic fertilizers cheap for farmers, such as fertilizer price subsidies, resource-poor farmers still are unable to fulfill crop fertilizer requirements and struggle to achieve and sustain high productivity in intensively planted fields (Partey, 2011).

Chemical fertilizer has detrimental impacts on the soil and plants in addition to synthetic and chemical fertilizer, pesticides that have been used for years to improve global food supply (Mondal *et al*., 2015). Composting is the ultimate form of trash recycling since it produces fertilizer from a variety of organic materials that have decomposed. It is made up of generally stable decomposed organic compounds that are the outcome of rapid biological breakdown of organic materials under controlled aerobic conditions. For agricultural production, it is created from leftover plants and animals (Adugna, 2016). Vermicompost fertilizer has been made using a variety of organic waste products, including rice straw, dry grass, chippings, cow manure, dried leaves, rotten watermelon,

papaya, pine apples, custard apples, and guavas (Mondal *et al*., 2015; Devi and Prakash, 2015). Both conventional compost and vermicompost fertilizer are excellent sources of micro- and macro-mineral nutrients that, when added to the soil, improve soil nutrients and organic matter (Hernandez *et al*., 2010, and MongJam *et al*., 2019). Based on how much a plant needs to thrive, soil nutrients are classified as either micro or macro nutrients (Akenga *et al*. 2014). According to their requirements and the relative necessity for fertilization, the fourteen mineral nutrients are categorized as either micro or macro nutrients (Sneha *et al.*, 2018).
However, soil chemistry and physical conditions can also have an impact on how quickly litter decomposes. Decomposition is primarily fueled by microbial activities and can be best anticipated by environmental parameters like temperature and precipitation as well as litter quality (Liu, *et al*., 2006). Quantitative characterization of nutrient cycling in terrestrial ecosystems depends critically on the study of the variables influencing litter decomposition. This section discusses the key influences on the decomposition process, including plant litter properties, soil qualities, and environmental factors.
In recent years, increasing soil fertility through fertilizer application has been the norm. However, because chemical fertilizers are either uncommon or expensive in Nigeria, many farmers cannot afford to buy them, and those who might do so do not have access to them when they are needed. The use of agroforestry tree species, which have the ability to fix nutrients and ease the issues associated with soil fertility decline, is a sustainable method of addressing the problems of soil fertility reduction. As a result, nitrogen-fixing agroforestry plants could be employed to supplement soil improvement for increased crop yield. In terms of nutrient release and decomposition, chemical compositions of the leafy biomass that are influenced by biological and environmental factors (such as decomposers, litter quality, temperature, and moisture, etc.) are another crucial area of concern. The term "macro nutrients" refers to those nutrients that plants need in relatively high concentrations. Examples of macro nutrients include nitrogen (N), phosphorus (P), potassium (K), calcium (C), magnesium (Mg), and sodium (Na). A certain amount of moisture is necessary for the release of these nutrients. According to studies Ajayi *et al*. (2007); Sanchez (2002), leguminous tree leaf litter mulching in agroforestry plots increases crop productivity. However, these macronutrient concentrations differ from one species to another depending on the organism. The concentration of macro-nutrients in a few chosen, widely used agroforestry tree species and the nutrient status of the adjacent farm area must thus be evaluated.

METHODOLOGY

The research was conducted at forest Arboretum of the Department of Forestry and Wildlife Management Federal University Dutsinma, Katsina State Nigeria. The area lies between (Latitude 8^0 29 N, Longitude 4^0 35 E and 307 meter (above sea level), during the 2018 dry seasons. Dutsin-ma is characterized by an annual rainfall of 1,186 mm while the mean annual temperature and relative humidity are 29^0 and 85 % respectively. The soil is well drained, and the order is Alfisols belonging to the Tanke series (23).The underlying geologist is made of sand stone ranging from fine to coarse grained light brown colour. The dominant soil types include; sand, silt, clay and textural class (Lukman, 2018).
Plant materials were collected *from Faidherbia albida, Leuceana leucocephela, Senna siamen, Gliricidia sepium, Albizia lebbeck*. A plot of 50 m by 50 m was measured and the trees were counted. Five trees were randomly selected from each selected tree species out of which the leaves were collected. In each of the collected samples was pooled /bulked together while composite samples was also taken. The leafy biomass was air- dried and the sample was grounded and passed through a sieve of 2 mm size. Then, 2.0 g of each sample of the selected species was put into a digestion flask which was washed with distilled water.10 ml of 4 % perchloric acid ($HCLO_4$) was added to the samples under a fume cupboard. The contents was mixed and heated strongly on digestion block under the $HCLO_4$ fume cupboard. The contents were allowed to cool and then 50 ml of distilled water will then be added. The solution was transferred into a 100 ml Pyrex volumetric flask.
The volume was made up to mark with distilled water. Then the solution was stored in plastic bottles and labelled for analysis. The digested sample solutions of the plants was subjected to laboratory analysis to determine the Total Nitrogen (N), Potassium (K), Calcium (Ca), Magnesium (Mg), and Sodium (Na). Total Nitrogen was determined by Macro-Kjeldahl method as described by Jackson (1985) Phosphorus was detemined by Vanadomolybdo Phosphoric yellow colour as described by Kitson and Milton (1994).
The air-dried sample was taken to laboratory for physico chemical analysis. The grounded samples that was analysed include: organic carbon content which was determined by wet oxidation method of Walkley-Black as described by Allison (1965). Total Nitrogen was analysed by Macro-Kjeldahl digestion, followed by distillation and titration (Brandstreet, 1965; Anderson and Ingram, 1993). The C: N ratio was computed as ratio of N to C. Available P was extracted by Bray method. The P concentration in the extract was determined calorimetrically by using the Spectronic 20 and absorption was read-off as described by Bray and Kurtz (1945) and modified by Murphy and Riley (1962). Exchangeable base, Na, K, Ca and Mg were extracted using ammonium acetate. K was determined on flame photometer and Ca and Mg by Atomic Absorption. Soil sample was randomly collected from five locations at the depth of (0-30 cm) both from Arboretum and adjoining agricultural farm for physical and chemical analysis which include: Sand, silt, clay and, textural class, pH, organic carbon, total nitrogen and available phosphorus, using standard methods. Total nitrogen was analyzed by Macro-Kjeldahi digestion,

followed by distillation and titration (Brandstreet, 1965; Anderson and Ingram, 1993). Ammonium was determined by the salicylate-hypochlorite colorimetric method (Anderson and Ingram, 1993) whereas NO_3^- plus nitrate (NO_2) was determined by cadmium reduction method (Dorich and Nelson, 1984).

Data analysis

One-way analysis of variance was employed to test for the significant differences in the micronutrients and physico-chemical composition of the soil. Significant means were separated using the Fishers Least Significant Difference (LSD) at P=0.05

RESULTS

The results of the physico-chemical properties and exchangeable bases (cations) of the soils type on arboretum and adjacent agricultural farm soils are presented in table 1 below. The soil physical and chemical properties revealed that arboretum had 780 g/kg sand, 100 g/kg silt and 120 g/kg clay. The chemical properties also showed that pH of the soil was 6.20, organic carbon 7.00g/kg, total nitrogen 0.42 g/kg, carbon to nitrogen ratio 16:67 and available phosphorus 3.10g/kg respectively. Soil exchangeable bases/cations were observed to have 2.70 mg/kg, calcium, 0.50 mg/kg, magnesium, 0.31 mg/kg, potassium and 0.12 mg/kg sodium. Furthermore, it was also observed that adjacent agricultural farm soil physical and chemical properties had 820 g/kg sand, 80 g/kg silt and 120 g/kg clay while chemical properties also showed that pH was 6.10, organic carbon (5.00 g/kg), total nitrogen (0.28 k/kg), carbon to nitrogen ratio (17:86) and available phosphorus (2.20 g/kg) respectively. Soil exchangeable bases/cations showed 2.12 mg/kg of calcium, 0.61 mg/kg of magnesium, 0.34 mg/kg of potassium and 0.11 m/kg of sodium respectively

Table 1: Physico-chemical properties and exchangeable bases of the soils

Soils type	Physical properties(g/kg)				Chemical properties					Exchangeable bases (mg/kg)			
	Sand	Silt	Clay	Textural class	pH	OC (g/kg)	TN	C:N	AP (mg/kg)	Ca	Mg	K	Na
Arboretum	780	100	120	Loamy sand	6.20	7.00	0.42	16:67	3.10	2.70	0.50	0.31	0.12
Adjacent agricultural farm	820	80	100	Loamy sand	6.10	5.00	0.28	17:86	2.20	2.12	0.61	0.34	0.11

N:C: Nitrogen carbon ratio; **K:** Potassium; **Ca:** Calcium; **Mg:** Magnesium; **Na:** Sodium, OC Organic carbon, TN=Total nitrogen, Av = Available phosporus

Table 2 shows the chemical composition of the selected leafy biomass of agroforestry tree species. The result shows that the highest nitrogen content (4.10) was found in *Gliricidia sepium*, while the least (3.20) was found in *Leuceana*. However *Fadheibia* gave the highest concentration of carbon (77.43) followed by AL and the least (48.04) was found in GS. Carbon to Nitrogen ration was highest (21.51) in FA and lowest GS (11.72)

Table 2 shows the chemical composition/concentration of the selected leafy biomass of agroforestry tree species the result revealed that *Faidherbia albida* have significantly higher values (77.43, 21.51 and 14.81) in carbon, C:N ratio and PP:N ratio, while Leuceana *leucocephala* also had significantly higher value (20.00a) in cellulose than other selected leafy biomass. However, Senna siamen was noticed to have significantly higher value (0.41a) in polyphenol, whereas Gliricidia sepium had (4.10a) in nitrogen than in other selected leafy biomass. Albizia lebbeck was discovered to have significantly higher values (15.59a, 54.29a, 4.15a and 4.22a) in lignin, lignin to polyphenol ratio, lignin to nitrogen ratio and lignin plus polyphone to nitrogen ratio respectively than in other selected agroforestry tree species leafy biomass (Table 2).

Table 2: Mean chemical composition/concentration of the selected leafy biomass of agroforestry tree species

Species	N	C	C:N	L	PP	L:PP	L:N	PP:N	(L+PP):N	Cellulose

Mean concentration of macro nutrient in the selected leafy biomass of agroforestry tree species was presented in table 3 below. The result shows that the nitrogen content of *Gliricidia sepium* (4.1%) was significantly higher than all the other species, while there were no significant difference in the nitrogen content of FA, SS and AL (3.60%.3.20% and3.75%).

The table revealed that *Faidherbia albida, Leuceana leucocephala, Gliricidia sepium* and *Albizia lebbeck* had same significant higher values (0.10%, 0.10%, 0.10% and 0.10%) in magnesium while *Senna siamen* had significantly lower values (0.070.012%) in magnesium than in other selected leafy biomass. *Gliricidia sepium* also had significantly higher values (4.100.012%, 460.100.058ppm, 1.500.115%) in nitrogen, phosphorus and sodium respectively; meanwhile, *Leuceania leucocephala* and *Albizia lebbeck* had significantly higher values (0.230.011% and 1.340.017%) in calcium and potassium than other selected leafy biomass

Table 3: Mean concentration of macro nutrient in the selected leafy biomass of agroforestry tree species

Species	N %	P ppm	K %	Ca %	Mg %	Na %

Figure 1 below shows that *Gliricidia sepium* had significantly higher nitrogen value (4.10%) followed by *Albizia lebbeck* (3.75%) and the least was observed in *Leucaena leucocephala* (3.20%). Furthermore, *Albizia lebbeck* was significantly higher (1.34%) in potassium, followed by *Faidherbia albida* (1.02%) and the least was noticed in Senna siamen (0.84%). Meanwhile, *Gliricidia sepium* had higher significantly value (1.50%) in sodium followed by *Albizia lebbeck* (0.62%) and *Leucaena leucocephala* was observed with least value (0.56%).

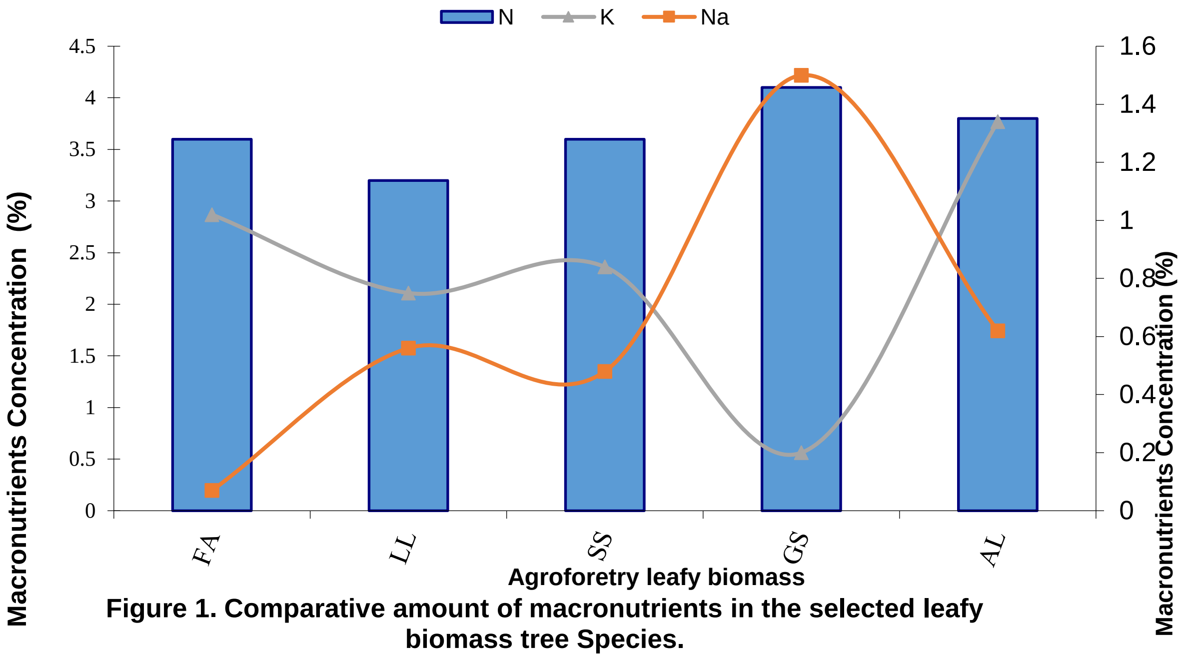

Figure 1. Comparative amount of macronutrients in the selected leafy biomass tree Species.

FA: *Faidherbia albida;* ***LL:*** *Leuceana leucocephala;* ***SS:*** *Senna siamen;* ***GS;*** *Gliricidia sepium; AL: Albizia lebbeck*
Figure 2 below revealed that *Gliricidia sepium* had higher significantly value (460.10%) in phosphorus, followed by *Senna siamen* (420.60%) and *Leucaena leucocephala* had the least value (380.70%). Furthermore, *Gliricidia sepium* had significantly higher value (0.10%) in calcium, followed by *Leucaena leucocephala* (0.10%) and *Faidherbia albida* with least value (0.09%). Meanwhile, *Gliricidia sepium* had significantly higher value (1.5%) in magnesium, followed by *Albizia lebbeck* with value (0.62%) in magnesium and the least value was observed in *Leucaena leucocephala* (0.55%).

DISCUSSION OF FINDINGS

The results of the study revealed that nitrogen and organic carbon in Arboretum soil was slightly higher than that of adjacent agricultural farm. These soil chemical properties in the Arboretum soil actually indicates the quality of the soil, owing to the influence of nutrient contents resident in it as a result of biomass and litter that has decomposed and in turn added nutrients to the soil as fertility improvement. This is in line with Oyebamiji *et al.* (2017) who stated that, biomass decomposition increase the nutrient content of the soil per period of time. Similarly, Smithson and Giller (2002) reported that the higher nutrients composition of the Arboretum can be due to reduced leaching at the arboretum floor due to canopy cover and thereby preventing direct run-off of water in form of erosion. It has been documented that agroforestry remain one of the important and efficient means by which nutrients leaching can be reduced (Odiwe *et al.*, 2016). This leafy biomass optimally functioned as nutrient fixer and agents of leaching control because they were allowed to decompose without being fed on by animals. The University arboretum is a restricted area for research, and this has led it to have minimum entrance and zero encroachment. The soil types of arboretum and adjacent agricultural farm land belong to loamy sand textural class; so also, the soils exhibit weak acidity respectively. However, the disparity in the nutrients composition of the two (2) study areas might be due to differences in the micro climatic and edaphic structures of each of the places and this is in line with Makaza and Shoko (2013). The chemical composition or concentration of the selected leafy biomass showed that *Gliricidia sepium* among other biomass will decompose faster and will release mineral nutrients due to its high nitrogen content and low carbon to nitrogen ratio contents. The better performance of *Gliricidia sepium* in terms of nutrients release agrees with Oyebamiji *et al.*, (2017).The rate of nutrients release by the leafy biomass differs from one species to the other. Similar result of this was reported from other agroforestry leafy biomass in Indonesia (Matheus *et al.,* 2013).

Although, the results of the nutrients composition analysis of the leafy biomass were found to be significantly different from one another, it has however been established that *Gliricidia sepium*, *Leuceana leucocephala* and *Senna siamen* are excellent Nitrogen fixer (Budelman, 1989). The polyphonol content of the leafy biomass are generally low and still significantly different though, this might cause a faster release of the nitrogen content of the leafy biomass. Decomposition and quick nitrogen release have been found to be enhanced by lignin and polyphenol (Makaza and shako, 2013). Furthermore, the value of the macro nutrient in Nitrogen for *Albizia lebbeck* in the present study is below the macro nutrient of nitrogen in *Albizia lebbeck* (5.60) obtained elsewhere Bichi, (2012). Similarly, both phosphorus (370.2 ppm) and potasium (1.34 %) of the present study were lower than those obtained in Bichi (2012). This disparity in the macro nutrient content is an indication of different nutrient content influenced by variation in locations. However, it is noteworthy that all the biomass species have significant amount of the macro nutrients required in agroforestry system

CONCLUSION

This study conclude that *Gliricidia sepium* and *Albizia lebbeck*contained higher concentration of macro nutrients; nitrogen, phosphorus, magnesium and sodium, which are pertinent in plant development. Arboretum has better soil physical, chemical and exchangeable bases composition than adjacent agricultural farm. The soil is neutral while the textural class is loamy sand an indication of its suitability for agroforestry purpose *Albizia lebbeck and Faidherbia albida*were found to be superior in terms of the chemical decomposition, while *Gliricidia sepium* was higher in nitrogen release among all the selected leafy biomass.

RECOMMENDATIONS

Due to high fertility and chemical content in the Arboretum soil, it is therefore advisable that it should be used for agroforestry activities leafy biomass in forms of alley cropping. Moreover, *Gliricidia sepium, Albizia lebbeck* and *Faidherbia albida*should be employed or considered while selecting species for soil fertility improvement. Agroforestry trees that are rich in nitrogen and other macro nutrient capacity should be used as alternative to inorganic fertilizer that are relatively scarce, costly and adversely affecting soil improvement.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This research was conducted with the view of assessing Soil Composition of Abadole Arboretum and Adjacent Agricultural Farms at Federal University Dutsinma. Plant materials were collected from; Faidherbia albida, Leuceana leucocephela, Senna siamen, Gliricidia sepium, Albizia lebbeck. A plot of 50x50 m was measured and trees were counted. Total Nitrogen was analysed by Macro-Kjeldahl digestion, followed by distillation and titration. Soil samples were randomly collected from five locations at the depth of (0-30 cm) from Arboretum and adjacent agricultural farm for physical and chemical analysis which include:Sand, silt, clay and, textural class, pH, organic carbon, total nitrogen and available phosphorus respectively. Prior to the commencement of the experiment using standard methods. Total nitrogen was analyzed by Macro-Kjeldahi digestion, followed by distillation and titration. The result of this research revealed that,Gliricidia sepium and Albizia lebbeck contained the higher mean concentration of macro-nutrients, nitrogen, phosphorus, magnesium and sodium which are pertinent in plant development. Arboretum has better soil physical, chemical and exchangeable bases composition than adjacent agricultural farm. The soil types were also noted to be nearer neutral, meaning that, contain weak acidity and loamy sand in nature.Furthermore, Albizia lebbeck and Faidherbia albida were found to be superior in terms of the chemical decomposition, while Gliricidia sepium was higher in nitrogen release among all the selected leafy biomass. As a result of high fertility and chemical content in the Arboretum soil, it is therefore advisable that it should be used for agroforestry activities leafy biomass in forms of alley cropping. Moreover, Gliricidia sepium, Albizia lebbeck and Faidherbia albida should be employed or considered while selecting species for augmenting soil potential and/ or improving soil fertility for various agroforestry activities

INTRODUCTION
Decomposition of leaf litter is an important source of nutrients in forest ecosystems and farming systems. In most forests and farming systems in the tropics the major source of nutrients for trees and food crops is from the decomposition of plant material. Decomposition refers to the process that converts fresh and dead organic matter into smaller and simpler compounds. Decomposition is mainly a biological process carried out by insects, worms, bacteria, and fungi both on the soil surface and in the soil. The products of complete decomposition include carbon dioxide, water, and Inorganic ions (e.g. ammonium, nitrate, phosphate, and sulphate). The fresh and dead organic matter, which is referred to as mulch, is broken down by microbial decomposers and insects. Organically bound nutrients are then released as free ions to the soil solution which are then available for uptake by plants. Vegetative materials that are used as mulching material include grass, crop residues and leaves from pruning of trees. It is mainly a practice in which organic materials are placed on the surface or incorporated in the soil to maintain and improve soil fertility (Food and Agriculture Organization, 1975).
The rate of decomposition of mulch is influenced by many interacting factors which include the composition of bacteria, fungi, invertebrates, temperature, soil moisture and quality of the mulch as a food source for the decomposers. For soil moisture, decomposition of mulch is inhibited in very dry soils because bacteria and fungi dry out. Decomposition of mulch is also slow in very wet soils because anaerobic conditions develop in saturated soils.

Anaerobic decomposition of mulch is less efficient than aerobic and as a result is slower. Thus, decomposition of mulch proceeds fastest at intermediate water contents

Litter decomposition plays a crucial role in the budget of forest ecosystem where vegetation depends mainly on the recycling of nutrient contained in the plant detritus. During the process, litter fall and decomposition is influenced by environmental factors and also by physical and chemical properties of plant parts such as stem wood, leaves, root etc. (Temel, 2003; Oyebamiji *et al.,* 2017). Litter fall is a fundamental process in the nutrient cycling and it is the main means of transfer of organic matter and mineral element from vegetation to the soil surface (Reginal *et al.,* 1999). Litter fall has also been described as a major pathway for the return of organic matter and nutrients from aerial parts of the plant community to the soil surface. Decomposition is a key process in the nutrient cycling and formation of soil organic matter (Berg and McClaugherty, 2002). The decomposition of leaf litters is a major source of nutrient in forest ecosystem (Temel, 2003).

Agroforestry is the production of trees and of non-tree crops or animals on the same piece of land and provide diverse output from the same land units. These land use types were conserving different types of plant species diversity in pieces of land and minimizes the impacts of community in the natural forest. Agroforestry systems make maximum use of the land. Every part of the land is considered suitable for useful plants. Emphasis is placed on perennial, multiple purpose crops that are planted once and yield benefits over a long period of time. Such benefits include; construction materials, food for humans and animals, fuels, fibers, and shade. Trees in agroforestry systems also have important uses such as holding the soil against erosion and improving soil fertility. Soil nutrient declining is considered to be a major threat to food security and natural resource conservation in Sub-Saharan Africa (SSA). According to Bationo *et al*. (2006), Africa loses US$4 billion per year due to soil nutrient declining. The problem is pervasive among mixed crop and livestock farming systems of the region, especially Nigeria where competing uses for crop residues such as livestock fodder or household fuel mean that nutrients are not sufficiently replenished into the soil. Nutrient replacement using mineral fertilizers is a limited option for many smallholder farming households of Nigeria. It is observed that, region with lowest mineral fertilizer application rates will experience, much lower crop yields than those using organic fertilizer (Morris *et al.,* 2007). In Southern Africa, the consequent downward spiral of soil fertility has contributed to a corresponding decline in crop yields, an increase in food insecurity, food aid and environmental degradation (Mafongoya *etal.*, 2006).

Decomposition is primarily driven by microbial activities and can be best predicted by environmental factors such as temperature and precipitation, as well as litter quality, but soil chemistry and physical conditions can also influence the rate of litter decomposition (Liu, *et al*., 2006). Study of the factors that affect litter decomposition is fundamental to quantitative analysis of nutrient cycling in terrestrial ecosystems. Plant litter qualities, soil qualities, and environmental conditions are discussed as main impact factors of decomposition process in this section. Decomposition is one of most important processes that accounts for carbon and nutrient cycling on planet Earth. Decomposition or litter mass loss is regarded as the sum of CO_2 release and leaching of compounds, including both C compounds. Organic compounds in residues are classified into soluble components, hemicelluloses, cellulose, and lignin based on molecular size, solubility and primary constituent. Litter decomposition is complex and involves physical, chemical, and biological processes. It generally follows a sequential pattern with different classes of organic compounds dominating the decay process as it proceeds. When plant parts fall onto the soil surface, soluble organic substances such as sugars, phenolic, hydrocarbons, and glycerides are leached rapidly by water. This process is highly affected by climate conditions. At the same time, under soil microbial effects and external forces (such as wind, rain and cultivation), large pieces of plant residues are physically broken down into small bits, which provide greater surface area for microbial colonization and attack. Under the action of rapidly growing microorganisms, some sugars, low-molecular-weight phenolics, and some nutrients are readily lost from the litter. Following this, the plant detritus (cellulose, hemicellulose and lignin) undergoes chemical alteration by microbes, encompassing both fungi and bacteria (Fioretto *et al.*, 2005).

The effectiveness of different sources of organic matter varies depending upon their physical and chemical nature, rate of nutrient cycling and release of nutrients. Many farmers cannot afford to buy chemical fertilizers, or fertilizers are not available when needed. The use of agroforestry practices can alleviate some of the problems of declining in soil fertility. Leguminous plants can produce large amount of foliages which can release nutrients to enhance soil fertility and increase yields (Albercht and Kandji, 2003).

Many farmers in Nigeria for example, cannot afford chemical fertilizers and even those who can afford, cannot access the fertilizer when needed, because they are relatively unavailable or scarce. However, the use of agroforestry tree species which fix nutrients can at least alleviate some of the problems of declining soil fertility. Hence, nitrogen fixing agroforestry trees could be used to complement the improvement of soil for better yield of crops. Chemical compositions of the leafy biomass which are been determine by biological and environmental factors (such as decomposers, quality of litter, temperature and moisture etc.) are also vital area of concern as far as decomposition and release of nutrients are concern.

Study and research on macro nutrients contents and the soil composition status will assist in planning to improve the richness of the arboretum for economic, ecological, educational, recreational and research purposes. Moreover, the leafy biomass of some of the leguminous agroforestry trees within the arboretum can also be used to improve the soil quality of an improved or increased crop production. Leaves and pruning of some agroforestry trees incorporated or applied to the soil have the chance to improve the yield of many crops (as a result of nitrogen that will be released as nutrient through the leaves after decomposition) trees (Ajayi *et al.,* 2007). However, leguminous agroforestry trees can produce large amount of foliages which can release nutrients to enhance high soil productivity and increase yield (Albercht and kandji, 2003).

Litter decomposition plays a crucial role in the budget of forest ecosystem where vegetation depends mainly on the recycling of nutrient contained in the plant detritus. During the process, litter fall and decomposition is influenced by environmental factors and also by physical and chemical properties of plant parts such as stem wood, leaves, root etc. (Temel, 2003; Oyebamiji *et al.,* 2017). Litter fall is a fundamental process in the nutrient cycling and it is the main means of transfer of organic matter and mineral element from vegetation to the soil surface (Reginal *et al.,* 1999). Litter fall has also been described as a major pathway for the return of organic matter and nutrients from aerial parts of the plant community to the soil surface. Decomposition is a key process in the nutrient cycling and formation of soil organic matter (Berg and McClaugherty, 2002). The decomposition of leaf litters is a major source of nutrient in forest ecosystem (Temel, 2003).

MATERIALS AND METHODS

The Study Area

The research was conducted at Forest Arboretum of the Department of Forestry and Wildlife Management Federal University Dutsinma, Katsina State Nigeria. The area lies between (Latitude 8^0 29 N, Longitude 4^0 35 E and 307 meters above sea level. It was conducted in 2018 during dry seasons. Dutsin-ma is characterized by an annual rainfall of 1,186 mm while the mean annual temperature and relative humidity are 29^0 and 85 % respectively. The soil is well drained and the other is Alfisols belonging to the Tanke series (23). The underlying geology is made of sand stone, ranging from fine to coarse grained light brown colour. The dominant soil types include; sand, silt, clay and textural class (Lukman, 2018).

Soil sample collection

A plot of 50x50 meters was measured and trees were counted, soil samples were randomly collected from five locations at the depth of (0-30 cm) both from Arboretum and adjacent agricultural farm for physical and chemical analysis which include: Sand, silt, clay and, textural class, pH, organic carbon, total nitrogen and available phosphorus respectively. Prior to the commencement of the experiment using standard methods. Total nitrogen was analyzed by Macro-Kjeldahi digestion, followed by distillation and titration (Brandstreet, 1965; Anderson and Ingram, 1993). Ammonium was determined by the salicylate-hypochlorite colorimetric method (Anderson and Ingram, 1993) whereas NO_3^- plus nitrate (NO_2) was determined by cadmium reduction method (Dorich and Nelson, 1984).

Procedure

Plant materials were collected from *Faidherbia albida, Leuceana leucocephela, Senna siamen, Gliricidia sepium, Albizia lebbeck*. Five trees were randomly selected from each selected tree species out of which the leaves were collected. In each of the collected samples was pooled /bulked together while composite samples will also be taken.

The leafy biomass was air- dried and the sample was grounded and passed through a sieve of 2 mm size. Then, 2.0 g of each sample of the selected species was put into a digestion flask which was washed with distilled water.10 ml of 4 % perchloric acid ($HCLO_4$) was added to the samples under a fume cupboard. The contents were mixed and heated strongly on digestion block under the $HCLO_4$ fume cupboard.

The contents were allowed to cool and then 50 ml of distilled water was then added. The solution was transferred into a 100 ml Pyrex volumetric flask. The volume was made up to mark with distilled water. Then the solution was stored in plastic bottles and labeled for analysis. The digested sample solutions of plants were subjected to laboratory analysis to determine the Total Nitrogen (N), Potassium (K), Calcium (Ca), Magnesium (Mg), and Sodium (Na). Total Nitrogen was determined by Macro-Kjeldahl method as described by Jackson (1985) Phosphorus was detemined by Vanadomolybdo Phosphoric yellow colour as described by Kitson and Milton (1994).

RESULTS

Soil physical and chemical properties of the study area

The results of the physical, chemical properties and exchangeable bases (cations) of the soils type on arboretum and adjacent agricultural farm soils were presented, (Table 1) where the soil physical and chemical properties revealed that arboretum had 780 g/kg sand, 100 g/kg silt and 120 g/kg clay while chemical properties also showed that pH had 6.20 organic carbon 7.00g/kg, total nitrogen 0.42 g/kg, carbon to nitrogen ratio 16:67 and available phosphorus 3.10g/kg respectively. However, soil exchangeable bases/cations were observed to have 2.70 mg/kg calcium, 0.50 mg/kg magnesium, 0.31 mg/kg potassium and 0.12 mg/kg sodium. Furthermore, it was also observed that adjacent agricultural farm soil physical and chemical properties had 820 g/kg sand, 80 g/kg silt and 120 g/kg clay while chemical properties also showed that pH had 6.10, organic carbon 5.00 g/kg total nitrogen 0.28 k/kg carbon to nitrogen ratio 17:86 and available phosphorus 2.20 g/kg respectively. Moreover, soil exchangeable bases/cations were observed to have 2.12 mg/kg in calcium, 0.61 mg/kg in magnesium, 0.34 mg/kg in potassium and 0.11 m/kg sodium respectively (Table 1).

Table 1: Physical, chemical properties and exchangeable bases of the soils

Soils type	Particle size (g/kg)				Chemical properties					Exchangeable (mg/kg)			bases
	Sand	Silt	Clay	Textural class	pH	Organic carbon (g/kg)	Total nitrogen	C: N	Available phosphorus (mg/kg)	Ca	Mg	K	Na
Arboretum	780	100	120	Loamy sand	6.20	7.00	0.42	16:67	3.10	2.70	0.50	0.31	0.12

Chemical composition/concentration of the selected agroforestry tree species

Faidherbia albida was observed to have significantly higher values (77.43a, 21.51a and 14.81a) in carbon, C:N ratio and PP:N ratio, while *Leuceana leucocephala* alsohad significantly higher value (20.00a) in cellulose than the other selected leafy biomass. However, *Senna siamen* was noticed to have significantly higher value (0.41a) in polyphenol, whereas *Gliricidia sepium* had (4.10a) in nitrogen than the other selected leafy biomass. *Albizia lebbeck* was discovered to have significantly higher values (15.59a, 54.29a, 4.15a and 4.22a) in lignin, lignin to polyphenol ratio, lignin to nitrogen ratio and lignin plus polyphone to nitrogen ratio respectively than in other selected agroforestry tree species leafy biomass (Table 2).

DISCUSSION

The results of the study revealed that nitrogen and organic carbon in Arboretum soil was slightly higher than that of adjacent agricultural farm. These soil chemical properties in the Arboretum soil actually determined the quality of the soil, owing to the influence of nutrient contents resident in it as a result of biomass and litter that has decomposed and in turn added nutrients to the soil as fertility improvement. This is in line with Oyebamiji *et al.* (2017) who stated that, biomass decomposition increases the nutrient content of the soil per period of time. Similarly, according to Smithson and Giller (2002) who reported that the higher nutrients composition of the Arboretum can be due to reduced leaching at the arboretum floor due to canopy cover and thereby preventing direct run-off of water in form of erosion.

Though, it has been documented that agroforestry remain one of the important and efficient means by which nutrients leaching can be reduced (Odiwe *et al.,* 2016). This leafy biomass optimally functioned as nutrient fixer and agents of leaching control because they were allowed to decompose without being fed on by animals. The University arboretum is a restricted area for research, and this has led it to have minimum entrance and zero encroachment. The soil types of arboretum and adjacent agricultural farm land belong to loamy sand textural class; so also, the soils exhibit weak acidity respectively.The chemical composition or concentration of the selected leafy biomass showed that *Gliricidia sepium* among other biomass decomposed faster to release mineral nutrients due to its high nitrogen and low carbon to nitrogen ratio contents. The better performance of *Gliricidia sepium* in terms of nutrients release agrees with Oyebamiji *et al.* (2017a).

Although, the results of the nutrients composition analysis of the leafy biomass were found to be significantly different from one another, it has however been established that *Gliricidia sepium*, *Leuceana leucocephala* and *Senna siamen* are excellent Nitrogen fixer (Budelman, 1989). The polyphonol content of the leafy biomass are generally low and still significantly different though, this might cause a faster release of the nitrogen content of the leafy biomass. Decomposition and quick nitrogen release have been found to be enhanced by lignin and polyphenol (Makaza and shako, 2013). Furthermore, the value of the macro nutrient in Nitrogen for *Albizia lebbeck* in the present study is below the macro nutrient of nitrogen in *Albizia lebbeck* (5.60) obtained elsewhere Bichi, (2012). Similarly, both phosphorus (370.2 ppm) and potasium (1.34 %) of the present study were lower than those obtained in Bichi (2012). This is an indication of disparity in the innate macro nutrient of the two study areas. However, it is noteworthy that all the biomass species have significant amount of the macro nutrients required by agroforestry.

CONCLUSION AND RECOMMENDATIONS

It was observed that *Gliricidia sepium and Albizia lebbeck* contained the higher mean concentration of macro nutrients, nitrogen, phosphorus, magnesium and sodium which are pertinent in plant development. Arboretum has better soil physical, chemical and exchangeable bases composition than adjacent agricultural farm. The soil types were also noted to be nearer neutral, meaning that, contain weak acidity and loamy sand in nature. Furthermore, *Albizia lebbeck* and *Faidherbia albida* were found to be superior in terms of the chemical decomposition, while *Gliricidia sepium* was higher in nitrogen release among all the selected leafy biomass.

Due to high fertility and chemical content in the Arboretum soil, it is therefore advisable that it should be used for agroforestry activities leafy biomass in forms of alley cropping. Moreover, *Gliricidia sepium, Albizia lebbeck and Faidherbia albida* should be employed or considered while selecting species for augmenting soil potential and/ or improving soil fertility for various agroforestry activities.Agroforestry trees that are rich in nitrogen and other macro nutrient capacity should be used as alternate fertilizer to inorganic fertilizer that are relatively scarce, costly and adversely affecting soil improvement.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was conducted to assess the effect of flooding on livestock production in Hadejia Local Government Area of Jigawa State, Nigeria and to offer possible solution to the problems. Two hundred (200) well-structured questionnaires were designed and allotted to 200 victims of flood as respondents. The result showed that, majority of respondents in the study area were males and married, with a wide age range 20 – 60 years. Majority of the farmers kept their flock under intensive and semi-intensive systems of production, and they experienced challenges during flooding period, especially mid and late of rainy season. During this period most of the farmers lost their animals, due to diseases, death, suffocation and feeding problems that were brought about by the menace. The ultimate effects of floods include the agony of survivors, the spread of an epidemic, non-accessibility of essential commodities, medicines, and loss of the dwellings which compel the affected people to perceive such floods as the most feared among the natural disasters being faced by mankind. This can be prevented or minimized when the incidences of floods are not catching individuals and communities by surprise and unaware in a repeatedly exasperating way and causing disruption of social activities, damages of infrastructure and even death of people and livestock. Also more attention is needed to be paid to the flooding by both the community, the government and any relevant stakeholder.
Keywords: *Farmers, Flooding, Hadejia, Livestock, Production*

INTRODUCTION
The world has had already witnessed devastating effects on properties and livelihoods as well as economic losses due to floods than any other hazard (Armah *et al*., 2010). A flood is a natural event that can have far reaching effects on people and the environment. Put simply, a flood is too much water in the 'wrong' place. Flooding occurs most commonly from heavy rain fall when natural water courses do not have the capacity to convey excess water. Flooding is the most common of all environmental hazards and it regularly claims over 20,000 lives per year and adversely affects around 75 million people world-wide (Adewuyi and Olofin, 2014; Akukwe and Ogbodo, 2015). In Nigeria, the pattern is similar with the rest of world. Flooding in various parts of Nigeria have forced millions of people from their homes, destroyed businesses, polluted water resources and increased the risk of diseases (Bastakoti *et al*., 2014; Obeta, 2014; Emeriobeole 2015). Emeriobeole (2015) asserts that floods are among the most devastating natural disasters in the world, claiming more lives and causing more property damage than anyone would imagine. According to him, in Nigeria though not leading in claiming lives, flood affects and displaces more people than any other disaster. It also causes more damage to properties and at least 20 percent of the population is at the risk from one form of flooding or another. Floods often occur in Hadejia and other part of Jigawa State. From the year 2020 and 2022, Hadejia was affected by the terrible floods which happened to be severe ones as many towns and villages under the emirate council were affected by floods, while causing havoc in the entire state. Further, many hectares of land under cropping well as animal life got affected by floods in these years, which leads to the poor economy especially among the livestock-rearers, who depend, solely, on animals for their livelihood. (Mishra, 2017). Therefore, it was thought essential to document the impact

of the flood on the economic condition of livestock-rearers as well as livestock production in Hadejia local government area.

MATERIALS AND METHODS

The study was conducted at Hadejia Local Government Area of Jigawa State, Nigeria (12^0 27'N / 10^0 2'E and $12^0$45'N / 10^0 033'E). Hadejia has an area of 32km^2 and a population density of 4,356 people/km^2, the population was approximately 105,628 in National Census of 2006. It falls into the ecological zone of Sahel savannah, characterized by a short rainy season with annual rainfall of about 200mm to 600mm, during the period of late May to September. It has an average low temperature during cold between 15^{0}C and 21^{0}C and temperatures between 27^{0}C and 42^{0}C during hot season. The relatively humidity is very low often between 10% to 30% in January and 60% to 80% during the rainy season. The town lies to the north of the Hadejia River and upstream of the Hadejia Nguru wetlands. Hadejia Local Government Area has a total of Eleven (11) wards which include Atafi, Dubantu, Kasuwar Kuda, Kasuwar Qofa, Majema, Matsaro, Rumfa, Sabon-Garu, Yankoli and Yayari wards. The people of Hadejia are largely Muslim, although some follow indigenous belief system. Most of the people of Hadejia are Hausa and Fulani by tribe. Their occupations are farming, rearing of animals, fishing, trading and civil services (Bird Life International, 2021; Muhammad *et al*., 2023). The area is conducive for livestock production, the common livestock species in the area includes; cattle, sheep, goat, rabbit and poultry.

Data collection and analysis

Data was collected through the use of two hundred (200) structured questionnaires and organized informative oral interview with selected respondents using their local language (Hausa language). Data collected was stored in MS excel and later analyzed using simple descriptive statistics.

RESULTS AND DISCUSSIONS

Distribution of the respondents according to socio-economic characteristics

The distribution of the respondents according to socio-economic characteristics were given in table 1, where (93%) of the respondent were male and (7%) were female. Most (36%) of the respondent were in the range of 20-40 years of age and mostly married (64%) with low to mid-level of formal education. Most of the respondents (93%) were male indicating that males are more actively involved in livestock farming in the study area. The age of respondents were highest in the range of 20–40 years (36%) indicating most of the farmers were young. Majority (64%) were married and have some form of formal and qur'anic education. Qur'anic education (33%), adult education (13%), primary (20%), secondary (24%), and tertiary (9%). Qur'anic education could be describe as literate in terms of reading and writing.

Table 1. Distribution of the respondents according to socio-economic characteristics

Socio-economic characteristics	Frequency	Percentage (%)
Sex		
Male	186	93.0
Female	14	7.0
Age		
< 20years	54	27.0
20-40	72	36.0
41-60	34	17.0
Above 60	40	20.0
Marital status		
Single	64	32.0
Married	128	64.0
Divorced	6	3.00
Widower	2	1.0
Educational background		
Qur'anic	68	34.0
Adult education	26	13.0
Primary	40	20.0
Secondary	48	24.0
Tertiary	18	9.0

Distribution of the respondent based on livestock destroyed, action taken, number of animals destroyed and Destruction cause to the animal.

Table 2 shows the distribution of the respondents based on livestock destroyed, action taken, number of animals destroyed and destruction to the animals. The study shows that, nineteen percent (19%) lost their sheep, (18%) cattle, (18%) goat, (12%) poultry, (14%) sheep and goat, (15%) sheep, goat and cattle, (4%) combination of all and the action taken from the respondent was (22%) slaughtered, (22%) sold, (18%) attend veterinary clinic and (38%) lost animal. According to the respondents the destruction cause to the animals was (37%) death, (38%) diseases, (20%) suffocation, and (5%) lost. The number of animals destroyed per household of the respondents was 1-5 (67%), 6-10 (20%), 10-20 (8%), above 20 (5%).

Table 2. Distribution of the respondent based on livestock destroyed, Action taken, number of animals destroyed and Destruction to the animal.

Variable	Frequency	Percentage
Livestock destroyed		
Goat only	36	18.0
Sheep only	38	19.0
Cattle only	36	18.0
Camel	0	0.0
Poultry only	24	12.0
Sheep and goat	28	14.0
Sheep, goat and cattle	30	15.0
Combination of all	8	4.0
Action taken		
Slaughter	44	22.0
Selling	44	22.0
Animal Lost	76	38.0
Attend veterinary clinic	36	18.0
Destruction to the animal		
Death	74	37.0
Disease	76	38.0
Suffocation	40	20.0
Others	10	5.0
Number of animals destroyed		
0-5	134	67.0
6-10	40	20.0
10-20	16	8.0
Above 20	10	5.0

Distribution of respondent based on effect of flooding.

Table 3 shows the effect of flooding in causing destruction of lives and properties. The study shows that, there was (10%) loss of lives, (77%) damage to roads and (25%) lost of property. All respondent (100%) Lost their farm land, some confirmed flooding caused erosion (66%) and (95%) livestock destruction.

Table 3. Distribution of the respondents based on effect of flooding

Variable	Frequency	Percentage
Loss of life		
Yes	20	10.0
No	180	190.0
Loss of property		
Yes	50	25.0
No	150	75.0
Lead to bad road		
Yes	154	77.0
No	46	23.0

Loss of farm land		
Yes	200	100.0
No	0	0.0
Caused erosion		
Yes	132	66.0
No	68	34.0
Livestock destruction		
Yes	190	95.0
No	10	5.0

Thousands of people die, millions become homeless, and properties and infrastructures are greatly damaged by the calamities of flood every year all over the world (Obeta, 2014). The effect of flooding in study area was worst in terms of losing of homes, properties, infrastructure, livestock as well as farmland. The study revealed that, there were lost of farmlands, lives, properties, damage roads, erosions, livestock destructions in the study area, which agrees with Emeriobeole (2015) that asserts floods to be among the most devastating natural disasters in the world, claiming more lives and causing more property damage than anyone would imagine. The result was also in line with the findings of Obebi (2013) who reported for instance, Abia, Adamawa and Akwa Ibom states that witnessed heavy downpour and rain storm which affected about 5,000 people. Explaining further, Obebi (2013) confirms that in the same year, about 12,300 people were displaced by torrential rain which destroyed livestock and farmlands, damaged properties and submerged buildings in Zamfara state.

CONCLUSION

It is concluded that most of livestock farmers in Hadejia Local Government Area kept different types of livestock, and were faced with a lots of problems. Among other disasters, floods have escalated intensive harm to their crops and livestock. During this period most of the farmers lost their animals, due to diseases, death, suffocation and feeding problems. The ultimate effects of floods include the agony of survivors, the spread of an epidemic, non-accessibility of essential commodities, medicines, and loss of the dwellings which compel the affected people to perceive such floods as the most feared among the natural disasters being faced by mankind. This can be prevented or minimized when the incidences of floods are not catching individuals and communities by surprise and unaware in a repeatedly exasperating way and causing disruption of social activities, damages of infrastructure and even death of people and livestock. Also more attention is needed to be paid to the flooding by both the community, the government and any relevant stakeholder.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Despite being a protected area, Old Oyo National Park (OONP) still experiences myriads of illegal activities. The study highlighted the implications of herders and cattle infiltration into OONP. The study driven by qualitative research approach with document analysis, unearth the recurring challenges that have been the obstacles to achieving sustainability and conservation of OONP biodiversity. The study showed that the most prevalent challenges to the conservation of natural resources in the study area was illegal grazing. The study recommended the establishment of cattle grazing reserves as well as strict adherence to all existing local, national and international policies regarding ranching and pastoralism.
Keywords: *Herders, Conservation, Biodiversity, Cattle infiltration, Old Oyo National Park*

INTRODUCTION
Unregulated nomadic grazing, apart from its potential to increase insecurity and conflicts, also has an adverse impact on the environment. Over grazing causes severe damage to the environment such as the exposure of fragile soils leading to severe erosion and subsequent downstream siltation and the introduction of aggressive weeds by the cattle (Asadu, 1999). Pastoralists are people whose major source of livelihood is livestock herding (Bhasin, 2011). In Nigeria, migration is part of a comprehensive economic strategy (NEST and Tegler, 2011). The movement of the pastoralists is governed by livelihood norms associated with the needs of their cattle for pasture. In different countries in Africa, nomadic pastoralists are usually a mix of both the indigenous ones and those who migrated from other neighbouring African countries in search of water and pasture. The latter movement is known as transhumance, even though the movement of the nomadic pastoralists within a country is also regarded as transhumance by some authors (Agyemang, 2017). However, in recent times, the practice has resulted in severe conflicts wherever nomadic pastoralists and their herds pass through or attempt to settle temporarily. The purpose of this review was therefore to highlight the implications of herders and cattle infiltration into Old Oyo National Park, Nigeria.

MATERIALS AND METHOD
Study Area
Old Oyo National Park (OONP) has a total land mass of 2512 km^2 and is located in the South Western part of Nigeria, specifically Northern part of Oyo State. OONP is geographically located between latitudes 8°15' and 9°.00'N of the equator and longitudes 3°35' and 4°42'E of the Greenwich meridian.

Data Collection and Analysis
The qualitative research approach was utilized for the study. This was due to the fact that the researcher collected and examined numerous secondary data such as previously published articles, public reports (Creswell, 2009; Narayanan, 2015) related to fauna and flora conservation. The research was mainly driven desk research and interpretative document analysis were the main research methods that guided the finding, selecting and rigorous examination of important documents. The secondary data was analyzed quantitatively. Categories and themes were generated to give detailed comprehension of the secondary data reviewed (Denzin and Lincoln, 1994). Finally, the facts were evaluated and presented using descriptive statistics.

RESULTS

Table 1 below showed that most occurring offence in Old Oyo National Park was grazing with overall total of 445. Highest record of illegal activities occurred in year 2018 (150), while the least record of illegal activities occurred in year 2014 (45). Hunting activity (225) was more prominent after grazing in Old Oyo National Park.

Table 1: Records of Illegal Activities in Old Oyo National Park from 2014-2021

Offences	Arrests								
	2014	**2015**	**2016**	**2017**	**2018**	**2019**	**2020**	**2021**	**Total**
Hunting	13	33	23	31	64	10	19	32	**225**
Grazing	5	21	42	50	79	104	81	63	**445**
Logging	7	6	6	2	-	-	3	3	**27**
Honey trapping	-	-	2	-	-	2	10	5	**19**
Mining	20	46	12	-	-	-	6	-	**84**

Source: Old Oyo National Park Research Unit

Furthermore, grazing activity was more pronounced when compared to hunting activity, as shown in Figure 1 below. For instance, in years 2006 (G= 42; H= 33), 2007 (G= 50; H= 33), 2008 (G= 79; H= 64), 2009 (G= 104; H= 10), 2010 (G=81; H= 19), 2011 (G= 47; H= 32), 2012 (G= 63; H= 0), 2013 (G= 61; H= 53), 2014 (G= 65; H= 24) and 2015 (G= 64; H= 24). On the other hand, hunting activity was more in years 2004 (H= 13; G= 5) and 2005 (H= 33; G= 21).

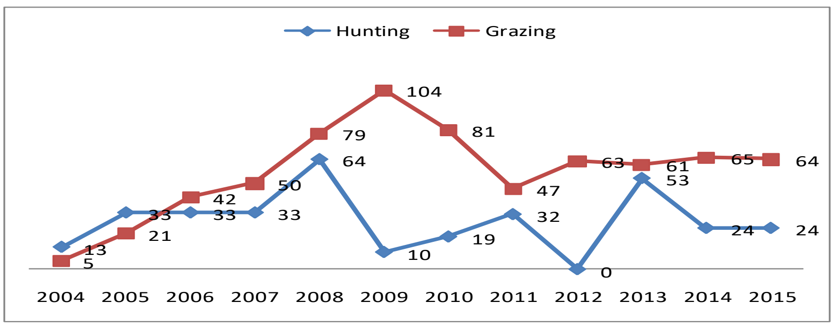

Figure 1: Arrests made on grazing and hunting activities in OONP, Nigeria
Source: Adapted from Old Oyo National Park Research Unit

DISCUSSION

Grazing, hunting, mining and logging were obviously the most engaged illegal activities in Old Oyo National Park. These may not be unconnected to the proximity of the Park to the locals as echoed by Hames (1988) and Alvard (1994) in Adedoyin *et al*. (2018) that most illegal activities occur near human settlements. Furthermore, the infiltration of herders and cattle into the Park is a huge threat on the conservation of biodiversity. Out of the twelve (12) years under review, illegal grazing occurred more in ten (10). This reveals how porous and unguarded the Park is. The implications of this is that fauna, flora and forms of life existing within the Park are prone to global warming through greenhouse emissions (Havlik, 2014); diseases transmission (either vertically or horizontally); as well as loss of lives (field staff). The evidence of intensive grazing is obvious in Old Oyo National Park as reflected by the crisscross of trampling marks, in some cases resulting in permanent tracks. Such level of grazing intensity will lead to the process of irreversible environmental degradation (such as soil surface compaction, erosion and invasion of non-native plant species) whereby the ecosystem is incapacitated to support regeneration.

CONCLUSION

Cattle grazing and rearing, as is being practiced currently in Nigeria, is not environmentally sustainable. Several gaps relating to lack of robust mechanism for stakeholders participation in land reform processes has exacerbated the spate of land grazing conflicts and disputes in Nigeria. Conservation managers should therefore devise means to drastically reduce incessant infiltrations into our National Parks.

RECOMMENDATIONS

i. There should be the establishment of cattle grazing reserves in the first instance, while the pastoralists and other stakeholders are being prepared to adopt the ranching method of cattle rearing.

ii. Both the federal and state governments should work together with National Environmental Standards and Regulations Enforcement Agency (NESREA) and the State Environmental Protection Agencies in creating the grazing reserves and eventually, the ranches to ensure that existing environmental legislation are complied with.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The level of heavy metals concentration in the soil around Cassava Processing Mill at Oja Oba in Igboora, Nigeria was assessed around Oyo State College of Agriculture and Technology, Igboora, Nigeria. Soil samples were collected at a distance of 0-10, 10-20, 20-30, 30-40, 40-50, 50-60m away from the point of discharge of the cassava processing effluent. However, the control sample taken from the adjacent soil that did not receive cassava processing effluent. Three samples were collected from each distance range and analyzed for Pb, Mn and Cu after digesting the samples with nitric-perchloric acid at the ratio of 2:1. The data collected were subjected to ANOVA and means separated using DMRT at 5% level of probability. The concentration of Pb significantly varied ranging from 5.00-16.07 mg kg^{-1}; Mn (82.13-183.33 mg kg^{-1}) and Cu (4.94-12.83mg kg^{-1}). These values were significantly different at 5% level of probability except for Mn. The concentration of these metals were found to increase with the distance away from the point of discharge of the cassava processing effluent except Mn. Comparing the concentration of Pb, Mn and Cu in the study area with the World Health Organization (WHO) permissible level in soil, the concentration of Pb, Mn and Cu were found to be within the safety limit. This implies that the soil around the cassava processing mill at Oja Oba, Igboora is still contamination free but, caution must be taken not to load the soil beyond the safety limit to avoid potential water contamination in the study area.

Keywords: *Cassava effluents, environment, heavy metals, pollution, soil properties*

INTRODUCTION
Cassava processing involves wastes generation in different zones including peels from the peelings stage, cassava mill effluents from the dewatering/pressing zone and gaseous emissions from the frying stage (Ohimain *et al*., 2013). The liquid waste popularly known as cassava mill effluents is generated in the grating and dewatering zone and it account for about 16% of total weight of cassava tuber (Ohimain *et al*., 2013). The wastes are discharged into the environment without any form of treatment (Izah *et al*., 2017). The toxicity of cassava mill effluent is basically associated with its acidic pH and cyanide content. In acidic soils, plants are likely to take up toxic metals, which may prevent seed germination or eventual death (Olorunfemi *et al*., 2008). When these cassava mill effluents are improperly disposed, they generate offensive odour and unsightly scene (Okafor, 2008).

The discharge of waste products and contaminants into surface runoff get into rivers through drainage systems, leaching into liquid spills, groundwater and wastewater discharges and littering. Soil contamination in our case occurs when drains from cassava processing factory are released by spill or underground leakage. This cassava effluent has a negative effect on our environment. Effluent wastes contain varying concentration of heavy metals either as simple metals or complexes (Agwa *et al*., 2014). The increasing level of heavy metals in the environment from various anthropogenic sources like cassava mill effluent should be a source of concern for environmentalists (Iwegbue, 2007; Osakwe and Egharevba, 2008). These heavy metals that are released into the environment tend to persist indefinitely, accumulating in living tissues through food chain causing diseases to man (Enerjiofi and Ajuzie, 2012).

Therefore, the objective of this study was to evaluate Lead (Pb), Manganese (Mn) and Copper (Cu) status of the soil around cassava processing mill at Oja-Oba, Igboora, Nigeria.

MATERIALS

Soil, Cassava extract, Metals e.g. lead, manganese and copper, Nitric acid, Perchloric acid, Volumetric flask and Measuring cylinder

METHODS

Study Location

The study was conducted in the Oyo State College of Agriculture and Technology, Igboora Oyo State, Nigeria. Igboora is located between Latitude 7^0 40' N and Longitude 3^0 30' E, 27.5m above the sea level. The natural climate is characterized by both the wet and dry seasons with the rainy season beginning from April lasting till October while the dry season begins from October and ends in April.

Soil Sampling and Analysis

Surface samples (0-20cm) were collected at the site from 0 -10m, 10-20m, 20-30m, 30-40m, 40-50m, 50 - 60m away from the point of discharge of the effluent. The control was taken from the adjacent field (plot where there is no cassava effluent discharge). Three soil sample collection. The sample collected were air dried and passed through a 2mm sieve.

The dried soil samples were digested using nitric-perchloric acid (2:1). The dried soil sample were digested using 10ml of 2:1 by volume of nitri-perchloric acid until dense white fumes appeared. The digest was allowed to cool and some quantity of distilled water was added to the digest. The solution was filtered into a 50ml volumetric flask and diluted to volume (SSA, 1996). The amount of Pb, Mn, and Cu in the digest was then determined using atomic absorption spectrophotometer (AAS).

Statistical Analysis

All data collected were analyzed using ANOVA and means separated using Duncan multiple range test (DMRT).

RESULTS AND DISCUSSION

Concentration of Lead (Pb) in soil around cassava processing mill at Oja Oba

The concentration of Pb in the soil around the cassava processing mill at Oja Oba is presented in Table1. The concentration of Pb in the soil varied greatly ranging from 5.00 to 16.07 mg kg^{-1}. The highest amount of Pb (16.07 mg kg^{-1}) at the Cassava processing mill was observed in the control sample while the lowest value (5.00 mg kg^{-1}) was recorded in the samples taken between 0-10m farther away from the point of discharge of the cassava effluent. The results also showed that the concentration of Pb increased with the distance away from the point of discharge of the cassava processing effluent. However, it is important to know that the amount of Pb observed in the soil fell below the maximum permissible level of Pb in soil (85 mg kg^{-1}) by the World Health Organization (WHO).

The increase in the concentration of Pb as the distance increased from the point of discharge may be due to the slope nature of the study area. Soil nutrients are known to move down the slope.

Concentration of Manganese (Mn) in soil around cassava processing mill at Oja Oba

The concentration of Mn in the soil around cassava processing mill at Oja Oba is presented in Table 2. The results showed that there was no significant difference amongst the treatment means. However, just like it was observed for Pb, the highest amount of Mn in this soil was recorded in the control (183.33 mg kg^{-1}) while the lowest value of 82.13 mg kg^{-1} was observed in the soil collected between 10-20m away from the point of discharge of the cassava processing effluent. Contrary to Pb that showed an increase with distance as you move away from the point of discharge, Mn did not follow a particular trend.

The concentration of Mn also fell below the permissible level of Mn in soil (2000 mg kg^{-1}) given by WHO.

Concentration of Copper (Cu) in soil around cassava processing mill at Oja Oba

The results in Table 3 showed the concentrations of Cu in the soil around cassava processing mill at Oja Oba. The concentration of Cu in this soil varied greatly with the distance including the control. The highest amount of Cu (12.83 mg kg^{-1}) was recorded in the control while the lowest value of 4.94 mg kg^{-1} was observed from 0-10m from the point of discharge of the cassava processing effluent. The concentration of Cu increased with distance as observed for Pb. The amount of Cu recorded in all the samples was below the WHO recommended permissible level of Cu (36 mg kg^{-1}) in soil.

Table 1: Concentration of Pb, Mn and Cu (mg kg^{-1}) in soil around cassava processing mill at Oja Oba, Igboora.

Treatment (m)	Pb (mg kg^{-1})	Mn (mg kg^{-1})	Cu (g kg^{-1})
0 – 10	5.00c	103.20a	4.94b
10 – 20	6.67bc	82.13a	4.99b
20 – 30	6.67bc	116.07a	5.15b
30 – 40	10.87ab	171.00a	5.53b

40 – 50	9.73bc	127.00a	5.06b
50 – 60	10.93ab	141.40a	5.46b
Control	16.07a	183.33a	12.83a

Means with the same letters are not significantly different at 5% level of probability using DMRT

CONCLUSION AND RECOMMENDATION

The study showed that all the metals evaluated were present at the cassava processing mill at Oja Oba, Igboora. The concentration of Pb and Cu were observed to increase with distance away from the point of discharge of the cassava processing effluent except for Mn. The concentration of Pb, Mn and Cu in the study area are still within the permissible limit of WHO. It was also observed from the study that cassava processing effluent could reduce the concentration of these metals in the soil. Therefore, further study should be conducted on the impact of cassava processing effluent on heavy metals availability in soil.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Open Grown Trees (OGTs) are reliable source of income for rural farmers and populace; and very critical for biodiversity conservation, food security interventions and livelihoods development. The diversity of tree species available on farmlands help to sustain the farming system and also uplift the economy of rural households. This paper highlights the Contributions of OGTs to Rural Livelihood Development; provisions of non-financial benefits obtainable on farmlands and the Non-Timber Forest Products (NTFPs).
Keywords: *Farm trees, farmers, NTFPs, rural development, sustainable livelihood*

INTRODUCTION
As human population increases, the demand for forest products also increases. Therefore, to meet these demands, several tree planting initiatives were encouraged as a potential strategy to meet the forest product needs of growing populations (Bergsten et al., 2014). The 1970's environmental degradation provoked a rush of aid to countries hit by drought and desertification. Within this period, rainforests were also threatened through logging and agricultural expansion received unprecedented consideration and tree planting was encouraged (Aju, 2012,). In the 1980's, interest also mounted in Non-Timber Forest Products (NTFPs) which were previously relegated to the status of minor products. It was at this time that trees especially 'trees outside the forest' (T.O.F), a phrase coined in 1995 (FAO, 2001), began to be considered in terms of their contribution to the well-being of people and their environment.

What are Open Grown Trees (OGTs)?
Open Grown Trees (OGTs) can be described as trees growing outside of officially designated forest areas, such as on agricultural lands, along railway lines, in orchards, on parklands, along roads, ponds and homesteads. It is difficult to measure OGT's economic contribution at the local and regional levels because of its diversity (both in terms of the resource itself and where it occurs). Over the years, farmers have tried to retain, protect, plant and manage trees on their farmlands (Onilude, 2018). These trees are referred to as the T.O.F and also known as the OGTs. They comprise all trees excluded from the definition of forest and other wooded lands (FAO 2001; Bellefontaine et al., 2002; Yadav et al., 2020). OGTs are important natural resources that contribute to the livelihood of people in many localities and have significant importance and perform a number of ecological, economic and socio-cultural functions (Schnell et al., 2015; Yadav et al., 2020; Onilude, 2018, 2021).

OGTs on farmland form an important part of the farm landscape that is very important for sustainable land use, carbon sink and organic matter, biodiversity conservation for both above and below ground and informing food security interventions (Endale *et al*., 2017). OGTs can contribute to the ecological and economic functions of an ecosystem. It can provide wood fuel, promote dry seasonal flow, stabilize soils, and ameliorate the micro-environment making it more conducive for enhanced biodiversity of flora and fauna in an area or/and farmlands (Endale *et al*., 2017).

The diversity of tree species available on farmlands help to sustain the farming system and also uplift the economy of rural households (Garforth et al., 1999). The production and retention of tree species on farmlands by the farmers in Saki, Ibadan, Oyo and Ogbomoso agricultural zone of Oyo State, Nigeria earned about ₦33,500; ₦22,666; ₦34,083 and ₦26,000 monthly respectively (Onilude, 2021). Similarly, forest trees, agricultural crops and livestock are interwoven in Nepali farming system and thus sustainability of farming system depends on the continuous existence of tree resources on the farming system (Yadav et al., 2020).

Furthermore, there are several reports of tree species growing on farmlands in Nigeria (Ajake 2012; Aju 2012; Onilude 2018). These reports elucidated the significant importance of OGTs to rural livelihood development. Table 1 showed the non-financial benefits and Non-Timber forest Products (NTFPs) obtainable from the farmlands.

Table1: List of Non-timber Forest products and Non-financial benefits of OGTs on Farmlands

S/N	Non-financial Benefits	Non-timber Forest products
1	Shade	Fuel wood
2	Windbreaks	Sponges
3	Fencing	Leaves
4	Animal feed	Fruits
5	Soil improvement	Chewing
6	Fuel wood	Sticks
7	Construction materials	Vegetables
8	Stalk	Wildlife

Contributions of OGTs to Sustainable Livelihoods

The total contribution of trees on farmlands to livelihoods is difficult to quantify. A significant proportion of these products are consumed by those who collect them, with the amount or volume collected varying according to seasonality, access and options (Kunarattanapruk et al., 1995). The rural people often produce, process and sell forest products (e.g. making mats and baskets and selling fuel wood) in the absence of other employment opportunities, often as a part-time activity within farming households (Dewees and Scherr, 1996). However, the general contributions of OGTs to livelihood are summarized below:

1. Improved Food Security: Food security is a key element of livelihood. The majority of rural households in tropical countries, and a large proportion of urban households, depend on plant and animal products of forests to meet some parts of their nutritional, cooking and/or health needs (Byron and Arnold, 1999).
2. Reduced vulnerability: People who often live precariously, with no cushion against adversity. OGTs have an important role as a reserve or safety net, providing both subsistence and income in times of crop failure, shortfall, unemployment or hardship, or to meet exceptional needs. OGTs are sometimes used by farmers to help meet dietary shortfalls during particular seasons in the year.

Other contributions of OGTs may include:

3. Building soil carbon and soil organic matter
4. Providing a framework for both below and above ground diversity to flourish
5. Helping innovating diversified farm enterprises.
6. Providing shelter and fodder for all livestock
7. Having ecological, economic and socio-cultural values

The fundamental appeal of farm trees as T.O.F. is that, in addition to addressing environmental concerns such as deforestation and climate change (Kiyingi et al., 2016; Hemida and Adam, 2019), farm forestry realized as a tool for improving livelihoods of the rural communities through supplying wood products market (FAO, 2001), which could encourage the rural poor households to participate in establishment of farm trees and could improve their livelihoods and alleviate their poverty (Oksanen et al., 2003; Hemida and Adam, 2019).

CONCLUSION

Trees left on farmlands are consciously managed by farmers to form an integral part of the farming systems and have great impacts on forest management. The role of farmland trees as part of OGTs on rural livelihood is of great extent as farmers make valuable use of the tree resources on their farmland by getting both non-financial benefits as well as major NTFPs from the farmlands. However, the act of retaining trees on farmlands has the capacity to reduce the pressure which human population is mounting on the primary forest especially in the conserved natural forest ecosystem of Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The trade-off between environmental quality and economic goods within the forest environment is raising a serious policy concern especially now that most forest is gradually lost to degradation. Productive operations within forest environment may be profitable with concomitant burden on the environment. The study examines the economics NTFPs production with data from 80 agro-forest prenures selected across the state using a two-stage sampling procedure and analyzed using cost and returns as well as simple descriptive statistic. The result presents a male dominated (52.5%) agri-forest prenure with secondary education and a mean forest area 1.92ha under NTFP production. There is net returns of ₦19,614.19/ha from leafy vegetables, like ukazi; (Gnetum africanum), utazi (Gangronem alatifolium) and uzuza (Piper guineense) with a rate of returns to capital of 1.76/ha, hence about ₦0.76 returns per hectare in every ₦1.00 total private cost per hectare in the forest environment. Again, a gross and net private margin of 0.657 and 0.534% respectively to the total cost of oil palm fruit harvest is made within the forest. This implies that there's a rate of return to operating expense and total capital invested of 65.7% and 53.4% respectively. Hence, for every ₦1.00 spent on operating expense in oil palm tree maintenance and fruit harvesting an additional ₦0.65 per agro-forest prenuers while ₦0.53 will be generated. The total private return of N189, 695.12 per farmer in snail production within the forest is a better improvement with a return to capital of 134.5%. There is a more than proportionate increase in return to capital invested of ₦1.35 with every ₦1.00 spent in snail production within the forest environment in the state. The result shows that the total social cost of ₦156,100.00 from all the productive operation within the forest environment in the state was higher than the social benefit ₦91,000.00 derived from the forest environment with a negative net social benefit (₦65,100.00). The use the forest for NTFP production is difficult to exclude other social benefits it has generated or derived from the outside the immediate private operations in the state. The study recommends that agro-forest prenures should intensify more wedges (transactional cost) against negative externalities in all their productive operations. This will increase the social benefit, reduce external cost thus sustain the net private gains in NTFP production in the state.

Keywords: *Economics, Non-Timber, Forest and Products and production*

INTRODUCTION

In Africa, more than two-third (2/3) of the people, which is about 600 million people, depend on forest resources either in a type of subsistence use or as source of revenue (Timko, *et al*., 2010). The forests apart from providing timber also provide biological products called non-timber forest products (NTFP). Non-Timber Forest Products are other forest materials outside timber which are produced for human use and satisfaction. The Nigerian rural economy is highly dependent on these forest products to generate income and to provide medical care. They've valuable resources that provide a variety of goods and services for millions of people particularly those living in the rural areas in the developing countries including Nigeria. According to Agbogidi and Okonta (2003), a large proportion of urban and rural household depend on the collection or extraction, production and sales of NTFPs to earn their livelihood. According to Ogundele *et al*., (2012), NTFPs are very useful in sustaining livelihood and generate input for secondary production. Studies carried out by Shackleton (2004) showed that extraction, processing, and trading of NTFPs is a common employment opportunity for the teeming population in remote rural areas. Adepoju and Salau (2007) pointed out that NTFPs are a reliable source of income and food supply in the rural areas and several opportunities for improved rural development are allied to NTFPs. The trade-off between environmental quality and economic goods from the forest environment are often overlooked especially when the massive profit from NTFP is considered.

Non-timber forest products according to Centre for International Forest Research, CIFOR (2013) includes forest products such as; nuts, vegetables, fruits, fish, medicinal plants, resins, essences, a range of bark and fibre, bamboo, rattans, honey, insects, animals, fodder, fertilizers, medicinal extracts, construction material, cosmetic and cultural products, natural dyes, latex, tannins, and gums. They also include essential oils, spices, edible oils, mushrooms, horns, tusks, bones, decorative articles, pelts, plumes, hides and skin, non-wood ligno-cellulosic products, phyto-chemical and aroma chemicals. They may be gathered from the wild, or produced in forest plantations, agro forestry schemes and from tree outside forest. More attention is now focused on Non-Timber Forest Products because of the immense benefits they provide for the advancement of man. NTFPs are also described as parts of the plant that have perceived economic or consumption value sufficient to encourage their collection and removal from the forest (Okpachu, *et al.*, (2013).

Non-timber Forest Products (NTFPs) cover a wide range of products with different uniqueness, which are utilized in a variety of context and play significant roles in a range of household livelihood sustenance. This involves thousands of plants, tree and animal species, most of which are consumed within the household of the gatherers and are not traded in markets. Non-Timber Forest Products (NTFPs) have become a topical issue that have attracted global interest in recent times. Forest plays a crucial role in promoting the economic advancement and welfare of the people by its preservative characteristics. Apart from its veritable means of alleviating poverty among rural communities and its livelihood sustenance, forest provides security to the environment (Fisher *et al*. 2010). Removal of timber and other non-timber forest products like food, medicine, aesthetics and other income generation activities for livelihood sustenance by people living around and outside the forest communities is a tragedy to future use of the faming environment. The rate of use or extraction of Non-timber Forest Products is exacting much pressure on the environment as management practices may not economically sustainable. Production of non-timber forest product by agro foresters can sustain the livelihood and the environment but it cannot ascertain economic sustainability when the private benefit of agro foresters exceeds social benefit.

Ehirim (2014), opined that economic viability of farming environment may collapse at the point where economic burden has placed more negative externalities on the environment. According to his studies, such activities removes, some resource stock from the earth surface and replaced it with a heavy volume of waste generated during the process and it builds beyond the carrying capacity of the farming environment with a nuisance value. A technical term used to describe this situation is *externality*. Formally, we define externalities as conditions arising when the actions of some individuals have direct (negative or positive) effects on the welfare or utility of other individuals, none of whom have direct control over that activity. In other words, externalities are incidental benefits (costs) to others for whom they are not specifically intended (Hussen, 2005). Production of NFTPs has been taken for granted for a long time. They have thus been subjected to misuse, overuse and gross undervaluation, and consequently, most NTFPs remain as minor products of the forest. Nigeria and Imo State in particular has a serious issue of market failure from excessive extraction of forest products, which the productive operations of transforming farm inputs into economic goods (NTFPs) has failed sustain. Is it that the replacement of removed NTFPs through productive operations in the forest areas not viable? However, generating the volume of social cost and social benefit from productive operations in NTFPs production is a policy issue and no study has assessed the economic viability of such production in Imo State at least to understand the social benefits that can allow its sustainability in the area. This study wants to address this by investigating the economics of NFTPs production in Imo State.

The rural smallholder economic operators are important stakeholders in natural resource use landscape. In rain crop and livestock production environment, understanding who and how people use, and control forests and farmlands are issues to sustainable agricultural and forest development in Nigeria. Forest and farming environments are common good/property with a third party effect. Its ownership is common to all and any private use is a cost to another. Common property ownership of resources such as the atmosphere has traditionally meant no ownership at all and free access to all users. Environmental degradation of such resources has occurred when the demand has risen to overwhelm their limited capacity to absorb wastes. Individual maximizing behavior becomes perversely inefficient when property rights to resources are held in common and government assertion of public property rights is required to assure efficient resource allocation.

The transformation process involving the activities of productive operators in NTFPs production must create social cost to the environment in form of externalities. Colfer and Pfund (2011) noted that the management of NTFPs in Nigeria does not encourage a viable outcome, because of excessive social cost from negative externalities. Negative externalities can threaten the purity of the forest and natural landscape. Protecting the purity and vitality of the forest and natural landscape is a hard when it has been tempered by the productive operations of transforming material inputs (land, labor, capital and raw materials) into economic goods (NTFPs). There must be inevitable residuals like pollution and environmental degradation. To address this issue, advocating for the use forest environment for the production of NTFPs may be an important condition for preserving the forest but not sufficient enough to sustain such production. FAO (2003) opined that livelihood sustenance of the forest system must ensure a sustainable harvest of NTFPs.

Empirical evidence has shown that concentrating on ecological sustainability at planting and harvesting level is important, but natural regeneration process of NTFPs in the wild is not enough to sustain the pressure exerted on the forest by livelihood activities by the households (Pandey, Triphati and kumar, 2016). The natural environment (forest) has its own self-degrading ability with a million of decomposer population which, given adequate time, will transform the waste (pollution) into harmless material, and/or return it as a nutrient to the ecosystem. In the case of forest environment, extraction and gathering of NTFPs places a burden and replaces the products removed with waste. The forest environment assimilative capacity increases as it rejuvenates by a natural regeneration process. It has a high self degrading ability. The self-degrading capacity of the natural environment is known as *assimilative capacity*. The *quality* of a particular environmental medium (air, water, land and forest) is determined by the extent of its capacity to assimilate (degrade) waste and that depends on the following important factors: First, the assimilative capacity of the environment is *limited*. The forest is not bottomless sink or an infinite repository of waste. This capacity to degrade waste has made the forest and other natural environment a *scarce* resource. Second, the assimilative capacity of the natural environment depends on the flexibility of the ecosystem and the nature of the waste. That is, the natural environment will not degrade any and all waste with equal efficiency. For *degradable* pollutants, such as sewage, food waste, papers, etc., the natural environment can degrade them with relative ease. On the other hand, it is quite ineffective in dealing *with persistent* or *stock* pollutants, such as plastics, glass, most chemicals, and radioactive substances as most of them not bio-degradable.

MATERIALS AND METHODS

The study was carried out in Imo state, Nigeria. The state lies between latitude 14°4' and 8°15'N and longitude 6°4'E. (Onweremadu *et al.,* 2007). The state has 27 local government area and is divided into three Agricultural zones; namely; Okigwe Agricultural zone, which in turn consist of six local government area (LGA's), Owerri Agricultural zones consist of eleven and the remaining ten LGA's are mapped under Orlu Agricultural zone. Imo State has a population of 3,927, 563 with population density of 230 persons per km^2 (NBS, 2009). The area lies within the humid tropical climate, characterized by rain forest vegetation agro-ecology with abundant forest and non-forest resources.

The area has a population of agro-forest prenures with intensified forest, lands and other natural resources operations for livelihood (Ejiogu, 2009). The forest corridor of the state may not be distinctively link, but their features remained the same with rain forest agro-ecology. The productive operations within the forest environment include farming and gathering of non-timber forest products, quarterly maintenance and harvesting of wild palm trees (*Elaeis guineesis*) by the agro forest prenures in the state. While gathering of vegetables like; ukazi (*Gnetum Africanum*), utazi (*Gangronemalatifolium*) and uzuza (*Piper guineense*) and livestock like snails (*Achatinafulica*) appeared very insignificant the production of these different enterprise have dominated the productive economic operations of the agro-forest prenures in the state.

A two-stage sampling technique was used to ensure that the entire State is properly represented in the study. Imo state with the three agricultural zones; Okigwe, Orlu and Owerri zone where used for the study. The rural population of agro-forest prenures were used as the respondents for the study. In the first stage, Local Government Areas (LGA's) known for intensive non-timber forest product operations were purposively selected from the three agricultural zones of the State. They're Ngor-Okpala, Oru East and Onuimo in Owerri, Orlu and Okigwe zone respectively.

In the second stage, a list of agro-forest prenures who were registered with the agricultural department in the selected LGA headquarters was used as sample frame for the study. The list was divided into three (3) set of respondents, which include; the edible oil palm fruit processors, leafy vegetable producers, and snail producers. Due to the unequal number of non-timber forest product producers in the list, the study will use a proportion of 40% of each set of respondent was used to select 55 edible oil palm fruit processors, 38 leafy vegetable and 27 snail farmers respectively in the area using a stratified random sampling technique.

Data were analysed using both descriptive statistical tools (percentages, mean and frequency distribution) and inferential analysis tools. To identify the various social cost and benefits/economic activities associated with different NTFP in the area was analyzed using functional analysis, mean and percentages of the distribution of farmers in the area. To determine the cost and quantity of various inputs and outputs for non-timber forest production in the area was achieved using frequency distribution tables, percentage and mean. To determine the profit and profitability of the selected non-timber forest products in the area was achieved using the cost return model.

Relationship between Net Social Benefit and Net Private Income

The items of social cost (SC) in this study are negative externalities from the productive operations within the forest environment. They are the value of clearing the bush to allow space for planting and replacing leafy vegetables, values of pruned tree branches used as fuel wood/lumbering activities to allow sunrays, value of losses to headers conflicts, shadow values on poaching, wind accidents and breakages and value of ruins to crops and livestock due to erosion and diseases or pest and shadow values on health challenges. Social benefits (SB) must include the benefit derived from the forest environment during productive operations by the agro-forest prenuerus. It include all the values of rejuvenating the forest, forest regeneration and security, value of local fence less its depreciation and value of product used for goodwill and social promotions. 'Internalizing an externality', in the case of an external cost, can be achieved by a government levying taxes equal to the difference between a private cost and a social cost.

Net private benefit is the difference between the total revenue and the total cost productive operation within the forest environment. There is a serious economic consequence on externality when there is a divergence between private and social evaluation of cost and benefit.

Social benefits (SB) = Total Private Benefits (TPB) + External Benefit (ExtB) 1

Social cost (SC) = Total Private Cost (TPC) + External Cost (ExtC) 2

Net income (Π) = Total Private Benefit – Total Private Cost. 3

TPB = SB – ExtB and TPC = SC – ExtC (from equation 1 and 2 above)

Net Income = SB – ExtB – (SC – ExtC)

Therefore, Π = SB – SC + ExtC –ExtB 4

From equation 4, it could be deduced that Π = (SB – ExtB) + (ExtC – SC). Real externality exists when the net social (external) benefit is greater than the net private income (Hussen, 2005). Externality is *positive externality if* net social benefit > Net income and negative otherwise.

The Quantity of Input and Output of NTF Products in Imo State.

The study centres on only red palm oil fruit harvesting, vegetables (ukazi, uziza and utazi) and snail (*AchantinaFulica*). The various inputs and their prices were analysed in a tabular form.

Model Specifications

Cost, Returns and Profitability Index

To determine the profit and profitability of non-timber forest products in the area, will be achieved using the cost return model. The value of sales and costs incurred in harvesting red palm fruits (*Elaeis guineesis*), vegetables such as ukazi (*GnetumAfricanum*), utazi (*Gangronemalatifolium*) and uzuza (*Piper guineense*) and snail (*Achatinafulica*), will be estimated at the current market price. The quantity and unit market price of these various outputs will be used to generate their returns. Hence, the profit of each product will be obtained using the expression:

$II_{i,ii,iii}$ = TPR – TPC

Where; TPR Total private income called total revenue and TPC, measure total private cost from productive operations in the forest environment

II_{i} = Profit (Net income) from edible red palm oil products.

II_{ii} = Profit (Net income) from the aggregate vegetables produced in the area.

II_{iii} = Profit (Net income) from snail products.

RESULTS AND DISCUSSION

Table 1 Socio-economic profile of agro-forest preneurs on NTFPs production in Imo State

The socio-economic profile of the agro-forest prenures is shown in Table 1 below.

Table 1. Socio-Economic profile of Agro-forest prenuers on NTFPs production

Age (years)	Frequency	Percentages (%)
30 – 37	4	5.0
38 – 44	2	2.5
45 – 51	36	45
52 – 58	29	36.3
59 – 65	9	11.3

Source: Field Survey 2023

The result shows that 36.3% of the NTFP agro-forest prenures were in the age category of 52 – 58 years, 11.3% of them were in the age category of 59-65 years, 4.5% of them were in the age category of 38 – 44 years while only 5% of them were in the age category of 30 – 37 years. The mean age in the study area was 54 years. This is an indication that NTFP agro-forest prenuers are gradually ageing. The ageing population in forestry management and productive operations may imply that productivity may drop if nothing is done to raise youth's appetite in forestry activities of the state. There is a sharp contrast with Fakayode et. al. (2008); Larinde and Santus (2014) observations who reported that majority of agriprenures are mostly young and within their productive age. Agro-forest prenures on NTFP production were mostly males (52.5%) and 47.5% of them were females indicating that NTFP productive operations are male dominated giving the intensive physical labour requirement involved in the operation.

The result further reveals that 53.8% of the NTFP agri-forest prenuers had between 4 – 6 persons in their households; about 36.3% of them had 7 – 9 persons in their households while only 10% of them had 1 – 3 persons in their households. The mean household size was 5 persons per household, which implies that the agri-forest prenures could probably have reasonable farm hands that could help in NFTP productions. There is a positive side to this finding. The intensive labour demand of NTFP production in the state can be sourced within the household, thus reducing cost of hiring labour for their operations. This finding is consistent with Larinde and Santus (2014) as well as Mujawamariya and karimov (2014) both observed that large household size could be an advantage in the farm operations to reduce cost of hiring labour. Again, majority (36.0%) of agro-forest prenures on NTFP production has completed secondary education and 15% of them have attained tertiary education. It could be deduced from this finding that agri-forest prenures have acquired enough formal education and skills for a productive NTFP production. This evidence conforms to earlier results of Mujawamariya and karimov (2014) and Newton et al. (2016) that observed that education attainment enhances the ability of agro-forest operations.

NTFP agro-prenures were mostly (83.8%) married, 15% of them were widowed and only 1.2% of them were single. NTFP productive operation is dominated by married people and a commitment for family upkeeps and responsibility can engender rational productive activities by the people. It could also be seen from the result that 67.5% of the NTFP agro-forest prenuers had between 1 – 10 years of experience, about 31.3% of them had between 11 - 20 years of experience and only 1.3% of them had 21 – 30 years of experience. The mean year of experience was 8 years. This indicated that most NTFP agro-forest prenures are well experienced and knowledgeable in the business as shown by their years of engagement in the productive operation. This will enhance their performance in terms of improved production and marketing techniques to ensure profitability of their enterprise. Ehirim, Onyeagocha, Ben-Chendo, Essien, Osuji and Okwara (2016) argued that more experienced farmer could predict the future outcome of production with some probability by considering performance of past years.

Table 2 Private Cost and Benefits of NFTP Productive Operations in Imo State

Private net returns of leafy vegetable production in the state

The cost and returns analysis for leafy vegetables per hectare of forest farmland in Imo State is contained in Table 2.

Table 2. Cost and Returns for Leafy Vegetables produced

Variables Private Revenue	Detail Description	Amount/*ha*	%
Ukazi (*Gnetum africanum)*	89.5kg of *Gnetum africanum* @ N203.00/kg	18,168.50	69.9
Utazi (*Gangronem alatifolium*)	122kg of *Gangronem alatifolium* @N117.23/kg	14,302.06	55.0
Uziza (Piper guineense)	126.9kg of *Piper guineense* @ N103.43/kg	13,125.27	50.5
A. Total private revenue	-	45,595.83	175.5
Private Cost	-		
Labour	5 man-days @ N1814/man-day	9,207.00	35.4
Cost of planting materials	-	3,686.04	14.2
Cost of fertilizer	-	6,681.60	25.7
B. VARIABLE COST		19,574.64	75.3
Rent on farmland	-	5,500.00	21.2
Depreciation on fixed assets	-	907.00	3.5
C. Fixed cost	-	6,407.00	24
D. Total private cost	-	25,981.64	100.0
Gross Margin (A - B) = E	-	26,021.19	100.2
Net Returns (E - C) OR (A - D) = F	-	19,614.19	75.5
Return to capital (A / D)	-	1.755	

Source: Field Survey 2023

The gross margin, which is estimated as total private income (revenue) less total private variable cost of the operations, which is ₦26,021.49/ha. The proportion of total leafy vegetables, like ukazi; (*Gnetum africanum*), utazi (*Gangronem alatifolium*) and uzuza (*Piper guineense*) produced and sold (revenue) actually dominated the private variable cost of production of ₦25,981.64/ha by 100.2% implying that for every ₦1.00 private variable cost of operation can quickly be recouped the immediate input requirement of productive operation with an additional ₦1.02 per hectare in the forest environment. The immediate returns from the productive operations within the forest environment is as high as 100.2% of the total private cost, suggesting that the possible external cost is less than external benefit to allow the forest environment produce such high immediate returns. In the same way, the net returns of ₦19,614.19/ha resulting to a rate of returns to capital invested in the productive operations within the forest environment of 1.76/ha. There is about ₦0.76 returns per hectare from every ₦1.00 total private cost per hectare in the forest environment. This finding supports the observation of Tekwe, Ndam and Nkefor (2003) that G. africanum produced within agro-forest environment will enhance trade and sustain the livelihood giving the increasing returns to capital invested.

The positive net private returns can exist in future if the net social benefit is continually positive. The possible external benefit from the forest environment can allow a positive transformation of inputs to generate an additional of ₦19,614.19/ha from leafy vegetable in the area. This may not continue in the very long run if there is any external cost due to the productive operation in the forest environment. The effect on the future productive operation in forest environment is dependent on the nature of net social benefit. Since the private net return is positive, there is the possibility that the positive private net revenue is drawn from other positive social benefit contributed by the operations outside their immediate forest environment.

Table 3 The Net Returns from Oil Palm Fruit Harvesting

Table 3 presents the result of net returns on oil palm fruit harvesting within the forest environment in the state.

Table 3. Cost and Returns on Palm Fruit Harvesting

Variables Private Revenue	Detail Description	Amount/ farmer	%
Sales of red palm oil fruits (*Elaeis guineesis*)	652.2kg of *Elaeis guineesis* @ ₦903.00/kg	485,674.44	149.6
Sales of palm fronds and shelled bunches	-	10,334.56	3.2
A. Total private revenue	**-**	**498,009.00**	153.4
Private Cost	-		

Labour	133 man-days @ N1252.12/man-day	166,532.00	51.3
Haulage and Transportation	652.2kg of *Elaeis guineesis* @ ₦75.79	49,432.98	15.2
Pruning and harvesting cost	-	54,904.01	16.9
Cost of maintaining the palm stand	-	13,994.66	4.3

C. Fixed cost	-	**39,719.30**	12.2
D. Total private cost	-	**324,582.95**	100.0
Gross Margin (A - B) = E	-	**213,145.35**	65.7
Net Returns (E - C) OR (A - D) = F	-	**173,476.05**	53.4
Return to capital (A / D)	-	**0.5344 53.44%**	

Source: Field survey 2023

The total private cost of harvesting oil palm fruit harvesting in the state N324,582.95 per farmer. The private variable cost is about 87.8% of the private total cost while the fixed cost dominated only 12.2% of the total private cost in oil palm fruit harvesting in the area. Cost of labour (51.3%) dominated the greater part of the private variable cost followed by pruning and harvesting cost per farmer. Oil palm fruit harvesting is very labourous and can only be taken by young energetic men in the area. This finding is not consistent with Eforuoku (2016) observation that Nigerian farming population is ageing and the ageing population is becoming practically impossible to deliver the expected productivity that will meet the need of the growing population. Again with the growing labour crunch in oil palm production and management in the forest environment may be the reason for the high cost of labour. Alabi et al. (2020) identified that harvesting among other productive operations in oil palm management within the forest environment is manually done with only traditional or semi-skilled mechanized methods, which is very labour intensive.
The findings of the study showed that total private revenue of ₦498,009.00 is generated from sales of harvested oil palm fruits per agro-forest prenuer. The gross margin was however, estimated to be ₦213,145.35 and the net returns were further estimated as ₦173,476.05 per farmer in the state. The gross and net private margins are 0.657 and 0.534% respectively to the total cost. This implies that a rate of return to operating expenses and total capital invested of 65.7% and 53.4% respectively were presented. For every ₦1 spent on operating expense in oil palm tree maintenance and harvesting of oil palm fruits within the forest environment will give an additional ₦0.65 per agro-forest prenuers while ₦0.53 will be generated from ever ₦1.00 capital invested in the state.

Table 4 Net Private Benefit in Snail Production

The gross margin analysis of snail production within the forest environment of the state is shown in Table 4

Table 4: Cost and Returns for Snail production in the State

Variables	Detail Description	Amount ₦/farmer	%
Private Revenue			
Sales of table size snails	978 pieces of table size snail @ ₦152.04/each	148,695.12	183.8
Sales of breeding stock	205 pieces of breeding stock @ ₦200.00 each	41,000.00	50.7
A. Total private revenue	-	**189,695.12**	234.5
Private Cost	-		
Labour	23 man-days @ ₦1500.00/man-day	34,500.00	42.7
Haulage and transportation	-	12,701.77	15.7
Feeds, concentrates and drugs	-	8,448.00	10.4
Juvenile stock	120 pieces of juvenile stock @ ₦100.00 each	12,000.00	14.8
B. Variable Cost	-	**67,649.77**	83.6
Rent	-	12,000.00	14.8

Depreciation on fixed assets	-	1,229.89	1.52
C. Fixed cost	-	**13,229.89**	16.4
D. Total private cost	-	**80,879.66**	100.0
Gross Margin (A - B) = E	-	**122045.35**	150.9
Net Returns (E - C) OR (A - D) = F	-	**108815.46**	134.5
Return to capital (A / D)	-	**1.35 134.5%**	

Source: Field Survey 2023

The total private return is ₦189, 695.12 per farmer in the area and there is a better improvement in production in the state with a return to capital of 134.5%. There is a more than proportionate increase in return to capital invested of 1.35 in the state. This implies that there is a more than ₦1.35 returns from every ₦1.00 spent in snail production within the forest environment in the state. The reason for this high rate of returns to capital can be explained by the low cost implication of the enterprise in the state. The total private cost of production is ₦80, 879.66 with total variable cost of ₦67, 649.77 recording of about 83.7% of the total private cost dominating the capital investment of the enterprise in the state. Although labour cost (42.7%) is higher than other input requirement in snail production, labour demand is relatively lower compare to other productive operation within the forest environment.

Table 5 Social Cost and Social Benefits of NTFP Productive Operation in Imo State.

The result in Table 5 presents the estimated social cost and social benefit arising due to externalities from productive operations within the forest environment in the state.

Table 5. Social Cost and Benefits of NTFP from Productive Operations in Forest Environment of the State

Variables	**Detail Descriptions**	**Amount (₦)/*ha***
Social Cost		
Value of bush clearing by burning.	Value of clearing the bush to allow space for planting and replacing leafy vegetables.	6,000.00
Pruning/ lumbering, deforestation, cattle headers and conflict	Values of pruned branches for fuel/lumbering activities to allow sunrays. Headers conflicts	93,100.00
Amount spent on erosion control, drainages and poaching	Shadow values to poaching, wind brakes and erosion, crop failure to disease and pest, health	57,000.00
Total		156,100.00
Social Benefits		
Value for forest guards and patrol team	Value of product saved by the patrol team	10,000.00
Value of local fences within forest, tree planting, mulching & soil amendments	Dep. of local fence, manuring, afforestation, erosion control, drainages and irrigation	28,000.00
Value of product shared with people	Value of social promotion and goodwill	53,000.00
Total		91,000.00
Net Social Benefit (NSB)		- 65,100.00
External Cost		
Value of crop destroyed by flooding		
External Benefit		
Value of		

Source: Field Survey 2023

The total social cost of ₦156,100.00 from all the productive operation within the forest environment in the state was higher than the social benefit derived from the forest environment, which is ₦91,000.00 in the state. Negative net social benefit (₦65, 100.00) may generally be due to increasing external cost within the forest environment. The forest environment naturally provides enough social benefits for a sustainable NTFP productive operation. The advantages provided by the forest environment and the high negative externalities due to productive operations are at the crossroads. The private productive operators within the forest environment have recorded more net benefit and that has an additive impact on the degenerative development of the forest environment and sustainable NTFP production becomes elusive. The use the forest for NTFP production is difficult to *exclude other social benefits it has generated or derived from the outside the immediate private operations in the state*.

Forest resource is a common property and by its very nature, has a *non-rival* consumption implication, and hence, subject to *joint consumption*. 'Internalizing an externality,' in this case, due to the external cost from productive operations of NTFP production, can be achieved by a government levying taxes at least less or equal to net private benefit. The taxes and levies will be used to provide other social benefits that builds more external benefit within the forest environment in the state. Alternatively, the private agro-forest industry can build a wedge (internalizing) between extreme externalities using part of their net private benefit as *transaction cost*. Again, when the *transaction cost* of internalizing the externality is excessively high that the private operators within the forest environment cannot meet up with the extreme social cost, giving part of their returns to the environment inform of tax or levies to government may ensure sustainability (Hussen, 2005).

In a similar manner, NTFP productive operations enjoyed a non-exclusive property right of the forest environment in the state to attain a high net private benefit. The stakeholders in NTFP production are not excluded from the positive externalities within the forest environment. Their positive net private returns, which drew strength from the external benefit of forest environment, may've extended production capacity of the operators in the long run. The inclusive impact of external benefits, apparently from net social benefit of other forest users or the regenerative capacity of the forest resources in the state may've enhanced this sustainable NTFP production. The non-exclusive property of forest environment in the state extended its sustainable production of NTFP in the state. If the forest environment had an exclusive property implication, the productive operation may shut down and cannot operate even when they have met with all their fixed input in the near future giving the negative net social benefit from private operators in NTFP production in the state.

CONCLUSION AND RECOMMENDATIONS

The forest resources as a common property with non-rivalry consumption implication and non-exclusive property provide the forest environment can attract more external cost giving the adverse operations of agro-forest prenuers. NTFP productive operations in the state may not continue in the future despite their net private gains. Sustainable NTFP production cannot continue in the future without cushioning the effect extreme negative externalities of productive operations in the forest. The difference between the positive net private gains from NTFP productive operations and the negative net social benefit derived from the forest suggest that there is an increasing external cost from the productive operation within the forest environment. There sustainability of NTFP production in the state can only be achieved if the productive operations within the forest environment enhance its external benefit. The study therefore recommends the following:

i. Encouraging the youths in NTFP productive operations will not only provide employment opportunities to the youths but also reduce the cost of labour to increase net private profit within the forest environment in the state.
ii. Agro-forest prenures should intensify more wedges (transactional cost) against negative externalities in all the productive operations. This will increase the social benefit, reduce external cost and improve external benefits of the forest areas.
iii. Government policies should move towards encouraging farmers to pay levies and environmental tax to help internalize externalities coming from the productive operations within the forest environment in the state.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The significance of biodiversity research is to understand the structure and function of an ecosystem or community, and then to protect and monitor their biodiversity. Thus, this study reviewed the tree species diversity index (species richness, dominance, evenness etc.) as a management tool that can be used to assess the ecological variables present in an ecosystem. The role of species diversity index in biodiversity and ecological assessment was also highlighted.
Keywords: *Biodiversity conservation, ecosystem, richness, species diversity*

INTRODUCTION
The structure and tree composition of forest is a vital instrument for forest managers in assessing the sustainability of the forest, species conservation, and management of forest ecosystems (Zhao et al., 2022). The relationship between biodiversity and ecosystem functioning and productivity has received increasing attention within the scientific community recently (McNaughton, 1994; Hooper et al., 2005). However, many of these biodiversity in the tropical forests are under great anthropogenic pressure and require management interventions to maintain the overall biodiversity, productivity, and sustainability (Kumar et al., 2006). Biodiversity research has therefore developed to become an important part of functional ecology and conservation biology (Ma, 2016).
Tropical forests are the subject of several studies to better understand the role they could play in sustainable development, climate change, and floristic biodiversity (Djuikouo et al., 2010). Globally, 52% of the total forests are in tropical regions and they are known to be the most important areas in terms of biodiversity (Djuikouo et al., 2010). This diversity is an indicator that allows appreciating links between the richness and the abundance of individuals' trees; it reflects the degree of heterogeneity or stability of vegetation (Ifo et al., 2016). It is widely accepted that biodiversity can be divided into three spheres: genetic diversity (within-species diversity), ecosystem diversity (diversity of communities) and species diversity (number of species). It is important to understand that biodiversity has a broader meaning than species diversity because it includes both genetic diversity and ecosystem diversity. Nevertheless species diversity is a large part of the focus of biodiversity at the local and regional scale. However, for this review, the focus will be on species diversity.

1. Genetic diversity (within-species diversity)
   This refers to the range of different inherited traits within a species. In a species with high genetic diversity, there would be many individuals with a wide variety of different traits. Genetic diversity is critical for population to adapt to changing environments. The primary sources of genetic diversity are mutation, genetic recombination and gene flow in the population.
2. Ecosystem diversity (diversity of communities)
   Ecosystem diversity describes the number of niches, trophic levels and various ecological processes that sustain energy flow, food webs and the recycling of nutrients. Three indices or varieties of ecosystem diversity or community diversity are Alpha diversity, Beta diversity and Gamma diversity.
3. Species diversity (Number of species)

This is the number of different species present in an ecosystem and relative abundance of each of those species. A quantitative assessment of species diversity is very important for effective biodiversity conservation and management (Magurran, 2004).

Over the years, trees have undergone different levels of disturbance due to unprecedented increase in human population, which have led to cutting of trees for firewood collection, charcoal production, and infrastructural developments (Kacholi et al. 2019). However, in order to protect the trees from declining, it is essential to examine the status of species diversity, composition, and abundance as it will provide guidance for their management and valuable reference for assessment as well as improve the knowledge in identification of ecologically useful species (Kacholi et al., 2019). Also, for the protection and sustainability of forest ecosystems, development of management plans focusing on the dynamics and biodiversity of these ecosystems can only be possible if the processes of the ecosystems are learned, and the information collected is institutionalized.

Measures of biodiversity

Various indices have been proposed to capture information about the diversity of a plant community (Margalef, 1958; Magurran, 2004; Hui et al., 2011; Chao et al., 2013). The principal objective of a diversity index is to obtain a quantitative estimate of biological variability that can be used to compare biological entities in space or time. Species diversity indices can be divided into two components: species richness and species evenness. Species richness represents the total number of species within a given area, while species evenness measures how similar species are in their abundances (Hurlbert, 1971; Magurran, 2004). These two diversity components may vary independently and could be influenced by different ecological processes.

The biodiversity of an ecosystem often depends on multiple measurements. While these measurements are often confused, they all represent individual values that are non-synonymous. The most confused measurements of an ecosystem include:

- Species richness
- Species abundance
- Species diversity
- Species evenness
- Species dominance

Species richness

This is the simplest measure of species diversity and is either a count of the number, or the list of species inhabiting a given area or habitat. Measures of species diversity are formed from species richness by further classification to other attributes such as abundance, size or ecological role. Species richness is the value derived when the number of species in an area is estimated either by direct counting or using evaluating index. This is a good measure of biodiversity because it directly measures the biologic difference between organisms that coexist in a given biome. It explains the ecological resilience and degree biologic homogeneity of a given region.

With high species richness, food chains and energy pyramids become more active and productive, as organisms form complex inter-species relationships that enable them adapt and thrive under various environmental circumstances. Example of index to use for assessing richness are Menhinick and Margalef's index.

Menhinick index (dm): This is a particular measure of species richness. Species richness is a measure of the number of species found in a sample. It is calculated thus:

$D_m = \frac{S}{\sqrt{N}}$………………………………………. Equation 1

Margalef's index (d): This is used to calculate the species richness. It is based on the relationship between total number of species (S) and total number of individuals (N). It is given as follows:

(d) = $\frac{S-1}{Ln(N)}$……………………………....Equation 2

Where S is the total number of species; N is the total number of individuals and Ln is the natural logarithm, dm is the *Menhinick index,* d is the Margalef's index

Species abundance

This is the total number of individuals that make up each species within an ecosystem. It is often mistaken with species richness. For example a forest that has deer, trees, and snails. The species abundance of this forest may report that there are 15 deer, 10 trees, and 45 snails. The species richness of this forest, however, would be reported as 3 species. Thus, species abundance versus richness portrays different ecosystem values.

Species diversity

This is another measurement to understand the biodiversity within an ecosystem. Where abundance is the number of individuals and richness is the number of species, species diversity considers both. Species diversity is usually calculated and compared to a scale or index. Thus, the reported value is a single value that attempts to categorize ecosystems so that they may be compared and does not represent a counted value. Example of index to examine the species diversity of a community is the Shannon-Weiner index.

Shannon-Wiener Diversity Index (H'): This is a useful index in community ecology assessment. The index standardizes the percentage abundance of species in a proportionate way (Turkis and Elma, 2018) and expresses the proportion of the coverage of a given species in the total sample. The negative multiplication value of the summation of the "ln" values of all species multiplied with their own numbers yield the Shannon-wiener value (Zhang 2004; Turkis and Elma, 2018). It is given by:

$H' = -\sum_{i=1}^{S} PiLnPi$ ....Equation 3

Where: H' is the Shannon-Wiener diversity index; S is the total number of species in the community; pi is the proportion of *S* made up of the *i*th species; Ln is natural logarithm.

Species evenness

This is a measure of how evenly spread a species is within a community. Species evenness applies to all three above defined measurements when scale is applied. When a species is evenly spread across sites, its abundances and contribution to richness appears similar from site to site. When a species is not evenly distributed across sites, it may or may not contribute to a particular sites diversity and may contribute to high numbers, or not at all, to richness depending on if pockets of organisms are found. Because both richness and abundance contribute to diversity and evenness can affect both, evenness also impacts diversity. Example of index to examine the species eveness of a community is the Pielous evenness index.

Pielou's Species Evenness Index (E'): The ratio of the observed diversity (H) to the maximum diversity (Hmax) is taken as a measure of evenness (E).

$E' = \frac{\sum_{i=1}^{S} PiLnPi}{Ln(S)}$ ……………………………………….Equation 4

Where, S is the total number of species. E is constrained between 0 and 1.0 with 1.0 representing a situation in which all species are equally abundant.

Tree species dominance

Tree species dominance calculated by using Simpson's dominance index (D). It is represented as

D = Σ (ni * (ni – 1)/(N *(N – 1)……….. ……………....Equation 5

Where ni – Number of individuals in the ith species and N – the total number of individuals

The reciprocal (*D*) of Simpson's index (number of very abundant species) will ensure that the index *D* increases with increasing diversity.

Roles of species diversity indices in biodiversity and ecological assessments

Kacholi et al. (2019) stated the followings:

i. A better understanding of the mechanisms that contribute to species diversity will allow for a better predict and management of future biodiversity
ii. Provide important information about rarity and commonness of species in a community.
iii. It provides information on the stability and sustainability of the forest communities (Sakar and Devi 2014).
iv. Information obtained from studies on forest species richness and diversity is a very important component in management in terms of economic value, regeneration potential and for biodiversity conservation value

CONCLUSION

Regular assessment the biodiversity and forest ecosystems using standard ecological index tools will go a long way to assist ecologists and forest conservationists for a better understanding of operating dynamics in their ecosystem to ensure sustainable management of the resources therein.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted to examine the challenges faced by beekeepers in the major beekeeping locations in Oyo state. Informed questionnaire was administered to 82 and 89 respondent beekeepers in Ibadan and Saki respectively with a target to reach at least 70% of the total number of beekeepers in the study areas. Location, sex and age distribution of beekeepers were recorded, also the anthropogenic activities affecting beekeeping was ranked alongside with management practices of pest of honeybees in the study areas. Descriptive statistics such as percentages, bar chat and frequency were used to analyze the data obtained. The result showed that the larger percentage of beekeepers were 85.4% male while 14.6% were female. Also, the survey revealed that larger number of beekeepers in the study area are youths and are between the ages of 18 and 40. Theft was the most serious constrain of beekeeping in the study area followed by herders issue, bush burning and uncontrolled use of pesticides. The most effective means of preventing bush burning as reported by beekeepers was 77.77% fire tracing followed by positioning beehives on tall trees and weeding at 7%. The use of spent engine oil at the base of hive stands was the most ranked by respondents with 48.53%, and avoidance of scattering harvested honeycomb and removal of dirt in the apiary and the least ranked were smoking of hives and spreading of wood ash as local insect repellant. 57.3% of the beekeepers were of the opinion that hiring security guards is the most effective means of protecting hive from thieves and herders also, 30.4% were of the opinion that fencing of apiary will serve as the most effective means of securing hives and 12.28% supported the use of bee pen. It was concluded that If the constrains of beekeeping in the study area is curbed 100% of beekeepers were ready to go into beekeeping at a commercial scale.
Keywords: *Anthropogenic, beekeeping, fire tracing, honeycomb, beehive.*

INTRODUCTION
In Nigeria, beekeeping has been part of the existing traditional agricultural venture of Oke ogun people in Oyo and the Tivs in Benue States but despite the long term of beekeeping practice in those locations honey production has always been insufficient and never satisfied local demand not to talk of exportation (Akinwande *et al.*, 2013). The lucrativeness of beekeeping to the society is unique as the enterprise is a means of empowering people economically because of its numerous advantages over other types of agricultural enterprises, Beekeeping doesn't require owning a land and the fertility of the soil has nothing to do the productivity of the enterprise because hives are either placed on the trees or on the ground (Lawal *et al*., 2020).
Despite the known defensive mechanism of honeybees there are serious problems in honeybee production, ranging from hive that houses the bees to hive produce and insect pest infestation, anthropogenic activities and incessant use of pesticides and many more (Shu'aib *et al*., 2009; Oyerinde and Ande, 2009; Lawal *et al*., 2021).

METHODOLOGY
Mixed methods such as key informant interviews and observations were utilized for data collection so as to capture all relevant information. A total number of 171 copies of the questionnaire were administered purposively to members of the Federation of Beekeepers Association of Nigeria (FEBKAN). The leadership of the association in the study areas (Saki and Ibadan) served as facilitators towards getting 82 and 89 respondent beekeepers from the two purposively selected locations. The administered number was targeted to meet up with at least 70% of the total population of beekeepers in Ibadan and Saki respectively, the study locations were chosen based on the fact that Ibadan

and Saki are known for beekeeping with numerous numbers of beekeepers and established apiaries. The data retrieved after administering the questionnaire included: demographic features of beekeepers, human activities causing problem to beekeeping and methods used in solving problems encountered. The survey was conducted between January to October 2021. Data collected were subjected to different procedures such as descriptive statistics for demographic features of beekeepers while bar chart and pie chat was used to show the frequency distribution.

RESULTS AND DISCUSSION

The demographic features of the respondents were assessed under location, sex and age distribution. The respondent beekeepers from Saki West, East and Atisbo Local Government of Oke, Ogun State were 89 in number equivalent to 52% while the informed questionnaire was administered to 82 (48%) to apiary farmers in Ibadan (Table 1). Beekeepers in Ibadan and its environs had larger percentages of beekeepers which were male (85.4%) while 14.6% were female reflecting male dominance in beekeeping sector. This can be traced back to honey hunting known to be origin of ancient beekeeping majorly engaged by men (hunters). It involved tedious work of tree climbing, encountering bee stings and moving inside thick forest which is naturally undesirable for women. This could be ascribed to earlier reports by (Olana and Demrew, 2018) that women participation in beekeeping was low compared to men. This survey revealed that larger number of beekeepers in the study area were youths between the ages of 18 and 40 showing that they could actively participate in beekeeping activities ranging from hive making, installation, baiting, harvesting and other rigorous unforeseen challenges that might occur in the apiary compared to older people. This corroborates the findings of Oluwatosin (2008) who reported the age range of beekeepers to be between 31 – 40 years and 31 – 35years at Ekiti and Borno State, respectively.

Table 1: Location, sex and age distribution of respondent beekeepers

Variable		
LOCATION	**RESPONDENT**	**%**
Saki	89	52
Ibadan	82	48
TOTAL	171	100
SEX		
Male	146	85.4
Female	25	14.6
TOTAL	171	100
AGE		
18 – 40	88	51.5
41-70	73	42.7
71ABOVE	10	5.8
TOTAL	171	100

Beekeepers in the study locations were asked to rank some of the crucial challenges associated with beekeeping in the area in the order of their importance. The results of the survey are presented in (Table 2) which shows that 100% of the respondent beekeepers indicated that theft was the most serious constraints and could be attributed to local hunters that sets beehives on fire or use insecticide on bees and kill them then go away with honey thereby leaving main hives and top-bars burnt. Other constraints included human activity such as herders (53.8%) where cattle invade hives thereby leading to beekeepers/herders clash. The third ranked factor was bush burning with 36.25% and lastly incessant use of pesticide 20.46% leading to mortality of bees. This concurs with earlier report by (Tijani *et al*., 2011) that the major problems of beekeeping were theft, inadequate credit to purchase inputs for beekeeping, absconding of bees and inadequate improved technologies.

Table 2: Anthropogenic activities affecting beekeeping in Oyo State

S/N	Activities	Rank	Frequency	Percentage
1	Theft	1	171	100
2	Herdsmen	2	92	53.8
3	Bush burning	3	62	36.25
4	Pesticidal use	4	35	20.46

The management techniques used in curbing the menace of bush burning as a serious issue in beekeeping productivity were ranked and the following frequencies and percentages were recorded. The most effective means of preventing bush burning as reported by beekeepers was fire tracing 77.77% (Figure 1) followed by positioning beehives on tall trees, weeding at 7% and cleaning of the apiary.

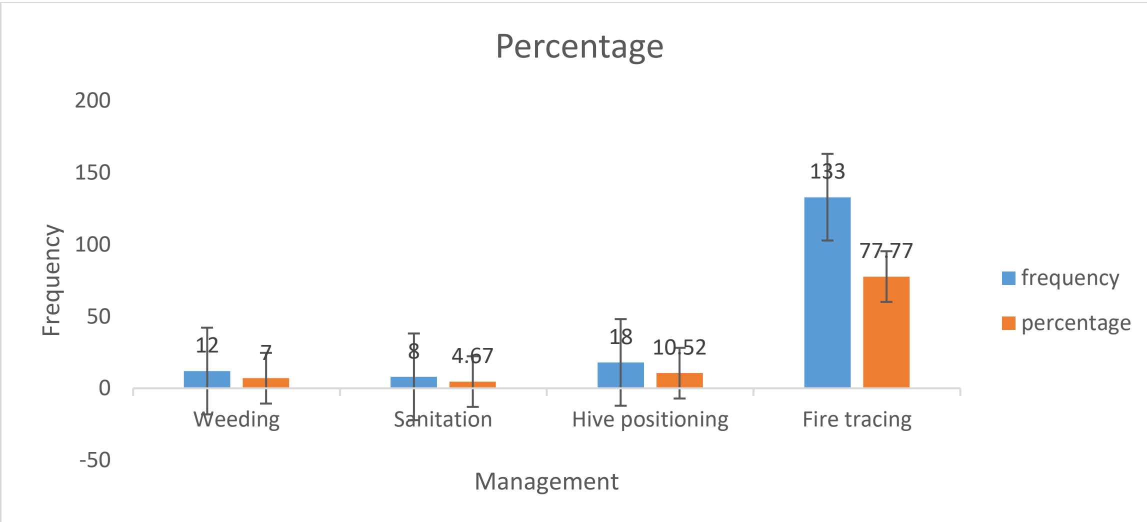

Figure 1: Management techniques in curbing the menace of bush burning in beekeeping

There are eco-friendly management practices that are known to be effective in the management of insect pest of honeybees, the use of spent engine oil at the base of hive stands was the most ranked by respondents (48.53%) (Figure 2) and avoidance of scattering harvested honeycomb followed by removal of dirt in the apiary so as to reduce the possibility of carrying insect pest developmental stages that can be easily transferred from one hive to the other and burning and/or burying the said materials at a faraway place in order to reduce pest load in the apiary while the least ranked management practices were smoking and the use of ash in the control of insect pest. This was in line with the report of (Rachna, 2004).

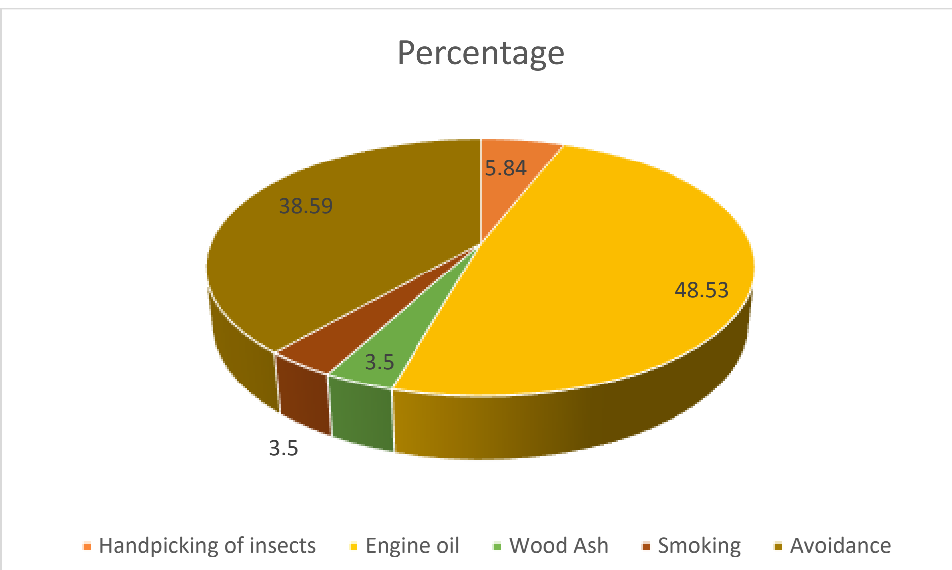

Figure 2: Pest management techniques in beekeeping

Three management practices were ranked by respondent beekeepers in the study areas, the dominant percentage of 57.3% (Figure 3) were of the opinion that hiring security guards will bring a lasting solution to the challenges caused by herders and stealing of hive resources while 30.4% were of the opinion that fencing of apiary will serve as the most effective means of securing hives and 12.28% supported the use of bee pen. This conforms with (Famuyide *et al.*,

2014) who reported that beekeeping was seriously affected by stealing and vandalization of beehives in Oyo state and the need to provide a lasting solution to such menace will increase the production capacity of apiaries.

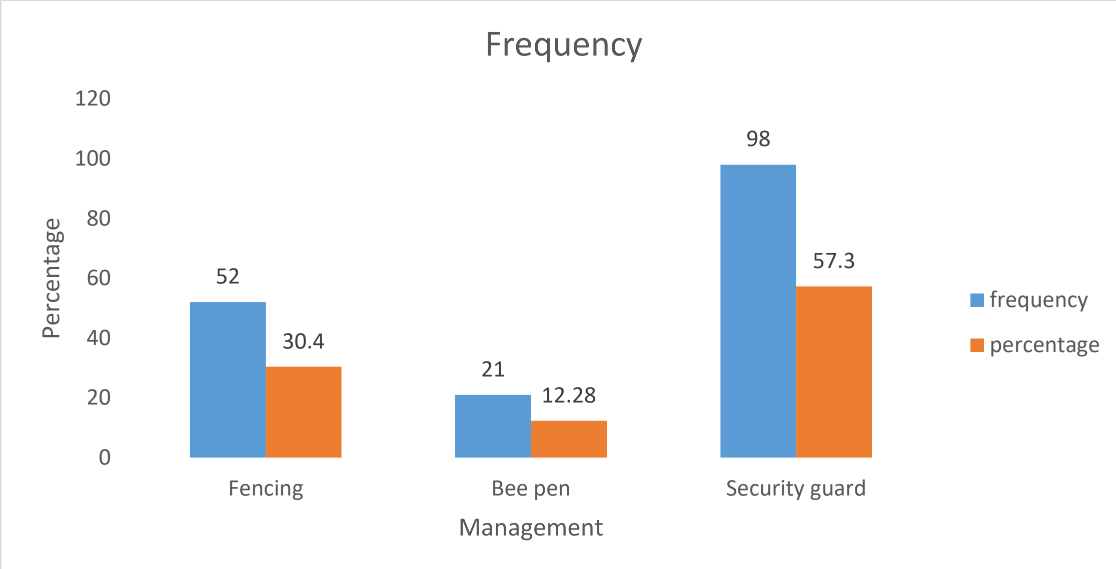

Figure 3: Percentage and frequency of management practices used in curbing theft and herders problem

CONCLUSION

The study concluded from the findings from the respondent that beekeepers are ready to go into beekeeping at a commercial scale if the major constrains of beekeeping are adequately curbed.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study examined the effect of beekeeping on the livelihood of bee farmers in Abia State, Nigeria. A multi stage sampling technique was used in selecting 120 bee farmers for the study. Data collected was analyzed using descriptive and inferential statistics such as frequency count, percentages, mean and t-test. The result revealed that 51.67% of the bee farmers have acquired tertiary education. About 55.00% of the bee farmers had farming experience of 11-20 years. Majority of the respondents (75.97%) are part-time bee farmers. The result on the income showed that 45.00% of the bee farmers had annual income that fell between ₦300,000 - 400,000. The mean income of bee farmers before and after utilization of improved honey production technology was ₦222.666.7 and ₦377.333.3. The result shows that improved honey bee production technology has increased the farmers output and income, thus improving their livelihood and economic status.

INTRODUCTION
Livelihood of communities living in rural areas is typically dependent on subsistence agriculture and smallholder farming. The needs of smallholder rural farmers for livelihoods cannot be addressed without providing them alternative source of income within available resources. Beekeeping has been identified generally as one of the most lucrative enterprise and an alternative livelihood option with potential of providing alternative income security to smallholder farmers living in rural areas. Previous studies indicates that the beekeeping activity provide benefits in terms of employment, pollination of crops and conservation of biodiversity (Uchechukwu *et al.,* 2020). It also generates income through hive products. It is a liable key in reducing poverty and starvation through job creation particularly for the unemployed youths and poor rural populace. The products of bees are source of income and have the potentials to enhance livelihood opportunities for small scale bee farmers. Honey is highly nutritious, has medicinal values and can be used to make products that can generate income for farmers who might lose crops due to inconsistent rainfall or drought. Uchechukwu et al. (2020) reported that food, pharmaceutical, cosmetic as well as brewery industries depend on honey as part of their raw materials in the production of their commodities. There is inadequate information on use of bee honey, technology and income of bee farmer in the study area. Hence, the study aimed to assess the effect of beekeeping on the livelihood of bee farmers in Abia state, Nigeria.

METHODOLOGY
The study was conducted in Abia state. A multi stage sampling technique was used to collect data for the study. In the first stage, the three Agricultural zone of the state namely Aba, Umuahia and Ohafia Zone were involved. Secondly, two blocks were randomly selected from each of the zone, making it twelve circles. Finally, ten bee farmers were randomly selected from the circles making it a total of 120 bee honey farmers for the study. Data were collected through structured questionnaire and data analysis was done using descriptive and inferential statistics such as frequency count, percentages, mean and t-test.

$$z = \frac{\left|\bar{x}_1 - \bar{x}_2\right|}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

Where z= calculated value of difference between means
$\bar{x}$= Mean yield score of bee honey income in ₦ before use of the technology
$\bar{x}$= Mean yield score of bee honey income in ₦ after use of the technology
n_1= Sample size of bee farmers before use of technology
n_2= Sample size of bee farmers after use of technology
S_1^2=standard deviation of respondents before use of technology
S_2^2= standard deviation of respondent after use of the technology

RESULT AND DISCUSSION

Socio-economic characteristics of honey bee farmers

The result in Table 1 revealed that 51.67% of the bee farmers have acquired tertiary education. This indicates that the bee farmers in the study area were educated. Higher level of literacy and experience often transform to positive strategies on the bee farmers leading to higher productivity (FAO, 2018). The result showed that majority (55.00%) of the bee farmers had farming experience of 11-20 years. This implies that most of the beekeepers had adequate beekeeping experience which has influenced their use of the improved bee honey technologies. Furthermore majority of the respondents (77.97% are part-time bee farmers. The result on the income showed that majority (45.00%) of the farmers had annual income that fell between ₦300,000 - 400,000 and this implies that honey producers in the study area are poor farmers who still need to improve on their income. Majority (65.00%) of the beekeepers had between 1-10 bee hives and this could be attributed to the high cost of hive construction and their low capital. This finding agrees with that of Uchechukwu, *et al.* (2022).

Table 1: Selected socioeconomic characteristics of Bee Farmers

Variables	Frequency	Percentages
Educational Level		
Primary	4	3.33
Secondary	54	45.00
Tertiary	62	51.67
Farming Experience (years)		
1-10	42	35.00
11-20	66	55.00
21and above	12	10.00
Operational Status		
Part time	92	77.97
Full time	26	22.03
Annual income (₦)		
100,000-200,000	42	35.00
300,000-400,000	54	45.00
500,000 and above	24	20.00
Number of hives		
1-10	78	65.00
11-20	40	33.33
21 and above	2	1.67
Total	**120**	**100.00**

Source: Field survey, 2023

Farmers' income before and after utilization of improved honey production technology

Table 2 shows that the mean income of bee farmers before the utilization of improved honey production technology was ₦222,666.7 while the mean income after use of the technology was ₦377,333.3. This implied that utilization of the improved technology has greatly increased the production output of honey bee farmers. Utilization of improved honey production technology offers opportunity to increase production and income to a large extent.

Table 2: Difference between farmers' income before and after utilization of improved honey production technology

Source of variation	Mean(N)	Standard error
Income before	222,666.7	11721.40
Income after	377,333.3	19435.57

Source: Field survey, 2023

The z-test analysis of farmers' income before and after use of honey bee production technology

Table 3 shows that there was significant difference in income obtained in honey before and after using the improved bee honey production technologies. The z-test statistic shows significant difference ($P < 0.05$) in income obtained from bee honey before and after the use of improved bee production technologies in South-East, Nigeria. From the result, mean of income from honey before the use of improved bee production technologies was ₦222,666.7, while the mean of income after using the improved honey production technologies was ₦377,333.3. There was difference in income of ₦154,666.6 between income before and after using of the improved bee honey production technologies.

The value of z-calculated (6.8148**) is greater than the value of z-tabulated (1.67). This implies that improved honey bee production technologies increased bee farmers' income. Hence, the z-test rejects null hypothesis which stated that there is no significant difference between income from bee honey before and after use of improved honey bee production technologies. Use of improved honey bee production technologies has significantly increased the farmers' income.

Table 3: z-test analysis of farmers' income before and after use of honey bee technology

Optimum	N	Mean	Standard deviation	Standard error	Difference (N)	z-cal.	z-tab
Income before	120	222,666.7	11721.4	128401.5	154,666.7	6.814**	1.67
Income after	120	377,333.3	19435.5	212906.0			

Source: Field survey, 2023. Null Ho rejected significant at 5% level

CONCLUSION AND RECOMMENDATION

The study concluded that improved honey bee production technology has increased the farmers output and income, thus improving their livelihood and economic status. Based on the findings of this study, it is therefore recommended that bee farmers in Abia state should use the improved honey bee production technology to increase their income since it was found in the study that the use of improved bee honey technology increased the farmers' income. Also, bee farmers should increase the number of hive to enable them expand the bee farming size which will in turn bring about increased honey yield and income.

EFFECT OF HERDSMEN-FARMERS CRISIS ON WOMEN AND GIRLS IN BENUE STATE, NIGERIA

Adiele, J.G. and Nwafor, S.C*.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study evaluated the impact of herdsmen-farmers crisis on women and girls in Benue State, Nigeria. Primary data were obtained from 120 women and girls through personal interviews, focused group discussions (FGDs) and key informant interview (KII). The result showed that the main livelihood activities of women and girls were farming (production of crops and rearing of livestock), processing and sale of farm produce, with a few engaging in petty trading as well. The result holds that the conflict in the area was politically orchestrated. Considering the average mean score, lack of access to health care, displacement, psychological trauma and loss of lives of family members and loved ones stood out as major impacts of herdsmen-farmers conflicts in Benue State. Unanimously, the women and girls solicited for intervention in medical/health services and empowerment in the form of skill acquisition and low or no interest loans. Government at all levels, local institutions and relevant stakeholders should set up a mechanism of ensuring peace, security of lives and properties in these areas and assist the victims of the conflicts through skills acquisition, provision of functional primary health care centers and revive educational system to get the children back to school as quickly as possible.
Keywords: *Herdsmen, farmers, crisis, women, girls, food security*

INTRODUCTION
Violent clashes between herdsmen-farmers are largely viewed as attacks perpetrated by male aggressors while women, girls and children are categorized as vulnerable groups who are caught up in a vicious web of violence. They endure the most of the violent conflicts. Women accounting for such a high percentage of smallholder farmers in sub–Saharan Africa, about 70 percent, implies that they are directly or indirectly affected by the conflicts. The fractured relationship between farmers and herdsmen is not just having a direct impact on the lives and livelihoods of those involved, economic costs and losses from the conflict are significant (Ademola-Adelehin *et al*., 2018). All these have negative implications on the livelihood, social status and role of women within the communities involved in conflict. The conflicts weaken the social capital such that the cohesive forces that bond members of a community are broken. Women play major roles in the cohesion of the community, performing reproductive and community management roles to ensure that the relationship among the community members is sustained. However, the hardships women often experience during and after conflict negatively influence these social cohesion roles.

In Benue State, the frequent clashes between herdsmen and farmers in the predominantly farming areas of the state have resulted in the destruction of lives and farmlands. According to Apenda (2016), nine out of the 23 local government areas (LGAs) in Benue state, namely Guma, Gwer-West, Agatu, Logo, Kwande, Ukum, Tarka and the Northern part of Makurdi are mostly affected. Adetula (2016) as cited in International Crisis Group (2017) said that Benue State seems to be the hardest hit. These clashes are becoming as potentially dangerous as the Boko Haram insurgency in the Northeast. At present, responses to the crisis at both the federal and state levels have been poor.

Despite the fact that some studies have been conducted on herdsmen-farmers lingering conflict in Nigeria, from the literature reviewed, none has precisely focused on the impact this conflict have on the most vulnerable groups - women and girls. Hence, this study evaluated the impacts of herdsmen-farmers crisis on livelihoods of women and girls. The objectives were to ascertain the socio-economic status of women and girls in the study area, identify causes of herdsmen-farmers conflict in the area and ascertain the impact of the conflict on women and girls in Benue state.

METHODOLOGY

This work was conducted in three LGAs - Guma, Gwer-West and Makurdi of Benue State. Two communities from each of the selected LGAs were purposively selected. The communities were selected based on the high frequency of herdsmen-farmers conflict and its effects on women and girls. Primary data used for the study were obtained through personal interviews, focused group discussions (FGDs) and key informant interview (KII). The FGDs and KII were conducted by the researchers and the natives for ease of communication and interpretations. They provided data on general community information, livelihood activities of women and girls, major crops grown by the female farmers, causes of herdsmen-farmers conflicts in the communities, and impact of the conflicts on women and girls.

RESULTS AND DISCUSSION

Causes of Herdsmen-Farmers Conflict in Benue State

This result in Table 1 agrees with the findings of Okereke (2012) and Bello (2013) who listed the causes of the conflict to include theft of cattle, destruction of crops, rape of women, and indiscriminate bush burning. The act of damaging the crops and farm produce by the cattle and the herdsmen is one of the main reasons for the tension between the farmers and herdsmen. According to the women farmers, the herdsmen move their cattle to graze at night, destroying all their farms and crops. Some also move their cattle to feed on harvested agricultural produce stored in the farms, as the women temporary store or keep some harvested crops such as maize, yam, watermelon, cassava and groundnut in the farms for immediate processing before transporting them to the market. However, the herdsmen intentionally move their cattle to feed on those harvested crops. An elderly woman and a farmer at Daudu village explained that *"last year, the herdsmen and their cattle destroyed all my 8 hectares of rice farm. This time around, it was 10 hectares. They intentionally grazed my rice farm even when they were aware that it has not been harvested".*

Any attempt by the farmers to prevent the herdsmen usually leads to conflicts and in most cases the death of the farmers. When the herdsmen kill the farmers, they do not run away for hiding as in previous occasions. Rather, they inhabit the houses of the farmers and use their farms as grazing field for their cattle. The herdsmen further kill any farmer that goes close to the seized houses, or who attempts to repossess their habitation. The study established that, across Guma, Makurdi and Gwer-West LGAs, destruction of crops by cattle ranked as the major cause of the conflicts. However, the discussants accused the ruling class and politicians as the major instigators of the conflict, alleging that the politicians seize the opportunity to acquire land and make more money through camps built for Internally Displaced Person's (IDP). They observed that the politicians were always soliciting for fund from national and international organizations to help control the factors causing the conflicts, but never deployed those funds to anything relating to the conflicts. They gave instances of the government's refusal of the IDPs to return to their homes even when normalcy had returned in the area. They were also restricted from talking to anyone who came to visit for research purposes, unless under strict monitoring. Those suspicious acts agrees with the assertions of the respondents who states that the conflict is now a tool for further enrichment by the corrupt political class.

Effects of the Herder-Farmer Conflict in Benue State

Loss of human lives is one of the major consequences of the continuous conflict, attacks and counter-attacks between farmers and herdsmen in Benue state. It has caused massive death toll of many innocent lives. By implication, loss of family members and relations represent one of the most traumatic experience of women during and after the conflicts subsides. The trauma of losing husbands and children is the greatest psycho-social impact on the women (Hassan, 2018), resulting in post-traumatic stress disorder (PTSD) which manifests in poor mental and physical health, reduced quality of life and difficulties in managing work and family life.

The loss of a husband creates a vacuum in the family and often pushes the bereaved women into unprepared breadwinner roles and decision making for their families. This sudden single parenthood increases women's burden of care often not just for their immediate family but also to provide care for extended family members who were wounded, sick, despairing and displaced because of the conflict. The additional role and associated demand often push families into poverty and dependence, especially when the women lack the skills, experience, and support to take up such huge roles. Lack of resources to meet the demand increases the vulnerability of women to exploitation and forces the children especially girls out of school and sometimes into early marriages. Besides the loss of lives, valuable properties and vast expanse of arable agricultural farmlands are lost during the conflicts, thereby posing serious threat to food security since farmers for fear of attack could no longer go to farm and harvest their farm produce. During the attacks, the women often flee leaving behind cultivated farmlands, which they are often unable to access to harvest the produce. In many cases, women who were able to access their farms after the violence found out that the crops were spoilt, either harvested by other people, or destroyed by cattle. Such losses of farm produce and subsequent rise in food prices in the area have increased poverty and food insecurity (Crisis Group, 2016).

These women are forced to abandon their homes and farmlands for safety and now reside in the IDP camps with little or no care in terms of health care, finances, and general wellbeing. Displaced women and girls suffer the most because they mostly move with the children while men largely move as individuals. Many girls affected by the conflict have not been able to continue schooling. That either their parents or sponsors could not afford the fees, or they are advised to get married or in most cases, the schools were closed-down due to the conflict.

Table 2: Effect of the herder-farmer conflict in Benue State. N=120

CONCLUSION AND RECOMMENDATION

Women, girls and children are adversely affected by the conflict and consequently, the farming, economic and social activities are fast deteriorating. However, the attackers do not usually select their victims when they shoot to kill, women and young girls feel and bear the greater brunt of the conflict. The conflict has evidently created many widows, widowers, and helpless young orphans who add to the existing large number of beggars in both rural and urban centers and or become liabilities to other families. These conflicts reinforce circles of extreme poverty, hunger, illiteracy, and moral decadence in the society.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study considered the perceptions of beekeepers on the production of bee honey in Southwestern states of Nigeria. Socioeconomic factors of beekeepers were investigated to deduce their influence on outputs of apiary hives. Multistage sampling technique was used: Oyo, Osun and Ogun states were purposively chosen, and three Local Government Areas were purposively selected from each Senatorial District in the states. Questionnaires were administered to 130 associated beekeepers. Opportunistic approach was used to administered the questionnaires Descriptive statistical analysis was used to analyse data obtained and mean values were separated using Duncan Multiple Range Test. A total of 83 out of the 113 retrieved questionnaires, representing 74% of respondents were males and married. A larger proportion of the beekeepers in the study area had tertiary education certificate 70 (61.9%). A total of 52 (46.0%) respondents were farmers and majority 30 (26.5%) of the respondents earn between 40,000-59,000 Naira only, monthly. The level of variance within the beekeepers' perceptions on production of bee honey was highly significant ($p<0.05$). The mean value of perception on production of bee honey for Ogun state in the rain forest agro-ecological zone was ranked highest (4.2), while Osun state in Southern guinea savanna agro-ecological zone was 3.7. The correlation between socioeconomic factors confirmed that some factors are significantly correlated; while others are highly significantly correlated. Age, marital status and religion were highly significant ($p<0.01$) for the production of bee honey, while educational background and occupation were significant ($p<0.05$). The adjusted R^2 (0.096) between age and perceptions of beekeepers on production of bee honey confirm that age of beekeepers has only 9.6% influence on the individual's output and was returned highest among other socio-economic factors. It was therefore concluded that age is a symbol of experience and maturity to discern best practices in the art of beekeeping and should be reckoned with for better output of hive products.
Keywords: *Socio-economic factors, Beekeepers, Perceptions, Hive products, Output*

INTRODUCTION
The southwestern Nigeria is a region dominated by moist and dry rain forest and guinea savanna agro-ecological zones. A tropical rain forest and guinea savannah region with many beekeepers that have limited experience in colony establishment and management. Incidence of pests and diseases, pesticide poisoning, poor hive and seasonal management, ecological problems and disturbances from Fulani herders and their cattle had been potential problems identified by beekeepers (Hung *et al.*, 2021; Manley *et al.*, 2019). Akinwande *et al.* (2013) reported that environmental factors of high temperature, high rainfall and hive's high relative humidity enhanced the spread of pests and disease pathogens. For Nigerians to have economic breakthrough and improved livelihood in beekeeping, the perceptions of beekeepers on production processes of bee honey should be assessed in various agro-ecological zones to ascertained areas that requires improvement.

METHODOLOGY

The Study Area: The study was conducted in the Southwestern Zone of Nigeria. Southwest zone comprises 6 states, namely: Oyo, Ekiti, Osun, Ondo, Lagos and Ogun. Of which Oyo, Osun and Ogun states were purposively chosen. The weather conditions vary between the rainy season (March - October) and the dry season (November - February); with the dry season accompanied by Harmattan dust, cold dry wind from the northern desert blown into the southern regions around this time. Longitude 30^0 and 7^0E and Latitude 4^0 and 9^0N (Oni and Odekunle, 2016). It has rainfall of 2000-3000mm, and temperature of over 17 degrees Celsius (Uzoh, 2021).

Sampling Technique: A multistage sampling technique was used to purposively select states located within the agro-ecological zones (Rain Forest in Ogun state, Southern guinea savanna in Osun state and Northern guinea savanna in Oyo state) of interest in south-west Nigeria. Three Local Government Areas were purposively selected, one from each Senatorial District in each State for even sampling of locations. A total of 135 questionnaire were administered. Opportunistic approach was used to choose 45 Beekeepers (45), from beekeepers Association, in each Local Government Area chosen, for consultation and administration of questionnaire, which elicited information on socio-economic data and production system.

Data Analysis: Descriptive statistical analysis (frequencies, percentages, and means) was used to analyse data obtained and Duncan Multiple Range Test was used to separate the means.

RESULTS

For this study, a total of 135 questionnaire were administered, of which 113 (83.7%) were retrieved. Each state was assigned 45 questionnaire, of which 38 in Oyo, 41 in Osun and 34 in Ogun states were retrieved respectively. About 38 (33.6%) of the respondents were from Oyo state whereas, 41 (Osun state) and 34 from Ogun state (Table 1). A total of 83 out of the 113 respondents were males compared to 28 females. There were more of tertiary education certificate holders (70), followed by secondary (29) and primary (12) education certificate holders. Yoruba ethnic group was highest (108 representing 95.6%) compared to Hausa 3 (2.7%) and Igbo 2 (1.8%) respectively. Out of the total respondents, 57 (50.4%) were Islam, 55 (48.7%) were Christians and 1 (0.9%) was a traditionalist. A total of 52 (46.0%) respondents are farmers, 23 (20.4%) are civil servant, students 19 (16.8%), while retirees are 9 (8.0%) and Artisan and trader are both 5 each (4.4%). Majority, 30 (26.5%) of the 113 respondents receive between 40,000-59,000 Naira only, monthly, followed by 15 (13.3%) for those receiving 100,000 Naira and above. The least among the group (1 representing 0.9%) are those receiving between 80,000 – 99,000 Naira only and less than 20,000 Naira only. The remaining 45 (39.8%) respondents (missing values) did not disclose their monthly realizations. In Table 2, The level of variance within the beekeepers' perceptions on production of bee honey was highly significant ($p<0.05$). The mean value of perception on production of bee honey (Figure 1) for Ogun state in the rain forest agro-ecological zone was ranked highest (4.2) (Table 3); followed by that of Oyo state in the Northern guinea savanna agro-ecological zone with 4.02; whereas that of Osun state in Southern guinea savanna agro-ecological zone is 3.7. The correlation between socioeconomic factors confirmed that some factors are significantly correlated; while others are highly significantly correlated. For instance, gender and age with ethnic group and age are both significantly correlated; while marital status and age, religion and local government area, religion and age, occupation and gender with occupation and marital status are all highly significantly correlated (Table 4). The result further shows that to produce bee honey; age, marital status and religion were highly significant ($p<0.01$); while educational background and occupation are significant ($p<0.05$) (Table 5). The adjusted R^2 (0.096) between age and perceptions of beekeepers on production of bee honey shows that the age of the beekeepers has only 9.6% influence on the individual's output and was returned highest among other socio-economic factors. The adjusted R^2 (0.064) between marital status and perceptions of beekeepers on production of bee honey shows that the marital status of the beekeepers had only 6.4% influence on the individual's output. Likewise, the adjusted R^2 (0.051) between religion and perceptions of beekeepers on production of bee honey shows that religion of beekeepers had only 5.1% influence on individual's output. Educational background ($R^2 = 0.039$) and occupation ($R^2 = 0.030$) of beekeepers had 3.9% and 3.0% influences respectively on individual's output.

DISCUSSION

Bee honey production is practiced in Oyo, Osun and Ogun states and the producers are basically between the ages of 30 – 50 years (Table 1). This observation is like the report of Aiyeloja *et al*. (2010) whose preliminary investigations in Ondo and Osun indicated that bee honey production is widely practiced in south-west Nigeria and Babatunde *et al.* (2007), in Oyo state, who likewise stated that majorities of beekeepers were between 36 and 45 years of age. However, Chanthayod *et al.* (2020) in the Laos reported between 40 to 60 years. It was stressed that people, both at youthful age and middle age were involved at different stages of bee honey production. This could be purely due to the nature of their community, endowed with forest containing varieties of trees (Oil palm *Elaeis guinneensis*, Cocoa *Theobroma cacao*, Sunflower *Helianthus annus*, and Queen Elizabeth/Ewe Akintola/Ewe Awolowo *Chromolaena odorata*) that produces nectar required by bees to synthesis bee honey.

It was observed that more males were involved in the production of bee honey than females. This observation is like the report of Bekuma (2018) and Obayelu *et al*. (2020) who concluded that there is gender gap in agricultural labour participation where males played dominant roles compared to their female counterparts. In a similar trend, more married respondents engaged in bee honey production. This observation is consistent with the report of Tadesse *et al.* (2021) and Akinmulewo *et al.* (2017) where they both stated that greater percentage of respondents were married as against the remaining few singles. This could be related to the fact that married people have more responsibilities to cater for; hence, must embark on beekeeping though scary for many, because of bee stings. The respondents had educational background ranging from primary to tertiary level. This observation is similar to the report of Bihonegn and Begna (2021), in Ethiopia, which stated that greater percentage of beekeepers had primary to secondary school level education; that can significantly influence the effectiveness of improved beekeeping adoption. More Yoruba respondents are apparently involved in bee honey production in the study area. This observation is justified by the fact that the region is Yoruba land and Yoruba indigenes dominated.

Beekeepers in the south-west, Nigeria, practice majorly Islam and Christianity as a religion; with few that are into traditionalist religion. This support the findings of McKinnon (2021) who reported that the major religion practiced in Nigeria are Christianity, Islam, and ethnic religions. The beekeepers were mostly farmers, though there are other professions like civil servant, students, retiree, trader and artisans. This is consistent with previous reports (Paul, 2022; Camden, 2015) that most beekeepers are also farmers. Camden (2015) affirmed that beekeepers who were formerly classified under state tax code as a service, like doctors or lawyers are now officially designated as farmers, a recognition the industry has sought for years. It was also observed that the larger percentage of the respondents earn between forty thousand Naira to fifty-nine thousand Naira only (an equivalent of ₦480,000.00 to ₦708,000.00 per annum). This finding is higher than that of Akinmulewo *et al.* (2017) who reported majority annual income of three hundred thousand Naira to three hundred and ninety-nine thousand, nine hundred and ninety-nine Naira only (₦300,000.00 to ₦399,999.00) for the beekeepers in Federal Capital Territory (FCT) communities, Abuja. This would go a long way to determine the extent to which the respondents would be involved in bee honey production or beekeeping expansion. With the prevailing economic situation in Nigeria today, this amount might be insufficient to cater for various family needs e.g. rent, food, children’s school fees and other bills; talk less having extras to construct bee hives.

The building of beehive was generally accepted to be the first activity in the process of bee honey production. It was confirmed that whatever level of involvement in the process of beekeeping, participants are bound to gain as all level of activities yield its own benefits. It was observed that majority of the beekeepers used Kenyan top bar hives. This is in line with the findings of McMenamin *et al.* (2017) and Onwubuya *et al.* (2013) that reported uses of Kenyan top bars by beekeepers. For instance, McMenamin *et al.* (2017) reported that the rate of occupation of Kenyan top bars followed Langstroth and is ahead of traditional log hive. The larger majority of beekeepers harvest bee honey from their hives only once in a year. This correlate with the findings of Godifey *et al.* (2018) whose overall majority also harvested once a year. The quantity of bee honey harvested varies by individual beekeeper's capacity and season, but majority harvested less than fifteen litres of bee honey per hive per year. This is consistent with the findings of Falade *et al*. (2012) where 4litres and 12litres were harvested per hive per year after a period of 4months and 6 months, respectively. Majority of the beekeepers possessed less than ten hives. This is far lesser compared to the findings of Akinmulewo *et al.* (2017) who reported that in FCT, Abuja, each beekeeper possessed 36 beehives on average. In Table 2, the level of variance within the beekeepers' perceptions on production of bee honey was highly significant ($p<0.05$). The mean value of perception on production of bee honey (Figure 1) for Ogun state in the rain forest agro-ecological zone was ranked highest (4.2) (Table 3); followed by that of Oyo state in the Northern guinea savanna agro-ecological zone with 4.02; whereas that of Osun state in Southern guinea savanna agro-ecological zone is 3.7.

The perception of respondents differs on processes of production of bee honey. The mean value of perception varies among beekeepers in the various agro-ecological zones in south-west Nigeria. Ogun state beekeepers in the rain forest agro-ecological zones have the highest mean value of perception, this affirmed that they have a more divergent opinion about the production processes of bee honey. While Osun state in the southern guinea savanna agro-ecological zone have the least mean value of perception, which confirm that they have a more convergent view about the production processes of bee honey. The mean value of perception of the respondents across Oyo, Osun and Ogun states is found to be significant and an ad hoc test conducted ranked Osun state beekeepers as having the most convergent perceptions about the production processes of bee honey; while Ogun state beekeepers has the least.

The correlation between socioeconomic factors confirmed that some factors are significantly correlated; while others are highly significantly correlated. For instance, gender and age with ethnic group and age are both significantly correlated; while marital status and age, religion and local government area, religion and age, occupation and gender with occupation and marital status are all highly significantly correlated (Table 4). The regression equations established the various level of influences that beekeepers' view has on the methods of production of bee honey in Oyo, Osun and Ogun states (Table 5). The socioeconomic factors that are highly significant are age, marital status and religion, of which age was returned highest having the most influence on production of bee honey.

CONCLUSION

The awareness about the importance of honey for food and medicinal purposes is rising and consequently there are increasing demand. Despite all hurdles in the production system, extant beekeepers should brace up and exchange ideas with others in the industry to optimize their perceptions on bee honey production processes. It was therefore concluded that age is a symbol of experience and maturity, to discern best practices in the art of beekeeping and should be reckoned with for better output of hive products.

ACKNOWLEDGEMENT

Appreciation goes to TETFUND for financial support to execute this research.

ABSTRACT
This study examined the production function among cassava farmers as a means of strengthening agriculture for food and nutrition security in south-east, Nigeria. The cardinal objective of this study was to determine how allocative efficiency of resource use can bring about knowledge creation and transfer among cassava farmers for food and nutrition security in the study area. Two hundred and fifty respondents were randomly selected from the five south eastern states using multi-stage random sampling technique. Primary data for the study was collected using a well-structured questionnaire and interview schedule. Multiple regression model was used to analyze the objective of the study. The multiple regression analysis result had coefficient of determinations (R^2) of 0.764. Thus, there is need for appropriate policy formulation in order to ensure cassava farmers' access to credit facility, educational programmes, labour saving devices and extension services.
Keyword: *Production function, Resource use, Cassava farmers, Strengthening agriculture*

INTRODUCTION
Cassava production is a powerful weapon for poverty reduction and sustainable economic development in the south eastern region of Nigeria. The consumption of cassava by most households in Nigeria, especially in the South-east is in processed form of the root like gari, fufu, starch, fresh and dry flakes (abacha*)* and tapioca (Ibekwe *et al*., 2012). In addition, FAO, (2019) reported that cassava serves as cash crop to farmers in the producing areas in the country, as about 45% of it is sold to upset innumerable family earnings needs. Apart from human consumption and cash income purposes, cassava could be used as livestock feed and industrial needs (for plywood, textile and bakery industries, and cassava starch for pharmaceutical, industrial alcohol, processed foods and laundry industries (Esheya, 2019).

In 2018, global production of cassava stood at more than 278 million tons, of which Africa produced 170 million, accounted for over 56% of world production. In the same year under review, Nigeria produced 60 million tons, accounting about the world's largest producer (approximately 22% of global production) with a 37% increase in the last decade ((FAO, 2019). Nevertheless, despite the cassava production feat of Nigeria, yet the average yield per land area of the crop has remained relatively low, with average yield per hectare of about 7.7 metric tonnes compared with 23.4 metric tonnes and 22.2 metrics in Indonesia and Thailand, respectively (FAO, 2019). The low yield of the crop according to Otekunrin and Swawica, (2019) could be correlated to low productivity, hence aggravating poverty and food insecurity. Low productivity in agriculture in general could be enhanced through efficiency in resource use. The analysis of efficiency is generally associated with the possibility of farm production to attain optimal level of output from a given bundle of input at least cost (Gani and Omonoma, 2012).

Since time immemorial, agribusiness managers have sought a competitive advantage that would allow it to serve customers as efficiently as possible, maximize profits and develop loyal customers. How and where farmers search for the knowledge to fuel their innovation processes has been a focus of extensive research over the past decade. Collaboration between farmers and agro-companies constitutes planned knowledge spillovers or exchanges, as firms work together at particular stages in the production chain.

Organizations that often view knowledge as their product adopt the transfer of such product (newly discovered knowledge) as a business strategy as other competing industries will view them as leading in discovering creative ideas. In reality, knowledge is created in the organization by socialization as a result of communication and interactions such as discussions, sharing experience, simulation, practice observation and other social contacts that could exist among members of an organization. Knowledge could also be created in an organization by externalization which is a process that converts tacit knowledge to explicit knowledge in the shapes of concept, metaphors, hypothesis, description and models (Project Reserve, 2023).

Knowledge creation is the formation of new ideas through interactions between explicit and tacit knowledge in individual human minds. It involves socialization (tacit to tacit), externalization (tacit to explicit), combination (explicit to explicit), and internalization (explicit to tacit). Knowledge transfer is the conveyance of knowledge, expertise, skills and capabilities from universities as the academic knowledge base to companies or organizations in need of the knowledge, such as non-government organizations, commercial and industrial sectors, and various non-academic beneficiaries (Project Reserve, 2023). Thus, this study was undertaken to determine how allocative efficiency of resource use can contribute to the creation and transfer of knowledge among cassava farmers for strengthening agriculture for food and nutrition security in south- east Nigeria.

MATERIALS AND METHODS

The study was carried out in the five south eastern states of Nigeria namely Abia, Anambra, Ebonyi, Enugu and Imo states. Five (5) local government areas were drawn from each of the states while 10 registered farmers were randomly selected from each of the 25 selected local government areas to obtain a total of 250 cassava farmers from the list of registered cassava farmers obtained from the respective local government headquarters. Thus, a sample size of 250 cassava farmers were sampled through a multi-stage purposive sampling and interviewed. Information was obtained directly from the cassava farmers through interviews using interviewer-administered structured questionnaires. Multiple regression model was used for data analysis.

Multiple regression is used to obtain allocative efficiency indices b_i coefficient was estimated by means of ordinary least squared regressions method. The explicit production function was estimated by:

$Y = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + b_5x_5 + e$ ……… (1)

Where: Y = value of cassava output (₦),

x_1 = farm size (ha),

x_2 = labour (mandays),

x_3 = cassava stem (bundle/kg),

x_4 = fertilizer (kg),

x_5 = capital (₦)

$x_1 – x_5$ = coefficient of the parameters to be estimated,

e_1 = error term

b_0 = coefficient.

Four functional forms of the multiple regressions were employed in order to select the one that has provided the best fit. The functional forms tried were:

Linear function: $Y = b_0 + b_1 x_1 b_2 x_2 + b_3 x_3 + b_4 x_4 + b_5 x_5 + ei$ . . ………………. (2)

Double log function Y: $\ln(y) = \ln b_0 + b_1\ln x_1 + b_2\ln x_2 + b_3\ln x_3 + b_4\ln x_4 + b_5\ln x_5 + ei$ ……… (3)

Semi log : $Y = \ln b_0 + b_1\ln x_1 + b_2\ln x_2 + b_3\ln x_3 + b_4\ln x_4 + b_5\ln x_5 + ei$ ………… (4)

Exponential function: $\ln Y = b_0 + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4 + b_5x_5 + ei$………… (5)

The choice of the double log function was based on the magnitude of the R^2 value, the high number of significance, size and signs of the regression coefficients as they conform to a priori expectation.

RESULTS AND DISCUSSION

Allocative efficiency of resource use among cassava farmers

This section examined the allocative efficiency of resource use indices for cassava farmers in south east, Nigeria. Table 1 shows the result of multiple regression analysis.

Table 1: Estimated multiple regression production function for cassava farmers

Variable	Linear	Exponential	Double Log+ (Cobb Douglas)	Semi Log
Constant	9.689	6.6477	6.074	3.123
	(4.790)***	(3.009)***	(3.741)***	(3.2001)***
Farm size	1.413	0.169	0.196	0.799
	(2.227)**	(0.027)	(3.201)***	(0.009)
Cassava Cutting	0.431	0.690	- 0.108	1.021
	(0.547)	(0.508)	(2.111)*	(-0.423)
Fertilizer	0.427	0.0189	0.473	-2.123
	(-1.536)	(2.347)**	(3.331)***	(2.344)**
Labour	0.933	0.471	0.182	-0.315

	(3.082)***	(4.0123)***	(1.442)***	(0.308)
Capital	-0.519	-0.449	0.162	0.024
	(-2.733)	(-1.049)	(0.226)	(0.019)
R^2	0.628	0.557	0.764	0.655
F Value	42.486***	36.641***	56.782 ***	54.771***

Source: Field Survey, 2021; *, **, *** significant at 1.0%, 5.0% and 10.0% levels of probability respectively; figure in parenthesis is the t-ratio.

The multiple regression analysis result had coefficient of determinations (R^2) of 0.764, which indicated that 76.4% of the variation in the output of cassava was explained by the model and the remaining 23.6 % were due to error term. The statistically significant F- ratio value of 56.782 of the regression model shows that variation in cassava enterprise was jointly influenced by the independent variable incorporated in the equation. The coefficient of cassava cutting (-0.108) was negative and significant at 10%, implying that a unit increased in the cassava cutting will result to a decrease in cassava output by -0.108 %. The sign identity of the variable could be related to over utilization of the factor input in relationship to other productive resources such as fertilizer, pesticides and labour used in cassava production. The over utilization of the input could be because of numerous cassava varieties in the study area made available by Agricultural Development Programme (ADP) extension agent and National Root Crop Research Institute (NRCRI) Umudike, Abia State experimental stations (Nnadozie *et al*., 2015).

On the contrary, the coefficients of fertilizers (0.473), labours (0.182) and farm size (0.196) were positive and significant at 1% respectively, implying that increasing the level of either fertilizers, labours and herbicides or all will result to a significant increase in the cassava output in the study area. This concurs with Ume *et al*. (2018) who stated that agricultural productivity can be enhanced through an increase in the quantity of a particular input.

CONCLUSION AND RECOMMENDATIONS

This study presents a general overview for understanding how production function can contribute to knowledge creation and transfer among cassava farmers for strengthening agriculture for food and nutrition security in the study area. The result of the allocative efficiency showed that none of the respondents achieved absolute efficiency of resource use as they either underutilized of over utilized the farm resources. The over utilization resources were fertilizer, farm size and capital, while the underutilized resources were cassava stem cutting and labour. There is need for government at all levels to encourage financial institutions to provide credit facilities to cassava farmers so as boost farm productivity and strengthen agriculture. Besides, extension agents should train cassava farmers on improved production management practices to enable them use the available resources effectively and efficiently to enhance food and nutrition security in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was conducted to determine the viability of date palm production. To achieve this objective a field survey was carried out and information were collected regarding various inputs and outputs and their prices and much other information. 113 farmers were verified for this study as small-scale date palm producers, two (2) wards and three (3) villages each were purposively selected from Dutse and Kiyawa L.G.As. NPV and BCR were used to determine the profitability of the date production. The result reveals that 86.7% had their trees in scattered/different locations and 81.4% possess the date palm tree by planting. The NPV was estimated to be ₦126,557.55 per 14 tree stands and BCR of 1.44 meaning for every ₦1 invested there is ₦1.44k revenue, this indicates that the date palm production is profitable in the study area. Positive NPV also highlight that the date palm cultivation will continue to provide positive returns for a long period of time. It was recommended that improved technologies should be channeled to the growers in the area so that they will improve their production and productivity, government should encourage the growers by policy and subsidy of production inputs.

INTRODUCTION
Date palm (*Phoenix datylifera* L.) is thought to have been introduced to Nigeria in the early 17th century via the Trans-Saharan trade route from North Africa and the Middle East by traders and the Muslim pilgrimage to the holy cities of Mecca and Medina (Sanusi *et al*., 2014). Since that time, date palm farming has only been recognized in the northern region of the country in orchards, compounds, and homesteads. It is grown mainly as an ornamental for aesthetic purposes in the southern part (Omoti and Okolo, 2000). Dates are produced in hot, dry regions of the world and marketed as high value confections worldwide. In the vast majority of the world's desert regions, dates are regarded as an important subsistence crop (Dada *et al*., 2012). The Nigerian Institute for Oil Palm Research has so far conducted research on the yearly date production level in several states of the nation, which would give data for research planning, industry growth and development (Dada *et al*., 2012).

The Nigerian Institute for Oil Palm Research was granted the responsibility to conduct research on oil palms by the Nigerian Institute Act No. 33 of 1964. Major research efforts started in the early 1980s when prospection/diseases surveys were carried out by breeders, crop protectionists, soil scientists, and agricultural economists in various northern regions. Significant progress has been made in crop protection, agronomy, soil chemistry, breeding, and nutrition (NIFOR, 2008). Despite the existence of local varieties with good fruit quality and favorable soil and climate conditions for date production, date palm farming is still at the subsistence level, and domestic production is only estimated at 19580 metric tons (Sani *et al.,* 2010).

According to Harbo and Isiaku (2007) an average fruiting female palm in Nigeria can produce 40–60 Kg/year using a recommended number of 200 stands per hectare. Dates are nutrient-dense because they are abundant in carbohydrates, fiber, potassium, vitamins, and minerals; they are also low in fat, almost cholesterol- and sodium-free. Nigeria has a great potential to expand its date palm output, increase productivity, becomes a net exporter of date fruit (Dada *et al*., 2012). Production of date palm in Nigeria has not yet been determined due to the non-availability of annual date production statistics in the country (Dada *et al*., 2012). Information on date production levels in nine states in Nigeria is available, viz; Bauchi 6000 mt, Adamawa 600 mt, Borno 1000 mt, Gombe 1500 mt, Jigawa 5000 mt, Kano 6000 mt, Plateau 100 mt, Taraba 200 mt and Yobe 2000 mt (NIFOR, 2008) since then the information has not been updated. The Nigerian date palm sector has the potential to export date fruit and its by-products to the international market, but Nigeria is now more of a consumer and importer of date fruit, and the absence of plantations and information on the production capacity prevents the nation from being one of the top exporters of date products in west Africa (Mani, 2014).

As with any economic analysis, the profitability of an investment is based on a comparison of the returns and cost of the investment. Hence, the profitability of crop production depends on reducing the farming cost as much as possible, and at the same time maximizing the income from the sale of crop. The potential of earning and maintaining profitability serves as an incentive for farmers to be creative and efficient. Profitability stimulates risky ventures and drives farmers to develop ways of cutting cost and improving technology always in an effort to satisfy consumer interest (Troke, 2008). Profitable agriculture is dependent on productive soil and date palm production is not an exception. This study attempts to assess the cost of date palm production and to assist producers in determining how the date tree they are cultivating affects profitability.

METHODOLOGY

The study area: With an estimated population of roughly 246,143 and 172,913, Dutse and Kiyawa Local Government Areas are located in Jigawa State, Nigeria, between latitude $11^0$42'04"North - $11^0$47'05"North and longitude $9^0$20'31"East - $9^0$36'30"East (Jigawa State, 2017). Dutse and Kiyawa share a border, as well as an inter-state border with Kano and Bauchi state. This provides a unique opportunity for inter-state trading in date palm fruit produced in the area and other surrounding states. Annual rainfall is estimated to be between 600mm - 1,000mm with an average of about 650mm over the last few years. Temperature ranges from 10^0C during the harmattan season to about 42^0C during the dry season and annual mean relative humidity of 30.8%.

Sampling Procedure: Due to the concentration and high intensity of date palm production in Dutse and Kiyawa, six villages were randomly selected from both L.G.As. A simple census was conducted in each community based on the owners of date palm trees, and a total of 113 were identified and verified to be small-scale date palm growers, which were used for assessing information on production costs and income-related factors.

Data Collection: Primary data were used as a source of information in this study. The data was collected with the aid of a structured questionnaire administered to the date palm producers.

Data Analysis: Simple descriptive statistical tools such as frequency and percentages were used for the socio-economic characteristics of the farmers, and Net Present Value and Benefit cost ration was used to estimate the costs and benefit of date palm production.

Model Specification: Date trees do not start yielding fruit until the fifth to eighth year of their establishment, therefore the annual fruit harvest is separated into two different yield cycles: the first from the eighth to the end of the thirteenth year, and the second from the fourteenth to the twenty-fifth year. The average annual harvestable number of date fruits per tree is the primary difference between the two cycles. In comparison to the first cycle, the yield is significantly higher in the second. It was also assumed that the selling price of date produce and input prices would remain constant during the course of the business. This approach is commonly used to avoid the complications that may occur when attempts are made to include inflation in input and output prices. The costs were divided into four categories: the initial year of establishment, years 2 to 7, years 8 to 13, years 14 to 19, and years 20 to 25. The cost of various inputs used in growing date palm was determined using the methods adopted by Sarfraz *et al.* (2006).

In the case of the date palm tree being a perennial crop, net present value (NPV) and benefit cost ratio (BCR) budgeting tools were employed to estimate the profitability of date palm cultivation in the study locations.

Net Present Value (NPV): is specified as; $NPV = \frac{B_0 - C_0}{(1+i)^0} + \frac{B_1 - C_1}{(1+i)^1} + \cdots + \frac{B_t - C_t}{(1+i)^t}$

Benefit Cost Ratio (BCR); $BCR = (\frac{B_0}{(1+i)^0} + \cdots + \frac{B_t}{(1+i)^t}) \div (\frac{C_0}{(1+i)^0} + \cdots + \frac{C_t}{(1+i)^t})$

Where: NPV= Net Present Value, t = year, B = benefits, C = cost, i=discount rate. BCR = Benefit Cost Ratio,

RESULT AND DISCUSSION

The results of the analysis presented in Table 1 show that 86.7% of the respondents having their date trees in scattered areas, including homesteads and other people's farms near and far. It also shows that the majority of respondents obtained their trees through planting and inheritance.

Table 1: Descriptive Statistics of Qualitative socioeconomic characteristics

Items		Frequency	Percent %
Sex of the respondent	Male	113	100.0
Trees at scattered locations	Yes	98	86.7
	No	15	13.3
Self-Planting	Yes	92	81.4

Items		Frequency	Percent %
	No	21	18.6
Possessed by Purchase	Yes	37	32.7
	No	76	67.3
Possessed by Inheritance	Yes	73	64.6
	No	40	35.4

The initial costs of establishing a date palm plantation were computed using various input costs reported by 113 date palm growers in Dutse and Kiyawa L.G.A. The results in Table 2 show the initial costs of establishing a date palm plantation with an average of 14 trees. The compiled results indicated that the total variable costs on initial development of date palm accumulated to ₦84,300/14trees. The details regarding the economic analysis of the initial costs on date palm plantation development indicate that construction of tube-well for irrigation were the cost items with the highest amount costing about 71% of the initial cost.

Table 2: Estimated cost for establishment and maintenance of date palm

	Years				
Items	1 year	2 - 7 years	8 - 13years	14 - 19 years	20 – 25years
Planting Materials	6,900.00	0	0	0	0
Organic Manure	4,000.00	30,400.00	36,000.00	42,400.00	42,400.00
Plant Protection Measures	3,900.00	32,100.00	40,800.00	47,600.00	47,600.00
Irrigation	60,000.00	42,000.00	60,000.00	70,000.00	70,000.00
Labour	9,500.00	12,000.00	13,800.00	16,100.00	16,100.00
Total	84,300.00	116,500.00	150,600.00	176,100.00	176,100.00

Source: Field Survey, 2021

According to Barreveld (2011), date palms can last for more than 100 years and start increasing their fruit yields between the ages of 6 and 20 years, reaching full maturity in 12-13 years. Table 3 reveals the estimated cost of date palm production starting with the establishment cost (year 0-1) estimated at ₦84,300.00 and the annual maintenance for a period of 25 years. The maintenance cost continues to increases as it grows. Eight (8) years was used for the date to start fruiting this is based on the report from the farmers and this might be due to the fact that most of the varieties grown in the area are local varieties. At the ages before it start fruiting the maintenance requirement is only organic manure, protection (by fencing and pesticide application) where necessary, then irrigation which is the most important though date palm can resist harsh climatic conditions. But after it start yielding the maintenance cost will increase more especially with regards to protection measures, at this stage there is need to protect the fruits from pest, wind and sometime rain to avoid losing the fruit.

As previously mentioned, date trees begin fruiting between the ages of 4 and 5 years for improved varieties and 5 to 7 years for local varieties. Nevertheless, based on the responses of the farmers contacted, dates begin fruiting 8 years on average after planting. Since it was believed that the date palm may produce fruit that could be marketed at this age, the output and returns were taken from 8 years onward. Table 3 shows that the yield in the second age group, between 8 and 13 years, can reach 1358kg on average for 14 trees, and a total of ₦679,000.00 revenue can be realized. The third and fourth category yield keeps increasing. The trees will not stop producing at this age, but will instead continue to fruit for a longer period of time.

Table 3: Projected Output and Revenue

Items	**Output Quantity (kg/14stands)**	**Total Revenue (N/14stands)**
year 8 – 13	1358	679,000.00
year 14 – 19	2800	1,400,000.00
year 20 – 25	2940	1,470,000.00

Source: Field Survey, 2021

Table 4 summarises the viability result for date palm production investment in the study area. It is well known that date production is a long-term enterprise, and for the purposes of this study, the date palm generates income eight (8) years after planting. Costs and returns, on the other hand, do not serve as true yardsticks for deciding whether or not to invest in date palm production. This is because the costs and returns from date trees are not comparable unless such costs and returns are discounted. The cash flow statement was prepared by computing the PVC and PVR at a 10% discounting rate. PVR was assumed to be zero for the period of 1 to 7 years because date trees usually don't bear fruit during this time (if fruiting occurs during this time, it is insignificant). The NPV was estimated to be ₦126,557.55 per 14stands and BCR was 1.44, this demonstrates that investment in date palm cultivation could be considered significant and economically justifiable. Based on the BCR, investing one Naira in date trees yields a return of ₦1.44, which is acceptable from an economic point of view. The estimated 1.48 BCR for date palm farming by Sarfraz *et al*. (2006) and 1.56 BCR for oil palm by Ukwuteno et al. (2018) are comparable to the estimates obtained in this study.

Table 4: Financial Analysis of date palm

Items	**Years**			
	1-7yrs	**8-13yrs**	**14-19yrs**	**20-25yrs**
Capital cost (N/14trees)	220,216.69	-	-	-
Maintenance Cost	-	150,600.00	150,942.84	150,942.84
Total Cost (N/14stands)	220,216.69	150,600.00	150,942.84	150,942.84
Total Revenue (N/14stands)	-	679,000.00	1,400,000.00	1,470,000.00
Net Revenue (N/14stands)	-220,216.69	528,400.00	1,249,057.16	1,319,057.16
Present Value of total cost	178,828.48	56,096.93	31,737.34	17,914.90
Present Value of Net Revenue (PVNR)	-178,828.48	173,658.70	259,750.50	156,554.48
Net Present Value (N/14stands)	126,557.55			
Benefit Cost Ratio (BCR)	1.44			

Producer Price = ₦500.00/Kg fresh fruit, Discount rate = 10%

CONCLUSION AND RECOMMENDATIONS

According to this study, a small scale date palm farmer with an average of 14 tree stands can make discounted gross revenue of ₦233,333.00 to ₦245,000.00 per year with maintenance costs ranging between ₦25,100 and ₦25,157.14. Based on this research, it was concluded that date palm production is a profitable enterprise with a 1.44 BCR, but production of date palm is at subsistent level in the study area.

Date palm production is a profitable venture which must be encouraged and at the same time is less capital intensive. Effort should be put to restore the date production at a capacitated level. Research institute in the area should disseminate the new and improved technologies for date palm production to the date palm farmers in the area. Government could encourage transformation of date palm industry through subsidy and other incentives that will enhance date production in the area. Due to Perishability nature of the date fruits modern harvesting technologies and proper packaging, storing and transporting facilities should be provided to reduce postharvest loss.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A pot trial was conducted at Igboora, to evaluate the growth and yield performances of maize as influenced by Moringa leaf extract (MLE), and NPK 15:15:15 (NPK) fertilizer. MLE was extracted using standard procedures. The treatments were 25 ml foliar application of MLE at 2, 4 and 6 weeks after planting (WAP), NPK at 150 kg/ha, combined application of NPK at 75 kg/ha + MLE at 12.5 ml and control respectively. The experimental design was Completely Randomized Design (CRD) replicated 5 times. Data were collected on plant height, number of leaves, leaf area, stem diameter and yield of maize. Data were analyzed using Analysis of Variance, and significant differences were separated using Fisher's Least Significant Different (F-LSD) at $p \leq 0.05$. The result revealed that NPK (at 75 kg/ha) + MLE (at 12.5 ml) gave the highest significant plant height (202.25 cm), number of leaves (10.00), leaf area (271.71 cm^2) and yield of maize (5.71 t/ha) than other treatments and control. These are therefore, recommended for optimum growth and yield of maize in the study area.
Keywords: *Moringa leaf extract, NPK fertilizer, maize,*

INTRODUCTION
Maize (*Zea mays* L.) is ranked first in global production among grain crops (FAOSTAT, 2018). Nigeria is currently the tenth largest producer of maize in the world and the largest maize producer in Africa (IITA, 2010). *Moringa oleifera* (Moringa) is a tropical multipurpose tree and one of the most used plants in the world. However, there are limited reports on the frequency of application of the MLE and its impact on maize productivity in Nigeria. Moringa contains zeatin, a member of the plant growth hormone family known as cytokinins. These plant hormones help cell division differentiation, growth and nutrient assimilation respectively, as well as protect against oxidation (Hwang *et al*., 2012). Fajemisin (2015), reported that maize has established itself as a very significant component of the farming system, by determining the cropping pattern of predominantly peasant farmers. The maize crop requires an adequate supply of nutrients particularly nitrogen, phosphorus and potassium for optimum growth and yield. However, declining low soil fertility is the major constraint to maize production in Nigeria. Therefore, farmers will most likely embrace the use of inorganic fertilizers to augment soil nutrients and boost yield, especially with the unfortunate, inadequate availability of inorganic fertilizers or expensiveness, hence, out of reach to smaller holder farmers. Also, continuous use of inorganic fertilizer damages the soil and the environment. Thus, sustainable and environmentally friendly approaches have to be developed in the face of the negative prolong use of inorganic fertilizer on soil structure. It is based on the aforementioned that this study examined the growth and yield of maize as influenced by MLE and NPK fertilizer.

MATERIALS AND METHODS
The experiment was carried out in the screen house of Crop Production Technology Department, Oyo State College of Agriculture and Technology, Igboora, Nigeria, from July to October, 2022. Igboora is located in Ibarapa Central Local Government Area of Oyo State. The town shares boundaries with Abeokuta, Ibadan and Oke-Ogun. It is located

in the Derived Savanna Zone and has two distinct seasons (the dry season: from November to March; wet season: from April to October). The average monthly high and low temperatures are 33°C and 22°C, respectively.

Composite soil samples were collected at 0 – 20 cm depth using a soil auger. The samples were air dried, sieved with a 2 mm aperture sieve and taken to Department of Agronomy, University of Ibadan, Ibadan, Nigeria to determine their physical and chemical properties. The soil pH in H_2O (1:1) was determined with a pH meter, while available phosphorus was estimated using Bray and Kurtz (1945) method. The soil particle size was determined using the hydrometer method (Bouyoucos, 1962), while the Macro-Kjeldahl method was used to estimate total nitrogen (Jackson, 1958). The exchangeable calcium, magnesium, potassium, sodium and effective cation exchange capacity were determined using atomic absorption spectrophotometer (Tel and Hargerty, 1984).

Fresh Moringa leaves were harvested from a Moringa plantation at Igboora. The leaves were rinsed with distilled water and air dried. The dried leaves were milled and stored in sample bags. Moringa leaf powder (20 g) was added to 675 ml of ethanol in a 2.5 l, Winchester bottle and left for 24 hours (Makkar and Becker, 1996) to extract the chemicals from the leaves. The chemical composition of the leaf extract was determined at Department of Agronomy Laboratory, University of Ibadan, Ibadan, Nigeria. Oba super-1 (white variety) maize seeds were obtained from Agro-allied company in Igboora. Two maize seeds were planted at 2 cm depth into twenty experimental pots containing 8 kg soil. The seedlings were later thinned to one per pot one WAP. The four treatments (25ml of MLE, 150 kg/ha of NPK, 12.5 ml of MLE + 75 kg/ha of NPK and control),were laid out in a Completely Randomized Design, and replicated five times. A syringe was used for foliar application of MLE at 2, 4 and 6 WAP (Biswas, 2016). The application of NPK fertilizer was carried out at the standard rate of 150 kg/ha (Dugue, 2010) at 2 WAP using side dressing method. The combined application of MLE and NPK was done at 12.5 ml MLE at 2, 4 and 6 WAP + 75 kg/ha of NPK at 2 WAP as proposed by Shehu and Okafor, (2017). The untreated maize plants (control) had no application of NPK or MLE.

Data collection commenced from 3 WAP up to 13th week. A meter ruler was used to measure plant height from base to the tip of the main shoot, as well as the leaf length (L) and width (W). Leaf area (LA) was estimated using the leaf area model, $LA = 0.75LW$ (Lizaso *et al*., 2003). Number of leaves and cobs were physically counted, while the stem diameter was determined using Vernier minicalliper. Fresh shoot, fresh root and cob weights were measured using Falcon electronic scale BL 3002. All data were subjected to Analysis of Variance (ANOVA) and significant means were separated using F-LSD at 5 % level of probability.

RESULTS

Physical and chemical properties of experimental soil

The soil (table 1), on which the experiment was carried out was observed to be moderately acidic with a pH value of 6.47, low in essential plant nutrients: nitrogen (1.70 g/kg), phosphorus (9.97 mg/kg) and potassium (9.97 mg/kg), generally observed to be below the critical values of soils in the Derived Savanna Ecological Zones. The textural class was sandy loam, with 89.4 g/kg sand, 58 g/kg silt, and 48 g/kg clay.

Table 1: Physical and chemical properties of experimental soil

Elements	Values
pH (H_20)	6.47
Ca (Cmol/kg)	3.65
Mg (Cmol/kg)	0.76
K (Cmol/kg)	0.36
Na (Cmol/kg)	0.54
ECEC (Cmol/kg)	5.34
Total N (g/kg)	1.70
Total Org. C (g/kg)	8.70
Available P (mg/kg)	9.97
Particle size analysis	
Sand (g/kg)	89.4
Silt (g/kg)	58
Clay (g/kg)	48

Chemical composition of Moringa Leaf Extract

Essential plant nutrients present in the MLE were nitrogen (11.68 mg/kg), phosphorus (5.24 mg/kg) and potassium (4.20 cmol/kg). Also, some natural growth enhancers, Zeatin (4.94 mg/kg) and Giberrelin (2.80 mg/kg) were found in the MLE (Table 2).

Table 2: Chemical composition of Moringa Leaf Extract

Elements	Nitrogen (mg/kg)	Potassium (cmol/kg)	Phosphorus (mg/kg)	Zeatin (mg/kg)	Giberellins (mg/kg)
Value	11.68	4.20	5.24	4.94	2.80

Growth responses of Maize as influenced by MLE and NPK fertilizer in Igboora, Oyo State, Nigeria

The growth parameters of maize as affected by single and combined application of NPK and MLE are shown in table 3. MLE and NPK significantly ($p \leq 0.05$) enhanced height of maize. Highest significant ($p \leq 0.05$) height of maize (119.80 cm and 202.25 cm) was observed at MLE+NPK at 11 and 13 WAP, while the lowest significant plant height was observed at control (93.40 cm and 100.80 cm respectively). However, at 9 WAP, MLE+NPK produced the highest significant ($p \leq 0.05$) leaf area (271.71 cm^2), followed by NPK (230.68 cm^2), while MLE (218.70 cm^2) was not significantly ($p \leq 0.05$) different in leaf area compared to control (214.30 cm^2).

From 3 to 7 WAP, the treatments did not significantly different ($p \leq 0.05$) affect number of leaves of maize. At 11 and 13 WAP, NPK+MLE produced the highest ($p \leq 0.05$) number of leaves (12.60, 10.00), followed by NPK (11.40, 7.60) and MLE (11.20, 8.00) respectively, compared to control (9.00, 6.80). Also, highest ($p \leq 0.05$) stem diameter was observed with NPK+MLE (7.42 mm), followed by NPK (7.10 mm) and MLE (6.60 mm), while the lowest ($p \leq 0.05$) stem diameter was observed on control (6.06 mm) at 13 WAP.

Yield responses of Maize plants as influenced by MLE and NPK in Igboora, Oyo State, Nigeria

The yield responses of maize plants to single and combined application of NPK and MLE are shown in table 4. The application of NPK+MLE produced 1.40 cobs, but was not significantly higher ($p \leq 0.05$) than other treatments. The highest ($p \leq 0.05$) yield of cobs was produced by NPK+MLE (5.71 t/ha) as compared to NPK (3.57 t/ha), MLE (2.26 t/ha) and the control (2.16 t/ha). Also, NPK+MLE produced the highest ($p \leq 0.05$) fresh shoot weight (102.08 g), compared to control (20.26g) and MLE (71.00 g), but not significantly higher ($p \leq 0.05$) than NPK (82.02 g). Also, NPK+MLE produced the highest ($p \leq 0.05$) fresh root weight (36.40 g), compared to control (9.06 g) and MLE (25.08 g), but not significantly different ($p \leq 0.05$) from the NPK (29.48 g).

Table 4: Yield responses of maize plants as influenced by MLE and NPK at Igboora, Oyo State, Nigeria

Treatment	Number of cobs	Yield of cobs (t/ha)	Fresh Shoot weight (g)	Fresh Root Weight (g)
Control	1.00	2.16	20.26	9.06
MLE	1.20	2.26	71.00	25.08
NPK	1.40	3.57	82.02	29.48
NPK+MLE	1.40	5.71	102.08	36.40
LSD	NS	1.13*	28.90*	10.50*

DISCUSSION

The single application of NPK, MLE and combined application which enhanced some of the growth and yield attributes of maize (height, leaf area and number of leaves), agree with Chattha *et al*. (2015), who reported that application of MLE enhanced the growth rate, number of leaves plant height, shoot and root fresh weight and dry weight of shoot, root of maize. The significant increase in growth and yield of maize treated with the combined application of MLE at 25 ml and NPK at 75 kg/ha was attributed to the high level of essential macro nutrient (nitrogen, phosphorus, potassium), present in the inorganic fertilizer and in the MLE due to presence of zeatin and gibberellin which are growth enhancers. Nitrogen, phosphorus, potassium, and other nutrient elements play great physiological importance in formation of chlorophyll, nucleotides, enzymes, hormones and vitamins for optimum grain yield Mohamed *et al*. (2008). Also, Khan (2008) reported that phosphorus is essential for maize growth, and plays a vital role in grain production.

CONCLUSION AND RECOMMENDATION

Based on the results of this study, it is concluded that NPK and MLE enhanced the growth and yield of maize, therefore, may be used to boost growth and yield of maize. Combined application of NPK at 75 kg/ha + MLE at 12.5ml gave the highest growth and yield parameters of maize. The high level of nitrogen, phosphorous, potassium, zeatin and gibberellin present in the MLE are generally assumed to be responsible for the enhanced growth and yield of maize, complimented by zeatin and gibberellin which are growth enhancers present in the MLE. Moringa leaf in combination with NPK fertilizer is therefore, recommended for use by maize farmer for optimum growth and yield of maize.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Evaluation of selected herbicides for user in zero-tilled maize production field experiment was conducted at Ogbomoso farm settlement in Oyo State. The treatments were laid out in a Randomized Complete Block Design (RCBD) with three replicates. The treatments consisted of paraquat at 1.5.0 a.i/ha, glyphosate at 3.0 a.i/ha, fusilade at 1.0 a.i/ha 2,4-D amine at 3.0 a.i/ha and hoe weeding. The herbicides were applied using Knapsack sprayer which was caliberated to deliver at 200 litres/ha. Application of the herbicides was done one week after slashing, when the cut weeds has resumed active regrowing. Result showed that paraquat and glyphosate herbicides had no significant effect on the germination of maize. The highest germination occurred under paraquat (100%) and glyphosate (100%) while the least occurred under Fusilade (58.7%). The highest yield per plant of maize was recorded under paraquat and glyphosate (36g and 30g) respectively while the least was obtained under fusilade (23g). This implies that both paraquat and glyphosate has very good weed control efficiency, here they are the most suitable for zero tilled maize. While 2,4 D amine had a very good control efficiency in terms of the weed population and biomass both at four (4) weeks after sowing and at flowering, the growth and yield performance of maize was hampered possibly due to the phytotoxicity of the herbicide. Fusilade was not able to control the weeds effectively due to fact that majority of the weeds on the plot were dicots. Fusilade is indicated for the control of grass weeds.

INTRODUCTION
Maize (*Zea mays* L.) is a member of the grass family (Graminae). It originated from South and central American Okoroafor *et al.*, 2013. It was introduced to West Africa by the Portuguese in the 10th century. Maize is one of the most important grains in Nigeria, not only on the basis of the number of farmers that engaged in its cultivation, but also in its economic value. Maize is a major important cereal being cultivated in the rainforest and the derived savannah zones of Nigeria. Maize has been in the diet of Nigerians for centuries. It started as a subsistence crop and has gradually become a more important crop. Maize has now risen to a commercial crop on which many agro-based industries depend for raw materials (Iken and Amusa, 2004). Maize is the most important cereal in the world after wheat and rice with regard to cultivation areas and total production (Purseglove, 1992; Osagie and Eka, 1998). According to Khawar *et al*. (2007), maize has a variety of uses. Its grain is a rich source of starch, vitamins, proteins and minerals. Studies in maize production in different parts of Nigeria have shown and increasing importance of the crop amidst growing utilization by food processing industries and livestock feed mills (Ogunsumi *et al*., 2005; Khawar *et al*., 2007; Abaduhaman and Kolawole, 2008). The crop has thus grown to be a local ''cash crop'' most especially in the southwest part of Nigeria where at least 30 percent of the cropland has been put to maize production under various cropping system (Ayeni, 1991; Degrande and Danjuma, 2000).
Zero tillage also known as no-till farming refers to a cultivation that leaves fields unturned and allow crop stubble to remain on the soil surface from harvesting to sowing. The stubble protects the soil surface. Experimental studies have confirm that no-till farming markedly reduces erosion, nitrogen runoff and particulate phosphorus runoff (Soileau *et al*., 1994, Stonedhouse 1997). These findings have prompted interest in no-till as a cultivation technology that would benefit both farmers and the environment. However, no-till has been linked to undesirable environmental effects, in

particular increased loading of dissolved reactive phosphorus (Holland 2004, Puustinen *et al*., 2005) and leaching of herbicides due to increased herbicide application (Holland, 2004, Rose and Carter, 2003). The use of contact herbicides is very paramount in no-till due to the need for the elimination of the weed without turning the soil. Contact herbicides kill only the parts of the plants they touch by moving quickly into the shoots, the roots, the leaves, rhizomes, stolon and growing point of the treated plants. Therefore, uniform spray coverage and particle size are essential for adequate control. Contact herbicides do not kill perennial underground structure such as tubers and bulbs. Repeat applications to re-growth may eventually drain the plants underground resources. Examples of herbicides are glyphosate, paraquat and 2, 4-D.

Tithonia diversifolia commonly known as Mexican sunflower, is an annual, aggressive leafy weed shrub commonly found in many parts of the world. It grows to a height of 0.3m or more and it is adaptable to most soils (Jama *et al*., 2000; Olabode *et al*., 2007). In the south-western Nigeria, the weed had predominantly suppressed many common weeds including *Chomolaena odorata*, grassy weeds including *Imperata cylindrical* and many crop-plants such as maize plant, in competition (Jama *et al*., 2000; Nziguheba *et al*., 2002; Olabode *et al*., 2007; Chukwuka and Omotayo, 2008) The aggressive nature and high growth rate of Mexican sunflower has been attributed to its possible allelopathic effects on the neighbouring weed seeds, crop-plants and the smothering effects on their seedlings (Baruah *et al*., 1994; Boureima *et al*., 2007). Mexican sunflower possess both fertilizer attributes as well as phytotoxic growth inhibiting (Baruah *et al*., 1994; Ayeni *et al*., 1997).

MATERIALS AND METHODS

The field experiment was conducted at Ogbomoso farm settlement in Oyo State. The five treatments were laid out in a Randomized Complete Block Design (RCBD) with three replicates. The treatments consisted of paraquat at 1.5. a.i/ha, glyphosate at 3.0 a.i/ha, Fusilade at 1.0 a.i/ha 2,4-D amine at 3.0 a.i/ha and hoe weeding. The size of the experimental plot is 19m by 8m with three replicates. Each plot was separated with an alley 1m between the replicates and plots.The application was done using the knapsack sprayer which was calibrated to deliver at 200 litres/ha. The experimental plot was slashed and the debris removed to allow the herbicides have a direct contact with the weeds regrowth. Application of the herbicides was done one week after slashing and packing was done to allow the cut weeds to resume active regrow. The herbicides were applied at the recommended rates. Glyphosate was applied at 3 litres/ha, Fusilade at 1litres/ha, paraquat at 1.5 litres/ha and 2,4-D amine at 3litres/ha. Maize variety, OBA SUPER was obtained from farmers shopping centre in Ogbomoso, and was planted after packing of debris and after spraying. Thinning was done 2 WAS to reduce the plant to two plants per stand. The post emergence application of atrazine was done at 3 WAS at the rate of 5 litres/ha. This was done when there was appearance of undergrowth following the killing of the established weeds.

RESULTS AND DISCUSSION

The effect of selected herbicides on the germination of maize was presented in Table 1. The highest germination percentage were recorded under paraquat (100%) and glyphosate (100%), followed by 2, 4-D amine (98.7%). There were no significant differences between these treatments ($p \leq 0.05$) on the germination percentage. However, hoe weeding treatment recorded 85% of germination when compared with the herbicide treatments but more effective than fusilade (58.7%) for percentage germination. The effect of the herbicides on maize stem diameter is also presented in table 1. Glyphosate has the highest value (1.1cm) followed by paraquat (0.8cm), hoe weeding (0.8cm) and 2,4-D amine (0.7cm). Fusilade produced the thinnest stem diameter (0.5cm). There were no significant difference between the treatments and control with respect to leaf area at flowering, plant height at 4 WAS.

Table 1: Effect of Selected Herbicides on Growth Parameters of Maize

Treatments	%Emergence	%Survival	Stem diameter at 4WAS (cm)	Stem diameter at flowering (cm)	Plant height at 4WAS (cm)	Plant height at flowering (cm)	Leaf area at flowering (cm)
Paraquat	100a	98.7a	0.8b	2.9a	70.1a	176.0ab	710.3a
Glyphosate	100a	100a	1.1a	2.5a	75.5a	188.5a	835a
Fusilade	58.7c	30.7c	0.5c	2.8a	63.2a	157.7c	693a
2,4-D amine	98.7a	97.3a	0.7bc	2.7a	58.6a	165.3bc	651.7a
Hoe weeding	85b	83.3b	0.8b	3a	64a	185a	747.7a

Means followed by the same superscript are not significantly different by DMRT ($p \leq 0.05$)

At flowering however, glyphosate produced significantly taller plants (188.5cm) which was comparable to hoe weeding (185.0cm) and paraquat (176.0cm). Fusilade produced the shortest plant (157.7cm) at flowering.

Table 2 present the effect of selected herbicides on the yield parameters of maize. There were no significant differences among the treatments with respect to number of days to flowering and number of cobs per plant. The earliest maize tasselling was recorded under glyphosate (53 WAS) while the late to tasseled was recorded under 2,4-D amine (60.7 WAS). The highest number of grain per cob was recorded under the control (310.3) and this is not significantly different to 265.5 grains produced by glyphosate (Table 2). The least number of grains per cob was recorded under paraquat (130.8), but was not significantly different from 2,4-D (174.7) and fusilade (166.7). The highest weight of

100 seeds (36g) was obtained under paraquat which is significantly superior to glyphosate (30g) and hoe weeding (25.7g). Fusilade and 2,4-D amine produced the lightest seeds (23g and 24g respectively).

Table 2: Effect of selected herbicides on the yield parameters of maize

Treatments	Days to flowering	No of grain per cob	No of cob per plant	Weight of 100 seeds(g)
Paraquat	56.7a	130.8b	1.5a	36a
Glyphosate	53a	265.5a	1.3a	30b
Fusilade	56a	166.7b	1.0a	23c
2,4-D amine	60.7a	174.7b	a.2a	24c
Hoe weeding	54a	310.3a	1.2a	25.7bc

Means followed by the same superscript are not significantly different by DMRT ($p \leq 0.05$)

Table 3 presents the weed density of selected herbicides on maize plot. The weed population was calculated by Quadrat method. A 25 cm by 25cm Quadrat was used for sampling. At 4 WAS, the treatment show no significant differences for weed population and weed biomass. At flowering however, fusilade has the highest weed biomass (112.3g) which is significantly different from paraquat (82.7g). Glyphosate and hoe-weeded control show no significant differences with 56.3g and 56.5g respectively. 2,4-D amine recorded the lowest biomass of 44.8g. At flowering, fusilade recorded the highest population of weeds (28 m^{-2}) which is significantly different from glyphosate and control that recorded 17.5 m^{-2} and 16 m^{-2} of weeds respectively both of which are only comparable to paraquat that recorded 10.6 m^{-2} of weeds and 2,4-D amine that recorded 13 m^{-2}. 2,4-D amine has the lowest weed population and weed biomass. Fusilade was the poorest as it recorded the highest weed population and highest weed biomass, respectively.

Table 3: Weed density of selected herbicides on maize plot

Treatments	Weed biomass at 4WAS(g)	Weed population at 4WAS	Weed Biomass at flowering (g)	Weed population at flowering
Paraquat	9.3a	6.3a	82.7b	10.6c
Glyphosate	7.5a	7.5a	56.3c	17.5b
Fusilade	20.3a	10.7a	112.3a	28a
2,4-D amine	5.7a	5.7a	44.8d	13bc
Hoe weeding	19a	10.7a	56.5c	16b

Means followed by the same superscript are not significantly different by DMRT ($p \leq 0.05$)

CONCLUSION AND RECOMMENDATION

From the result, glyphosate and paraquat had the best result in terms of maize growth and yield parameters. This may be due to effective weed control efficiency. The growth and yield performance of maize was hampered possibly due to the phytotoxicity of the herbicide. For Fusilade, it was not able to control the weed effectively possible due to the fact that majority of the weeds on the plot were dicots. Fusilade is indicated for the control of grass weeds. From the above, it could be concluded that both glyphosate and paraquat could be used effectively for weed control on zero-tilled maize plots.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Yields of cowpea have been reported to be low due to inappropriate spacing of genotypes with different maturity periods. Therefore, this study was conducted to assess the effect of plant spacing on growth and grain yield of two cowpea varieties (Oloyin and Seyin). The two varieties associated with contrasting maturity dates were sown under three different intra-row spacings (60 cm x 30 cm, 60 cm x 40 cm and 75 cm x 30 cm). The experiment had 18 plots with 1.5 x 1 m plot size. The results showed that variety 1 (Oloyin) was significantly different ($p \leq 0.05$) with respect to number of days to flowering and plant height, while 60 cm x 30 cm plant spacing was observed to be significantly higher ($p \leq 0.05$) with respect to weight of 100 grain and grain yield as compared to other plant spacing. Therefore, variety 1 (Oloyin) is recommended for the farmers at planting spacing of 60 cm x 30 cm.

INTRODUCTION
Cowpea (*Vigna unguiculata* (L.) Walp) is of major importance to the livelihoods of millions of people in the developing countries of the tropics (Singh *et al*., 1997). Cowpea provides essential protein requirements in human diet. It is reported to contain the highest (23-25 %), protein (Singh *et al*., 1997). Like other legumes, cowpea fixes atmospheric nitrogen (N) through Biological Nitrogen Fixation (BNF), a symbiotic association between soil dwelling bacteria, commonly known as rhizobia, and legume host plants. This symbiosis results in nitrogen replenishment as evidenced in many experimental findings that have illustrated increasing soil N levels following cowpea cultivation (Thies *et al*., 1995).

The total area harvested with cowpea worldwide is about 10, 979 841 ha. As a result, annual world cowpea seed production is 364, 817 tonnes (FAO, 2010). West and central Africa are reported to be the leading cowpea producing regions in the world, accountable for 64 % of the annual estimation of 3 million tonnes of cowpea (IITA, 2009). Nigeria is the leading cowpea producer in Africa responsible for 68 %, followed by Ghana, Niger, Senegal and Cameroon (IITA, 2009). Subsistence farmers in the semi-arid and sub-humid regions of Africa are the major producers and consumers of cowpea. These farmers not only grow cowpeas for dry seed, but also utilize the leaves and pods as vegetables (IITA, 2009). Fresh tender leaves, immature pods and fresh peas are consumed as vegetables, while several snacks and main dishes are prepared from the dry grain. All plant parts that are used for food have been found to be nutritious, providing protein, vitamins and minerals. The other plant parts, besides dry seeds, are commonly consumed as young leaves, immature pods and immature seeds (IITA, 2009).

The price of cowpea especially Oloyin is becoming exorbitant and unaffordable to an average man, hence, the need to examine if the other local varieties may be a used as substitutes. Also, plant spacing is an important factor in crop production as an efficient way to optimise space and as well, reduce competition among plants with similar cultural requirements, while simultaneously enhancing nutrient composition of the soil. Also, without promoting pests, or providing shade, but strengthening the microclimate (wind, moisture, and improves the interaction of beneficial microorganisms within the soil's rhizosphere), (Nnoke, 2001; Godasu and Rajkumar, 2021). The objective of the study was therefore, to evaluate the effect of spacing on growth and grain yield of 2 varieties of cowpea (*Vigna unguiculata* (L.Walp) at 3 different plant spacings.

MATERIALS AND METHODS

The research was conducted at the Teaching and Research Farm, Oyo State College of Agriculture and Technology, Igboora, located in the rainforest vegetation zone of South-Western Nigeria.The two cowpea varieties (Oloyin and Seyin) used for the study were purchased from Towobowo market, Igboora and Anko market, Eruwa respectively. The experiment was carried out during the late wet season (September, 2022). The land used for the study was cleared and ploughed mechanically with the use of tractor. Subsequent field activities were done manually by weeding, hoeing and use of a cutlass. The experimental site measured 8.5 m by 6 m, with sub-plots of 2 m x 1.5 m. Three spacings were used; 60 cm x 30 cm, 60 cm x 40 cm, 75 cm x 30 cm, with two plant rows per plot. Spacing 1 had 10 stands, spacing 2 had 8 stands, while spacing 3 had 10 stands. The treatments were arranged as a split-plot in a Randomized Complete Block Design (RCBD) with three replications, totalling of 18 plots. The following agronomic data were collected on 5 randomly selected plants per plot: Days to flowering, plant height at flowering, number of peduncles per plant, length of peduncle per plant, length of pod, number of days to 90 % maturity, number of grains per pod, weight of 100 cowpea grains and grain yield per plot. Data were subjected to analysis of variance (ANOVA) and significant means were separated using Duncan's Multiple Rang Test (DMRT) at 5 % level of probability.

RESULTS AND DISCUSSION

Mean performance of 2 varieties of Cowpea at three planting distances

The highest ($p \leq 0.05$) grain weight (16.49 g) was observed in variety 1 (Oloyin) at the spacing of 60 cm x 30 cm, while the lowest ($p \leq 0.05$) grain weight (5.29 g) was recorded in variety 2 (Seyin) at the spacing of 75 cm x 30 cm. The highest ($p \leq 0.05$) grain yield (16.47 g) was observed in *Oloyin* at th spacing of 60 cm x 30 cm, while the lowest ($p \leq 0.05$) grain yield (5.29 g) was observed in *Seyin* at the spacing of of 75 cm x 30 cm. *Oloyin* flowered earlier (48 days) while Seyin flowered later (50 days after planting). also, Oloyin was observed to have the highest($p \leq 0.05$) plant height (21.67 cm) at 75 cm x 30 cm while *Seyin* had the lowest ($p \leq 0.05$) plant height (13.67 cm) at 60 cm x 30 cm spacing.

Mean performance of 2 varieties of Cowpea at three planting distances

The highest ($p \leq 0.05$) number of peduncle (5.93) was observed with Seyin at 60 cm x 40 cm spacing, while the lowest ($p \leq 0.05$) number of peduncles 3.63 was recorded at 75 cm x 30 cm spacing. Variety 1 (Oloyin) recorded the highest ($p \leq 0.05$) pod length (9.93 cm) at 60 cm x 30 cm spacing, while the lowest ($p \leq 0.05$) pod length (8.60 cm) was observed at on Seyin at 60 cm x 40 cm spacing. The highest ($p \leq 0.05$) number of pod (5.93) was observed at variety 2 (Seyin) at 60 cm x 40 cm spacing, while least ($p \leq 0.05$) number of pod (3.63) was observed at 75 cm x 30 cm spacing. Also, the highest l($p \leq 0.05$) ength of peduncle (25.67 cm) was observed in variety 2 (Seyin*)* at 60 cm x 40 cm spacing, while lowest($p \leq 0.05$) length of peduncle (13.67 cm) was recorded on variety 1 (Oloyin) with planting distance of 75 cm x 30 cm. The highest number of grains (6.23) was observed at variety 1 (*Oloyin*) at of 60 cm x 40 cm while variety 2 (Seyin) recorded the lowest ($p \leq 0.05$) number of grains (4.27) at 75 cm x 30 cm. *Oloyin* had the least number of days to maturity (61.33) with planting distance of 60 cm x 30 cm while Seyin had the highest ($p \leq 0.05$) number of days to maturity (63.00) at of 60 cm x 40 cm spacing.

Table 1: Performance of 2 varieties of Cowpea at three planting distances

CHARACTER	VARIETY	PLANT 60 x 30 cm	DISTANCE 60 x 40 cm	75 x 30 cm	
Weight of 100 grains	Oloyin	16.49	7.32	7.48	NS
	Seyin	13.96	9.97	5.29	NS
		15.23a	8.65ab	6.38b	
Grain yield /plot	Oloyin	16.47	7.32	7.48	NS
	Seyin	13.96	9.97	5.29	NS
		15.22a	8.64ab	6.38b	
	Seyin	4.93	5.93	3.63	
		NS	NS	NS	
Days to flowering	Oloyin	48.33	48.00	48.33	48.22b
	Seyin	50.67	51.00	51.00	50.89a
		NS	NS	NS	
Plant height	Oloyin	20.67	21.00	21.67	21.11a
	Seyin	13.67	14.67	14.00	14.11b
		NS	NS	NS	
Number of peduncles	Oloyin	5.00	4.20	4.80	
	Seyin	4.93	5.93	3.63

	Seyin	25.53	25.67	20.60
		NS	NS	NS
Number of grains	Oloyin	5.60	6.23	4.80
	Seyin	5.13	4.67	4.27
		NS	NS	NS
Days to maturity	Oloyin	61.33	62.00	61.67
	Seyin	62.00	63.00	62.00
		NS	NS	NS

Means followed by the same letters in a column are not significantly ($p \leq 0.05$) different; NS: Not Significant

CONCLUSIONS AND RECOMMENDATION

The study showed that Oloyin flowered earlier than Seyin attributed to earlier initiation of flowering in Oloyin and consequently, ripening and early pod rupturing and seed maturity. Also, the study showed that Oloyin produced higher yield which will be of greater advantage to farmers. Oloyin is therefore recommended to the farmers in the study area to at 60 cm x 30 cm spacing.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

*This experiment was conducted in 2021 cropping season at Anyigba (latitude 7˚28′ N, longitude 7˚10′ E) in the southern guinea savannah agro ecological zone of Nigeria to determine root yield and nutritional composition of two varieties of orange flesh sweetpotato UmuSPO 1, UmuSPO 3 with NPK fertilizer. . The experiment was laid out in a randomized complete block design with three replications. The plot size was 2m x 3m and planting distance of OFSP varieties were 1m x 0.30m. Sweetpotato roots (t/ha) were harvested at 16 weeks after planting. Nutritional composition analyses of the two varieties of OFSP were determined using the standard procedure of Association of Official Analytical Chemists. The results obtained showed that 400kg/ha of NPK 15:15:15 fertilizer gave the highest root yield irrespective of variety. However, there were significant differences in the proximate composition (%) of the varieties. UmuSPO 1 recorded the higher fat content (0.7±0.15), protein (6.5±0.00) and carbohydrate content (25.35±0.12) while UmuSPO 3 recorded the higher moisture (6.50±0.01), ash (3.04±0.02) and crude fibre (1.72±0.02). Mineral composition (mg/kg) UmuSPO 1 had the higher Ca (68.39±1.0), Na (33.64±0.11), K (51.10±1.14) and Mg (18.17±0.0) while UmuSPO 3 had higher Fe (11.18±0.10) and P (110±20.0). For vitamin composition UmuSPO 3 recorded the higher Beta-carotene (*μg/100g*) (2473±1.16), vitamin A (158.4±1.10* μg/RE)*) and vitamin C (14.12±0.01mg/100g).*

Keywords: *Orange flesh sweetpotato, NPK fertilizer, root yield, nutritional composition*

INTRODUCTION

Sweet potato (*Ipomoea batatas*) is a dicotyledonous plant that belongs to the family convlvulacea. The crop is grown in many countries globally, but production primarily occurs in tropical and subtropical areas where it is an important staple food in the diet of many people. It is one of the most important root crops in sub-Saharan Africa with both domestic and industrial uses and its nutritional value far exceed that of yam, cocoyam and cassava (Nmor and Okobia, 2017). Orange flesh sweetpotato has been reported to increase children's levels of vitamin A and serum retinol concentration and has been used to fight global vitamin A deficiency (Islam *et al*., 2016).

Low soil fertility has been recognized as one of the major production constraints affecting agriculture. Soil fertility depletion in small holder farms is the fundamental issue (Sanchez *et al.,* 1996). This depletion is mainly due to intensive and continuous cropping with low application of nutrients. The low and declining productivity of many tropical soils are the major constraints limiting the realization of the improved genetic potential of crop that is now available. As poor soil fertility limits the realization of the genetic potential of the crop, fertilization of the sweetpotato crop becomes inevitable.

Fertilizers are known to have significant influence on vegetative growth of crops and subsequently increased in root yield (Toungos, 2016). The three major fertilizer elements known to be deficient in most Nigerian soils due to intense pressure on land because of continuous cropping are Nitrogen (N), Phosphorous (P) and Potassium (K) (Toungos, 2017). Fertilizers, especially NPK, promote vegetative growth and impart deep green colour characteristics essentially for photosynthesis. Research has shown that application of inorganic fertilizer increases root yield (Okpara *et al.*, 2011)) Research reports on sweetpotato response to fertilizer in Nigeria has been on the white fleshed type while little is known about nutrient management for orange-fleshed sweet potato. The present study examined the response of two varieties orange-fleshed sweetpotato (UmuSPO 1, UmuSPO 3) to the nutrient management strategy involving NPK 15:15:15. However, there is dearth of information on the magnitude effects on root yield and yield components of orange flesh sweetpotato genotypes in soils of Kogi state. The objective of the study was to determine root yield and nutritional composition of orange flesh sweetpotato with NPK 15:15:15 fertilizer in Anyigba, Kogi State Nigeria

MATERIALS AND METHODS

The experiment was conducted at the botanical garden of Prince Abubakar Audu University, Anyigba Kogi State in the Faculty of Natural Sciences of the University. Anyigba is located on latitude 7˚28ʹ N and longitude 7˚10ʹ E in the Eastern part of Kogi state in the DenikaLocal Government Area of Kogi State. The experiment was laid out in a randomized complete block design (RCBD) with three replications. The experimental treatments were two varieties of orange flesh of sweetpotato (UmuuSPO 1 and UmuSPO 3) and 4 levels of fertilizer (0, 200, 400 and 600).The clearing of the site was done manually with machete and hoe. Ridges were done manually using hoe. The planting distance was 1m x 0.30 and length of vine was 30 cm which may contain 3 - 4 nodes. Two varieties of orange flesh sweetpotato vines were collected from National Root Crops Research Institute, Umudike. The healthy vines of OFSPO UmuSPO 1and UmuSPO 3 were planted at the botanical garden ofPlant Science and Biotechnology Department and the planting depth was 5 – 10 cm. The planting was done on 01/08/2021 and good agronomic practices were carried out. Roots were harvested at 16 weeks after planting and (WAP) measurements were taken on number of roots per plant, weight of roots/plant (g) and weight of root/ ha which was subjected to analysis of variance using Genstat discovery 1 edition. Tthe proximate composition (%) of the OFSP varieties (moisture, ash, crude protein, crude fat, crude fibre) were determined according to the method of AOAC (2012) and total carbohydrate was calculated by Atwater factor..

RESULTS AND DISCUSSION

The effect of NPK 15:15:15 fertilizer on two varieties of orange flesh sweetpotato showed that irrespective of fertilizer levels used there is no difference on the number of roots. (Table 1 and Table 2) UmuSPO 3 gave the highest root yield and 400Kg/ha of NPK 15:15:15 fertilizer gave the highest root yield across followed by 600Kg/ha while 0Kg/ha gave the lowest root yield. Yield is an important component of any crop and means of increasing yield is through good agronomic practices which fertilizer application is one of them. Application of fertilizer increases the number of roots in respective of the variety. According to Okpara *et al*., (2011) confirmed that application of NPK 15:15:15 fertilizer increased root yield of sweetpotato.

The results of the effects of NPK 15:15:15 on the proximate composition of two varieties of OFSP showed that there was a difference ($P<0.05$) for all the proximate composition % (moisture, ash, crude protein, crude fat, crude fibre and carbohydrate) analyzed (Table 3). UmuSPO 1 had the highest fat content (0.7 ± 0.15), (protein 6.5 ± 0.00)) and carbohydrate content while UmuSPO 3 obtained the highest moisture (24.35 ± 0.12), ash and (crude fibre (3.04 ± 0.02). There were differences in moisture content of two varieties OFSP which could be a result of genetic composition (Wenkam, 2008). Crude protein content was higher in UmuSPO 1 variety compared to UmuSPO 3. Sweetpotato could serve as an excellent source of protein in diet if consumed regularly. Protein provides essential amino acids to the body, and protein content in food varies widely (Senannayake et al., 2013). Sweetpotato has low fat content, the result obtained for low fat content (0.2% and 0.17%) were similar to work of Tumuhimbise *et al*., (2013). The ash content of UmuSPO 3 was higher but UmuSPO 1 the ash content was low. The ash content refers to complete oxidation of organic matter in the sample which gives an overview of the mineral content of the material (Agbede and Adekiya, 2011). UmuSPO 3 was likely to be better source of nutrient in the diet as compared to UmuSPO 1. Nutritionally, ash aids in the metabolism of protein, carbohydrate and fat. (Abbasi *et al*., 2011). Carbohydrate content is higher in UmuSPO 1than in UmuSPO 3 and carbohydrate provides energy to cells in the body, particularly the brain, the only carbohydrate dependent organ in the body (Islam *et al*., 2016). Orange flesh sweetpotato could be supplementary for carbohydrate need in the diet.

The results of the effects of NPK 15:15:15 on the mineral composition of two varieties of OFSP (Table 4).There was a significant difference ($P<0.05$) for mineral contents (mg/kg) (Ca, Na, K, Mg Fe and P) analysed. UmSPO 1 variety obtained the highest Ca (68.39 ± 1.0), Na (33.64 ± 0.11), K (±51) and Mg (18.17 ± 0.00) while UmuSPO 3 variety recorded the highest Fe (11.18 ± 0.10) and P (110 ± 20.0). The results of the effects of NPK 15:15:15 on the vitamins composition of two varieties of OFSP (Table 5). There was a significant difference ($P<0.05$) for all the vitamin constituents ($\mu g/100g$) (B carotene2473 $\pm$ 1.16), Vitamin A (158.4 ± 1.10) and Vitamin C constituents $\mu g/RE$)(14.12 ± 0.01). UmuSPO 3 contains higher vitamin A and C while UmuSPO 1 had the least content. Vitamins are generally needed in small amount from foods. They yield no energy directly but may contribute to energy yielding chemical reactions in the body and promote growth and development (Islam *et al*., 2016). Vitamin C is mainly used in synthesizing collagen, a major protein for connectives tissues. It is generally antioxidant, enhances iron absorption and is needed for synthesizing some hormones and neutron transmitters.

CONCLUSION

NPK 15:15:15 fertilizer increased root yield and yield component of root yield of two varieties of OFSP. The nutritional compositions of the two varieties of OFSP were enhanced by fertilizer application. Carbohydrate content is higher in UmuSPO 1than in UmuSpo 3 and UmuSPO 3 contains higher vitamin A and C while UmuSPO 1and the least content. This study further confirmed that application of fertilizer to crops is necessary for improvement in root yield.

RECOMMENDATION

Application of 400Kg/ha of NPK 15:15:15 fertilizer is recorded for production of root yield and yield component of OFSP varieties. Fertilizer contributed to increase in root yield of OFSP. And OFSP should be consumed for good health as it contains high quantity of Beta-carotene and vitamins

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Pot experiment was conducted at the Screen House of Faculty of Agriculture Shabu-Lafia Campus, Nasarawa State University, Keffi, to determine the effect of different levels of poultry droppings and cow dung on growth and yield of okra. The experiment consisted of 4 × 4 factorial combination of four levels each of poultry droppings (0, 10, 15 and 20 tons/ha) and cow dung (0, 20, 30 and 40 tons/ha) and arranged in Completely Randomized Design (CRD) with three replications. The results obtained showed that application of 15 t/ha of poultry droppings produced significantly the tallest plants, more number of leaves, number of capsules per plant, capsules length, fresh and dry weights of capsules and green capsules yield against any other levels of poultry applied droppings. The results also revealed that application of 30 and 40 t/ha of cow dung recorded the greatest values in all the variables measured in this study. From the study it was observed that 15 t/ha of poultry droppings enhanced the vegetative growth of okra (i.e. plant height, number of leaves) while 30 and 40 t/ha of cow dung significantly enhanced all the yield components of okra. Based on the results, application of 15 t/ha of poultry droppings and 30 and 40 t/ha of cow dung is recommended for sustainable production of okra in the study area.
Keywords: *Cow dung, growth, poultry dropping, yield*

INTRODUCTION
Okra (*Abelmoschus esculentus*) is one of the most important vegetables grown in Nigeria. It is an annual crop grown mainly as fruits and leafy vegetables in both green and dried states in the tropics (Gibbon and pain, 1984). The crop is used as soup thickener which may also be served with rice and other food types. The fresh fruit is a good source of vitamins, minerals and plant proteins (Eke *et al*., 2008). Rehn and Espig, (1991) stated that Okra contains 20% edible oil and protein, while the mucilage is utilized for medicinal purposes. The mature stem contains crude fiber which is used in paper industries and for making ropes. Okra flowers can be very attractive and sometimes used in decorating the room (Schippers, 2000).

Vegetable growing is one of the major enterprises in horticulture which is becoming more popular due to the greater appreciation of their food values (Gardner, 2004). Okra is essentially a tropical crop and among the most commonly grown vegetables throughout Nigeria. The stem is useful as fiber, while the leaves are considered good for cattle feeds and are consumed sometimes. The seed sometimes can be roasted and used as a substitute for coffee (Farinde and Owolarefe, 2007). The essential and non-essential amino acids which Okra contained is comparable to that of soybean (Farinde, 2007).

The production of Okra is seriously affected by the use of local varieties (low yielding), sub-optimal and inappropriate manure doses. Inorganic fertilizer has not been helpful under intensive agriculture because it is often associated with reduced crop yield, soil acidity as well as nutrients imbalance (Kang and Juo, 1980; Obi and Ebo,1995; Ojeniyi, 2000). Published work on the Organic manures use in Nigeria is rather scanty. The need to use renewable forms of energy and reduce cost of fertilizing crops has revived the use of Organic fertilizer worldwide. Improvement of environmental conditions and public health are important reasons for advocating increased use of organic materials (Seifritz, 1992; Maritus and Vlelc, 2001).

Organic manures when efficiently and effectively applied or used, ensures sustainable crop productivity by immobilizing nutrient that are susceptible to leaching. (Abou El-magd, *et al.,* 2006). Nutrients contained in Organic manures are released more slowly and are stored for a long period of time in the soil, thereby ensuring long residual effects (Makinde and Ayoola,2008) supporting better root development, leading to higher crop yield (Abou El-magd *et al.,* 2005). Apart from economic cost, the use of chemical fertilizers under continuous cultivation in the tropics is not adequate to sustain crop yield. Their continuous application has been found to deplete soil organic matter (Madeley, 1990) and consequently leading to reduction in crop yield and serious degradation as well as decline in soil productivity (Adediran *et al.,* 2004).

The increased demand for Okra by greater number of people today makes it necessary to find a way of increasing its yield through the application of nutrients and adopting best agronomic practices as well as continuous cultivation throughout the year. The use of poultry droppings and cow dung do not only increase the yield of crop, but also improve the soil physical and chemical properties. Therefore, this work seeks to evaluate the effects of poultry droppings and cow dung manure on growth and yield of okra and to determine the best rate of application under irrigation.

MATERIALS AND METHODS

Pot experiment was carried out in the Screen House of the Faculty of Agriculture Experimental Farm, Nasarawa State University, Keffi Shabu-Lafia Campus (from June to October, 2015). Lafia is at altitude 181.53m above sea level. Latitude 08° 33'N and Longitude 08° 32' E. Soil sample was collected from the College of Agriculture Lafia Experimental Farm along Akurba road. The sample of top soil (20 cm) depth was collected, air dried and sieved with 2mm sieve and analyzed for physical and chemical properties before and after the experiment. Forty two pots were arranged in a Completely Randomized Design (CRD) filled with 5 kg of soil each after the pots were perforated in order to provide proper drainage. The planting material used was NH47-4 (NIHORT). The experiment consist of 4 × 4 factorial combination of four levels of cow dung (0, 20, 30 and 40 t/ha equivalent to 0g/5kg, 66.6g/5kg, 100g/5kg and 133.4/5kg of soil) and four levels poultry droppings (0, 10, 15 and 20 t/ha also equivalent to 0g/5kg, 33.3g/5kg, 50g/5kg, and 66.7g/5kg of soil) and replicated three times. The three levels of Cow Dung and Poultry Droppings were properly mixed with the soil and incorporated into pots according to the treatments combination and properly mixed with the soil. Water was then applied for 1-7 days for proper decomposition of the manures (Cow Dung and Poultry Droppings).

Two seeds of improved variety (NH47-4) were sown per pot at a depth of about 1.5cm and watered. The seeds were then thinned to one stand per pot after full emergence. Water was provided at regular interval especially at the early stage of growth and flowering stage so as to meet the crop water requirement for proper growth and development of the crop. Weeds in the pots were removed by hand pulling at regular intervals of 1-2 weeks until the day of final harvest; this is done to reduce competition for the available nutrients. Insect pest and black ants were noticed at two weeks after emergence and controlled by hand picking and application of insecticide (Karate). Matured green pods/capsules were harvested from each pot at regular intervals of 4-5 days to obtain total number of pods per plants while pod length and pod weight were measured using measuring tape and weighing scale. The pre-harvest parameters such as plant height (cm) and number of leaves were measured at 4, 6, 8 and 10 WAS. While at harvest, post-harvest parameters such as number of pods per plant, pods length (cm), fresh pod weight (g), dry pod weight (g) and green capsule yield were also measured. The data obtained were statistically analyzed using Genstat statistical software (10th Edition). Means were compared using the Duncan Multiple Range Test at 5 % level of significance.

RESULTS AND DISCUSSION

Table 1 shows the results of the effects of poultry droppings and cow dung on height of okra. The results obtained showed that application of poultry droppings at 15 t/ha produced consistently the tallest plants as compared to any other rates of poultry droppings at 4, 6, 8 and 10 WAS. However, at 8 WAS, 20 and 15 t/ha poultry droppings produced similar height of okra but they were significantly higher than those produced under 10 and 0 t/ha treatments. Similarly, at 4 WAS, 30 t/ha of cow dung produced significantly taller plants followed by 40 t/ha while 0 t/ha produced the shortest plants.

At 6 and 8 WAS, 40 t/ha of cow dung recorded the tallest plants compared to other rates of cow dung applied. At 10 WAS, every increase in the rate of cow dung significantly increased height of okra.

The significant increase in plant height with the application of 15t/ha of poultry droppings as well as 30 and 40 t/ha of cow dung this could be attributed to the fact that manure contains nutrients that are necessary for plant growth and development (Brady, 1974).

Table 1: Effect of Different Levels of Poultry Droppings and Cow Dung on Height of Okra (cm) during 2015 Dry Season

Treatment	4WAS	6WAS	8WAS	10WAS
Poultry Droppings (t/ha)				
0	16.50^{b}	20.00^{c}	22.20^{c}	25.00^{c}
10	16.60^{b}	21.27^{b}	22.43^{b}	26.73^{b}
15	17.20^{a}	22.87^{a}	24.20^{a}	28.03^{a}
20	16.63^{b}	21.47^{b}	24.27^{a}	26.93^{b}
Mean	16.75	21.15	23.03	26.17
SEM ± (0.05)	0.79	0.52	0.11	0.64
Cow Dung (t/ha)				
0	12.20^{d}	16.00^{c}	20.90^{b}	21.80^{d}
20	14.37^{c}	18.10^{b}	21.04^{b}	22.67^{c}
30	16.40^{a}	18.67^{b}	21.17^{b}	24.67^{b}
40	15.80^{b}	20.00^{a}	24.17^{a}	26.20^{a}
Mean	15.94	22.19	25.17	28.39
SEM ± (0.05)	0.11	1.01	2.21	1.55

Means having different letters along the column are statistically different at 5 % Level of significance (P<0.05).

Table 2 shows the results of the effects of poultry droppings and cow dung on number of leaves of okra. The results obtained showed that at 4 WAS, 20 t/ha of poultry droppings produced significantly higher number of leaves per plant against any other rates of poultry droppings applied. At 6 and 8 WAS, 15 and 20 t/ha produced similar number of leaves but significantly higher than 10 and 0 t/ha respectively. Meanwhile at 10 WAS, 15 t/ha of poultry droppings recorded more number of leaves, followed by 20 t/ha while 0 t/ha gave the least number of leaves of okra. The results further revealed that application of cow dung significantly enhanced number of leaves. From 4 WAS, every increase in the rate of cow dung applied significantly increased number of leaves. Application of 15 and 20 t/ha of cow dung produced similar numbers of leaves and these were significantly higher than those produced with 10 and 0 t/ha at 6, 8 and 10 WAS.

The results further indicated that number of leaves was significantly influenced by the application of 15 t/ha of poultry dropping as well as 30 and 40 t/ha of cow dung. This result obtained could be attributed to the fact that manure contains nutrients that are necessary for plant growth and development (Brady, 1974).

Table 3 shows the results of the effect of different levels of poultry droppings and cow dung on number of capsules, capsules length, fresh capsule weight, dry capsules weight and green capsules yield of okra. The results obtained showed that poultry droppings at 15 t/ha produced significantly higher number of capsules, capsules length and green capsules yield than any other rates of applied poultry droppings. Meanwhile, application of 20 t/ha of poultry droppings gave the greatest fresh and dry capsule weight against other rates of applied poultry droppings.

Table 2: Effect of Different Levels of Poultry Droppings and Cow Dung on Number of Leaves of Okra during 2015 Dry Season

Treatment	4WAS	6WAS	8WAS	10WAS
Poultry Droppings (t/ha)				
0	6.00^{b}	6.13^{c}	7.00^{c}	7.67^{d}
10	6.67^{b}	7.00^{b}	8.00^{b}	9.00^{c}
15	7.67^{ab}	8.33^{a}	9.00^{a}	10.67^{a}
20	8.33^{a}	8.00^{a}	8.67^{a}	9.67^{b}

SEM ± (0.05)	0.79	0.81	0.78	0.58
Cow Dung (t/ha)				
0	4.33^{d}	5.00^{c}	6.33^{c}	7.00^{c}
20	5.33^{c}	6.33^{b}	7.67^{b}	8.00^{b}

30	7.00^{b}	7.60^{a}	8.33^{a}	9.50^{a}
40	7.67^{a}	8.00^{a}	8.67^{a}	9.33^{a}
Mean	6.84	7.58	7.33	9.25
SEM ± (0.05)	0.11	0.78	0.86	0.79

Means having different letters along the column are statistically different at 5% Level of significance (P<0.05).

Similarly, 30 t/ha of cow dung produced significantly more number of capsules per plant when compared to other levels of applied cow dung. The results further revealed that application of 30 and 40 t/ha of cow dung produced similar capsules length, fresh capsule weight, dry capsules weight and green capsules yield but these were significantly higher than that produced with 20 and 0 t/ha of cow dung. These results could be attributed to the fact that moderate amounts of manures promote reproductive growth while excess of it promote vegetative growth and reduce yield (Haruna *et al.*, 2011).

Table 3: : Effect of Different Levels of Poultry Droppings and Cow Dung on Number of Capsules, Capsules Length, Fresh Capsule Weight, Dry Capsules Weight and Green Capsules Yield of Okra during 2015 Dry Season

Treatment	Number of Capsules per Plant	Capsules Length (cm)	Fresh Capsule Weight (g)	Dry Capsule Weight (g)	Green Capsules Yield (kg/ha)
Poultry Droppings (t/ha)

Mean	5.90	7.30	16.78	10.69	1.70
SEM ± (0.05)	0.11	1.22	1.17	0.19	0.09

Means having different letters along the column are statistically different at 5% Level of significance (P<0.05).

CONCLUSION AND RECOMMENDATION

From the results of this study, it can be concluded that the application of 15 t/ha of poultry droppings, and 30 and 40 t/ha of cow dung produced significantly the highest values in all the variables measured than any other rates of applied poultry droppings and cow dung.

The application of 15 t/ha of poultry droppings, and 30 and 40 t/ha of cow dung may have a positive effect on the growth and yield components of okra and it seems to be the ideal rates and is therefore recommended. However, more research should be carried out so as to ascertain the best application rates of poultry droppings and cow dung for sustainable production.

PROCEEDINGS OF THE

57th Annual Conference of the

Agricultural Society of Nigeria

23rd – 27th Oct., 2023

ABSTRACT

A field trial was conducted to evaluate the growth of okra plant as influenced by poultry manure and NPK 15:15:15 fertilizer. The NPK 15:15:15 was applied at 50, 100 and 150 kg/ha two weeks after planting, while poultry manure was applied at 2, 4 and 6 tons/ha applied two weeks before planting. The okra seeds were obtained from a local farmer, planted at 3 seeds per hole and thinned to one stand after a week. The treatments were arranged in randomized complete block design (RCBD). The control plants were not treated with any fertilizer. Growth parameters data were collected which included plant height, number of leaves and stem diameter. The data collected were analyzed using Analysis of Variance (ANOVA) and significant means were separated using Duncan Multiple Range Test (DMRT) at 5% level of significance. Analyzed results showed significant differences in all the growth parameters. The results from the evaluation of growth parameters showed that plants treated with 150kg/ha NPK 15:15:15 and 6 tons/ha produced highest significant growth responses.

INTRODUCTION

Okra (*Abelmoschus esculentus* L. Moench) belongs to a family of Malvaceae. Okra is grown in many parts of the world, especially in tropical and sub-tropical countries (Arapitsas, 2007; Saifullah and Rabbani, 2009). This crop can be grown on a large commercial farm or as a garden crop (Rubatzky and Yamaguchi, 1997). Okra is a long vegetable which is grown in tropical climate. It is one of the most popularly cultivated and consumable vegetables in Nigeria and some tropical countries in the world. Okra leaf is widely consumed in the study area as Ilasa soup. It is highly cultivated fruit vegetable in almost every market in Nigeria and Africa. The crop is usually grown on small farm holdings in mixture with staple food crops such as maize, yam, cassava, cowpea and pepper with various vegetable crops. Okra is also related to cotton and hibiscus. Okra, also referred to as lady's finger, is heat loving vegetable in the hibiscus family. Okra is important because of its nutritive values present in the leaves and fruits (Schipper, 2000). Despite the nutritive value of okra, its production is very low in most developing countries.

Okra grows in all types of soils, thriving best in a moist friable well manured soil (Kochhar, 1986). The production and economic importance of okra as vegetable in Nigeria has rapidly increased in recent years. It is therefore necessary to supplement the amount of nutrient present in the soil to meet soil requirements (NAERLS, 1993). If the yield of okra is to be increased, the low fertility soil would require addition of nutrients. One of the major causes of low yielding in okra in Nigeria is inadequate information of application rate of inorganic fertilizer and organic fertilizers especially compound fertilizer like NPK (Awe *et al.,* 2006). Several experiments on crops have generally indicated yield increase due to fertilizer application (Cooke, 1982; Adenala, 1985). Most okra farmers produce the crop at low standard husbandry and rarely care about the application level of fertilizer to the crop which resulted to low yield and much labour. One way by which the growth of okra can be increased is by applying organic fertilizers and/or inorganic fertilizers. Therefore, this trial investigated the growth responses of okra plants as influenced by poultry manure and NPK 15:15:15 fertilizers.

MATERIALS AND METHODS

The experiment was conducted at the Teaching and Research farm, Oyo State College of Agriculture and Technology, Igboora. The land was manually cleared, soil samples were collected from 0 – 20 cm depth and taken to Agronomy department, University of Ibadan for physico-chemical analysis. The soil pH in H_2O (1:1) was determined with a pH meter, while available phosphorus was estimated using Bray and Kurtz (1945) method. The soil particle size was determined using the hydrometer method (Bouyoucos, 1962), while the Macro-Kjeldahl method was used to estimate total nitrogen (Jackson, 1958). The exchangeable calcium, magnesium, potassium, sodium and effective cation exchange capacity were determined using atomic absorption spectrophotometer (Tel and Hargerty, 1984). The seed of okra (Ila Iwo variety) was obtained from okra farmer in Ibarapa Central Local Government Area of Oyo State. Sowing of seeds was done at the rate of 3 seeds per hole at plant space of 1m by 1m. Seedlings were then thinned to one at one week after sowing (WAS). Regular watering was maintained. Also manual uprooting of weeds was done on regular basis. Treatments were allotted as follows: T0 (Zero application), T1 (2 t/ha poultry manure), T2 (4 t/ha poultry manure), T3 (6 t/ha poultry manure), T4 (50 kg/ha N.P.K), T5 (100 kg/ha N.P.K), T6 (150 kg/ha N.P.K). The poultry manure was applied two weeks before planting, while NPK 15:15:15 was applied two weeks after planting. The treatments were arranged in randomized complete block design (RCBD) and replicated four times. Data collection commenced at three weeks after sowing (3 WAS). The growth parameters taken were plant height, number of leaves, number of branches and stem diameter. Number of leaves was determined by visual observation and direct counting of all the fully opened leaves per plant. Plant height was determined by using meter rule while stem diameter was determined by using venier caliper. All data collected were analyzed using Analysis of Variance (ANOVA), while significant means were separated using Duncans Multiple Range Test (DMRT) at 5% probability level.

RESULTS AND DISCUSSION

Physical and chemical properties of experimental soil

The experimental soil was moderately acidic with a pH value of 6.47, low in essential plant nutrients like nitrogen (1.70 g/kg), phosphorus (9.97mg/kg) and potassium (9.97mg/kg), below the critical values of soils in the derived savanna ecological zones. The textural class was sandy loam, with 89.4 g/kg sand, 58 g/kg silt, and 48 g/kg clay (Table 1).

Table 1: Physical and chemical properties of experimental soil

Elements	Values
pH (H_20)	6.47
Ca (Cmol/kg)	3.65
Mg (Cmol/kg)	0.76
K (Cmol/kg)	0.36
Na (Cmol/kg)	0.54
ECEC (Cmol/kg)	5.34
Total N (g/kg)	1.70
Total Org. C (g/kg)	8.70
Available P (mg/kg)	9.97
Particle size analysis	
Sand (g/kg)	89.4
Silt (g/kg)	58
Clay (g/kg)	48

Effect of poultry manure and NPK 15:15:15 fertilizer on some growth parameters of okra

Application of NPK150 produced significantly higher number of leaves compared to other treatments except PM6 at 4 and 5 weeks after planting, and NPK100 at 6 weeks after planting. At 6 weeks after planting, PM4 (10.00), PM6 (11.50) and NPK50 (11.25) were not significantly different in number of leaves of okra plant. Also, the control (8.50) was not significantly different in number of leaves when compared to PM2 (9.25), While NPK100 and NPK 150 produced 13.25 and 13.00 number of leaves which are not significantly different, but significantly ($P \leq 0.05$) higher compared to other treatments.

There was significant difference in stem diameter of okra amongst the treatments except at 3 weeks after planting. At 4 weeks after planting, application of different rates of NPK was not significantly different in stem diameter, PM4 and PM6; and, PM2 and control are not significantly different in stem diameter. At 5 weeks after planting, NPK150 produced 0.79 stem diameter significantly ($P \leq 0.05$) higher than other treatments, while PM2 (0.61), PM4 (0.57), PM6 (0.59), NPK50 (0.61) and NPK100 (0.69mm) were not significantly different in stem diameter. At 6 weeks after planting, PM6 (0.79mm), NPK50 (0.75mm), NPK100 (0.77mm) and NPK150 (0.80mm) were not significantly different in stem diameter, but were significantly higher than control (0.63mm), PM2 (0.69mm) and PM4 (0.66mm). Significant ($P \leq 0.05$) difference in plant height of okra plant was observed at 4, 5 and 6 weeks after planting. At 6 weeks after planting, NPK150 (61.25cm) and PM6 (60.60cm) were not significantly different in plant height, but were significantly different from other treatments. PM2 (50.25cm), NPK 50 (52.00cm) and NPK 100 (53.50cm) were not significantly different, but significantly higher than control (45.25cm) and PM4 (49.50cm) at 6 weeks after planting.

Means follow by the same letter are not significantly different using Duncan Multiple Range Test (DMRT) at 5% probability level. WAP- Weeks after planting.

DISCUSSION

The results presented show that the growth of okra plant was significantly enhanced when treated with 150kg/ha N.P.K. 15:15:15 fertilizer and poultry manure at 6 tons/ha. These results corroborate the findings of Babatola (2006) and Sweeney *et al*. (1996) who reported enhanced crop performance as resulted from N.P.K 15:15:15 fertilizer application. This inorganic fertilizer produced equal effects on growth performance of okra treated with 6 ton/ha poultry manure.

CONCLUSIONS AND RECOMMENDATION

In conclusion, from the result obtained from the evaluation of growth of okra under different rates of poultry manure and NPK 15:5:15 fertilizer application, it was discovered that plants treated with 150kg/ha NPK 15:15:15 and 6 tons/ha poultry manure produced highest response in all the growth parameters considered in this experiment. However, the use of 6 tons/ha poultry manure is hereby recommended to okra farmers in the study area because of its role in soil nutrient management.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cajanus cajan (Pigeon pea) is a leguminous crop native to India which is widely regards to as an orphan crop and moderately used for subsistence farming in many parts of the world. This paper explores the role of Cajanus cajan in North Central Nigeria as an orphan crop in ensuring food and nutrient security and it economic and climate change impacts. The prevalence of food insecurity in North Central Nigeria is a major concern, further exacerbated by the prevalence of poverty and abject deprivation of access to food security amongst rural farming households. As such, Cajanus cajan has been identified as an orphan crop with the capacity to improve the livelihoods of smallholder farmers, providing both nutrition and economic opportunities. In terms of production, Cajanus cajan has been found to have a high nutritional value but with great sense of neglect in terms of production and research compared to other staple crops. The crop also is highly tolerant of environmental stress and can be grown in harsh climatic conditions. Thus, Cajanus cajan can play a role in mitigating the effects of climate change on North Central Nigeria, as it has been found to be productive even in areas with erratic rainfall and drought. In terms of nutrition, Cajanus cajan is a source of much needed protein for the population, with a protein content of 15-25%. This is especially important in the context of North Central Nigeria, where protein-energy malnutrition is rampant. Further, the crop is a source of other essential nutrients such as vitamins and minerals which play an important role in ensuring food and nutrient security in the region. In conclusion, Cajanus cajan has the potential to play a key role in improving food and nutrient security, as well as economic and climatic resilience, in North Central Nigeria. The crop can provide an important source of income for smallholder farmers, as well as much needed nutrition for the population. It is essential, therefore, that the crop be promoted and incentivised amongst the farmers of the region in order to reap the full potential of its economic and climate change impacts.
Keywords: *Cajanus cajan, Climate change, Economic, Orphan Crop, Nutrition.*

INTRODUCTION
Cajanus cajan, commonly known as pigeon pea, is an important orphan crop that plays a significant role in ensuring food and nutrition security in the North Central Nigeria. Orphan crop, as *Cajanus cajan* refers to traditional crops that have been neglected by modern agricultural practices and research, despite their potential to contribute to food security and resilience to climate change (Fatokimi, and Adeyemi 2021; Tadele, 2019; Pal *et al.*, 2011). To begin with, it is essential to understand the concept of orphan crops and why *Cajanus cajan* is considered as one. Orphan crops are traditional crops that have been cultivated for centuries by local communities but have received limited attention and investment in research and development compared to major crops. Despite their importance in local food systems, orphan crops like *Cajanus cajan* have been overlooked due to various reasons, such as lack of market demand, limited

commercial value, and insufficient knowledge about their potential contributions to food security (Wambrano *et al*., 2022). *Cajanus cajan* plays a crucial role in ensuring food and nutrition security in the North Central Nigeria. Some parts of the region heavily relies on this crop as a staple food, providing essential nutrients and calories to the local population and animals. Additionally, *Cajanus cajan* is known for its ability to fix atmospheric nitrogen, enriching the soil and improving overall agricultural productivity (Kinhoégbè *et al.,* 2020). Its versatility as a food crop, livestock feed, and fodder further enhances its significance in the local food system. However, the production and availability of *Cajanus cajan* are being affected by climate change. Changes in temperature, rainfall patterns, and extreme weather events pose significant challenges to its cultivation. Climate change impacts, such as water scarcity, increased pest and disease pressure, and reduced crop yield, threaten the overall sustainability and resilience of *Cajanus cajan*. (Neik *et al.,* 2023; Abaje and Oladipo 2019; Malhi *et al.,* 2021).

This article focuses on the role of *Cajanus cajan,* also known as pigeon pea, as an orphan crop in ensuring food and nutrition security in the North Central Nigeria, and its impact on climate change. The study highlights the importance of orphan crops like *Cajanus cajan* in providing food and nutrition security for smallholders, who heavily depend on these crops for household consumption. The extensive domestication and indigenization of *Cajanus cajan* through years of cultivation and natural and farmer selection classify it as an orphan crop, contributing to the conservation of agricultural biodiversity and agro-ecosystems. This article also emphasizes the need for investment in research and development efforts to enhance the productivity and resilience of *Cajanus cajan* in the face of climate change. It acknowledges the serious threats that climate change, including drought and unpredictable rainfall patterns, poses to food production and sustainable agriculture. Despite these challenges, the study highlights the resilience and sustainability of *Cajanus cajan* as a crop option for small-scale farmers in marginal lands.

The crop's ability to fix nitrogen, ease of harvest, and higher biomass production compared to other crops make it particularly preferred by smallholders. However, the article also emphasizes the significant implications of climate change on the production and availability of *Cajanus cajan*. Despite these challenges, the cultivation of *Cajanus cajan* the crop diversification can lead to positive livelihood outcomes and enhance food and nutritional security. Overall, this article provides valuable insights into the importance of orphan crops like *Cajanus cajan* in ensuring food security and highlights the need for further research to enhance their productivity and resilience in the face of climate change.

What is an orphan crop and why is *Cajanus cajan* considered as one?

Cajanus cajan, commonly known as pigeon pea, is considered an orphan crop due to its extensive domestication and indigenization through years of cultivation and natural and farmer selection (Fuller, *et al.* 2019). Orphan crops like *Cajanus cajan* play a vital role in food and nutrition security for smallholders, who often rely on these crops for household consumption (Tadele 2019; Mabhaudhi, and Chimonyo 2019). Pigeon pea is particularly preferred by smallholders because of its ability to fix nitrogen, ease of harvest, and higher biomass production compared to other crops (Mabhaudhi, and Chimonyo 2019). Additionally, *Cajanus cajan* is known for its tolerance to pests and diseases as well as its ability to grow in low-quality soils with minimal inputs such as pesticides and fertilizers (Fuller, *et al.* 2019). These traits make it a resilient and sustainable crop option for small-scale farmers in marginal lands. Orphan crops like *Cajanus cajan* are essential for the conservation of agricultural biodiversity and agro-ecosystems, contributing to the long-term sustainability of food and agricultural production (Fuller, *et al.* 2019). Furthermore, the adoption of orphan crops like *Cajanus cajan* can help reduce greenhouse gas emissions and the contribution of environmental contaminants by agriculture (Popoola *et al.,* 2022; Fuller, *et al.* 2019). Despite their importance, orphan crops have not received extensive research attention compared to major crops like rice, maize, and wheat, which provide a majority of the world population's dietary energy else why it is regarded as orphan crop. The unique characteristics of orphan crops, including their ability to grow in poor environments, resilience under stress, and provision of ecosystem services, make them a valuable resource that should be further explored and utilized (Popoola *et al.,* 2022; Fuller, *et al.* 2019). However, the seed systems of orphan crops are often associated with informal systems, with variable seed quality and minimal monitoring or control by government policies and regulations. Local technical knowledge, social structures, and norms play a significant role in driving the seed systems of orphan crops, highlighting the importance of community involvement and support for the cultivation and preservation of these crops (Mabhaudhi, and Chimonyo 2019; Fuller, *et al.* 2019).

Economic impacts of *Cajanus cajan* in North Central Nigeria?

Cajanus cajan, plays a significant role in ensuring food security in the North Central Central Nigeria. This legume crop serves as a crucial source of income for smallholder farmers in the region, particularly those facing economic challenges (Abebe 2022). Pigeon pea is ranked sixth globally among legume crops and contributes to both food and income security for farming households in Nigeria (Fatokimi and Adeyemi 2021). One of the key advantages of *Cajanus cajan* is its versatility as a multipurpose food legume, providing sustenance for resource-poor farmers in tropical regions (Kinhoégbè *et al.,* 2020). Additionally, pigeon pea by-products, when combined with grains, offer a well-balanced human diet and serve as a potential source of protein (Karri 2017). By cultivating and utilizing *Cajanus cajan,* farmers in the North Central Nigeria are able to enhance food security and improve their livelihoods.

What are the traditional uses of *Cajanus cajan* in the region?

Cajanus cajan, has a rich history of traditional uses in various regions. The roots of *Cajanus cajan* are known to possess medicinal properties and are often used as a remedy for fevers and as an anthelminthic, helping to expel parasitic worms from the body (Ayenan *et al.*, 2017; Abebe 2022).The leaves of *Cajanus cajan* have also been widely utilized in traditional medicine. They are used in the treatment of various diseases such as diabetes, fever, dysentery, hepatitis, and measles (Abebe 2022). Not only the leaves, but the seeds and roots of *Cajanus cajan* are also used for therapeutic purposes, demonstrating its versatility in traditional medicine across different nations (Ayenan *et al.*, 2017). Moreover, *Cajanus cajan* is known to be effective in addressing lung and chest disorders, further highlighting its medicinal value (Abebe, 2022). Different parts of the plant serve different purposes. For instance, the immature seeds of *Cajanus cajan* are recommended for kidney problems, while fresh seeds are used to address male urinary system problems (Ayenan *et al.*, 2017). Additionally, *Cajanus cajan* is employed in wound healing by stopping bleeding and promoting the recovery of wounds and sores (Abebe 2022).Furthermore, it is important to note that pigeon pea, the primary variety of *Cajanus cajan*,is primarily grown for human consumption in Benin and Kogi, reflecting its nutritional significance in the region (Ayenan *et al.*, 2017). Additionally, pigeon pea is integrated into cropping systems, particularly alley cropping, to restore soil fertility and manage pests (Ayenan *et al.*, 2017). Overall, these traditional uses of *Cajanus cajan* highlight its diverse range of therapeutic applications and its cultural significance in different regions.

Factors contributing to postharvest losses and storage issues in *Cajanus cajan*

Post-harvest losses and storage issues are significant challenges faced in the agricultural sector, particularly when it comes to crops like *Cajanus cajan*. However, despite its importance, post-harvest losses and storage problems continue to plague the production and utilization of *Cajanus cajan*. One of the main causes of post-harvest losses in *Cajanus cajan* is poor handling and storage practices. Farmers often lack access to proper storage facilities and knowledge on effective storage techniques, leading to spoilage and deterioration of the crop. Additionally, environmental factors such as temperature, humidity, and pest infestation can significantly impact the storage of *Cajanus cajan*, further contributing to post-harvest losses. Maintaining the quality of *Cajanus cajan* during storage poses another set of challenges. The crop is susceptible to insect pests, fungal and bacterial infections, and moisture-related issues, all of which can compromise its nutritional value and marketability. Ensuring the proper handling, processing, and storage conditions are crucial in preserving the quality of *Cajanus cajan* and minimizing post-harvest losses (Kumar and Kalita 2017).

What are the main causes of post-harvest losses in *Cajanus cajan*?

The main causes of post-harvest losses in *Cajanus cajan*, are insect pests (FRI 2021). These pests can damage the harvested crops and reduce their quality, leading to significant losses for farmers. However, it is important to note that insects are not the only culprits responsible for post-harvest losses in *Cajanus cajan*. Rodents and birds also contribute to these losses by feeding on the stored grains and causing physical damage to the harvested crops (FRI 2021). Therefore, effective pest management strategies need to be implemented to mitigate the impact of both insect pests and other potential causes of post-harvest losses in *Cajanus cajan*.

How do environmental factors affect the storage of *Cajanus cajan*?

Environmental factors play a crucial role in the storage of *Cajanus cajan*, also known as pigeon peas. One significant factor is temperature, as the temperature inside the storage bags follows the trend of the ambient temperature (Kumar and Kalita 2017). To address the issue of insect pests and improve storage conditions, various hermetic storage options have been developed, including Metallic silos, Purdue Improved Cowpea Storage (PICS) bags, and Super grain bags (Kumar and Kalita 2017). Grain temperature is another important factor that affects the respiration rate of *Cajanus cajan* during storage (Kumar and Kalita 2017). It has been found that for every 10-degree increase in temperature, the CO2 concentration in the bags increases by about 1.5% (Kumar and Kalita 2017). Environmental factors such as temperature, humidity, exposure to oxygen, CO2, and ethylene can significantly impact *Cajanus cajan* storage (Surbhit 2020). These factors can lead to major biological losses in *Cajanus cajan* during storage, resulting in lower income for farmers (Surbhit 2020). One of the significant losses is due to moisture loss, which decreases the weight of the product over time (Surbhit 2020). Therefore, it is crucial to consider and control these environmental factors to ensure proper storage of *Cajanus cajan* and minimize post-harvest losses. The use of hermetic storage bags has gained popularity in several countries as a practical and cost-effective technology for storing *Cajanus cajan*, as they not only provide protection against pests but also help maintain optimum storage conditions (Kumar and Kalita 2017).

What are the challenges in maintaining the quality of *Cajanus cajan* during storage?

Maintaining the quality of *Cajanus cajan* during storage poses several challenges that need to be addressed. One essential requirement for preserving the quality of pigeon pea is to ensure that the storage space is properly disinfected and free from any contaminants (FRI 2021). Adequate preservation techniques are crucial in maintaining the desirable characteristics of pigeon pea during storage (FRI 2021). The storage space should be covered, dry, and properly ventilated to prevent moisture buildup and the growth of mold or fungi, which can lead to spoilage (FRI 2021).

However, one of the major challenges in maintaining the quality of *Cajanus cajan* is the lack of appropriate technologies, such as integrated pest management practices, which can effectively control pests and insects that cause damage during storage (FRI 2021). Farmers use various storage containers, including calabash gourds, cans, and sacks, to store *Cajanus cajan* grains (FRI 2021). However, inadequate drying and storage facilities also contribute to post-harvest challenges, which can result in crop losses before and after harvesting (FRI 2021). In different regions, various traditional storage structures made from locally available materials are used for storing grains like *Cajanus cajan*. For example, in East and Southern Africa, cow dung ash in small bags, wood cribs, pits, iron drums enclosed with mud, and metal bins are commonly used for storing grains (Kumar and Kalita 2017). Similarly, in developing countries, simple granaries made from locally available materials are often used for grain storage (Kumar and Kalita 2017). The construction of many of these storage structures is not scientifically designed and relies on traditional knowledge and practices (Kumar and Kalita 2017). Different types of storage structures are used for short and long duration storage of *Cajanus cajan*, such as gunny bags, plastic/polythene bags, drums, and plastic containers (Kumar and Kalita 2017). In summary, ensuring proper disinfection, implementing effective pest management practices, and utilizing appropriate storage structures are vital in maintaining the quality of *Cajanus cajan* during storage.

How does *Cajanus cajan* contribute to food and nutrition security in the North Central Nigeria?

Cajanus cajan, plays a significant role in addressing food and nutrition security in the North Central Nigeria. The United Nations Sustainable Development Goals emphasize the importance of achieving food security, improving nutrition, and promoting sustainable agriculture, all of which *Cajanus cajan* contributes to. As an orphan crop, *Cajanus cajan* is recognized for its potential to contribute to sustainable food systems and enhance global food and nutrition security (Neik *et al.,* 2023). While no analytical data are currently available regarding the basic nutritional composition of *Cajanus cajan*, it is known that the protein content in both the leaves and seeds is approximately 20% (Yang *et al.,* 2020). The seeds, in particular, are highlighted as an excellent source of protein among legumes, containing the highest total amino acid content, total essential amino acid content, and branched-chain amino acid (BCAA) content (Sachanarula *et al.,* 2022; Yang *et al.,* 2020). BCAAs are essential for proper body functioning and cannot be produced by the body, necessitating dietary intake (Yang *et al.,* 2020). Additionally, *Cajanus cajan* seeds have higher nutritional properties compared to the leaves and roots, including protein, ash, and minerals such as calcium, magnesium, and iron (Sachanarula *et al.,* 2022). Furthermore, the roots exhibit better antioxidant activity compared to the seeds and leaves (Yang *et al.,* 2020). The key nutrient components in *Cajanus cajan* contribute to its antioxidant, hypoglycemic, and antibacterial effects, with the roots showing superior performance in these aspects compared to the seeds and leaves (Neik *et al.,* 2023; Yang *et al.,* 2020). Overall, *Cajanus cajan* is a grain legume crop that offers a rich source of proteins, minerals, unsaturated fatty acids in its seeds, and flavonoids, stilbenes, saponin, tannin, reducing sugars, resins, and terpenoids in its leaves (Pal *et al.,* 2011; Yang *et al.,* 2020). Further research is needed to explore unexplored areas related to the nutrient components of *Cajanus cajan* and their potential medicinal uses (Pal *et al.,* 2011).

How do these nutrient components contribute to human health?

The nutrient components found in *Cajanus cajan*, or pigeon pea (PP), have significant contributions to human health. PP seeds, in particular, are rich in carbohydrates, proteins, fats, and minerals, making them a valuable source of essential nutrients for the human body (Abebe 2022). With a protein level ranging from 18 to 25%, PP seeds serve as a valuable protein source for human nutrition (Gerrano, *et al*., 2022). While they may be deficient in sulfur-containing amino acids, PP seeds are significant sources of lysine, an essential amino acid important for human health (Abebe 2022). Additionally, PP seeds contain fiber, minerals, and vitamins such as Vitamin C and E, thiamine, riboflavin, and niacin in appropriate amounts, further contributing to overall human health (Gerrano, *et al*., 2022; Abebe 2022). The high digestibility of protein and carbohydrates in PP seeds makes them a crucial dietary component for individuals in underdeveloped nations to meet their nutritional needs (Abebe 2022). Furthermore, PP seeds have been found to improve the nutritional value of wheat-based diets by increasing the content of essential amino acids like lysine, threonine, leucine, and isoleucine. The presence of vitamin B and carotenes in PP seeds, which are often low in cereal crops, also makes them a beneficial supplement to standard cereal-based diets (Gerrano, *et al*., 2022). Overall, the abundant presence of carbohydrates, proteins, minerals, vital amino acids, and vitamins in PP seeds contributes to essential nutrients for human health (Gerrano, *et al*., 2022; Abebe 2022).

What are the specific health benefits associated with the consumption of *Cajanus cajan*?

In addition to its nutritional value, the crop has been associated with several specific health benefits. One notable benefit is its potential to lower cholesterol levels (Iweala *et al.,* 2019; Pal *et al.,* 2011). Research has shown that consumption of *Cajanus cajan* extract may have a hypocholesterolemic effect, which can be beneficial for individuals with high cholesterol levels (Chang *et al.,* 2019). Furthermore, *Cajanus cajan* has been found to have hepatoprotective activity, particularly in preventing alcohol-induced liver damage (Iweala *et al.,* 2019). Studies have shown that the methanol-aqueous fraction of the leaf extract of *Cajanus cajan* can decrease the activities of liver marker enzymes and increase antioxidant enzyme activities, indicating its therapeutic potential for alcohol-induced liver dysfunction

(Iweala *et al.,* 2019). Additionally, consumption of *Cajanus cajan* has been found to lower serum levels of liver marker enzymes such as ALT, SGPT, AST, and SGOT, further supporting its hepatoprotective properties (Chang *et al.,* 2019). Moreover, *Cajanus cajan* extract may promote bile acid synthesis and enhance the expression levels of hepatic Low Density Lipoprotein-receptor and cholesterol-7-alpha-hydroxylase, suggesting its potential role in regulating cholesterol metabolism (Chang *et al.,* 2019; Pal *et al.,* 2011). The extract-fraction from *Cajanus cajan* has also been found to reduce the atherogenic properties of dietary cholesterol in mice, highlighting its potential in preventing cardiovascular diseases related to high cholesterol levels (Chang *et al.,* 2019; Pal *et al.,* 2011). Overall, the consumption of *Cajanus cajan* shows promise in improving cholesterol levels and protecting against liver damage caused by alcohol consumption.

How does climate change affect the growth and development of *Cajanus cajan*?

Climate change poses significant challenges to the growth and development of *Cajanus cajan*, commonly known as pigeon pea. This crop, which plays a crucial role in ensuring food security, particularly in regions experiencing early impacts of global climate change, is susceptible to various stressors induced by climate change (Andrew and Martin, 2023; Musokwa and Mafongoya 2020). Changes in climatic patterns, such as increased temperatures, erratic precipitation, and flooding, can directly impact the growth of *Cajanus cajan* by causing heat stress, water stress, and waterlogging (Andrew and Martin 2023). Additionally, fluctuations in the incidence of pests and diseases, which are influenced by climate conditions, pose a significant constraint to pigeon pea production (Kinhoégbè *et al.,* 2020). However, *Cajanus cajan* has shown some resilience to these stressors, as it has been reported to be drought-tolerant and adaptable to varying nutritive profiles (Andrew and Martin 2023). Furthermore, intercropping systems involving pigeon pea, such as pigeon pea and maize intercropping, have been found to outperform sole cropping systems in terms of water use efficiency and grain yield, making them a potential adaptation strategy for smallholder farmers facing the risks and uncertainties of climate change (Musokwa and Mafongoya 2020). Despite these adaptive traits, the long vegetative cycle of *Cajanus cajan* can be a major constraint in its production, particularly in zones affected by climate change, where the lengthening of this cycle may further exacerbate the challenges faced by farmers (Kinhoégbè *et al.,* 2020). Therefore, it is crucial to develop and implement strategies that enhance the resilience of *Cajanus cajan* to climate change, such as breeding for improved tolerance to heat and drought stress, and promoting sustainable farming practices that integrate intercropping systems and pest management strategies (Musokwa and Mafongoya 2020).

What are the specific changes in temperature, rainfall patterns, and extreme weather events in North Central Nigeria?

The North Central region of Nigeria has experienced specific changes in temperature, rainfall patterns, and extreme weather events. Flooding has become more frequent in many parts of Nigeria, including the North Central region, leading to detrimental effects on infrastructure and agriculture. Rainfall patterns in Nigeria have become more variable, with increased durations and intensities, causing unpredictability in rainfall and drought patterns in the North Central region (Benson *et al.,* 2017). Rising temperatures have also been observed in Nigeria, including in the North Central region, which will lead to an increase in energy demand for air conditioning, refrigeration, and other household uses. Additionally, extreme weather events have increased in Nigeria, including in the North Central region, contributing to the current conflict and high level of insecurity in the region. These changes in temperature, rainfall patterns, and extreme weather events have significant impacts on various aspects of life in North Central Nigeria. For instance, the decrease in water levels in the Kainji Dam and other reservoirs negatively impacts the generation of hydroelectric power, affecting power distribution and industrial activities that rely on a constant power supply (Abaje and Oladipo 2019). Moreover, the region's reliance on underground water sources is likely to increase due to the expected increased variability in rainfall. The decreasing precipitation in the savannah north and increasing aridity in the northeast of North Central Nigeria have reduced opportunities for sustainable agriculture and could result in increased drought frequency and reduced surface water resources. Overall, these specific changes highlight the urgent need for adaptation measures and sustainable practices to mitigate the adverse effects of climate change in the North Central region of Nigeria (Ibebuchi and Abu 2023).

How do these changes in climate conditions impact the yield, quality, and overall production of *Cajanus cajan*?

The changes in climate conditions, including increased flooding, variable rainfall patterns, and rising temperatures, have significant implications for the yield, quality, and overall production of *Cajanus cajan,* also known as pigeon pea. Studies have shown that climate change and weather variability already affect farming conditions across sub-Saharan Africa, including Nigeria, where pigeon pea is cultivated (Renwick Leah *et al.,* 2020; Fadina and Barjolle 2018). Flooding, which has become more frequent in many parts of Nigeria, including the North Central region, can have detrimental effects on the growth and development of pigeon pea plants. Excessive water can lead to waterlogging of the soil, which negatively impacts root health and nutrient uptake, ultimately reducing the yield and quality of the crop. Additionally, variable rainfall patterns, characterized by increased durations and intensities, can also impact pigeon pea production. Low rainfall levels can result in moisture stress, leading to reduced corm growth, lower yields, and poorer quality of the harvested crop (Chemura *et al.*, 2022). Moreover, rising temperatures in Nigeria contribute to the overall impact of climate change on agriculture. Higher temperatures can accelerate evaporation rates, leading to increased water stress on pigeon pea plants. This can further exacerbate the negative effects of limited rainfall and result in reduced yields. Furthermore, elevated temperatures can also affect the flowering and pod formation processes of pigeon pea plants, potentially reducing the overall production of the crop. Overall, the changes in climate conditions pose significant challenges for *Cajanus cajan* production, and further research and adaptation strategies are needed to mitigate these impacts and ensure sustainable cultivation of this important crop in Nigeria and other affected regions (Chemura *et al.*, 2022; Fadina and Barjolle 2018; Emefiene, *et al.*, 2013).

What are the climate change impacts on *Cajanus cajan* production and availability?

Climate change has significant implications for the production and availability of *Cajanus cajan,*also known as pigeon pea. This crop, which is a vital source of dietary protein in the sub-Sahara Africa and Indian diet, plays a crucial role in global food and nutrition security (Mekonnen *et al.*, 2022; Babarinde *et al* 2020). However, the effects of climate change, including drought and unpredictable rainfall patterns, pose serious threats to food production and sustainable agriculture (Kumar *et al.*, 2022). As the impact of climate change on crop systems intensifies, there is an urgent need to develop stress-resilient crops to combat food insecurity (Malhi *et al.*, 2021). *Cajanus cajan,*as an orphan crop, has the potential to contribute to building resilience in marginal cropping systems as a climate change adaptation strategy (Mabhaudhi *et al.*, 2019). However, there are challenges associated with the underutilization of orphan legumes, including low productivity, insufficient genomic resources, hardiness, low germination, and anti-nutritional factors (Sagar *et al.*, 2022). Despite these challenges, crop diversification, including the cultivation of *Cajanus cajan,* can lead to positive livelihood outcomes and enhance food and nutritional security (Ayilara *et al.*, 2022). Therefore, it is crucial to invest in research and development efforts to improve the productivity and resilience of *Cajanus cajan* in the face of climate change.

In the face of climate change and its impact on food production, the promotion of resilient and nutrient-rich crops is essential for ensuring food and nutrition security. One such crop that plays a crucial role in the North Central Nigeria is *Cajanus cajan,*also known as pigeon pea or as an orphan crop (Popoola *et al.*, 2022; Odeny 2017). Incorporating under-exploited leguminous species like *Cajanus cajan* into food systems can contribute to both food and protein security, as these crops possess the ability to withstand adverse climatic conditions and provide essential nutrients (Sagar *et al.*, 2022; Popoola *et al.*, 2022). Consistent cultivation, conservation, and genetic characterization of under-exploited species like *Cajanus cajan* are imperative for ensuring sustainable food production and overcoming dietary deficiencies (Malhi *et al.*, 2021). However, despite their vast genetic resources and economic potential, orphan legumes like *Cajanus cajan* remain under-exploited (Popoola *et al.*, 2022). These climate-smart crops have significant agronomic features that can not only promote sustainable livelihoods but also contribute to achieving the United Nations sustainable development goals of zero hunger, improved nutrition, health, and sustainable agriculture (Odeny 2017). Unfortunately, research efforts on orphan legumes, including *Cajanus cajan,*have not received the same level of attention as commercial crops, leading to their decline in production and utilization (Sagar *et al.*, 2022). This overdependence on a few major staple crops further highlights the need to prioritize resilient and nutrient-rich crops like *Cajanus cajan* to ensure food and nutrition security in the face of climate change and unpredictable weather patterns in sub-Saharan Africa (Popoola *et al.*, 2022).

CONCLUSION

In conclusion, *Cajanus cajan,* as an orphan crop, plays a vital role in ensuring economic, food and nutrition security in the North Central Nigeria. However, its potential contributions to food security and resilience are hindered by limited research and the increasing challenges posed by climate change. This article has open and thrown more light on the importance of *Cajanus cajan* in the local food system, highlight the climate change impacts it faces and its contribution in mitigating climate change impact, and provide insights for promoting its sustainable cultivation and availability in the face of a changing climate. By addressing these issues, we can enhance food security and promote the resilience of the North Central Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A field experiment was carried out at the Teaching and Research Farm of Federal College of Agriculture, Ishiagu-Ebonyi state during the 2014 and 2015 planting seasons. Ishiagu is a tropical environment with an annual rainfall of 1350 mm, it has an average humidity of 88% and a mean annual temperature of 29^0 C and is situated on a gentle slope. The land was under grass fallow after five years of cropping.. The objective of the study was to determine effect of seedbed, cover crops species and densities on the control of weeds in yam/cassava/maize intercrop. The experimental design was a Randomized Complete Block Designin a split -split plot arrangement and replicated three times. The main plot was seedbed consisting of ridges and flats, while the sub plots were cover crop species of egusi melon, pumpkin and sweet potato. The sub-sub plots were cover crops densities of 10,000, 20,000, 30,000 plants/ha and 0 (control) plots. Data were collected on the following parameters: weed population, weed frequency and weed dry matter. Data were subjected to analysis of variance. (ANOVA) using Genstat® version 3.0 (2003) software package. Significant means were separated using Fisher's Least Significant Difference (F-LSD) at 5 % probability level. Weed population was not significantly ($p \leq 0.05$) affected by seedbed type or cover crop species. However, the density of the cover crops significantly ($p \leq 0.05$) reduced the population of weeds at 30,000 planting/ha density of cover crops, similar to the control. Also, weed dry matter was not significantly ($p \leq 0.05$) affected by the seedbeds. Similarly, cover crops species significantly ($p \leq 0.05$) reduced weed dry matter on sweet potato which maintained the least ($p \leq 0.05$) weed dry matter accumulation. Density significantly ($p \leq 0.05$) reduced weed dry matter at t 30,000 stands/ha.

Keywords: *Seedbed, Cover crop, Density, Intercrop, Weeds*

INTRODUCTION

Intercropping is the practice of growing two or more crops simultaneously in close proximity in a definite pattern, alternate rows or set of rows within the same plot (Reddy, 2012). Intercropping encourages intensification of crop production in both time and space. The most common goal of intercropping is to produce a greater yield on a given piece of land by making use of resources or ecological processes that would otherwise not be utilized by a single crop (Ouma and Jeruto, 2010). Yield advantage in intercropping occurs due to the component crops differences in the use of growth resources. When they are grown in combination, they are able to complement each other and to make better use of overall resources than when they are grown separately (Reddy, 2012). In dry land agriculture, intercropping is practiced mainly to minimize the risk of total crop failure due to the vagaries or uncertainty of rainfall rather than yield and economic advantage over sole cropping (Bello *et al*, 2013). When/where rainfall is heavy and soil depletion and leaching are eminent, intercropping acts as an insurance against failure of crops (Agris info.in, 2005). The advantages of intercropping include greater system resilience by the interplay of different crops, greater crop production (Ghaffarzadeh *et al*, 1997), reduced disease transfer and environmental benefits such as greater soil and water conservation (Gilley *et al*, 2002). These advantages occur because the component crops differ in their use of growth resources (Reddy, 2012). Also, intercropping of compatible plants encourages biodiversity, by providing a habitat for different insects and soil organisms that would not be present in a single crop environment (Altieri and Nicholls, 2004). Intercropping gives higher income per unit area than sole cropping. It acts as an insurance against monocrop failure in

abnormal year. Intercropping maintains soil fertility as nutrient uptake is made from both upper and lower layers (Reddy, 2012). There is also a reduction in soil runoff due to erosion. Several factors influence the adoption of intercropping of crops such as the region, maturity of crops, planting density, time of planting as well as socio-economic status of the farmer (Reddy, 2012). Smallholder farmers routinely intercrop cereal staple crops (maize, sorghum, millet etc.) with vegetables (pumpkin, squash, gourd, cucumber and water melon) and legumes (beans, cowpea and groundnuts), (Beatrice, 2014; Reddy, 2012).
The pulverization of the soil is aimed at obtaining good seedbed tilt, addition of humus and manure to increase soil fertility and also destruction of weeds and prevention of weed growth (Reddy, 2012). The recent increase in fuel prices has added to the cost of soil seedbed preparation thus resulting to more than 25 % of agricultural production (Reddy, 2012). Such concern has necessitated interest in finding systems that minimize negative impact on the soil, while maintaining sustainable crop production. Limited availability of additional land for crop production, with decline in yield of major food crops has heightened fear about agriculture's ability to feed a world population (FAO, 2009). This often means that newly planted lands is either located on fairly steep hillside or on relatively poor soil. In many developing countries, inequitable land distribution and land tenure and poverty had forced many families to farm on steeps and easily-eroded hillsides (Gashaw *et al*, 2017). Farmers are therefore confronted with intensification of land use with reduced fallow period because of increasing population and to maximize the acquired land (Reddy, 2012). This has led to low output with resultant low price income, reduced fallow periods with increased weed spread. Tropical farmers carry out weeding manually by hoeing and slashing. Manual hoe weeding is the most commonly employed method of weed control by the farmers. Frequent hoe weeding disturbs soil surfaces, stimulates weed germination, and weed persistence in many ways (Akobundu, 1987). Effective weeding using hired or family labour during peak periods of farm operation in certain areas of the country is not always feasible. This is because labour is scarce and the available one is being demanded by other economic sectors, thereby making wage payment to be high depending on location (Akobundu, 1987). The introduction of a smother crop like *Citrullus vulgaris* in an intercrop of Cassava/Maize/Melon is a measure against crop failure and it eliminates one or more numbers of hands weeding. Cowpea and 'egusi melon' are the most common herbaceous species intercropped with maize by traditional farmers in Nigeria (Wahua, 1984). Cowpea nodulates, fix nitrogen naturally in most tropical soils while melon protects soil from higher solar radiation and destructive impact of torrential rains thereby moderating soil temperature and reducing erosion (Wahua, 1984). In addition melon is being increasingly recommended for biological weeds control in crop mixtures as it does not reduced the yield of other inter crops (Akobundu, 1981). Cover cropping is adopted by farmers to ensure control of weeds in the farms and reduction in number of weeding. Research and experience from around the world have shown that intercropping and cover cropping system tend to suppress weeds better than sole cropping system. This is true especially with cover crops or smother crops such as forage legumes inter seeded with a main crop such as cereals. This experiment therefore was designed to determine the effects of seedbed practices, cover crops and density on the control of weeds in a yam/cassava/maize intercrop**.**

MATERIALS AND METHODS

This experiment was conducted at the Teaching and Research Farm of the Federal College of Agriculture, Ishiagu, Ebonyi State, Nigeria during the 2014/ 2015 planting seasons**.** The experimental design was a Randomized Complete Block Design (RCBD) and replicated three times and laid out as a split- split plot. The treatments were seedbed practice (factor a), cover crop species (factor b) and density (factor c). The total land area was 1825 m^2 (73 m x 25 m). The main plot size was 25 m x 13 m, the sub plot size was 25 m x 3 m and the sub-sub plot size was 5 m x 3 m with 1 m alley ways between plots and blocks. Two seedbed practices were adopted: (conventional seedbed ridges and harrowed seedbed flats). In conventional seedbed, the land was cleared by slashing weeds and ploughing. After two weeks the land was harrowed and ridged. On harrowed seedbed the plot was cleared by first slashing weeds, and ploughing after two weeks, followed by harrowing and marking out. Three cover crop species were used to control weeds, these iwere: *Citrullus vulgaris*, *Cucurbita moschata* and *Ipomea batatas*. The cover crops were planted at different densities, 10,000, 20,000 and 30,000 stands per hectare, while non was planted in the control (0 stands/ha)

Planting of Test Crops (Yam). Sets of 100 g of yam (*Dioscorea rotundata* L) cultivar '*agboghohu*' were measured out using Ohaus sensitive scale. The yam setts were planted on the crest of the ridges and on the flats, at a distance of 1 m x 1 m within rows and 1 m between rows (population density of 10,000 plants /ha).

Cassava. Cassava (*Manihot esculenta*, Crantz.), stem cuttings of 30 cm, variety TMS 0581 were planted mid-way down the ridge on the right side of the yam at a distance of 1 m x 1 m and also, on flat by the right side of yam stands at a density of 10,000 plants /ha.

Maize. The maize (*Zea mays* L) variety '*Oba super11'* seeds were planted. Planting was at the foot of the ridges and flats, opposite the cassava stands, 1 m within and 1 m between rows. Three seeds were planted per hole at a depth of 4 cm and thinned to one stand at two weeks after planting (2 WAP), (10,000 plants / ha).

Cover crops. Melon: *Citrullus vulgaris* (Schrad), (‘egusi’ melon) and Pumpkin**:** *Cucurbita moschata* (L.) ‘*Anyu*’ seeds were planted, 4 seeds per hole and at a depth of 4 cm. The seeds were planted mid-way on the ridges and flats at the same side with maize and in holes opposite the cassava stands at a distance of 1 m x 1 m. The seedlings were thinned to densities of 10,000, 20,000 and 30,000 plants/ha after two weeks of planting (2 WAP), while there was none planted on the control. Sweet potato: *Ipomoea batatas* (L.) Lam. Vines of variety TIS 2498, spreading type obtained from National Root Crops Research Institute Umudike were planted mid-way on ridges and flats. Sweet potato vine cuttings of 25 cm length with four nodes were planted at angle of 45^0 on the same side with maize opposite the cassava stands. This was done at a spacing of 1 m x 1 m for 10,000 plants/ha (15 stands), 0.5 m x1 m for 20,000 plants/ha (30 stands) and 33.3 cm x 1 m for 30,000 plants /ha (45 stands), while none was planted on the control. (0).
Staking. Yam vines were staked using bamboo sticks on which vines were trained after sprouting.
Weeding. Weeding was carried out on the entire plots at two weeks after planting using a small African hand-held hoe. The control plots (without cover crops) were weeded at the 5^{th} week and 9^{th} week after planting (farmers’ practice).
Fertilizer application. A blanket application of NPK (15:15:15) was applied at the rate of 200 kg/ha.
Data collection. Data were collected from the following parameters, weed population, and weed dry matter.
Weed population. The population of weeds per treatment was assessed with the use of a quadrat (Lado *et al.,* 2010). A 30 cm x 30cm (900 cm^2) quadrat was used to assess the population of the weeds. Using the quadrat, three random throws were made within plots. The weeds that were enclosed within the quadrat were counted, identified to species and means taken. Weed identification and naming were done using a Handbook of West African Weeds by Akobundu and Agyakwa, 1998)
Weed dry matter (g). The weed dry matter was determined using the weight of the dried weeds harvested at four weeks after planting 4 WAP, 8 WAP and 12 WAP. In the three throws of 30 cm x 30 cm quadrat into the experimental units, the weeds that were enclosed by the quadrats were harvested after identification and counting. The roots were washed to clean off the soil particles. The weeds were placed inside labeled envelops and dried in an oven at a temperature of 80^0 C for three days. At the end of the three days, when a constant weight was attained, they were removed and weighed using a sensitive measuring balance (Ohaus) and the average weight was taken (g/900 cm^2) (Longanathan, 1984)
Analysis of Data. The data collected were subjected to Analysis of Variance (ANOVA), using Gensat Version 3 statistical software. Significant means were separated using F-LSD at P= 0.05 as described by Wahua, (2010)

RESULTS AND DISCUSSIONS

Weed population.

Seedbeds and cover crop species were observed to have no significant ($p\leq 0.05$) effect on the weed population, however sweet potato maintained the least ($p\leq 0.05$) weed incidence compared to cover crops on both flats and ridges. Sarkar (1992) suggested that increase in the numbers of sweet potato vines per unit area leads to reduced weeds number. Cover crop density decreased the weeds population in both seedbeds. The 30,000 stands of cover crop density reduced the weed population similar to that of control which had few weeds. This report agrees with Holt, (1995) who reported that the manipulation of crop row spacing may reduce light interception by weeds leading to lesser weed incidence

Table 1: Effects of Seedbed, Cover crop and Density on Weed Population (900/cm^2) in 2014/2015 seasons

Seedbed	Cover crop	Density (population/ha)					Cover crop means
		No cover crop	10, 000	20, 000	30, 000	Mean

NS= Not significant. a =Seedbed, b = Cover crop species, c = (Cover crop) density

Weed dry matter.

Seedbed type had no significant ($p \leq 0.05$) effect on the weed dry matter. Weed dry matter was reduced by the cover crop species. Sweet potato plots had least weed dry matter as against other cover crops and this was followed by egusi melon and then pumpkin with least weeds dry matter. This suggests that the sweet potato leaves covered the ground more than the other cover crops. Dadashi *et al.* (2014), reported that due to the leaf geometry soybean reduced weed dry matter more than wheat in a weed and cover crop competition experiment. Shilling *et al.* (1985), also reported that rye cover crop in no-Seedbed system decreased weed biomass. The cover crop density significantly reduced the weed dry matter. Higher cover crop density reduced weed dry matter considerably. The control which had no cover crop but was weeded three times had the least weed dry matter followed by 30,000 stands, 20,00stands and 10,000stands of cover crops per hectare. This is in agreement with Hiroshi *et al.* (2011), who found that weed dry matter production varied greatly with the cover crop species.

CONCLUSION/RECOMMENDATION

Intercropping has a significant advantage over sole cropping. It is therefore, an important farming system that may be adopted by tropical farmers as a mitigating tool for crop failure. Also, it is likely to ensure continuous availability of food for the farmers. The cover crop in intercrops the reduced number of weeding in an intercropping system. The adoption of the intercropping system ensures minimum reduction of weeds in the farm. The cover crops ensured reduced effect of torrential rains on the soil avoiding erosion and runoffs. Higher cover crop density brought about weed reduction in the intercropping system. It is recommended that farmers should intercrop with cover crops to avoid crop failure and ensure reduction in weed dry matter accumulation by planting with population density that will not interfere with the performance of the test crops.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Biofortification of indigenous staple foods is essential in promoting food diversity, nutrients intake and tackling micronutrients deficiency diseases. Combinations of staples have been developed to improve the nutrient contents of indigenous diets. This study investigated the nutrients composition and sensory properties of cake produced from composite flours of wheat and pro-vitamin A cassava. The pro-vitamin A cassava tubers were processed into flour, which was used to substitute 10, 25, 50 and 75% of wheat flour in cakes.. The cakes were compared with 100% wheat flour cake (control) for the nutrients composition and sensory properties. The results showed that addition of pro-vitamin A cassava flour to wheat flour reduced the protein content from 11.92% in the control to 9.33% in the blend containing 75% pro- vitamin A cassava flour, while total ash, carbohydrate and β-carotene contents increased from 0.93 to 1.36%; 75.54 to 78.24% and 211.30 to 495.82μg /100g, respectively. The texture, taste and colour of all the cakes were acceptable to the panelists, with the control having the highest rating in texture (5.33), taste (5.20) and colour (5.13). Cakes with improved nutrients composition and acceptable sensory qualities can be produced from wheat flour and pro-vitamin A cassava flour blends. Thus, the use of composite flour is recommended for use in the production of acceptable cakes of high nutritional quality.

INTRODUCTION

Cakes are convenient food products that are usually sweet and often baked, prepared from flour, sugar, shortening, baking powder, egg, and essence as principal ingredients (Clerk and Herbert 2000; Atef *et al*., 2011). Cakes and other products from wheat flour are too expensive for an average person from a developing country to afford due to the increasing wheat price and importation cost, which has taken a toll on the resources of many nations around the world . Thus, there has been clamor for cheaper alternatives to wheat flour (Onyekuru *et al*., 2019). For this reason, the Food and Agriculture Organization of the United Nations (FAO) established composite flour program in 1964, having the broad objective of using local raw materials in the tropics for baking. Thus, over the years, researches have shown that High Quality Cassava Flour (HQCF) can be a good substitute for wheat (IITA, 2012, Giami*et al*., 2004).In Nigeria, there have been several policies on the use of cassava flour for bread making, but these policies have been continuously changed by successive governments for different reasons, making them ineffective (Onyekuru *et al*., 2019). Different levels of cassava flour can be used to replace wheat or rice, depending on the kind of product to be made. Cassava and wheat flours have similar properties and therefore, can be substituted for each other at different ratios for making different bakery products. The use of cassava flour was first introduced in Nigeria in 2002, via the presidential initiative on cassava, and in 2004, 10% inclusion was made mandatory for baking by the Federal Government of Nigeria (Onyekuru *et al*., 2019). This policy on cassava inclusion stipulated strategies for all categories of bakers to include cassava flour in their products in the country. This was for the reasons of stabilization of price, creation of new market, jobs and most importantly, reduction in expenditure on wheat importation (Gbola, 2012; Layi, 2012).

Cassava (*Manihot esculenta*) is one of the most important tropical root crops in developing countries and its starchy roots are a major source of dietary energy for more than 500 million people (FAO, 2005). It is the highest producer of carbohydrates among staple crops. Cassava tubers generally possess a cream or white flesh colour and do not contain a significant amount of carotenoids (Olatunde *et al*., 2020). However, the advent of yellow root cassava will complement current efforts (such as pill supplementation, food fortification etc.) to address Vitamin A deficiency (VAD) by delivering vitamin A through a staple food. Vitamin A remains a very important component of human nutrition, as it aids in vision, cell differentiation, synthesis of glycoprotein, reproduction and overall growth and development (Njoku *et al.*, 2014).Vitamin A deficiency can cause night blindness and other acute diseases. In many parts of the world, several intervention programmes aimed at reducing the associated menace caused by Vitamin A deficiency and other micronutrients deficiencies have been suggested. One of such interventions is the use of staples and snacks such as biscuits and other pastries as medium to reach the vulnerable groups, which in most cases are the pregnant women and infants. Cassava with improved nutritional value such as pro-vitamin A cassava is currently being used as an aid in reducing the prevalence of dietary Vitamin A deficiency due to its high content of β-carotene (Omodamiro *et al*., 2012). According to Aniedu and Omodamiro (2012), pro-vitamin A cassava has the potential of providing up to 25% of daily vitamin A requirements of children and women. This study therefore, reports on the chemical composition of flours and sensory properties of cakes produced from composite flours of wheat and Pro-vitamin A cassava.

MATERIALS AND METHODS

Materials

Pro-vitamin A cassava was harvested from a local farm in Makurdi, Benue state, Nigeria while whole wheat flour, sugar, margarine, salt, eggs and baking powder were purchased from Lafia modern market, Nasarawa state, Nigeria.

Processing of pro-vitamin A cassava into flour and formulation of composite flour blends

Edible Pro-vitamin A cassava flour was prepared from the raw roots by washing, peeling with knife, and slicing into 0.5cm chips, followed by oven drying (65°C, 8 hours) and milling. The powder was then, sieved with mesh of 75mm to obtain flour. The flour sample was kept in sealed plastics and stored in the refrigerator prior to use. The ratios of wheat flour and pro-vitamin A cassava composite flour blends used were 100:0, 75:25, 50:50, 25:75 and 0:100(cassava : wheat). Other ingredients used in cake production were added.

Production of Cake

Cakes were prepared by mixing 500 g flour, 250g sugar, 250g margarine, 10g baking powder, 4 eggs, water and 5gsalt in a bowl. The mixture was whipped for 30min and the other ingredients were added and thoroughly mixed. The cake batters were cut, shaped, put into greased baking pans, and s were baked at 170°C for 15min. The cakes were packaged in…. and then, stored at ambient temperature before used.

Determination of Chemical Composition of flour

Moisture, fat, ash, crude fiber, and protein contents of the flour blends were determined using the AOAC (2010) methods .Total carbohydrate was calculated by difference while energy was calculated using the Atwater Conversion factors of 4x% protein, 4x % carbohydrate and 9 x % fat) in Kcal.β-carotene content was determined spectrophotometrically as described by AOAC (2010) method.

Sensory Evaluation of cakes

Cakes were allowed to cool on racks for 30 minutes and were then assessed for the sensory attributes. Fifteen trained panelists were selected from staff and students of the Departments of Nutrition and Dietetics, and Home & Rural Economics, College of Agriculture, Sciences and Technology Lafia, Nasarawa state. The cakes were 3-digit coded and presented to the panelists in white plastic plates. Each sample was rated on intensities of sensory attributes of taste, colour, texture and general acceptability) using a 6-point scale with 6 as extremely liked and 1 as extremely disliked. Drinking sachet water was served in glass to the panelists, and they were told to rinse their mouths after tasting each cake sample. Most panelists were between the ages of 18–35 years and were regular consumers of cakes.

Statistical analysis

Experiments were conducted in 3 replicates. The means and standard deviations (SD) of the data were calculated. Statistical analysis was performed using SPSS (Statistical Package for Social Sciences, version 21.0). One-way ANOVA (Analysis of variance at the level of significance $p \leq 0.05$) was performed and means where significantly different were by least significant difference (LSD) test. Significance was accepted at $p<0.05$.

RESULTS AND DISCUSSION

Proximate composition and β-carotene contents of composite flours

Moisture, crude proteins, crude fats and carbohydrates were the major components of wheat-pro-vitamin A cassava composite flour (Table 1). The proximate composition of the composites flours were not significantly different ($p \leq 0.05$). The crude protein content of 100% wheat flour was the highest (11.92%), while that of 100% pro-vitamin A flour was the lowest (3.50%). Carbohydrate content was highest in 100% pro-vitamin A cassava flour while 100% wheat flour had the lowest. Addition of pro-vitamin A cassava flour to wheat flour reduced the protein and fat contents of the flour blends, while ash, carbohydrate and β-carotene contents increased. The proximate composition of the flours was similar to values reported in other studies on baked products produced from composite flours (Olatunde *et al*., 2016; Oyeyinka *et al*., 2014; Hooda and Jood, 2005; Oluwamukomi *et al*., 2011). Decrease in fat and protein contents and increases in carbohydrates, ash and contents of the flour blends could be attributed to the reduction in the amount of wheat flour in the composite flour blends. Wheat flour is a rich source of protein and fat compared to cassava flour, which has the bulk of nutrient as carbohydrate. The β-carotene contents of the composite flour blends s increased with increasing proportion of pro-vitamin A cassava flour in the blends, values ranged from 211.30 to 590.650 µg/100 g (Table 1). These values are also consistent with the results of Olatunde *et al*. (2016) who reported the β-carotene contents of biscuits made from composite flour of wheat and pro-vitamin A cassava to vary from246.80 to 352.40 µg/100 g). Also, the findings agreed with that of Sengev *et al*. (2016) who reported the β-carotene content range of 219-428 µg/100 g for biscuit prepared from sweet potato flour and mango mesocarp flour and bread with added mango mesocarp (Badifu *et al*., 2006). Pro-vitamin A cassava developed through food technology is relatively good source of β-carotene. Vitamin A is a fat-soluble vitamin that is naturally present in many foods as beta -carotene. It is important for normal vision, immune system, and reproduction. Vitamin A also helps the heart, lungs, kidneys, and other organs work properly. Deficiency of this nutrient is one of the major challenges facing developing nations. Vitamin A deficiency can lead to night blindness and other acute diseases.

Sensory properties of cake

The mean sensory scores for cakes from wheat and pro-vitamin A cassava flour blends are presented in Table 2. Sensory attributes (texture, taste, colour and overall acceptance) of the cake were slightly affected by the added pro-vitamin A cassava flour. Texture is characterized by the way the cake is felt in the mouth of the panelists. The brown colour of the cakes resulted from nonenzymatic reaction between sugars and proteins that occurred on heating (Maillard reaction) and also causes browning of some foods such as bread, cake etc. The scores for the sensory attributes indicate preference for cakes made with 100% wheat flour or pro-vitamin A cassava flour and others from composite flours. The texture, taste and colour of all the samples were acceptable to the panelists, with the sample from 100% wheat flour, which served as the control rated the highest in texture, taste and colour (5.33, 5.20 and 5.13, respectively). The scores for the texture and taste of the samples were consistent with the previous reports of Olatunde *et al* (2016) that cake made from wheat flour (100%) had the highest rating for colour, aroma, texture and overall acceptability. The higher rating for the control sample may be due to the fact that the judges are familiar with wheat cake, influenced their rating for the control sample. The added pro-vitamin A cassava flour affected the sensory attributes of the cake as evident in the rating by the panelists. The low ratings for cakes produced from composite flours and 100% Pro-vitamin A cassava may be due to the panelists not being familiar with the cakes. Generally, cakes produced from 100% wheat flour had and the highest ratings while cake from the composite flours and 100% Pro-vitamin A cassava flour had similar ratings for general acceptability. These results showed the possibility of utilizing wheat flour and Pro-vitamin A cassava flour in cake production.

Table 1: Proximate composition and β-carotene Contents of Wheat-Pro-Vitamin A Cassava Composite Flours

Sample	Moisture (%)	Crude Protein (%)	Crude Fat (%)	Total Ash (%)	Crude Fiber (%)	Carbohydrate (%)	Caloric Value (Kcal/100g)	β-carotene (µg /100g)

E	4.67^a	5.00^a	4.80^a	4.67^a

Values within a column with the same superscripts are not significantly>0.05) different. A: Cake produced from 100% Wheat flour, B: Cake produced from 75% Wheat and 25% Pro-Vitamin A cassava flour, C: Cake produced from 50% Wheat and 50% Pro-Vitamin A flour, D: Cake produced from 25% Wheat and 75% Pro-Vitamin A flour, E: Cake produced from 100% Pro-Vitamin A cassava flour.

CONCLUSIONS AND RECOMMENDATION

Cakes with improved nutritional values and acceptable sensory attributes can be produced by substituting wheat flour with pro-vitamin A cassava flour at different ratios. Sensory and nutritional qualities of cake and flour blends was affected by addition of pro-vitamin A cassava flour. Cakes from these composite flour are good sources of proteins, energy and β-carotene, which can be potentially used to address the prevailing acute malnutrition and vitamin A deficiency among vulnerable groups especially in developing countries like Nigeria. The use of composite flour, however, is recommended to produce acceptable cakes of good sensory and nutritional quality.

ACKNOWLEDGEMENT

The authors are gratitude to Mal. Muhammad Nura Yakubu and Fortune Oil Mills Limited, Quality Control Laboratory Kano who carried out the nutritional analysis of the samples. We thank Mr. Ingye Sefa Stephen, a volunteer with APIN Public Health Initiatives, Benue state, who sourced the Pro-vitamin A cassava tubers for the work.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23^{rd} – 27^{th} Oct., 2023

ABSTRACT

This study was carried out to evaluate the effects of different levels of dietary lysine and methionine on growth performance under the following parameters; feed conversion ratio, average daily weight gain and daily feed intake in broilers fed self-formulated ration coded T_1 (Control diet), T_2, and T_3. A total of 65day old Abor-Acre broiler chicks were used in the study. They broilers were housed in a brooder house for four weeks where they received equal treatment, then randomly distributed into three treatments T_1, T_2, and T_3, 20 birds per dietary treatment. Each treatment was further replicated 4 times with 5 broilers in each replicate, in a completely randomized design. Feed and water were provided ad–libitum, the research lasted for 50 days. The proximate composition of experimental ration CP, CF, EE and ME was same 23%, 4.33%, 7.9% and 3150Kcal/Kg, respectively, except lysine and methionine which were 1.465% and 0.38% (T_1) , 1.758 and 0.532% (T_2) and 1.44% and 0.410% (T_3). Average daily weight gain ranged from 33.53 – 39.38g/day in broilers fed T_2 diet, which was significantly ($P<0.05$) higher than broilers in T_3 but similar to T_1. Daily feed intake ranged from 59.50 – 64.00g and there were no significant differences among all the mean treatments. While feed conversion ratio ranged from 1.63 – 1.88, T_2 recorded least mean value of 1.63 which was better in performance when compared to T_3 (1.88). Therefore, use of lysine and methionine in broiler finisher diet, may yield a better result. Thus, broiler farmers may include dietary lysine and methionine up to 1.758% and 0.532%, respectively, when formulating ration for broiler finisher due to the positive effect on growth and development.

INTRODUCTION

Poultry business was first introduced to Nigeria in the late fifties with the importation of selected breeds of exotic birds. Poultry farming is the process of raising domesticated birds such as chickens, ducks, turkeys and geese for human and raw materials for industrial use (Ajala *et al.,* 2021). The country's standing poultry population is at present 180 million , a substantial increase from about 151 million in 2018. (FAO, 2018). Egg and meat production are the two major divisions of poultry production (USDA, 2018). Poultry meat account for about 33% of the world meat consumption and consumer's demand for high quality poultry meat is ever increasing, broilers bred for heavy deposition of muscle within short period of time reach slaughter weight between six and seven weeks of age hence, their performance is a function of genetic traits and environmental factor particularly housing and nutrition (Chen *et al*., 2013). . The component building blocks of proteins are amino acids. Amino acids requirements of broilers have been extensively studied, as well as factors that influence such requirements, such as sex, age, genetic strain, heat stress, dietary energy concentration and its interaction with crude protein level (Esonu, 2006). The wide variation in the composition and digestibility of amino acid present in feedstuffs is of great concern in diet formulation. The importance of feeding the correct amount of balanced dietary protein and amino acid for poultry is a priority for two reasons. First, protein and amino acid are some of the most expensive nutrients in feeds per weight unit (Dozier *et al.,* 2009). Second, there are environmental concerns as to nitrogen excretion in poultry waste. The concentration of protein and amino acid in broiler diets has a large impact on breast meat yield, feed to gain ratio, and number of days required to achieve the appropriate body weight for each type of market (Sterling *et al.,* 2006; Alagawany *et al.,*.2016; Bunchasak, 2009). Methionine is an amino acid of critical importance in commercial poultry diets, because it is typically the first-limiting amino acid and its deficiency may cause reduced growth performance, metabolic disorder and impaired immune system (Kidd *et al.,* 2004; Sterling *et al.,* 2006; Dozier *et al.,* 2006). It has been showed that the need for dietary lysine is greater for breast meat yield than for growth rate. The essential amino acids for the bird include methionine, lysine, tryptophan, threonine, phenylalanine, leucine and isoleucine (Esonu *et al*., 2006). Amino acids are organic compounds that contain amine (NH_2) and carboxyl (COOH) functional groups, along a side chain (R group) specific to each amino acid.

MATERIALS AND METHODS

The research was conducted in the Departmental Poultry Farm of Agricultural Technology Research Farm, Federal Polytechnic Nekede, Owerri, Imo state. The research lasted for 8 weeks but data collection started after 4 weeks of brooding. The feed materials were of same composition but vary in methionine and lysine. The experimental ration consisted of T_1, T_2 and T_3 where T_1 was the control (without lysine and methionine inclusion), T_2 and T_3 vary in methionine and lysine composition with T_2 (0.38 and 1.46%) and T_3 (0.41 and 1.44%) compositions. Table 1 shows the constituent of control T_1 diet and the nutrient composition of T_2 and T_3 with vary levels of methionine and lysine with their calculated proximate compositions. A total number of sixty-five day old broilers Arbor-Acre were used for the research. The birds were procured from a reputable source and before the arrival of the birds, the brooder house was prepared, washed, disinfected and sealed with transparent polythene for illumination, litter material was disinfected spread indoor to dry before it was spread on the floor of the prepared brooder house, and then old newspapers were used as carpet on the litter material. The brooder house was heated for 24 hours before the bird's arrival. The birds were brooded for 4 weeks under a strict observation where they received equal treatment such as feed, water, medication/vaccination, temperature and general management were performed and were fed *ad–libitum* and 3 mortalities were recorded. The birds were randomly distributed after 4 weeks of brooding into three treatments (T_1, T_2 and T_3) then, each treatment was replicated 4 times with 5 broilers in each replicate and weight of individual bird was taken for initial body weight. The treatments were randomly assigned to experimental diets; water and feed were provided *ad-libitum* for four weeks. The data collection was on the following parameters: average daily weight gain, daily feed intake, and feed conversion ratio. Data generated were subjected to analysis of variance and significant differences were established among means by using SPSS statistical software.. Least significant different was used to separate the means; the experimental design was completely randomized design.

Table 1: Feed composition and calculated chemical analysis of the experimental diets

Component amount (kg)	T_1	T_2	T_3
Maize	12	12	12
Soya	5	5	5
GNC	5	5	5
PKC	0.525	0.525	0.525
Rice bran	2	2	2
Fish	0.4	0.4	0.4

Premix	0.0625	0.0625	0.0625
Total	25kg	25kg	25kg
Calculated analysis			
CP (%)	23	23	23
ME (kcal/kg)	3150	3150	3150
CF (%)	4.33	4.33	4.33
EE (%)	7.9	7.9	7.9
LY (%)	1.415	1.758	1.44
METH (%)	0.355	0.532	0.410

RESULTS AND DISCUSSION

The overall performance of broiler birds fed the experimental diets, are shown in table 2), the average daily weight gain (ADG) ranged from 33.53 – 39.38g/d with T_2 recording the highest mean value which was a reflection of daily feed intake. (DFI). This may be attributed to breast muscle development due to level of lysine in T_2 compared to T_3 (Kidd *et al.,* 2004 and Kerr *et al*., 1999) recorded low level of lysine % against this current report which was higher (1.465%), followed by T_1 and T_3 that recorded the least value (33.53g/d) of ADG. There were significant differences ($p< 0.05$) among T_2 and T_3 but, T_1 was similar to T_2 and T_3 in ADG . The DFI range from 59.50 - 64.00g with T_2 recording the highest mean value, followed by T_3 and T_1 (control) recorded the least mean value on daily feed intake, no significant effect of trial diets was observed in term of DFI while FCR was significantly different among T_2 and T_3 conforming to earlier report (Mehrdad, 2013) who recorded significant different on feed conversion ratio but T_1 was similar to T_2 but significantly different from T_3..

Table 2: Performance of broiler finishers fed varied levels of lysine and methionine

Legend:

SUMMARY

Results from this study showed that birds fed treatments T_1 (control) and T_2 diets were significantly similar ($P < 0.05$) but higher than the birds fed T_3 in average daily weight gain. However, T_1 and T_3 were similar but there was significant different ($P < 0.05$) in mean values of T_2 and T_3. The daily feed intake showed that there was no significant differences among broiler finishers fed T_1, T_2 and T_3 diets whereas, feed conversion ratio was significantly different ($P < 0.05$) in T_2 and T_3 but T_1 and T_2 shows no significant different.

CONCLUSION

Therefore, use of lysine and methionine in broiler finisher diet, may yield a better result. Thus, broiler farmers may include dietary lysine and methionine up to 1.758% and 0.532%, respectively, when formulating ration for broiler finishers, due to the positive effect on growth and development.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Local indigenous cereals, legumes and dairy foods are good sources of cheap high-quality macro nutrients and micro nutrients. This study aimed at producing and evaluating the qualities of complementary foods formulated from locally available food materials. Five foods were formulated from blends of millet flour, soybean flour, and egg powder in ratio (100:0:0; 90:5:5; 80:15:5; 70:20:10; 60:25:15, millet: soybean: egg). The mineral composition antinutrients SCREENING and sensory properties of the formulated samples were determined using standard methods. The formulated was rich in iron (2.00-2.80mg/Kg), zinc (1.80 -2.30 mg/Kg), sodium (240.33-247.33 mg/Kg) and calcium (27.00-30.33 mg/Kg). F tannin was found t in all food samples, saponin was present in samples D and E while flavonoid was present in sample C. Oxalate was absent in all the food sample. The sensory evaluation results showed no significant difference (p<0.05) in all samples although sample D with 70% millet flour, 20% soybean flour and 10% egg flour ranked best in terms of color, aroma, mouth feel taste and general acceptability. This study has demonstrated that the use of millet-soybean-egg composite flour in the production of weaning food would help to improve the food.

Keywords: *Millet, Soybean, Egg, Minerals, Antinutrients*

INTRODUCTION

Complementary foods are foods given to infants in addition to breast milk when breast milk nutrients become insufficient to provide their nutritional needs(Onyekwere, 2007).Nutritious complementary foods, also known as weaning foods, are introduced and cover the period from the age of six to twenty- three months in developing countries (UNICEF, 2021). In Nigeria, as in most African countries, the introduction of complementary foods usually begins between the fourth and the sixth month of child's life and it involves the use of a semi-liquid porridge prepared from local staple cereals or tubers. During this period, infants are fed with complementary foods two to three times a day for children age between six to eight months and two to four times daily for children between nine and eleven months of age (WHO, 2023).

The lifelong impact of improper and inadequate feeding may include low school performance, reduced productiveness, low intelligent quotient and social development or chronic diseases (Nestel *et al.*, 2003). Hence, improved and adequate complementary foods at this period of life are needed for the child's normal growth and cognitive development.

Protein/energy malnutrition is mainly due to the unavailability of low-cost, high-quality food for the low-income family. However, local indigenous cereals , legumes and dairy foods are good source of cheap high-quality macro nutrients and micro nutrient (Muhimbula *et al.*, 2011). Thus, the present study aimed at producing and evaluating the nutritional qualities of complementary diets formulated from locally available food materials such as millet, soybeans, and egg

MATERIALS AND METHODS

Millet, soya beans and egg.s used in this study were purchased from a community market n Lafia Metropolis. The millet and soya bean were identified at the Department of Agronomy, Faculty of Agriculture, Nasarawa State University Keffi as *Pennisetum glacum* and *Gycine max*, respectively.

The millet grains were cleansed, washed, soaked to ferment for 24h, drained in a basket, cover ed with cotton material and put in a dark place, germinated for 72h, washed and sun dried for 72h, dry milled with attrition mill and sieved through a wire,mesh to produce millet flour.

Soybeans were sorted, cleansed, washed, soaked for 12hr to fermentation, drained , covered with a cotton material and kept at room temperature, germinated for 48hr, washed and removed seed coat, sun dried, dry milled with attrition mill and sieved through a wire mesh to produce soybean flour..

The eggs (whole) were carefully broken, whisked, oven dry (60^o C for 48h) and milled with attrition mill to produce egg powder.

he flour blends were formulated as shown in Table 1 to produce the complementary foods and were then stored in airtight containers at ambient temperature (25 - 30oC) until used.

Table 1: Blend ratios of the ingredients

SAMPLE	MILLET(%)	SOYBEAN(%)	EGG(%)
A	100	—	—
B	90	5	5
C	80	15	5
D	70	20	10
E	60	25	15

Mineral Determination

Mineral element (P, Mg, , K, Na Ca, Mn, Cu and Fe)concentrations were determined using Atomic Absorption Spectrophotometer (Hitachi,model 180-80). Phosphorus was determined Spectrophotometrically by the vanadomolybdate method (AOAC, 2012).

Antiinutrients screening

Oxalate in the flour samples was screening using the method of Peters *et al.*,(2016). Phytate, saponin and tannins in the flour samples were screened described by Awogbenja *et al.*, (2018] while those of the saponin and tannins were done using AOAC (2012) methods.

Evaluation of Sensory Properties

The sensory properties of the were evaluated on a 9-point Hedonic scale, where 9 represents liked extremely, 1 represents disliked extremely, and 5 neither liked nor disliked. Twenty (20) trained judges comprising of staff of the Department of Nutrition and Dietetics, Faculty of Agriculture, Nasarawa State University, Keffi evaluated the bread attributes crumb texture, crust colour, taste, aroma and overall acceptability. Panelists were provided with coded samples and warn water for mouth gargling after each session.

Statistical Analysis

All measurements were done in at least in two replicates, and the results were subject to one factor analysis of variance (ANOVA), using software package , SPSS 16.0.The significance of differences was evaluated by Duncan's test, at $P<0.05$. The results are represented as mean values ± standard deviation (SD). Significance was accepted at $p<0.05$

RESULTS AND DISCUSSION

The mineral composition of the formulated diet is presented in Table 2. The phosphorous concentrations ranged from 269.00mg/kg(sample B) to 285mg/kg (Sample E), Calcium contents ranged between 27.00mg/kg and 30.33mg/kg, increasing with decrease in the amount of millet.The highest concentration of iron was found in sample A, Zinc was highest in sample B (2.30mg/kg). Magnesium was the lowest mineral, being highest in sample A (0.60mg/kg). Mineral with the highest level was phosphorous , followed by sodium, then calcium and then iron. Phosphorus is the second most abundant mineral in the body after calcium. In form of various phosphates, phosphorus performs a wide variety of essential functions including liberation and utilization of energy from food. Ayo *et al*.(2018) reported lesser amount of potassium, calcium, phosphorous and sodium for bread made from a blend of acha and mushroom. The increase in potassium, calcium, phosphorous and sodium in the current study may be attributed to soybean and egg supplements. Calcium intake in diabetics has been shown to be beneficial and likely to reduce osteoporosis in older diabetics (Ayo *et al.,20*18). The increase magnesium level is vital, magnesium plays many crucial roles in the body, such as supporting muscle and nerve function and energy production. Low magnesium levels usually don't cause symptoms. However, chronically low level, can increase the risk of high blood pressure, heart disease, type 2 diabetes and osteoporosis. The moderate sodium level is also vital as the human body requires a small amount of sodium to conduct nerve impulses, contract and relax muscles, and maintain the proper balance of water and minerals.

Table2: Mineral Composition (mg/kg) of Millet -Soybean-Egg complementary foods

Sample	Fe	Zn	Mg	Ca	Na	P
A	2.80±0.00^{a}	2.00±0.10^{b}	0.60±0.02^{a}	30.33±1.53^{a}	247.33±2.52^{a}	280.00±2.00^{c}
B	2.63±0.15^{b}	2.30±0.10^{a}	0.58±0.02^{b}	28.67±2.08^{b}	244.67±2.08^{b}	269.00±1.00^{d}
C	2.00±0.10^{d}	1.97±0.21^{bc}	0.55±0.03^{d}	27.33±1.53^{bc}	242.00±1.00^{c}	287.33±3.05^{a}
D	2.33±0.15^{c}	2.27±0.15^{a}	0.56±0.01^{bc}	27.00±1.00^{c}	245.67±5.86^{b}	269.67±2.08^{d}
E	2.10±0.10^{d}	1.80±0.10^{bc}	0.54±0.01^{d}	27.00±1.00^{c}	240.33±0.58^{d}	285.00±1.00^{b}

Means (±SEM) with different superscripts in the same column are significantly different at P<0.05. A= Millet:100 %, B=Millet:90,% Soybean :5:% Egg:5%; C=Millet:80%, Soybean :15%: Egg:5%; D= Millet:70%, Soybean :20%: Egg:10%; E= Millet:60%, Soybean :25%: Egg:15%

The screening of the f antinutrients in the formulated diet is presented in Table3. Tannin was present in all the samples, saponin was present in samples D and E while flavonoid was present only in sample C. Oxalate was absent in all the food sample. The result of this study is similar to that of Karishma and Pravin (2016) who reported the presence of tannin in bread fortified with germinated horse gram.. Oxalate and tannin not only interfere with mineral absorption, but also impair protein digestibility. Therefore ,their presence indicates the need for further processing such as combination of germination and fermentation methods .

SAMPLE	TANNINs	SAPONINs	FLAVONOIDS	OXALATEs
A	+	-	-	-
B	+	-	-	-
C	+	-	+	-
D	+	+	-	-
E	+	+	-	-

A= Millet:100 %, B=Millet:90,% Soybean :5:% Egg:5%; C=Millet:80%, Soybean :15%: Egg:5%; D= Millet:70%, Soybean :20%: Egg:10%; E= Millet:60%, Soybean :25%: Egg:15% + . Present -. Absent

The sensory properties of the formulated diets are presented in Table 4. The sample D had the best appearance , scoring 7.40 in color, sample C had the best aroma with a mean score of (7.60) while sample D had the highest score(6.98) for mouth feel and sample D (7.93) had the best texture. For overall acceptability, sample D performed better than the other samples.There were significant(p<0.05) differences in colour and taste among samples. No panelist showed total dislike for the taste of any of the samples, implying that the taste of the samples was not affected by the level of supplementation. Aroma is related to taste, a good level of flavour intensity influences taste.

Table 4: Sensory properties of Millet -Soybean-Egg Complementary foods

Sample	Color	Aroma	Mouthfeel	Taste	General acceptability
A	6.56^{bc}	5.76^{a}	6.20^{b}	6.21^{b}	5.80^{a}

C	7.44^{a}	6.96^{a}	7.48^{b}	6.38^{b}	6.56^{a}
D	7.80^{a}	6.56^{a}	7.80^{a}	7.50^{a}	6.60^{a}
E	6.64^{b}	6.24^{a}	6.63^{b}	5.20^{b}	5.70^{b}

Means with different superscripts in the same column are significantly different at P<0.05

CONCLUSION

The study has demonstrated the use of millet-soybean-egg composite flour in the production of complementary foods the mineral contents t) as well as the sensory qualities of the formulated products. All the raw materials used for the production of the foods are locally available and the complementary foods do not require special skill for the preparation.

It is recommended that the use of indigenous food crops should be encouraged for the production of complementary foods as they cheap and provide adequate nutrients needed for growth and development of infants

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study aimed at determining the nutrients and mineral composition in the Dried Moringa oleifera. Leaves were removed from leaf branches, spread on a clean plastic tray and air dried at room temperature for 3 weeks, grounded and was taken to laboratory for the determination of selected mineral and proximate analysis which was done by standard method. The result indicated that Moringa oleifera had highest value of Magnesium (61.74 mg/L) followed by Calcium (19.14 mg/L) while Lead had the lowest percentage of (0.01 mg/L). It was revealed that Carbohydrate had the highest percentage composition of (50.20%), Crude fibre (20.50%) while Fat content had the lowest percentage composition of (2.68%). However, from this study, it was discovered that Moringa oleifera contained high amount of magnesium which is needed for more than 300 biochemical reactions in the body. It was discovered from the findings, that Moringa oleifera has all the necessary minerals in right proportions and is fit for consumption.
Keywords: *Moringa oleifera, Magnesium, Zinc, Carbohydrate, Lead, Crude fibre and proteins*.

INTRODUCTION

Moringa oleifera commonly referred to as "Drumstick tree" belongs to the plant family *Moringaceae*. It is widely cultivated in semiarid, tropical and subtropical areas. The plant may be consumed as vegetable to improve nutrition, can be taken as medicinal plant to cure ailments and improve health, cultivated as forage for livestock, and used as live fencing. Powder produced from the seed is used as an effective primary coagulant for water treatment, and also possess the potential to remove cadmium from aqueous system (Pritchard *et al*., 2010; Sánchez- Martín, 2010). The seed extract has been shown to have ameliorative effect on liver fibrosis in rats and also contain certain antitumor promoter. Crude extracts and essential oil from *Moringa oleifera* possess anti-fungal activity against certain dermatophytes (Chuang *et al.,* 2007). The leaves possess antioxidant properties (Hamza, 2010). Some phytochemicals derived from the seeds possess insecticidal properties against mosquito (Prabhu *et al*., 2011).

This plant contains a considerable amount of various nutrients, and has been suggested as a good supplement for such nutrients as protein, fibre and minerals. Also, it can be included in diets to supplement daily nutrient needs which could help to fight against many diseases as nutraceuticals. *Moringa* is rich in many vitamins, including vitamin A, several forms of vitamin B, vitamin C, vitamin D and vitamin E. In fact, it has more of these vitamins than a variety of foods (such as carrots, oranges and milk) that claim to be excellent source of these vitamins. The *Moringa* tree grows quickly in many types of soil environments. Much of the plant is edible by humans or by farm animals. *Moringa oleifera* leaves can be used in food preparation and also brewed as a tea, either alone or in combination with milk (Fuglie, 2006).

The term heavy metal refers to any metallic chemical element that has a relatively high density and may be toxic or poisonous even at low concentrations (Alloway and Ayres, 1993). Heavy metals include zinc, lead, calcium, mercury etc. Heavy metals are natural components of the earth crust. They cannot be degraded or destroyed. To a small extent they enter our bodies via food, drinking water and air. As trace elements, some heavy metals (e.g. Cu, Zn, Fe) are essential for maintaining the human body metabolism. There are several sources of metal poisoning which include water contamination via lead pipes, food contamination and inhalation of contaminated dust (APHA, 2000). Heavy metals are dangerous, because they tend to bioaccumulate. (Bio accumulation means an increase in the content of a chemical in a biological organism over time, compared to the chemicals content in the environment). Diverse amounts of heavy metals are cosmopolitan in soil, water, air, sediments and plants.

Therefore, this research is interested in studying the nutrient and proximate composition of fresh and dried *Moringa oleifera* to ascertain whether it has the nutrient contents in the right proportion that can serves medicinal purpose or other functions.

MATERIALS AND METHODS

Study Area: The experiment was carried out at the Research Laboratory of Oyo State College of Agriculture and Technology, Igboora. Igboora lies on latitude 7° 15'North and longitude 3° 30' East of the equator with annual rainfall of 150mm and temperature of 27°C Oyo State. The area falls within Southwest region of Nigeria and noted for both hot and cold weather condition (Sanusi, 2011).

Sample Collection and Preparation: The Fresh leaves of *Moringa oleifera* were plucked from the Moringa tree growing at Igbo-ora. The leaves were removed from leaf branches, spread on a clean plastic tray and air dried at room temperature for 3 weeks until no traces of water was founded in it. This was done to avoid interference during analysis and also to reduce the level of water content.

Nutrient determination of *Moringa oleifera*

Determination of Calcium: washed moringa sample was left in water to make it alkaline (pH 12.5 to 13). An indicator that can form a colored complex with EDTA is then added to the solution, and the solution is titrated with EDTA which later showed colour blue (Joseon, 2005).

Determination of Magnesium: Magnesium was determined using EDTA titrimetric method. 10ml of the digested sample was pipetted into 250ml conical flask, a pinch of KCN, a pinch of hydroxyl ammonium chloride solution and 5ml of 10% potassium hydroxide was added and shaken gently until the solid dissolved. A pinch of Eriochrome black T indicator was added and the mixture was titrated with 0.01M EDTA solution until the wine-red colour changes to blue which is the end point (Andreaw *et al.*, 2005).

Determination of Ash Content: The ash content was determined using AOAC method. 5g of the sample was weighed into a crucible in a muffle furnace and heated at 550°C for six hours until it became gray ash. The dish was removed from the muffle furnace using crucible tong and placed in a desiccator to cool. After cooled it was re-weighed and the weight of ash was obtained by the differences (Wang, 2005).

Determination of Moisture content: The moisture content of the sample was determined using the procedure prescribed by Fuglie (2005). The Petri-dish was cleaned thoroughly and placed in oven to dry. 5g of the sample was poured into a pre-weighed Petridish, and then placed in an oven to dry at 105°C for two hours. The dish and dry sample were transferred into a desiccator to cool at room temperature before being weighed again. The experiment was repeated until constant weights were obtained.

Determination of Fat content: Fat was determined using soxhlet fat extraction method. 250ml boiling flask was cleaned thoroughly and dried in oven at 105°C for 30 minutes and then placed in a desiccator to cool. 2g of the dried sample was weighed accurately into labeled thimbles. Cooled boiling flask was filled with 200ml of petroleum ether and boiled at 40-60°C. The extraction thimble was plugged lightly with a cotton wool and the boiling flask containing the petroleum ether was placed in the extraction thimble to boil and the soxhlet apparatus was allowed to reflux for six hours. The thimble was removed carefully, and the petroleum ether on top of the container was collected and drained into another container for reuse. When the flask is free of petroleum ether, it was removed and boiled for an hour at 105°C. It was finally transferred from the oven into a desiccator to cool before weighing (Amaglo *et al.,* 2010).

Determination of Crude Fibre content: Crude Fibre content was determined by Weende's method. 2g of the sample was weighed into a 250ml conical flask and 200ml of 1.25% H_2S0_4 was added and the mixture was boiled under reflux for 30minutes. The solution was filtered with a filter paper; the residue was later rinsed thoroughly with hot water until there was no more acidic content when tested with pH paper. The residue was transferred into a 250ml beaker and 200ml of 1.25% NaOH was added and boiled for 30minutes in a digestion apparatus after filtered and rinsed with distilled water until the filtrate was neutral when tested with pH paper. The residue was transferred into a crucible and placed in electric oven at 100°C for eight hours to dry. It was then removed and placed in a desiccator to cool before weighing. After weighing, the sample was incinerated, cooled in a desiccator and reweighed (Lowel *et al.,* 2006).

Determination of Protein: Protein content of the moringa sample was determined using the Kjeldahl method. The total nitrogen was estimated and multiplied by a conversion factor of 6.25 to obtain the protein content. 0.5g of the sample was weighed into a Kjeldahl digestion flask. A tablet of selenium catalyst was added to it. 20ml of H_2SO_4, 10g of $NaSO_4$, 1g of $CuSO_4$ were also added to the flask and digested by heating under a fume cupboard till the solution digested completely and changed to blue colour. The solution was carefully removed and allowed to solidify for 24hrs until a white colour obtained (Fuglie, 2005).

Determination of Heavy Metals in *Moringa oleifera*

Determination of Chromium: Chromium determination was carried out by EDTA titrimetric method using Xylenol Orange as an indicator. 15ml of the moringa sample was measured into a 250ml conical flask. Then 5ml of distilled water, 3 drops of xylenol orange indicator and 1 drop of dilute H_2SO4 was added to the sample solution. Thereafter, the colour turned to light red and hexamine powder was added until the colour changed to deep red. It was then titrated with 0.05m EDTA until colour change from deep red to initial red was observed (Fuglie, 2005)

Determination of Zinc: This was determined by EDTA titrimetric method. 2ml of moringa sample solution was measured into a conical flask and 2ml of buffer solution was added to it. Then, 2 drops of Eriochrome Black T Indicator was added and the mixture titrated with 0.01 EDTA until the colour changed from wine red to blue (Becher *et al.*, 1996)

Determination of Lead: The Lead content in the moringa sample was determined using Spectrophotometric method. 10ml of the sample solution was measured into a beaker, followed by addition of 5 drops of 10% KCN, 5ml of 1.2M NH_3 solution and 5ml of 10% $NaSO_4$. The resulting mixture was filled up to the 50ml with distilled water. The spectrophotometer was set at wavelength of 430nm after calibration and the absorbance reading of the sample solution taken (Makkar and Becker, 1996).

Determination of Iron: In determination of iron content, 5ml of the moringa sample was pipetted into a 50ml of volumetric flask. 5ml of 17% CH_3COONa was then measured into the digested sample in a volumetric flask followed by addition of 0.5ml of 10% hydroxylamine hydrochloride and 5ml of 0.25% O-phenanthroline. Then the mixture was made up to 50ml with distilled water and allowed to develop for 30mins before the absorbance reading was taken using spectrophotometer. The wavelength of spectrophotometer was set at 510nm for Iron (Amaglo *et al.*, 2010).

Determination of Copper: In determination of copper content, 10ml of the digested moringa sample was measured into 50ml of volumetric flask. 10ml of 0.01M NH_4OH was added to the solution and the resultant mixture made up to 50ml using distilled water. It was allowed to develop for 30mins, before absorbance reading was taken with the aid of the spectrophotometer at wavelength of 620nm (Abalaka *et al.*, 2009).

RESULTS

The mineral elements determinations of *Moringa oleifera* showed different values. The obtained values varied from 61.74 – 0.01(mg/L) for nutrient. The *Moringa* leaves that were used in this study contained appreciable amount of minerals, which compared well with those of other authors. Among the mineral elements detected from *Moringa oleifera*, Magnesium had the highest percentage composition of (61.74 mg/L) while Lead had the lowest percentage of (0.01 mg/L). Calcium had (19.14 mg/L) while vitamin C had (16.23 mg/L) followed by Potassium (8.17 mg/L), Iron (3.5 mg/L), Zinc (2.13 mg/L), Copper (0.17 mg/L) and Vitamin B (0.12 mg/L) respectively. Chromium was not detected in the *Moringa oleifera*.

It was revealed that Carbohydrate had the highest percentage composition of 50.20% while Fat content had the lowest percentage composition of (2.68%). Crude fibre had (20.50%), Ash content was (12.30%), Protein had (9.0%) and Moisture content revealed (5.30%) respectively.

Table 4.1: Mineral elements Composition of *Moringa Oleifera*

Mineral Elements	Composition (mg/L)
Calcium	19.14
Potassium	8.17
Magnesium	61.74
Iron	3.5
Copper	0.17
Zinc	2.13
Chromium	Not Detected
Lead	0.01
Vitamin B	0.12
Vitamin C	16.23

Table 4.2: Proximate analysis percentage of *Moringa Oleifera*

Proximate Analysis	Composition (%)
Ash	12.30
Carbohydrate	50.20
Fat	2.68
Crude fibre	20.50
Moisture	5.30

Protein	9.02

DISCUSSION

The calcium for the present was low and is similar to the observation of low calcium reported by Thippeswamy *et al.* (2020). The present result deviated from high value of calcium (199.23ppm) reported Moringa by Mahima *et al.* (2014) in India. Potassium reported for this study was low compared to (430.00 ± 8.37) reported by Okiki *et al.* (2015). Mg reported for the present study was very high and is in agreement with observation of Okiki *et al.* (2015) in Ado Ekiti. Iron and Copper values from this study were very low to high values reported by Mahima *et al.* (2014) while similar observation of low Iron values was observed by Okiki *et al.* (2015). Deviated values of iron (19.05 ppm) and copper (8.733 ppm) which was high were observed by Thippeswamy *et al.* (2020) and Olugbemi *et al.* (2014) in *Moringa oleifera*. The low value of Zinc observed for this study could be due to low level of Zn in the soil used for moringa plantation. This present result is contrary to the observation of Okiki *et al.* (2015), Thippeswamy *et al.* (2020) and Olugbemi *et al.* (2014) in which all reported higher values of Zinc in their study areas. The reason for the variations in values can be associated to varied soil where the moringa was grown. Chromium was not detected at all in this study, which indicated low level of highly impacted metals in the soil. Lead values reported for this study was very low which may be due to low level of lead in the soil that moringa was planted. Vitamin B reported for the present study was low compared to the observation of Zahidul Islam *et al.* (2021) and recommended Dietry Allowance of 19% for vegetables. Vitamin C reported in this study was high more than the limit (12%) required by RDA. Similar observation of high values of Vitamin C was also reported by Zahidul Islam *et al.* (2021).

The determinations of some proximate in *Moringa oleifera* plant parts (leaves) materials were restricted to those that are cultivated in Igboora town and the results obtained from the analysis revealed that concentration levels of the sampled leaves varied in values for proximate analysis. Carbohydrate that has the highest percentage composition implies that the *Moringa oleifera* leaves examined are very rich in carbohydrate and serves as source of energy to the consumers. Similar observation was reported by Bamishaiye *et al.* (2011) and Okiki *et al.* (2015) who also reported high carbohydrate value, though, the present study observed high value more than (47.09%) and (37.87%) reported. Ash content had the lowest percentage composition and is in contrary with value of Ash reported by Akindahunsi and Salawu (2005) for *Ocimum gratissimum* and *Hibscus esculentus* leaves (8.00%) and (9.15%), (9.25%) reported for *Moringa oleifera* leaves by Mahima *et al.* (2014) and Bamishaiye *et al.* (2011). Fat content in this study reported low value which is necessary for good health, i.e. low cholesterol that can lower the risk of high blood pressure. This observation is in line with the report of Bamishaiye *et al.* (2011) in *Moringa oleifera* Akindahunsi and Salawu (2005) in *Amaranthus hybridus* and *Corchorus africanum*. Salma (2020) also reported low value of fat for *Moringa oleifera* leaves. Low fat contents have been previously reported by Makkar and Becker (1996), Oduro *et al.* (2008) and Fuglie (2001) for *Moringa oleifera.*

High value of crude fibre that was reported indicated high digestibility when the moringa is taken, and the value is lower compared to the report of Mahima *et al.* (2014) (23.09%), Olugbemi *et al.* (2010) (27.44%), Mutayoba *et al.* (2011) also reported (30.65%), all for *Moringa oleifera* leaves. Protein that revealed low value could be associated with dried leaves used for this study. Departed report was observed by Salma (2020) who reported high value of protein (29.36%) in their study of functional and nutritional properties of Moringa. Deviated observation of high value protein (28.08%) was also observed by Bamishaiye *et al.* (2011) and Okiki *et al.* (2015) for *Moringa oleifera* in Ado-Ekiti. Moisture content for this study is very low and may indicate a very high shelf life that can protect the leaves of moringa from attack of microbial spoilage. Similar observation of low value was reported by Okiki *et al.* (2015) while contrary observation was reported Mahima *et al.* (2015) in their study of nutritional potentials of *Moringa oleifera* leaves in India.

CONCLUSION

Moringa Oleifera which comprises of different mineral elements *(*Magnesium and others*)* contributes many to the human body, it helps in building body mineral elements. However, from this study, it was discovered that *Moringa oleifera* containied *high amount of* magnesium which is needed for more than 300 biochemical reactions in the body. It helps to maintain normal nerve and muscle function, supports a healthy immune system, keeps the heartbeat steady, and helps bones remain strong. Lack of magnesium may cause nerve dysfunction and promote mental health conditions. *Moringa oleifera* had high amount of carbohydrate which provide energy, store energy, build macromolecules etc. However, lack of carbohydrate will make level of sugar in blood to drop below the normal range (70-99 mg/dL), causing hypoglycemia. Therefore, this study showed that the *moringa* studied is good for healthy living as at time of this study.

RECOMMENDATION

Based on the findings of this research study; it is recommended that the planting of economical plants which have the nutritional and medicinal values became necessary in our environments, especially plants such as *Moringa oleifera* tree, which is rapidly growing, drought - resistant tree. It is also recommended that *Moringa oleifera* tree should be used as a demarcation plant in our farms, backyard farm gardens so as to have enough access to the plant parts material for provision of quick and safe supply of its nutritional values and health benefits.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The fortification of food products has been an important tool, not only to manage or prevent specific nutritional deficiencies, but also to promote a general state of well-being in different populations and possibly to prevent certain chronic diseases.. The aim of this work was to evaluate amino acid profile and antioxidant properties of bread produced from wheat, Acha, pumpkin and fish flour blends. Four composite flour blends were formulated in the ratio of A=85:5:0:10, B= 75:10:5:10, C=65:15:10:10, D=100:0:0:0 (wheat, acha, fluted pumpkin and fish). The flour blends were used to produce breads using the straight dough method of AOCC with the recipe with graded levels of wheat flour supplemented. . The result shows significant difference (p<0.05) among thefor the essential and non-essential amino acids. The total essential amino acid values of the samples ranged from 31.99 (sample A) to 44.29 (sample C) g/100g protein. Glutamic acid was found to be the most abundant amino acid and tryptophan was the first limited essential amino acid in this study. Furthermore, The antioxidant activity of formulated samples ranged from 51.99 to 68.22, 0.75 to 1.72 mg/g, 1.02 and 1.72% and 46.06 and 57.07% for (DPPH, FRAP, total Phenol and Fe2+ Chelation respectively. The study concluded that supplementation of acha, fish and fluted pumpkin can be used to improve the nutritional quality of bread especially in developing countries where malnutrition and diabetes is prevalent at all aged group.
Keywords: *Bread, DPPH, amino acids, anti oxidants*

INTRODUCTION
The fortification of food products has been an important tool, not only to manage or prevent specific nutritional deficiencies, but also to promote a general state of well-being in different populations and possibly to prevent certain chronic diseases (Białek *et al*. 2015). The identification and development of fortifying agents that would ensure high product quality and bioavailability pose some technological and scientific challenges (Revathy and Sabitha, 2013)
Diabetes consists of a group of metabolic disorder characterized by elevated blood glucose, either because insulin production is inadequate or because the body's cells do not respond properly, or both. The number of global diabetes cases was 171 million in 2010 and is predicted to rise to 366 million by 2030 (Olagunju *et al*., 2018). Its increasing worldwide incidence constitutes a global health burden. Maintenance of body antioxidant status is important in the management of type 2 diabetes mellitus (Olagunju *et al*., 2018). Currently, the constraint to the use of synthetic inhibitors such as acarbose, voglibose, and miglitol is the exorbitant prices and the associated clinical side effects such as hypoglycemia, weight gain and the non-tolerance by some patients (Dujic *et al*., 2015). Inhibitors derived from natural products do not have side effects, and the therapies are well tolerated. Hence, the increase in the search for food derived natural inhibitors of the key enzymes.
Pumpkin (*Telfairia occidentalis*), a tropical cucurbit (Kiin-kaban *et al*., 2020) is grown in Nigeria as a source of leafy vegetable, and for its oil-bearing seeds. Common names for this plant in Nigeria include 'ugu', and fluted gourd. *Tefairia occidentalis* grows in many countries of West Africa, but cultivated mainly in Nigeria where it is used primarily in soups and herbal medicines. Fluted pumpkin is rich in protein, vitamins and minerals(such as iron reported to be useful in the treatment of anaemia (Adegbenro *et al*., 2020). Consumption of fluted pumpkin leaves and seeds helps in preventing cancer, improves blood count, reduces blood glucose and cholesterol levels (Adegbenro *et al*., 2020).

Fish is valued for providing high quality protein than meat and egg. However, it is one of the most perishable of all the foods due to suitable medium for growth of micro-organisms after death. Catfish (*Clarias spp*) is highly nourishing. It contains lysine, vitamin A, calcium, phosphorus, fat, and other nutrients needed for human growth and health (FAO, 2003). Edible fish meal is the product obtained from the removing of water and oil from whole fish, thereby increasing the concentration of protein and other nutrients (Ibrahim, 2009). Edible fish meal provides the opportunity of utilizing other nutrients such as calcium that are available in the fish.

Acha (Fonio) is the term for two cultivated grains in the *Digitaria* genus which are notable crops in parts of West Africa. The grains are very small. The crops have C4 metabolisms and are medium in height. It has potential to improve nutrition, boost food security, foster rural development, and support sustainable use of the land (Ogori *et al.*, 2020). Fonio grains are considered as the best tasting and nutritious of all grains with about 7% crude protein that is high in leucine (9.8%), methionine (5.6%) and valine (5.8%). The aim of this work was to evaluate amino acid profile and antioxidant properties of bread produced from wheat, Acha, fish and pumpkin flour blends.

MATERIALS AND METHODS

Wheat, Acha and fluted pumpkin leaf were purchased from a local market in Lafia, Nasarawa State, Nigeria. While catfish was purchased from a fish farm in Lafia Nasarawa state. The products were processed at the food laboratory of the Department of Home Science and Management Nasarawa State University, Keffi Shabu-Lafia Campus.

Flour blends was prepared with graded levels of wheat flour supplemented with acha flour, pumpkin and fish. The graded levels ranged from 0 – 10% fish flour, 0 – 10% pumpkin flour 0-10% and 0 – 15 % acha flour, with 100% wheat flour as the control.

Table 1: Flour blend formulation

Food Material	A (%)	B (%)	C (%)	D (%)
Wheat	85	75	65	100
Acha	5	10	15	0
Pumpkin Leaf	0	5	10	0
Fish`	10	10	10	0
Total	100	100	100	100

Production of Experimental Bread

The flour blends were used to produce breads using the straight dough method of AOAC, (2012) The flour blends and other ingredients was mixed manually for 5 minutes. The dough covered with kitchen cloth and placed in the fermentation chamber for 90 minutes at the temperature of 37 ± 2^0C, relative humidity 85%, thereafter it was degassed. The baking pans was greased with fat, the dough pieces (250g) were manually molded and placed into the pans and proofed for 60 minutes and later placed in the pre-heated oven, baked at 200^0C for 30minutes. The loaves of bread were allowed to cool (3-4hours), dried, and grinded into powder form and left in polythene bags for storage.

Amino Acid Profile Determination

The amino acids profiles of the formulated blends were determined using AOAC (2012) method. The data were calculated as grams of amino acid per 100g crude protein of flour sample.

Anti oxidant activity Determination

Antioxidant activity DPHH, FRAP, total phenolic and Fe^{2+} Chelation ability was measured based on the modified methods described by Oboh *et al.,* (2010) and Ijarotimi *et al*., (2022).

Statistical Analysis

All measurements were done in at least two replicates, and the results were subject to one factor analysis of variance (ANOVA), applying software package SPSS 16.0.The significance of differences was evaluated by Duncan's test, at $P<0.05$. The results are represented as mean value ± standard deviation (SD)

RESULTS AND DISCUSSION

The result of the amino acid contents of bread produced from wheat, acha, fish and pumpkin blends are presented in Table 2. The result shows significant difference ($p<0.05$) among the treatments for the essential and non-essential amino acids. The total essential amino acid values of the samples ranged from 31.99 (sample A) to 44.29 (sample C) g/100g protein. These values are significantly higher than the recommended value (30.1g/day) by WHO/ FAO (2004). For the total non-essential amino acids, the values ranged between 46.56 and 54.37 g/100g protein with sample C scoring the highest value. Glutamic acid was found to be the most abundant amino acid and tryptophan was the first limited essential amino acid in this study. The high value for glutamic acid is similar and agree with the report of

Ijarotimi *et al.*, (2019) that the commonly most the predominant amino acid in plant foods is glutamic acid. Evidence have shown that both systolic and diastolic blood pressure is lower by the intake of plant proteins high in amino acids such as glycine, glutamic acid, histidine, cysteine and arginine (Ijarotimi *et al.*,2019).

The result of the antioxidant properties of bread produced from wheat, acha, fish and pumpkin blends are presented in figure 1 to 4. The result shows significant difference ($p<0.05$) was observed in the parameters assessed among the food samples. The antioxidant activity of formulated samples ranged from 51.99 to 68.22, 0.75 to 1.72 mg/g, 1.02 and 1.72% and 46.06 and 57.07% for (DPPH, FRAP, total Phenol and Fe^{2+} Chelation respectively. The higher antioxidant properties recorded in the enriched breads can be attributed to the addition of Telfairia occidentalis (fluted pumpkin), edible fish meal and acha in the bread formulation. This finding could be attributed to variations in food composition and bioactive components like phytochemicals, fibres and bioactive proteins, which were significantly present in the formulated food samples, especially in Telfairia occidentalis leaf. According to Oboh *et al.*, (2010),Telfairia occidentalis possess antioxidant property. This findings also agreed with the report of Ijarotimi *et al.*, (2022) and David *et al.*, (2022).

CONCLUSION

This work has shown that the incorporation of acha, fluted pumpkin and fish wheat in production of bread would result in products of high nutritional quality for the populace. Significant increase was observed in terms of the amino acid profile (essential and non-essential amino acids) and antioxidant activities of the bread which may be good in the management of Diabetes Mellitus.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The potential contribution of orange-fleshed sweet potato towards food security in Nigeria is underestimated as a huge gap due to the soil environment as an important yield determinant. The research into the soil nutrient conditions for sweet potato production has not been extensive. The study was conducted in the 2020 and 2021cropping seasons at the Eastern farm of National Root Crops Research Institute, Umudike, Abia State. The experiments was a 4 x 2 x 2 factorial experiment laid out in Randomized Complete Block Design (RCBD). NPK 15:15:15 at levels of 0, 200, 400 and 600 kg/ha with carbonize RMW at 0 and 5 t/ha and uncarbonize RMW at 0 and 10 t/ha giving a total of 16 treatment combinations replicated three times. The rice mill wastes were applied to the plots two weeks before planting. Mineral fertilizer was applied at 4 weeks after planting. The test crop orange-fleshed sweet potato, UMUSPO/3 variety (Mother's Delight) was obtained from Sweet potato Research Programme of NRCRI, Umudike. Data were collected on yield performance, total root weight, weight of marketable roots, number of marketable roots and other useful agronomic traits. The analysis was done following the procedures for randomized complete block design (RCBD) using the Genstat Discovery 12th edition Significant treatment means were separated using least significant difference (LSD) at 5% probability level. The result shows that there were significant (P<0.050 difference among the treatments used. The study also shows that integrated nutrient management (combining organic and mineral fertilizers) holds the key to improving the growth and root yield of orange-fleshed sweet potato. The application of rice mill waste had varied effects on the chemical properties of the soil as its application improved the growth parameters at different sampling periods as well as an increase in both the total and marketable root yield of orange-fleshed sweet potato. Based on the findings reported in this study, orange-fleshed sweet potato for commercial root production in the study area can be improved by combining organic materials such as rice mill waste (barn) with mineral fertilizers.
Keywords: *Orange-flesh Sweet potato, NPK 15:15:15, Rice mill waste,*

INTRODUCTION
Root and tuber crops are important sources of carbohydrate for millions of people throughout the tropics. Sweetpotato (*Ipomoea batatas (L) Lam),* a trailing perennial plant of the family Convolvulaceae (morning glory family), and the only member of the genus *Ipomoea* whose roots are edible, is undeniably one of the world's most important food crops due to its high nutritive value (França and Ritschel, 2002). It is believed to have originated from either Central America or within the tropical region of North Western parts of Central America (Onwueme, 1978; Hahn and Hozyo, 1984). It is one of the major root crops that had suffered neglect in the past but now appears to be gaining a prime position as a source of food and industrial raw materials. Globally, sweet potato ranks third among root and tuber crops after potato (281 million tonnes) and cassava (164 million tonnes), with a production of about 122 million tonnes (FAO, 1996). China accounts for the highest production of sweet potato (2,883,408 tonnes) making Asia the world's leading producer of sweet potato (FAO, 2012), followed by Uganda and then Nigeria in that order (FAO, 2004). In Nigeria, it is one of the four major root and tuber crops coming after cassava, yam and cocoyam (FAO, 2018). These crops play important roles in both social and economic development of the country.

The potential contribution of this crop towards food security in Nigeria is underestimated as a huge gap exists between its potential yield of 20 - 40t/ha and actual yield of 3 - 5t/ha in farmers' fields (Wabanechi, 2014). The constraints responsible for farmer's low yields could be as a result of weed competition and poor soil management (Atnafu, 2019).

Research into the soil nutrient conditions for sweet potato production has not been extensive. This may have been due to the notion that sweet potato is adapted to soil acidity and it is deep-rooting, with the ability to produce fairly good yield from poor soils. (Thorup-Kristensen and Kirkegaard, 2016).

The current revolution in the production of rice by the Federal government which has led to a sporadic rise in rice production in South-east Nigeria has made rice mill waste abundant. This organic material can be carbonized through the use of a carbonator machine and incorporated to the soil to increase soil fertility, increase agricultural productivity and provide protection against some soil acidity, foliar and soil-borne diseases (Warnock *et al.*, 2007). It serves as an alternative organic fertilizer additionally with NPK fertilizer for sustainable crop production in the agricultural sector have remarkable agronomic values and yield potential in poor degraded soils (Lashari *et al.,* 2013).

In response to this challenge, the objective of this study is to determine the response of orange-fleshed sweet potato to NPK-enriched rice mill waste (bran) forms for commercial sweet potato production.

MATERIALS AND METHODS

The study was conducted in the 2020 and 2021cropping seasons at the Eastern farm of National Root Crops Research Institute, Umudike, Abia State. Abia State is one of the states in the rain forest zone of the Southeastern geopolitical zone of Nigeria. The other states within the region include Anambra, Ebonyi, Enugu, and Imo. It lies within Latitude 4°15ʹ and 7°N and Longitude 5°29° North and 7°33ʹ east of the Equator with an elevation of 122m above sea level. It is therefore heated by the vertical rays of the sun all year round.

The land was slashed, ploughed, harrowed and ridged mechanically and the field was demarcated into plots and replicates. The experiment was a 4 x 2 x 2 factorial experiment laid out in Randomized Complete Block Design (RCBD). The plot size measured 3m x 3m with 0.5m space separating the plots and 1m space separating the replications. The materials for the experiment were mineral fertilizer (NPK15:15:15), carbonized rice mill waste and uncarbonized rice mill waste. NPK 15:15:15 at levels of 0, 200, 400 and 600 kg/ha was factorially combined with carbonize RMW at 0 and 5 t/ha and uncarbonize RMW at 0 and 10 t/ha giving a total of 16 treatment combinations replicated three times. The rice mill wastes were applied to the plots two weeks before planting. The sweet potato vine cuttings were planted on the crest of the ridge at a spacing of 0.3m within rows and 1m between rows giving a plant population of 33.333 stands/ha and the mineral fertilizer was applied at 4 weeks after planting.

All the data collected were subjected to analysis of variance, using the Genstat Discovery 12th edition (Genstat, 2009). Significant treatment means were separated using least significant difference (LSD) at 5% probability level according to Obi (2001).

RESULTS

Table 1 result shows that the application of NPK-fertilizer at 400 kg/ha on fresh total root yield weight of orange-fleshed sweet potato, recorded the highest (16.82 and 15.28 t/ha) total root yield weight compared to other rates of NPK -fertilizer application in 2020 and 2021 cropping seasons. The application of CRMW and UCRMW also recorded an increase in the total root yield weight (15.28 t/ha and 16.59 t/ha) in 2020 and 2021 (6.15 and 6.41 t/ha) cropping season respectively. However the application of NPK -fertilizer at 400 kg/ha x 5 t/ha of CRMW recorded the highest total of root yield weight (19.09 and 7.43 t/ha) in both cropping season throughout the year of observation.

A significant difference ($P<0.05$) was observed in the interaction between NPK-fertilizer x URMW in 2020 cropping season as well in the interactions between CRMW x URMW for both 2020 and 2021 cropping seasons. No significant difference ($P>0.05$) was observed in the interaction between NPK -fertilizer x CRMW in both 2020 and 2021 cropping seasons.

Table 1 result shows that the application of NPK-fertilizer at 400 kg/ha showed superiority over the others In both planting season,, giving a marketable root yield weight of 13.87 and 5.28 kg/plant, followed by the application of 600 kg/ha that gave 13.47 and 4.47 kg/plant while the control had the least of 8.12 and 3.81 kg/plant respectively. Both cropping seasons in 2020 and 2021 respectively, recorded an increase in the weight of marketable roots with the application of CRMW and URMW. The weight of unmarketable root yield of orange-fleshed sweet potato in 2020 and 2021 cropping seasons in Table 1, shows no significant difference ($P>0.05$) in the 2-way interaction: NPK - fertilizer x CRMW; NPK-fertilizer x URMW and CRMW x URMW, but the application of NPK-fertilizer at 400 kg/ha produced the highest unmarketable root weight of 1.275 kg/plant in 2020 cropping season while the application of 200 kg/ha of NPK-fertilizer produced the highest unmarketable root weight of 1.39 kg/plant in 2021 cropping season. Application of CRMW and that of URMW did not produce any effect on the unmarketable root weight in 2020 cropping season but did so in 2021.

Table 1 result revealed no significant differences ($P>0.05$) among the treatments that were applied in 2020 and 2021 planting seasons respectively. However the application of NPK-fertilizer at 400 kg/ha produced the highest number of marketable roots of 47.4 and 23.8 roots/plant respectively in the two years. The application of RMW forms also increased the number of marketable roots in the two years. The results shows a significant difference ($P<0.05$) only on the interaction between NPK-fertilizer x URMW in 2020 cropping season while the rest of sampled parameters did not show any significant difference both in 2020 and 2021 cropping seasons.

RESULT OF THE TREATMENT INTERACTION

The 3-way interaction between NPK-fertilizer × carbonized rice mill waste × un-carbonized rice mill waste effects on yield and yield components of orange-fleshed sweet potato in 2020 and 2021 cropping seasons is represented in Table 2. The number of marketable roots per plant did not show any significant differences (P>0.05) in both cropping seasons. However the application of NPK-fertilizer r at 400 kg/ha x 5 t/ha CRMW x 10 t/ha URMW gave the highest number of marketable roots/plant in 2020 cropping season, while the application of NPK-fertilizer at 600 kg/ha x 5 t/ha CRMW x 10 t/ha URMW gave the highest in 2021 cropping season. Significant differences (P<0.05) were recorded in the number of unmarketable roots per plant in 2020 cropping season with the application NPK-fertilizer at 0 kg/ha x 5 t/ha CRMW x 10 t/ha URMW having the highest number of 33.7 roots. No significant differences ($P>0.05$) were recorded in the number of unmarketable roots per plant in 2021 cropping season. Moreover, both weight of marketable roots per plant, weight of unmarketable roots per plant and total root yield did not record any significant differences ($P>0.05$) in the both years of the experiment.

The results of the combined analysis of variance of yield and yield attributes of orange-fleshed sweet potato across 2020 and 2021 cropping seasons are represented in Table 3. The analysis of variance indicated no significant differences ($P>0.05$) among the yield parameters measured. However, the results obtained showed good increase in the total root yield from 7.59 t/ha under no NPK-fertilizer (control) to 11.81 t/ha with the application of NPK-fertilizer at 400 kg/ha. The application of CRMW as well as URMW also indicated an

DISCUSSION

The highest total root yield obtained with the application of composite manure and mineral fertilizer in this study might be as a result of improvement in the physiochemical properties of the soil which led to the release of nutrients for crop uptake. Similar results were reported by Agyarkor *et al.,* (2014), with incorporation of organic manure and N:P:K fertilizer on sweet potato yield; Akinmutimi, (2014), with the application of cocoa pod husk ash and N:P:K-fertilizer on the yield of sweet potato as well as Onunka *et al*., (2012), with the application of organic and inorganic manure on root yield of sweet potato and Asawalam and Onwudiwe, (2011), with complimentary use of cow dung and mineral fertilizer on sweet potato; Yeng *et al.,* (2012), also reported similar results with the integrated application of chicken manure and inorganic fertilizer on the growth and yield of sweet potato while Ojeniyi *et al.,* (2012), with integrated application of N:P:K fertilizer and poultry manure on cassava. Santhi and Selvakumari (2000), have proposed that the application of organic manure sources to chemical fertilizer could increase the yield of crops through improving soil productivity and higher fertilize use efficiency. Moreover, Ayoola and Makinde (2007), also suggested that an integrated nutrient management programme in which both organic manure and inorganic fertilizer are used is a rational strategy. The combined use of organic manure and inorganic fertilizer will increase synchrony and reduce losses by converting inorganic N into organic forms (Kramer *et al*., 2002). It also reduces the environmental problems that may arise from the use of inorganic fertilizers alone and improve the microbial properties of the soil (Belay *et al*., 2001).

CONCLUSION

It can be concluded that integrated nutrient management (combining organic and mineral fertilizers) holds the key to improving the growth and root yield of orange-fleshed sweet potato. The results showed that application of rice mill waste had varied effects on the chemical properties of the soil as its application showed superiority in improving the growth parameters at different sampling periods as well as an increase in both the total and marketable root yield of orange-fleshed sweet potato.

RECOMMENDATIONS

Based on the findings reported in this study, orange-fleshed sweet potato for commercial root production in the study area can be improved by combining organic materials such as rice mill waste (bran) with mineral fertilizers. This will help in a big way to improve the soil properties and enhance an increase in sweet potato growth and yield.
Consequently,

- ❖ Application of 400kg/ha NPK + 5t/ha CRMW + 10t/ha URMW is recommended for good commercial root production of orange-fleshed sweet potato in the study area
- ❖ For vine multiplication, the application of still 400kg/ha NPK + 5t/ha CRMW + 10t/ha URMW is equally recommended.
- ❖ The economics of using organic and mineral fertilizer sources in crop production should also be part of soil studies in order to balance nutrient input with cost.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This research work was to determine the effect of wild mango seed (Irvingia gabonensis) oil on preserving the quality of freshly laid chicken eggs during storage at tropical ambient temperature of 30ºC to 35ºC. A total of 150 freshly laid chicken eggs were used. These eggs were obtained from 25 weeks old Black Harco layers at the University of Ilorin School Farm. The layers were fed diets that contain 3.75% calcium and 16.50% protein, divided into five (5) groups including the control. The eggs were treated with the treatment oil within 24 hours of lay. The results showed a significance difference (p<0.05) between treatments with respect to shell strength, Haugh unit, yolk index, and albumen pH of eggs. The wild mango seed (WMF) treatment has shell strength of 1.094, Haugh unit 64.15, yolk index(0.52) and albumen pH (8.90) being the highest values and significantly different (p<0.05) from other treatments. The other treatments were: Palm kernel oil (PKO) with shell strength of 1.084, Haugh unit 54.30, yolk index 0.43 and albumen pH of 8.90. Groundnut oil (GNO) with shell strength of 1.083, Haugh unit 55.20, yolk index 0.42 and albumen pH of 8.90. Shea butter fat (SBF) with, shell strength of 1.082, Haugh unit 53.50, yolk index 0.40 and albumen pH of 8.85. And control, shell strength of 1.0162, Haugh unit 35.60, yolk index 0.16 and albumen pH of 10.12. However, all treatments showed a significant difference with the control in respect to decline in shell strength, Haugh unit and yolk index and increase in albumen pH values. Also wild mango seed fat treatment was found to be the most effective in maintaining the shell strength, Haugh unit and yolk index. And the values were significantly different from all the treatments.

INTRODUCTION
Protein mal-nourishment is a problem among many people in the world especially in the developing countries like Nigeria. The chicken eggs help to supply this protein but these eggs have the challenge of deterioration (Shittu and Ogunjinmi,2011) These eggs start to deteriorate from the day they are laid, (Nongtaodun,2013). The chicken eggs undergo significant physical, chemical, structural and physiological changes during storage,(Okiki and Ahmed,2017). These eggs have to be preserved using many methods. One of this method is coating of eggs using fat and oil. The egg shell that covered the albumen and the egg yolk are structured with the, pores on the shell and albumen and yolk are inside the egg.The carbon dioxide help to preserve the albumen and the yolk from deterioration by micro organisms. (Nongtaodun, 2013), Ryu *et al.*, 2011). Also the carbon dioxide help to provide a continuously cool environment hence preserve the chicken eggs.

Many researchers have used fat and oil to coat eggs in order to preserve them. But the use of wild mango seed oil: *irvingia gabonensis* to coat and preserve chicken eggs is not common. The wild mango seed oil was extracted from wild mango seeds using the soxhlet extractor apparatus.The coating of chicken eggs with wild mango fat and other fat and oil sealed the egg shell pores to prevent evaporation of water vapour and carbon dioxide, this led to the preservation of the egg. The vegetable oil were used for coating of chicken eggs to preserve them. (Ryu et al 2011) and (Enefola et al 2022). During the storage mass losses of weight for control treatment were in agreement with those reported by (Hasan Akyurek *et al*., 2009).

The weight loss in the chicken egg in storage occur through evaporation, and this depend on the storage time, temperature, carbon dioxide, relative humidity and shell porosity. (Naheed *et al.,* 2014), (Almeida *et al*., (2016), (Ryu *et al*., 2011), and (Zhang *et al*., 2016), and (Wengerska *et al.,* 2023).

MATERIALS AND METHODS

Source of Sample

Freshly laid eggs were collected from University of Ilorin School Poultry Farm. The other oil and fat were bought from Oja oba Market. But the wild mango seed oil was extracted in the laboratory using the Soxhlet extractor apparatus.

Treatment of samples

The test eggs were produced by Black Harco layers. The eggs were purchased and treated with fat and oil freshly laid. Eggs were marked for identification purpose during the course of the experiment. The shell strength, Haugh unit, yolk index and the albumen pH of the chicken egg were determined.

Statistical Analysis

Data were subjected to analysis of variance and significant difference between means were accessed by applying Duncan's multiple range test. (Duncan 1955)

RESULTS AND DISCUSSION

Table 1 shows the effect of storage treatment on the egg shell strength. The wild mango seed oil treatment showed the highest shell strength of 1.094 at the end of 35 days in storage. Other treatments were in this order, palm kernel oil (1.084), Groundnut oil (1.083), shea butter oil 1.082 and the control was 1.0162.The results showed significant differences ($p< 0.05$) between the treatments and the control.

Table 2 shows the effect of storage treatment on the Haugh unit. The wild mango seed oil treatment has the highest Haugh unit of 64.15 at the end of 35 days in storage. The Haugh unit values for other treatments were palm kernel oil 54.30, groundnut oil 54.30 and shea butter oil 53.50, and control 35.60. The results showed significant differences ($p< 0.05$) between the treatments and the control.

Table 3 showed the effect of storage treatment on the yolk index value. The wild mango seed oil showed the highest yolk index value 0.52 at the end of 35 days in storage. The other treatments yolk index values were in this order, palm kernel oil 0,43, Groundnut oil 0.42 and Shea butter oil 0.40. and control 0.16. The results showed significant differences ($p< 0.05$) between the treatments and the control.

From table 4, the effect of storage treatment on the albumen pH. The four treatment have equal values of the albumen pH. The wild mango seed oil 8.90, palm kernel oil 8.90, Groundnut oil 8.90, shea butter oil 8.90 and control was 10.12. The results showed significant differences ($p< 0.05$) between the treatments and the control.

From table 5, the wild mango seed oil showed a significant difference ($p< 0.05$) with other treatments

Table 1; The effect of storage on (shell strength) of chicken eggs

	Duration of storage (days)					
Parameter	0	7	14	21	28	35
Wild mango seed oil	1.0912	1.0902	1.0920	1.0930	1.0935	1.0940
Palm kernel oil	1.0911	1.0910	1.0890	1.0880	1.0860	1.0840
Groundnut oil	1.0911	1.0890	1.0880	1.0870	1.0850	1.0830
Shea butter oil	1.0912	1.0910	1.0900	1.0890	1.0870	1.0820
Control	1.0911	1.0811	1.0512	1.0310	1.0190	1.0162

Table 2; The effect of storage treatment on Haugh unit of chicken egg

Parameter	Duration of storage (days) 0	7	14	21	28	35
Wild mango seed oil	80.40	76.10	72.11	70.10	67.12	64.15
Palm kernel oil	80.20	75.30	71.40	64.20	61.50	54.30
Groundnut oil	80.50	77.20	72.10	61.50	60.10	56.30
Shea butter oil	81.10	75.50	71.50	68.10	59.20	53.50
Control	81.20	65.10	62.30	58.20	36.60	35.60

Table 3; The effect of storage on yolk index of chicken egg

Parameter	Duration of storage (days) 0	7	14	21	28	35
Wild mango seed oil	0.56	0.55	0.54	0.53	0.52	0.52
Palm kernel oil	0.55	0.54	0.48	0.45	0.44	0.43
Groundnut oil	0.56	0.52	0.49	0.46	0.43	0.42
Shea butter oil	0.55	0.53	0.47	0.43	0.42	0.40
Control	0.55	0.42	0.40	0.38	0.30	0.10

Table 4; The effect of storage on albumen PH of chicken egg

Parameter	Duration of storage (days) 0	7	14	21	28	35
Wild mango seed oil	8.15	8.20	8.30	8.40	8.50	8.90
Palm kernel oil	8.10	8.28	8.40	8.44	8.60	8.90
Groundnut oil	8.15	8.20	8.45	8.50	8.55	8.90
Shea butter oil	8.10	8.33	8.38	8.51	8.57	8.90
Control	8.10	9.12	9.32	9.39	9.45	10.12

Table 5; The effect of storage on shell strength, Haugh unit, yolk index and albumen pH of chicken egg

Parameter	shell strength	Haugh unit	yolk index	albumen
Wild mango seed oil	1.094^{c}	64.15^{c}	0.52^{c}	8.90^{c}
Palm kernel oil	1.084^{b}	54.30^{b}	0.43^{b}	8.90^{b}
Groundnut oil	1.083^{b}	55.20^{b}	0.42^{b}	8.90^{b}
Shea butter oil	1.082^{b}	53.50^{b}	0.40^{b}	8.85^{b}
Control	1.0162^{a}	35.60^{a}	0.16^{a}	10.12^{a}

RECOMMENDATIONS AND CONCLUSION

This research work has showed that the wild mango seed oil and other oil and fat rubbed on a freshly laid chicken eggs was efficient in preserving the internal and external quality of the eggs for over one month at room temperature of 30ºC to 35ºC.

It is recommended that the wild mango seed oil should be used in coating chicken eggs to preserve the quality for at least 35 days in storage.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study focused on the Evaluation of the Proximate Analysis of Prepared Meat Suya using three Animal Products such as Beef, Chicken and Fish. The moisture, crude protein, carbohydrate, ash, fiber and fat content of the animal product that made up of the prepared meat suya were analyzed using standard methods. The Result of the findings shows the moisture content of the types of suya has the Result ranges of 7.20-9.20%. Fish suya constitute the high value of moisture contents of 9.20%. The relationship between the Ash content of the types of suya has the Result range of 4.20-4.40%. The ash content is often regarded as an index of mineral content in biological mass. However, the relationship between the protein content of the suya has the result range of 10.0-11.0%. Fish suya constitute the high value of protein contents of 11.00%. The Result of the findings shows the crude fibre content of the types of suya has the result range of 13.30-16.40%. Beef suya constitute the high value of crude fibre contents of 16.40%. Crude fiber is a diet component that aids bowel movement and it is relevant in digestion as this promotes better absorption of food into the body. The Result of the findings shows the crude fat content of the types of suya has the result range of 13.30-14.90%. Chicken suya constitute the high value of crude fibre contents of 16.90%. It was recommended that For health benefit, patients who are anaemia in nature are recommended to eat fish and chicken suya which have high protein content (Amino acids) and that form part of the hemoglobin of the blood. Similarly, Patients with hypertensive condition, can make a choice of the meat suya which are very low in fat contents as this, fat itself is an indicators of the weight of the body and the heart.
Keywords: *Suya, Beef, Chicken, Fishes and Spices*

INTRODUCTION
Suya is a spiced, barbecued, smoked or roasted meat product, prepared basically from meat of animals. In developing countries like Nigeria, protein intake has been a cause of concern and suya has become a major source of protein in Nigeria. (Ngozi N.A 2017).

Suya is a spicy, traditional stick meat product that is commonly produced by the Hausas in Northern Nigeria from beef. Where rearing of cattle are an important pre-occupation and major source of livelihood for the people. (Adeniyi M.D., 2016).This leads to the production of ready -to-eat beef products such as suya, kilishi, balangu and kundi. suya is however the most popular as its consumption has extended to other part of the country. According to Effiong G.S. (2010), Suya is a popular, traditionally processed, ready to eat Nigerian meat product, which may be served or sold along the streets, in club houses, at picnics, parties, restaurants and within institutions. It is a mass consumer fast food. Its preparation and sales along the streets are usually not done under strict hygienic condition because they are still done locally with crude tools. (Dagem., D. G , 2010).Traditionally, processed meat products were produced and consumed in different countries throughout the world. According to Edem C.A and I.D. Miranda (2011), Meat is a highly perishable food product, just like milk as described by which unless correctly stored, processed, packaged and distributed may spoil quickly and become hazardous to consumers due to microbial growth. (Armand, Y.N., 2012). The objective of this study is to examine the Proximate Analysis of Prepared Meat Suya using three Animal Products such as Beef, Chicken and Fish.

MATERIALS AND METHODS

Materials

The meat products are Beef, Chicken and Fishes and as well as the Ginger, garlic, West African black pepper, hot pepper and groundnut oils and as well as the respective laboratory analytical instruments

Source of Sample

The meat products and the Suya spices were purchased from lokoja market center, lokoja, capital of kogi State, Nigeria. All reagents and chemicals used were of Analytical grade. Samples were taken to the laboratory immediately and analysed immediately after collected.

Chemical Analysis

The proximate configuration (ash, crude protein, moisture, crude fiber and crude fat) of suya were determined as described by AOAC methods. Carbohydrates were determined by the percentage difference in sum of other proximate parameters (ash, crude protein, moisture, crude fiber and crude fat from 100) as described by AOAC (2010)

Statistical Analysis

Data obtained from the proximate analysis were analyzed using the single factor analysis of variance (ANOVA). Correlations between each of the parameter from each Animal product were evaluated. Also correlations between same parameters from the three study meat Suya were equally compared.

RESULTS AND DISCUSSION

Table 1: The Chemical Composition of the Animal meat products samples

The Table 1 shows the chemical composition of the three Animal meat products samples (Beef, chicken and fish) are;

	BEEF	CHICKEN	FISHES
Carbohydrate (%)	$47.70^{a}\pm0.20$	$49.00^{a}\pm0.50$	$47.50^{a}\pm0.30$
Crude Protein (%)	$10.90^{b}\pm0.40$	$10.00^{b}\pm0.20$	$11.00^{b}\pm0.20$
Crude Fat (%)	$13.30^{c}\pm0.60$		
Crude Ash (%)	$4.40^{c}\pm0.15$		
Crude Moisture (%)	$7.30^{c}\pm0.40$	$7.20^{d}b\pm0.50$	$9.20^{c}\pm0.20$
Crude Fiber (%)	$16.40^{c}\pm0.60$	$14.70^{c}\pm0.80$	$13.30^{d}\pm0.10$

DISCUSSION

Low moisture contents below 10% with significant differences were observed for all brands of animal products of suya in Table 1 above. The moisture, crude protein, carbohydrate, ash, fiber and fat content of the animal product that made up of the prepared meat suya were analyzed using standard methods. The Result of the findings shows the moisture content of the types of suya with the range of 7.20-9.20%. Fish suya constitute the high value of moisture contents of 9.20%. According to Adeniyi M.D. (2016), he stated that, the low moisture levels may suggested that they might be less prone to microbial attack. Effiong G.S. (2010), reported that levels of moisture content give meaning to the presence of microbes in foods. The moisture content of any food is an index of its water activity and is used as a measure of the stability and susceptibility to microbial contamination. The relationship between the Ash content of the types of suya has the result range of 4.20-4.40%. The ash content is often regarded as an index of mineral content in biological mass. Ash constitutes the inorganic component of food and this provides us with an estimate of the mineral constituents of the food. (Dagem., D. G, 2010), However, the relationship between the protein content of the suya has the result range of 10.0-11.0%. Fish suya constitute the high value of protein contents of 11.00%. According to Ngozi N.A .(2017), she stated that Protein are required for body building, renewal of body cells and a host of other physiologic functions, as such, its relevance cannot be over-emphasized. It was reported by Harold, SK (2018) similar values of the protein content of beef meat made up of suya. The Result of the findings shows the crude fibre content of the types of suya with the result range of 13.30-16.50%. Beef suya constitute the high value of crude fibre contents of 16.50%. Crude fibre is a diet component that aids bowel movement and it is relevant in digestion as this promotes better absorption of food into the body. (Armand., Y.N., 2012). The Result of the findings shows the crude fat content of the types of suya with the range of 13.30-14.90%. Chicken suya constitute the high value of crude fibre contents of 16.90%.

CONCLUSION

For health benefit, patients who are anaemia in nature are recommended to eat fish and chicken suya which have high protein content (Amino acids) and that form part of the hemoglobin of the blood. Variable Blood ABO group patients can make a choice of the meat suya which do not have effects on their blood clotting system. Similarly, Patients with hypertensive condition, can make a choice of the meat suya which are very low in fat contents as this, fat itself is an indicators of the weight of the body and the heart. Conclusively, Animal products consumption serves as a pivot to good healthy living among people in the society at large,

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
In order to evaluate the effect of cassava leaf meal as supplement in commercial concentrate diets on yolk colour of quail eggs, a trial was carried out in National Root Crops Research Institute, Umudike Poultry Unit for four months. The design was a completely randomized layout with two hundred and forty Japanese quail hens at twenty-one days, allocated to four different diets and three replicates. The treatments were: a commercial concentrate (CC); CC with 3% YRCLM (YRCLM3) and CC + 5% cassava leaf meal (YRCLM5). The degree of yellowness of yolks on the diet supplemented with 5% CLM was higher than for the control diet. The eggs from birds in the treatment with 5% CLM had darker and more chromatic yellow yolks than in the control treatment. The yolks of the Japanese quails supplemented with 5% CLM were heavier than the control treatments. The ratio between the weight of yolk and white was significantly higher in the diet with 5% cassava leaves meal than the control diet. Mean weight of Japanese quail eggs given the diet with 5% cassava leaves meal was significantly higher than for the other treatments as was laying rate and feed conversion.
Key words: *Quail eggs, yolk colour, cassava leaf meal.*

INTRODUCTION
Animal production in developing countries such as Nigeria is faced with various challenges mostly during the dry season of the year. The problem of feed shortage, high prices of feedstuffs and climate variation have been a major discussion in recent times (Agbabiaka, 2012) among poultry farmers. The effect of these challenges has reflection on the quality and quantity of animal protein available for human consumption (Agbabiaka, 2012; Ogbonna *et al*., 2000). To overcome some of these problems, attention of animal nutritionist must be focused on the utilization of lesser known unconventional feedstuffs that are readily available without stiff competition with humans and agro-allied industries such as cassava leaf meal.

Although there have been many studies carried out on the use of cassava products for livestock, little or no information is available on the effect of including them in diets for Japanese quails. The crude protein of cassava leaves can be as high as 350 g/kg of DM which under tropical conditions proved to be useful in diets for growing pigs to improve the dietary protein supply (Phuc *et al*., 2001).

Cassava leaves as food are a good source of protein, vitamins and minerals (Nassar and Marques, 2006). Cassava leaves contain significant amount of carotenoids, especially all-trans-beta carotene, a vitamin A precursor (Chavez *et al*., 2000). Vitamin A deficiency is a public health problem, which can lead to impaired ocular and immune systems growth and development, epithelial cellular integrity and reproductive functions (Wiseman *et al.*, 2017). Hence, increased use of cassava leaves may contribute to reducing vitamin A deficiency. Another important carotenoid present in cassava leaves is Lutein, which has an antioxidant potential (Ma and Lin, 2010).The objective of this experiment was to determine the effect of cassava leaf meal as feed supplement on the colour of the yolks in Japanese quail eggs.

MATERIAL AND METHODS

Experimental design

The study was conducted with one hundred and twenty Japanese quails at 21 days of age and lasted until the end of the fifth week of lay. The quails were allocated in a completely randomized design with three treatments and three replications. The dietary treatments were:

CC: Control (commercial concentrate)
YRCLM3: CC + 3% yellow root cassava leaf meal
YRCLM5: CC + 5% yellow root cassava leaf meal

Feeds and feeding system

The nutrient composition of the commercial concentrate used was as follows: crude protein 31% and crude fibre <6%. The control diet consisted of the concentrate only (Vital Feed Mill Company), while the test ingredient was mixed with maize and rice bran of the following proportions: (%, as fed): maize meal 45, rice bran 10.

Cassava leaves were collected from a farmer's demonstration farm in Amizi Olokoro in Umuahia South Local Government Area of Abia State. The clean, fresh, green cassava leaves were air-dried for two to three days and were then milled to a meal with a particle size less than 1 mm and stored in nylon bags before mixing with the control diet.

Measurements

Colour of yolk was measured by a colorimeter as described by Faquinello, *et al.,* 2004, which included three parameters: lightness or darkness of yolk (L); chromaticity coordinates (a and b), where a is redness, -a is greenness, +b is yellowness, and -b is blueness. The weights of albumen, yolk, and eggs were measured after collecting three eggs from each dietary treatment / replicate. The yolks of the quail eggs were analyzed for dry matter, crude protein, ether extract, calcium and phosphorus. Egg production and feed consumption were recorded every week from the sixth to fifteenth week of lay.

Statistical analyses

Data were analyzed by ANOVA using the General Linear Model and Turkey Test Comparisons of the Minitab Statistical Software version 12. The sources of variation were: treatments and error.

RESULTS AND DISCUSSION

The compelling need to harness the potentials of the numerous unconventional raw materials and agro-industrial by-products as part replacement for the more expensive conventional feed ingredients have been seriously expressed (Aderemi *et al.*, 2006). This need has arisen mainly from the increasing demand for and supply deficit of conventional feed resources with a concomitant sharp rise in their prices. The net effect of increased unit cost of the conventional feed resources is increased cost of the compounded rations, which by extension gives rise to increased cost of meat and animal products. It then becomes highly imperative that other sources for rapid livestock output to meet the growing human demands for animal protein foods are sourced. Such other sources should be cheap and nutritionally adequate for feeding animals with the aim of lowering the cost of producing meat.

Yolk colour

The quails fed the diets containing cassava leaf meal had yolks with lower values for lightness compared with the control (CC) (Table 1). Greenness, coming close to red, and chromatic value were higher for the yolk of eggs from the quails fed CLM5 than for the others.

Table 1. Effect of diet on yolk colour (Means and SEM)

	CC	YRCLM3	YRCLM5	SEM
Lightness "L"	$52.3^{b} \pm 0.18$	$51.3^{a} \pm 0.18$	$51.8^{ab} \pm 0.1$	0.25
Greenness "-a"	$-1.45^{b} \pm 0.13$	$-0.73^{a} \pm 0.13$	$-1.48^{b} \pm 0.13$	0.19
Yellowness "b"	$37.1^{b} \pm 0.31$	$39.7^{a} \pm 0.31$	$37.2^{b} \pm 0.31$	0.44

a, b: Means in the same row without letter in common are different at P<0.05

Yolk weight and the ratio between yolk and albumen weights

Eggs from quail fed the 5% cassava leaf meal (Table 2) had the heaviest yolks and the highest proportion of yolk. The nutrients in the 5% cassava leaf meal which was sourced from Pro-vitamin A variety was high, which also increased the pigmentation of the yolk which was converted into the nutrients of yolk by the laying quails. This explains why the quails supplied with 5% cassava leaf meal laid eggs with higher ratios between yolk and albumen and heavier yolk weight than the quails given the other diets.

Table 2. Effect of diet on yolk weight and the ratio between yolk and albumen weight

	CC	YRCLM3	YRCLM5	SEM
Albumen weight (g)	$5.62^{a}\pm0.051$	5.72a ±0.051	$5.64^{a}\pm .050$	7 .1
Yolk weight (g)	$3.35^{b}\pm0.033$	$3.36^{b}\pm0.033$	$3.48^{a}\pm0 .032$	6.2
Yolk, % of yolk+albumen	$59.9^{b}\pm0 .006$	$59.2^{b}\pm0 .006$	$62.0^{a}\pm .006$	0.8

a, b: Means in the same row without letter in common are different at P<0.05

Nutrients in the yolks

Cassava leaves have more carotene and other pigments that are incorporated into the yolk, which might explain why yolks of the quails fed 5% cassava leaf meal appeared to have the highest dry matter content (Table 4).

Table 3. Effect of dietary supplements on the nutrient composition of yolk (%)

Parameters	CC	YRCLM3	YRCLM5
DM	51.5	56.5	51.7
CP	30.9	29.0	29.3
EE	62.3	59.2	64.1
Ca	0.39	0.34	0.39
P	0.86	0.71	0.91

Egg weight and production

Eggs from quails fed 5% cassava leaf meal tended to be heavier and laying rate and feed conversion were better than on the other diets. It is probably because the rich array of nutrients in the leaf of the Pro-vitamin A Cassava was responsible for these effects.

Table 4. Effect of diet on egg weight and rate of production

Parameters	CC	YRCLM3	YRCLM5	SEM
Mean egg weight (g)	$10.6^{b}\pm 0.04$	$10.8^{ab}\pm 0.04$	$10.9^{a}\pm 0.04$	0.06
Egg production (%)	$87.8^{ab}\pm0.8$	$85.2^{b}\pm 0.8$	$89.6^{a}\pm 0.8$	1.2
Feed /egg (g /g)	$29.3^{ab}\pm 0.22$	$29.9^{b}\pm0.22$	$28.8^{a}\pm0.22$	0.3

a, b: Means in the same row without letter in common are different at P<0.05

CONCLUSION

It can be concluded based on finding of this study that supplementing rations with pro-vitamin "A" cassava leaf meal to improve japanese quail eggs yolk colour at the inclusion level of 5% of cassava leaf meal in quail diets improved yolk colour, feed conversion and mean egg and yolk weights.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This experiment was conducted to determine the effect of feeding tigernut meal on haematology and blood chemistry of female weaner rabbits at graded levels of inclusion (0%=T_1, 10%=T_2, 20%=T_3 and 30%=T_4). Twenty-four (24) clinically, healthy female weaner rabbits were used in the experiment to evaluate the effect of feeding varying levels of tigernut meal diet which was randomly divided into 4 groups of 6 animals per treatment with 2 animals per replicate given 3 replicates per treatment, in a completely randomized design. Water and feed were given ad libitum. The experiment lasted for 120 days. Simple Descriptive Statistics and Analysis of Variance were used to analyze the data while the New Duncan's Multiple Range Test was employed to compare treatment means. The blood chemistry and haematology showed no significant different ($P>0.05$) in PVC, Hb, RBC while MCV and MHC differed significantly ($p<0.05$) between WBC, neutrophil and lympocyte for T_1 to T_2, T_3, and T_4 showed no significant difference ($P>0.05$) among them. This study revealed that tigernut meal is rich in carbohydrate, it also showed that the tigernut meal could be used as a partial or total replacement for maize at upto 30% level of inclusion without any adverse effect on the blood indices of the female weaner rabbits.

INTRODUCTION
The high cost of maize as the main energy source for livestock and a staple food for Nigerians and Agro-allied companies including brewing industries cannot be over- emphasized. The resultant effect is high cost of animal protein hence inability of the populace to meet the minimum dietary protein intake of 56g per person per day as recommended by the Food and Agricultural Organization of the United Nation (Fasuyi, 2005).
Many attempts have been made to solve this problem through the use of some non-conventional energy sources in livestock such as maize offal (Vantsawa *et al.*, 2008), cassava (Udedibie *et al*., 2009). These tuber crops have been found to be of good potential but with limited crude protein content which is often below 3%.
Tiger nut is a tuber rich in energy content (starch, fat, sugar), minerals (mainly phosphorus and potassium), and vitamins E and C thus, making the tuber also suitable for diabetic patients to take (Ekeanyanwu and Ononogbu, 2010). Tiger nut tubers contain almost twice the quantity of starch as potato or sweet potato tubers. The oil of the tuber was found to contain 18.0% saturated (palmitic acid and stearic acid) and 82.0% unsaturated (oleic acid and linoleic acid) fatty acids (Ezeh *et al*., 2014). The moderately high content of phytosterols further enriches the quality and value of tiger nut oil as a food source, according to Consejo Regulador de Chufa de Valencia (Regulating Council for Valencia's Tigernuts, 2002).There is paucity of information on its potential as rabbit feedstuff in Nigeria, this study is therefore designed to evaluate its suitability as replacement for maize in rabbit production and the increase rearing of rabbit will improve and complement the quantity and quality of meat supply in the country.

MATERIALS AND METHODS
The experiments were carried out at the Rabbitary Unit of the Teaching and Research Farm of Abia State University, Umuahia Location. The Campus is located within the Southeastern Nigeria and lies between Longitude 07º 33' E and Latitude 05º 29' N at about 8km East of the Umuahia-Ikot Ekpene road. It is 140 km North of Port Harcourt International Airport, 135 km South of Enugu Airport and 80 km East of Owerri Airport. The experiment lasted for 120 days. The tiger nut seeds were purchased from "Ama Hausa" in Umuahia in Abia State, Nigeria. The milling was done at Feed Mill Unit of National Root Crops Research Institute, Umudike. Twenty-four female weaner rabbits were used for the experiment and were assigned to the four treatment diets following Completely Randomized Design,

where each treatment had six rabbits which was further replicated 3 times with 2 rabbits per replicate and the breed used for the studies was New Zealand White with an average weight of 980g and 6-8 weeks of age. The rabbits were purchased from the rabbit unit of National Root Crops Research Institute, Umudike.

RESULTS AND DISCUSSION

Effect of tigernut meal on blood chemistry and haematology of rabbits

Effect of levels of inclusion of tigernut meal on haematology is presented in Table 1. The result showed no significant ($P>0.05$) effect on packed cell volume (PCV), haemoglobin (HB) and Red blood cell (RBC). In mean corpuscular volume (MCV), there were no significant differences ($P>0.05$) among T_2 (10%), T_3 (20%) and T_4 (30%) but they differed significantly ($P<0.05$) from T_1 (0%). The PCV, HB and RBC values obtained in this study are similar to the values reported by Mohammed *et al.* (2005) who fed similar diets to growing rabbits. In Mean Corpuscular Haemoglobin (MCH) of rabbits that consumed diets containing 10%, 20% and 30% of tigernut meal. The parameters (MCV and MCH) had similar trend indicating lack of abnormality. The values are close to the normal range of 60 – 73 fl and 16.23pg for MCV and MCH respectively (Chmurska-Gasowska M, *et al;* 2021). No sign of ill-health or abnormal values were reported during the period of the experiment. Abnormal values may be an indication of anaemia (Abu *et al.*,1999). It also means that it is not toxic to feed rabbits with diets containing 30% tigernut meal.

The effect of levels of inclusion of tigernut meal on white blood count is presented in Table 2.

In white blood cells, there were no significant differences ($P>0.05$) among T_2 (10%), T_3 (20%) and T_4 (30%) but they differed significantly ($P<0.05$) from T_1 (0%) and it was the same in the case for neutrophil. In lymphocyte, T_1 differed significantly ($P<0.05$) from T_2, T_3 and T_4 but there were no significant differences ($P>0.05$) between T_3 and T_4. The values are similar and fall within the normal range for health rabbits as reported by Ahamefule *et al*. (2006). In basophil and eosinophils there were no result.

The white blood cell counts (%) of monocytes, lymphocytes, basophils, neutrophils and eosinophils were also not significantly different ($P>0.05$). The values are similar and fall within the normal range for healthy rabbits as reported by Ahamefule *et al*., (2006).

The effect of levels of inclusion of tigernut meal on serum biochemistry is presented in Table 3. The albumin values showed no significant differences ($P>0.05$) among the treatments and the values fell within the normal range of 2.5 to 4.0 g/dl reported by Chmurska-Gasowska M, *et al;* (2021) The globulin values (1.02 to 2.02 g/dl) showed significant differences ($P<0.05$) among treatments. The values for T_1, T_2, $T_3$and T_4 were lower than the values reported by Chmurska-Gasowska M, *et al;* (2021) but similar to 1.94-2.26 g/dl obtained by Ani, A.O and Ugwuowo, L. C(2011) who fed various tropical energy feed resources to growing rabbits. The total serum protein values (4.42 to 5.53 g/dl) were within the range reported by Chmurska-Gasowska M, *et al;* (2021) but lower than 5.81-6.75 g/dl reported by Ani, A.O and Ugwuowo, L. C(2011) . Since total serum proteins, albumin and globulin are generally influenced by total protein intake Ani, A.O and Ugwuowo, L. C(2011) the values obtained in this study seemingly indicated nutritional adequacy of the dietary proteins. Abnormal serum albumin usually indicates an alteration of normal systemic protein utilization (Apata, 1990). Awosanya *et al.* (1999) demonstrated the dependence of blood protein on the quality and quantity of dietary protein.

Glucose level was significantly different ($P<0.05$) among treatments, the blood glucose was within the range 4.2-8.9mmol/1 reported by Fudge (1999). Since glucose level was within the normal range, possibilities of anorexia, diabetes, liver dysfunction and mal-absorption of fat, which are the symptoms of abnormal glucose level in the blood (Bush, 1991) is ruled out. The blood urea values were within the range of 2.50 to 5.80 mmol/l reported by Njidda and Hambagda (2006), who fed sesame seed meal to growing rabbits in tropical environment. Decreased blood urea may be associated with severe liver disease or protein malnutrition (Bush, 1991). There was no sign of ill-health observed in the rabbits and from the result of the feed analysis all the diets met the minimum levels required in the diets of growing rabbits. Serum creatinine levels were within normal range and did not differ ($P>0.05$) among treatment groups. The values obtained for animals on diets T_1, T_2 and T_3 were in consonance with the findings of Ahamefule *et al.*, (2009), who fed cassava peels processed using different methods. The results also suggest that there was no wasting or catabolism of muscle tissues, and that animals were not surviving at the expense of body reserve. This was a good indication that dietary protein was well utilized by the rabbits.

CONCLUSION

The result of this study indicated that the tigernut inclusion up to 30% may not have adverse effects on haematology and serum biochemical indices on the female weaner rabbits

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Historically, adding herbs and spices to animal feed has helped manage diseases. However, due to the usage of synthetic antimicrobial growth promoters (AGP), they have been ignored. The plant Mondai whitei is useful for treating diseases. This research was conducted using a total of 105 indigenous layers comprising seventy-five females and thirty males to determine their responses to inclusion of Mondai whitei at five varying dietary levels (0mg/kg, 500mg/kg, 1000mg/kg, 1500mg/kg and 2000mg/kg). The birds were randomly assigned to five dietary treatments with each treatment comprising 3 replicates of 7 birds each. The experiment was laid out in a Completely Randomized Design. Data collected include; growth performance, Internal and external egg qualities as well egg lipid profile in three phases (I, II and III). The results showed that age at maturity, egg weight, and average body weight all varied significantly (p>0.05) at phase I, there were no variations in feed intake, hen day egg production, FCR, weight gain, daily weight gain, eggs per dozen that were statistically significant (p0.05). Packed cell volume recorded highest (31.00% and 28%) at inclusion levels of 500mg/kg and 1000mg/kg at phase II the packed cell volume recorded highest (30.00% and 35.67%) at the inclusion levels of 1000mg/kg and 2000mg/kg and red blood cell was highest (6.40g/dl) at the inclusion levels of 2000mg/kg at phase I while in phase II, total protein was highest (6.80g/dl) and at phase III it was highest (7.50g/dl) at control levels (0mg/kg) and lowest (551.87mg/dl) at inclusion levels of 1000mg/kg at phase I and phase II recorded higher (653.95 mg/kg) at inclusion levels of (0mg/kg) and lower (574.63 mg/dl) at 1500mg/kg inclusion levels. This study concluded that inclusion level of Mondai whitei up to 2000g improved the weight gain and egg laying performance.

Keywords: *Mondai whitei, Herbs, antimicrobial.*

INTRODUCTION
Due to the rising population, there is a greater need for protein, which can be produced efficiently and in large quantities through animal production. Nigeria has the largest population in Africa with a population of over 200 million. The severe lack of animal protein in the diet of the average Nigerian calls for a logical response, such as raising livestock output to meet animal protein needs. It is impossible to overstate the value of poultry to the national economy given that it has grown to be a popular business for small-scale farmers who make considerable economic contributions to the national GDP. According to Aboki *et al.* (2013), poultry production has a significant impact on increasing employment prospects and animal food production in Nigeria. In the rural parts of tropical and sub-tropical countries, indigenous chickens are commonly available and are retained by the bulk of the rural population. Native African chickens are often hardy, able to thrive in rural settings, require little to no care, and can adapt to changes in feed availability.

In the last ten years, there had been strong opposition to the use of antibiotics as growth promoters. It is reasonable to be concerned about the negative effects that could arise from their application, such as the emergence of resistant microorganisms and possible negative impacts on human health (Rahmatnejad *et al.*, 2009). Breeders have been led by this to look for alternative substances that remove unfavourable reactions in chicken and a potential risk to human health. To enhance the performance and immune response of chicken, probiotics, prebiotics, and medicinal herbs have been employed as natural additions in poultry feeding (Peric *et al.*, 2010). Every day, more medicinal plants become available as possible sources of herbal feed additives for laying hens (Suriya *et al.*, 2012). This study examines the chemical composition and egg laying performance of native layers fed diets containing *Mondai whites*.

METHODOLOGY

Study Area

This study was conducted at the Poultry Unit of the Teaching and Research Farms, Federal University of Agriculture Abeokuta, Ogun State, Nigeria's. The study area lies in South-Western Nigeria's. The area has minimum and maximum temperatures of 20.66^{0}C and 35.48^{0}C, respectively. It is located around latitude 7013'49.46"N and longitude 3026'11.98"E, 76 meters above sea level. It experiences 1037mm of precipitation on average per year (Google Earth, 2015).

RESULT AND DISCUSSION

Proximate composition of test ingredient (%)

The Proximate composition of the test ingredients is presented in Table 1. *Mondai whitei* has dry matter content of 95.6%, Crude protein of 12.38%, ether extract of 5.00%, ash of 6.00%, Crude fibre of 17.50% and NFE of 59.12%. The mineral composition of the test ingredients has magnesium 9.34, potassium 10.31, calcium 9.12, phosphorus 6.85, sodium 5.61, iron 0.20 and manganese (0.74). The quantitative assay of phytochemical contents of *Mondai whitei* has tannin 0.840, flavonoid 0.872, steroid 0.362, saponin 1.043 and alkaloid, 0.451.

Table I: Percentage chemical composition of *Mondai whitei*

Proximate (%)	Quantity	Minerals(mg/g)	Quantity	Phytochemicals	Quantity
Dry matter	95.23	Magnesium	9.34	Tannin	0.840
Ether extract	5.00	Potassium	10.31	Steroid	0.362
Crude protein	12.38	Calcium	9.12	Saponin	1.043
Crude fibre	17.50	Phosphorus	6.85	Flavonoid	0.872
Ash	6.00	Sodium	5.61	Alkaloid	0.451
NFE	59.12	Iron	0.20		

NFE= Nitrogen free extract

The result of *Mondai whitei* on body weight, age at maturity and first egg weight is presented in Table 2. *Mondai whitei* had no significant (p>0.05) effect on the age at maturity, body weight and egg weight of the birds. Birds on inclusion levels of 500mg/kg and 1000mg/kg recorded higher (182.33 and 182.00, respectively) age at maturity while average body weight was highest (950 g) at inclusion levels of 1500mg/kg and also egg weight was highest (38.03) at inclusion levels of 2000mg/kg.

Table II: Effect of *Mondai whitei* on body weight, age at maturity and first egg weight

Inclusion (mg/kg) Levels **Parameters/level of inclusion**	0	500	1000	1500	2000	SEM	P-Value
Age at maturity (days)	179.69	182.33	182.00	179.00	178.00	0.87	1.39
Egg weight (g)	33.50	37.18	30.31	34.54	38.03	0.003	0.83
Average body weight (g)	936.7	913.3	913.3	950.0	906.7	0.81	1.20

SEM= Standard error of mean

The result of the effects of *Mondai whitei* on the laying performance of indigenous layers is presented in Table 3. At 0 – 5 weeks of lay, the effects of *Mondai whitei* on total feed intake, hen day production, daily weight gain and eggs per dozen was not significant (p<0.05). Birds fed at inclusion levels of 500mg/kg had significantly (p>0.05) higher daily weight gain while birds on inclusion levels of 1000mg/kg and 1500 mg/kg recorded higher (89.33g and 89.00g) total feed intake while inclusion levels of 2000 mg/kg recorded the lowest. Egg per dozen recorded higher (0.61) at inclusion levels of 1500 mg/kg follow by 2000 mg/kg and lower in 500 mg/kg. Weight gain recorded highest (180g) at inclusion levels of 500 mg/kg while it is lower (140g) at inclusion levels of 0 mg/kg. Hen day production recorded lowest (11.63) percentage at 500 mg/kg but slightly higher 25.97% and 24.53% at inclusion levels of 1500 mg/kg and 2000mg/kg and no mortality recorded across the treatment.In phase II, the result shows that there is no significant (p>0.05) differences across the treatments. Total feed intake was highest (123.67g and 122.03g) at inclusion levels of 500mg/kg and 1500 mg/kg and daily weight gain was high (3.42g) at inclusion levels 1000mg/kg. In phase III, weight gain and daily weight gain were significant (p<0.05). There was no significant (p>0.05) differences in hen day production, FCR, egg per dozen and as well as mortality.

CONCLUSION AND RECOMMENDATION

In conclusion and feeding of birds with diets containing *Mondai whitei* improved the intake of feed at inclusion levels of 1000 mg/kg and 1500 mg/kg. Inclusion of *Mondai whitei* at 500mg/kg, 1000mg/kg, 1500mg/kg and 2000mg/kg improve the weight gain. Hen day production was influenced at inclusion levels of 1500 mg/kg and 2000 mg/kg respectively in phase I, and in phase II at inclusion levels of 500 mg/kg and 1500 mg/kg. The recommendation suggested that dietary supplementation of *Mondai whitei* at inclusion level of 500mg/kg, 1000mg/kg, and 1500mg/kg. At inclusion levels of 1000 mg/kg and 1500 mg/kg, feeding birds meals containing *Mondai whitei* enhanced feed intake. The weight gain is improved by adding *Mondai whitei* at doses of 500 mg/kg, 1000 mg/kg, 1500 mg/kg, and 2000 mg/kg. In phase I, inclusion levels of 1500 mg/kg and 2000 mg/kg, and 500 mg/kg and 1500 mg/kg, respectively, had an impact on hen day production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A field experiment was carried out to determine the effect of different rate of Poultry manure (PM) and NPK 15:15:15 on vine length, number of leaves, plant height, number and weight of harvested tubers with the Proximate contents of sweet potato. The experiment was laid out in a Randomized Complete Block Design (RCBD) with five treatments replicated three times. The treatments were 0 kg/ha of poultry manure (PM) (no treatment), 15 kg N/ha PM, 30 kg N/ ha PM, 45 kg N/ha PM and NPK 15:15:15.. The result showed that, application of PM at 45 and 30 kg N /ha had a positive response significantly on vine length than other treatments. Nitrogen sources also favoured production of leaves and number of tubers but 45 kg N/ha of PM produced tubers with more weight comparable to 30kg N/ha than other rates and sources. Treatment with NPK 15:15:15 gave high value of ash content, crude protein, crude fat and crude fibre which also increases with increase in the rate of PM application. However, increase in N rate or source decreased carbohydrate and moisture content of the crop. Application of PM at the rate of 30 kg N /ha is therefore recommended for best growth yield of and DM of sweet potato since it also increased the quality in terms of crude protein

Keywords: *Poultry manure, proximate, tubers, quality, sweet potato*

INTRODUCTION

Sweet potato (Ipomea batatas) is one of the major food crops in the world, and it rank second to yam in Nigeria as a major important tuber crop, contributing to the people food requirement (Karam *et al*., 2009). The crop is particularly important crop for subsistence farmers in Africa and other developing countries. Sweet potato is a very important food security crop due to its relatively short growing period, tolerance to drought and high yield from poor soils. It is used as a famine reserve for many of these households (Ofor, 2011).

Sweet potatoes possess many positive health benefits including sources of anthocyanins, phenolic compounds and other bioactive compounds (Alum *et al.,* 2013). The vegetable crop also possesses antioxidant activities. Sweet potatoes is highly rich in nutrient elements. A 100g edible portion of sweet potatoes yield 360kj energy, 20.1g carbohydrate, 3.0g dietary fibre, 0.1g fat, 1.6g protein, 30.0mg calcium, 0.6mg iron, 25.0mg magnesium, potassium 337mg, thiamine 0.1mg, riboflavin 0.1mg, phosphorus 47.0mg, sodium 55mg, zinc 0.3mg, folate 11Ng, pantothenic Acid 0.8mg, Niacin (B3) 0.61mg, 79.8% Water, about 2.4mg vitamin C is reported in sweet potato and 0.25mg Vitamin B6. In spite of these, the nutrient compositions as documented by several authors have been revealed to vary from cultivar to cultivar (Eleazu and Ironua 2014). In another study, it was discovered that root and vine proximate compositions were shown to vary with sweet potato cultivars (Gebreegziabher *et al.*, 2014).

The tuber also contains significant amount of vitamins A, B1, B2 and C and minerals such as K, Na, P and Ca. The young leaves are also rich in protein, minerals and vitamins (Onwueme and Sinha., 2011). The crop is efficient in the production of carbohydrates, proteins, vitamins and cash income per unit area of land and time also, the yellow-and orange-fleshed varieties of sweet potatoes are high in beta-carotene, which can be converted into vitamin A in the intestines and liver. It has been shown that even small amounts of these sweet potatoes as a regular part of the diet will eliminate vitamin A deficiency in adults and children. (Magagula *et al*., 2010).

Poultry manure (PM) contains all 13 of the essential plant nutrients that are used by plants. Using poultry manure as a fertilizer for crops or trees may provide a portion, or all, of the plant requirements. The amount of nutrients provided depends on the nutrient content of the manure (lb of nutrient / ton of manure) and the amount of manure applied (ton of manure / acre) (Zublena *et al*., 2006). Because of the high nutritional and economic value, it is necessary to improve yield and its related traits that can be achieve through balance availability of all the nutrients in the crop. This work is therefore targeted to examine the effect of different rate of poultry manure application on the yield and nutritional composition of sweet potato.

MATERIALS AND METHODS

The experiment was conducted behind the Horticultural Unit Experimental Site of the Federal College of Agriculture, Moor Plantation, Ibadan, Nigeria. Soil and poultry manure samples were collected prior to the commencement of the experiment at random from the site at a depth of 0.15 cm using soil auger soil samples collected were air dried and sieved through 2mm sieve for both physical and chemical analysis. The poultry manure used for the experiment was air dried and taken to the laboratory for analysis before incorporated into the soil.

The experimental plot size of 19 m x 11 m (209 m^2) was laid out in a Randomized Complete Block Design (RCBD) with five treatments replicated three times. The size of each replicate was 19 m x 3 m. each replicate was divided into five plots measuring 3 m x 3 m. the replicates were separated by 1 m alley in between while the plots were separated by 0.5 m. The treatments were 0 kg/ha (no treatment), 15 kg N/ha poultry manure, (PM), 30 kg N/ ha poultry manure, 45 kg N/ha poultry manure and NPK 15:15:15.

The land was cleared mechanically with the use of tractor, stumping was done manually using hoe and Cutlass, packed of debris and tilled. Heaps were made at a spacing of 1 m 1 m, the treatment poultry manure at specified rates were applied before planting (2 weeks before planting and was heavily watered for quick mineralization) Potato vine cuttings were obtained from a commercial farm in Ibadan. The variety used was Kenspot 4 (orange flesh with cream colour). The cuttings were planted at a space of 1 m by 1 m. NPK 15:15:15 was applied two weeks after planting. Weeding was done manually by hoeing before the establishment of the crop.

Data collection commenced 4 weeks after planting (WAP) and continued until eight weeks. Four plants were tagged on each plot for data collection Growth and yield parameters measured were; Vine length, Number of leaves, Number of tubers per plot and weight of tubers per plot which was converted to kilogram per hectare. .

Vine length of each sample plant was measured using a calibrated ruler. The number of fully expanded leaves of each tagged plant physically counted. The tuber of sweet potato harvested on each plot was weighed using the weighing scale in kilogram.

Harvesting was carefully done twelve (12) weeks after planting, by careful uprooting of the tubers with cutlass and hand. After harvesting, yield parameters were taken by weighing the harvested tubers and taken the samples to the laboratory for proximate analysis after air drying the sliced samples.

Data collected was subjected to Analysis of Variance (ANOVA) to test for significance of treatment on the crop and the significant means were separated using Least Significant Difference (LSD) $p<0.05$.

RESULTS

The result of the physical and chemical properties of the soil used for the experiment is presented in Table 1. It shows that the soil was slightly acidic with a pH of 6.8. Total nitrogen was at normal range (1.05 $mgkg^{-1}$) which falls within the normal standard value of 1-1.5, available phosphorus 12 $mgkg^{-1}$ compared to the standard value of 7-20 was high and organic carbon 1.42 $mgkg^{-1}$ compared to the standard value of 1.0 -1.4 was slightly high (FFD, 2021), Exchangeable base: potassium, calcium, magnesium and sodium were 0.30, 1.53, 0.41 and 0.31(cmol/kg) respectively. The textural class of the soil was sandy soil with sand (914 g/kg), silt (56 g/kg) and clay (30 g/kg). The result of the analysis of the Poultry manure used for the experiment is shown in table 1 and it revealed that the Nitrogen content is 18 %, Phosphorus is 24 % and Potassium is 0.90 %.

The effect of different rates of poultry manure on vine length of sweet potato was presented in Table 2.
At 4WAP, with 30kg N/ha poultry manure, the vine length (25.00cm) was significantly longer than control (16.01cm), 30kg N/ha poultry manure (16.95cm) and NPK 15:15:15 (15.83cm) but not significantly different from 45 kg N/ha poultry manure (23.50cm). At 6 WAP, 30kg N/ha poultry manure produced vine length 33.75cm which was significantly longer that control (20.50cm), 15kg N/ha poultry manure (20.67cm) and NPK 15:15:15 (22.42cm) but not significantly different from that of 45 kg N/ha poultry manure (30.42cm).
At 8 WAP the vine length of 45 kg N/ha poultry manure (48.58cm) and 15kg N/ha poultry manure (45.33cm) were significantly longer than control (31.42cm), 15kg N/ha poultry manure (30.33cm) and NPK 15:15:15 (33.08cm).
Effect of different rates of poultry manure on number of leaves of sweet potato was presented in Table 2. At 4WAP the number of leaves produced by 15kg N /ha poultry manure (11.33), 30kg N/ha poultry manure (11.50) and 45 kg N/ha poultry manure (11.83) were not significantly different from each other but were significantly higher than control (9.58) and NPK 15:15:15 (10.17) although control and NPK 15:15:15 were significantly different from each other. At 6 WAP 30kg N/ha poultry manure produced leaves which were significantly higher (19.17) than control (11.33), 15kg N/ha poultry manure (13.00), 45 kg N /ha (15.33) and NPK 15:15:15 (12.00) although control, 15kg N/ha poultry manure and NPK 15:15:15 were not significantly different from each other (Table 2). At 8 WAP, the leaves of 45kg N/ha poultry manure (31.50) was significantly higher in number than control (19.33), 15kg N/ha poultry manure (23.83), 30kg N/ha poultry manure (28.17) and NPK 15:15:15 (23.50) however, leaves of 15 kg N/ha and NPK 15:15:15 were not significantly different from each other.
The result of effects of different rates of poultry manure on number of tubers and tuber weight of sweet potato was presented in Table 2. The result revealed that, sweet potato responds positively to nitrogen fertilization from all the sources and rates also, sweet potato that received poultry manure of 30 kg N/ha produced tubers which were statistically similar in weight (281.33) with those that received 45 kg N/ha (271.00), but were significantly lower than other treatments.

Table 2: Effect of poultry manure rates and NPK 15:15:15 on vine length, number of leaves, number of tubers and tuber weight of sweet potato

Treatment	4 WAP	6 WAP	8 WAP
0 kg/ha (control)	16.01bc	20.50c	31.42b
15kg N/ha poultry manure	16.95bc	20.67c	30.33b
30kg N/ha poultry manure	25.00a	33.75a	45.33a
45kg N/ha poultry manure	23.50ab	30.42ab	48.58a
NPK 15:15:15	15.83c	22.42bc	33.08b
LSD (P=0.05)	7.53	8.48	7.71

Number of leaves

0 kg/ha (control)	9.58b	11.33c	19.33c
15kg/ha poultry manure	11.33a	13.00bc	23.83bc
30kg/ha poultry manure	11.50a	19.17a	28.17ab
45kg/ha poultry manure	11.83a	15.33b	31.50a

The result of nutritional composition of sweet potato is presented in Table 3. It was observed that sweet potato treated with NPK 15:15:15 had the highest value of ash content (2.30%) which was significantly higher than other treatments. This could be because, NPK 15:15:15 has the major macro nutrient to make adequate ash content available in the crop. Also, sweet potato treated with NPK 15:15:15 had the highest value of crude protein (8.60%) which was significantly higher than other treatments while the control had the least value of crude protein (1.90%).

Furthermore the highest moisture content (25.00%) was observed in sweet potato treated with control and was significantly higher than other treatments, while the least moisture content (21.00%) was observed in sweet potato treated with 30kg/ha poultry manure. Also the highest crude fibre (7.20%) and crude fat (3.15%) were observed in sweet potato treated with NPK 15:15:15 and were significantly higher than other treatment and the least crude fibre (2.09%) and crude fat (1.05%) were observed in control treatment. The result indicates that nitrogen in NPK 15:15:15 is enough for the crude fibre needed from sweet potato. However, application of PM at the rate of 45 kg N /ha can also provide reasonable amount of crude fibre from sweet potato (6.10).

Table 3: Proximate analysis of sweet potato

Treatment	Ash	Crude protein	Moisture content	Crude Fibre	DM	Crude fat	Carbohydrate
0 kg/ha (control)	1.03e	1.90e	25.00a	2.09e	68.93c	1.05c	69.93a

LSD(P=0.05	0.34	0	0	0	0.27	0.48	0

Significant means were separated by LSD P<0.05

DISCUSSION

The result of this experiment indicates that Nitrogen is needed for vegetative growth of crops and it buttresses the work of Zelalem *et al.*, 2009) who opined that Nitrogen in poultry manure is essential for increasing vine length plant height, leaf area index, shoot dry matter and tuber yield. This result shows the importance of Nitrogen for growth of crops and also that potato is highly responsive to N-fertilization and that N is usually the most limiting essential nutrient for potatoes growth and development (Mohammed *et al.*, 1998).

The result revealed that, sweet potato responds positively to nitrogen fertilization from all the sources and rates also, sweet potato that received poultry manure of 30 kg N/ha produced tubers which were statistically similar in weight (281.33) with those that received 45 kg N/ha (271.00), but were significantly lower than other treatments. This result corroborates the work of (Izunobi 2002) who reported that poultry manure, especially those provided from deep litter or battery cage house are the richest known farm yard manure supplying greater amounts of absorbable plant nutrient for optimum tuber growth and yield of crops.

Sweet potato is a tuber crop which although needs nitrogen but application of excess nitrogen affects the quality of the tubers. This also corroborates the work of Ahmad Ahmed *et al*., 2009) who also observed decline in some quality parameters of potato with increase in nitrogen rate. This could be the reason why the nitrogen in NPK 15:15:15 is sufficient for the crude protein in the crop.

The moisture content of any food is an indication of its water activity in the food and it is used to determine how stable and how susceptible the food is to microbial contamination (Howarth *et al*., 2001). The high moisture content recorded at zero application of PM implies that with increase in PM, concentration of other nutrients in the crop will decrease when dehydration occurs. This result corroborates the work of Idowu *et al*., 2023) who reported increase in the moisture content of eggplant, with increase application of PM. Fat is known to help the body to achieve satisfaction after eating and helps the body to absorb vitamin A, D and E (Agbenafle and Bart- Plange, 2015) and (Vishruta, 2014). The results shows that treatment with NPK 15:15:15 gave high value for crude fat significantly and that, increase in application of PM was decreasing the crude fat in the crop. .This could be because, sweet potato being a carbohydrate food, the normal N in NPK 15:15:15 is enough for the crop. (Idowu *et a*l 2023) also observed that increase in PM leads to decrease in the crude fat in egg plant.

Sweet potato treated with 30kg/ha poultry manure had the highest value off dry matter (79.00%) and was significantly higher than the other treatments. Furthermore, sweet potato treated with control had the highest value of carbohydrate content (69.93%) which was significantly higher than other treatments. (Idowu *et al*., 2023) also observed that control experiment gave the highest value for carbohydrate when different rate of PM was applied to the soil for planting eggplant.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Inadequate and poor weaning practices in addition to malnutrition remains' a serious public health challenge among the under-fives in developing countries, Nigeria included; since commercial weaning foods are not affordable and, to some extent, not available to the common man. Three weaning food samples (A, B, and C) were formulated from sweet potato, soybeans, groundnut, crayfish, and fish meal at the respective ratios of (70:10:5:15) for sample A, (60:20:5:10:5) for sample B, and (50:30:5:15) for sample C of varying quantities to make up 100g. Nutrend was used as a control (D) for commercial weaning food, and mineral composition was determined using the standard method. The mineral analysis of formulated sweet potato weaning food ranged from sodium (67.27 to 67.84mg/100g), potassium (39.17 to 45.29mg/100g), magnesium (66.44 to 67.37mg/100g), Phosphorus (425.04 to 446.22mg/100g) and calcium (8.38 to 9.05mg/100g) respectively. The mineral contents were significantly higher than the control sample except for calcium content, which had the lowest value.

Keywords: *Mineral composition, weaning food, sweet potato, formulated, malnutrition.*

INTRODUCTION
Weaning is a period of transition for the infant during which its diet changes in terms of consistency; therefore, the child is gradually introduced to semi-solid food (Garcia *et al.*, 2013). Weaning foods are foods and liquids given to infants other than breast milk or infant formulas for both nutritional and developmental reasons to enable the transition from milk feeding to family foods (Abeshu *et al*., 2016).

In developing countries, 70% of weaning foods are supplied by cereals, which are relatively poor sources of protein (Aduni *et al*., 2016). Apart from protein and energy, which infants need in their diet, magnesium, phosphorus, and microelements can be obtained by combining local staples. Unfortunately, the traditional methods also used in the preparation of these foods are accompanied by severe nutrient losses, which affect the nutrient quality of the diet, leading to a vicious circle of malnutrition and infection, possibly leading to death, resulting in high mortality and morbidity among weaning-age children (Mensa-Wilmot *et al.*, 2001).

Malnutrition is a major health problem in developing countries among children, which contributes to infant mortality, poor physical and intellectual development of an infant, lowered resistance to disease, and consequently stifles development. Protein-energy malnutrition occurs as a result of the unavailability of low-cost, high-quality food for low-income earners. This has led to the formulation and development of nutritious complementary foods from local and readily available food crops such as sweet potatoes (Mais and Brennan, 2008).

Sweetpotato (*Ipomoea batatas L*.) is one of the world's most important, versatile, and underexploited food crops (Olatunde *et al*., 2016). The sweetpotato (SP) tuber grows underground, ranges in flesh colour of pink to yellow, purple, or orange and is high in soluble carbohydrates, minerals, and vitamins. It plays an important role in improving household and national food security, health, and the livelihoods of poor families in Sub-Saharan Africa (International Potato Center, 2013).

Nigeria is the number one producer of sweet potatoes in Africa with an annual output of 3.36 million metric tons and is globally the second largest producer after China (FAO, 2000). The crop is grown for both human and animal consumption. It is the only crop among the root and tuber crops that has a positive per capita annual rate of increase in production in Sub-Saharan Africa. Food and Agricultural Organization (FAO) estimates of average potato yield of 5 to 8 t/ha are similar to the estimates from a survey conducted by State Agricultural Development Projects (ADPs) in Nigeria, which reported yields of popular local varieties of 7 t/ha in the south-eastern zones, 3.5 t/ha in the northern zone, and 7 to 8 t/ha in Plateau and Bauchi States (Tewe *et al.*, 2003). This study was carried out to assess the mineral composition of formulated sweet potato weaning foods.

MATERIALS AND METHOD

Sample Collection

Sweet potatoes (*Ipomoea batatas*-orange species) soy-beans (*Gylcine max*), Groundnut (*Arachis hypogaea*), crayfish (*Astacus Fluviatilis*) and dry-smoked catfish were all purchased from Eke-Awka market in Anambra State.

Sample Preparation

Sweet Potato: Exactly 8kg of sweet potatoes were weighed, washed, and then de-shelled. It was then cut into smaller pieces and weighed again which it now weighed 6kg. After which it was washed and cooked for 25 minutes in boiling water. It was then removed, sun-dried for 48 hours, and oven-dried at 70^{o}C for 24 hours. After which, it was blended, sieved, and packaged in an airtight container until use.

Soybean: The 2 kg of soybean was weighed, sorted, washed, and soaked for 3 hours. Thereafter, it was de-shelled and parboiled in boiling water for 30 minutes, after which it was de-shelled again before being sun-dried for 24 hours and oven-dried at 70^{o}C for 24 hours, making 48 hours of drying. This was then blended and sieved; it was then packaged in an airtight container until use.

Crayfish: Exactly 300g crayfish was weighed, then sorted and sun-dried for 48 hours, after which it was blended, sieved, and packaged in an airtight container until use.

Groundnut: A weight of 510g of groundnut was sorted and soaked for 30 minutes in slightly salty water, thereafter sun-dried for 48 hours. After which, it was blended and packaged in an airtight container until use.

The Fish Meal: The smoked fish weighing 500g was broken open and the head and some unwanted parts removed. It was pounded into pieces in a mortar using the pestle and sun-dried for 48 hours, after which both flesh and bones were blended, packaged, and kept for use.

The mineral analysis was determined using the Buck Scientific Flame Atomic Absorption Spectrophotometer.

RESULT AND DISCUSSION

Table 1 shows the sodium content ranged from 67.27-67.84mg/100g. There was a significant difference between the formulated samples and the control. The sodium content of the formulated food sample was higher than the control. Sodium is normally consumed in the form of salt. It is essential for the regulation of water content and in maintenance of the osmotic pressure of the body fluid (Okaka, 2010).

Potassium content shows a significant difference ($P<0.05$) across the formulated sweet potato weaning food blends and the control sample. Sample A (42.29mg/100g) was the highest among the formulated blends and was comparatively higher than the control sample (15.75mg/100g). The result is in agreement with the report of Laryea *et al.* (2018). It also falls short of the Recommended Dietary Allowance (RDA) of 60-160mg/100g day needed in children and infants (Koletzko *et al.*, 2008). Potassium is important in the body for the regulation of fluid, muscle control, and normal functioning of the nerves (Nieman & Butter, 1992).

The magnesium content obtained from the study shows there was no significant difference ($P<0.05$) in the magnesium content of samples A and B, though a slightly higher value was observed in sample A. The values were comparatively higher as compared to the control sample. This could be due to the blending effect, which might have increased the magnesium content (Laryea *et al*, 2018). Magnesium is needed in the body of an infant for a healthy immune system, strong bones, and to regulate blood sugar levels, thereby promoting normal blood pressure (Arinathan et al, 2003).

The phosphorus content of the blends ranged from 425.04 to 446.22mg/100g and was comparatively higher than the control sample with respect to samples A and B. It also fell short of the RDA of 200-1000mg a day needed in children and adults. Phosphorus is important for the synthesis of phospholipids and phosphor-proteins, viz., healthy bones and teeth (Jeremiah et al., 2017).

Calcium content of the formulated blends ranged from 8.38 to 9.05mg/100g and was comparatively lower than the control sample (10.16mg/g). Most of the commercial weaning foods are fortified, which could be a reason for the relatively high calcium content. The value fell short of the FAO/WHO recommendation of 210-500mg/100g.

Calcium forms a major component of bones, assists in tooth development, and plays a role in blood regulation (Okaka, 2005).

Table 1: Mineral Analysis of Formulated Sweet Potato Weaning Food

		Mineral	**(mg/100g)**		
Sample	**Na**	**K**	**Mg**	**P**	**Ca**
A	67.84 ± 0.00^d	45.29 ± 0.01^d	67.37 ± 0.00^c	446.22 ± 0.02^d	9.05 ± 0.07^c
B	67.59 ± 0.12^c	40.23 ± 0.01^c	67.27 ± 0.01^c	436.85 ± 0.09^c	8.78 ± 0.00^b
C	67.27 ± 0.35^b	39.17 ± 0.00^b	66.44 ± 0.01^a	425.04 ± 0.01^a	8.38 ± 0.04^a

D	66.95±0.01[a]	15.75±0.01[a]	66.92±0.09[b]	429.26±0.00[b]	10.16±0.08[d]
LSD	0.18	0.03	0.14	0.14	0.16

CONCLUSION

The study shows that formulated sweet potato weaning foods may serve as a good substitute for commercial weaning foods in the Nigerian market and in developing countries to improve the nutritional status of infants and help curb protein and energy malnutrition.

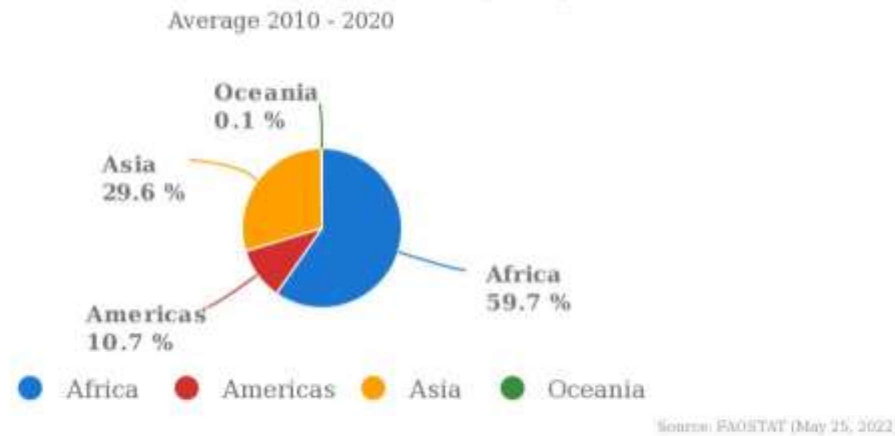
PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Nitrogen (N) is an important ingredient for the overall growth and development of all crop plants. Studies have shown that crops only utilize 50% of the applied nitrogen (N) in an efficient manner; the remaining 50% is lost through numerous pathways to the environment. Nitrogen loss pollutes the water body, soil, air and contributes to increased greenhouse gas emissions. Similarly, nitrogen fertilizers are usually costly and have a detrimental effect on the farmer's return on investment. In crop improvement programmes, increasing nitrogen use efficiency (NUE) is an important breeding objective. Nitrogen is highly mobile in the soil; volatilization, surface runoff, leaching, and denitrification of N are all responsible for low nitrogen uptake by plants. Therefore developing cassava variety with improved N uptake and utilization has become very fundamental since it would reduce the demand for extensive N application and reduce the damaging effects of N on the environment. Nitrogen use efficiency (NUE) is a polygenic trait, controlled by many genes, therefore, conventional breeding method, modern genomic tools, and high-throughput technology can be leveraged to engineer cassava varieties that respond to low-nitrogen tropical soils where cassava are predominantly grown. These would translate to a reduction in the economic and environmental costs of cassava production.
Keywords: *Cassava, nitrogen use efficiency, environment, sustainability, and productivity.*

INTRODUCTION
There is a lot of demand on arable land to produce more food and energy per unit area as a result of the pressure posed by the increasing global population. Agricultural practices must both intensify productivity and simultaneously protect the environment, human and animal welfare in order to achieve sustainable production. This approach includes improving the crop's nitrogen use efficiency (Xiong *et al*., 2018). According to IFAD (2021), over half of the entire world's arable land is degraded, and as a result, not all crops may be supported by its soil. The area of degraded soil is increasing at a rate of 12 million hectares annually or nearly 23 hectares per minute. The severity of the deterioration is endangering rural residents' livelihoods and access to food in addition to rendering the soil unprofitable. As a result, crops grown using artificial nitrogen (N) fertilizers contribute to the sustenance of over half of the global population (Zhang *et al*., 2015).
Nitrogen (N) is a key constituent of all living cells and is essential for the growth and development of plants. Nitrogen Fertilizer is the second largest requirement after water in crop production, and N is the most common yield-limiting nutrient in crop production (Marschner, 1995). Thus, the exogenous nitrogen supply, together with other essential nutrient elements, has allowed farmers to maximize genetic yield potential and boost crop productivity while satisfying the escalating need for food. Nonetheless, irrespective of the part of the world or crop genotype, crops do not use up to 50% of the nitrogen fertilizers applied to the field. The sustainability of ecosystems is now at risk as a result of the devastating effects of this nitrogen oversupply. The cultivation of cassava using inorganic nitrogen fertilizers has significantly increased the cost of production, caused soil acidification, more greenhouse gas emissions, and raised the level of nitrate in water bodies, all of which have severe adverse consequences on both the environment and humans (Behera et al., 2013; Ward *et al*., 2018).
As crop nitrogen recovery efficiency is less than 33% (Raun and Johnson, 1999), it is fundamental to boost the nitrogen use efficiency (NUE) of the crop, as an improvement in nitrogen use efficiency will not only decrease the excess nitrogen that gets to the cropland but also reduces nitrogen-provoked pollution in the environment (Norton *et al*.,

2015). Cassava (*Manihot esculenta* Crantz) has become one of the fastest-growing staple food crops in many regions of the world where it is cultivated and has continued to gain prominence globally, occupying a central place in food and feed industries that drive economic growth (FAO, 2018).

Fig 1.1 Production share of cassava by region



Cassava can be put to multiple uses, and the derived end products are essential in meeting the priorities of developing countries. World cassava production is estimated at 300 million metric tons; forty out of fifty-three countries on the African continent cultivate cassava, which amounts to more than half of the total cassava produced globally (FAO, 2019). In African sub-regions, where cassava is the major source of food for a huge proportion of people, yields have declined by 0.024t ha-^{1} year-^{1} (FAO, 2016). Nigeria's cassava production stands at approximately 60 million metric tons (FAOSTAT, 2019). Despite being the world's largest cassava producer, domestic consumption accounts for more than 90% of total cassava production (Denton *et al.*, 2004).

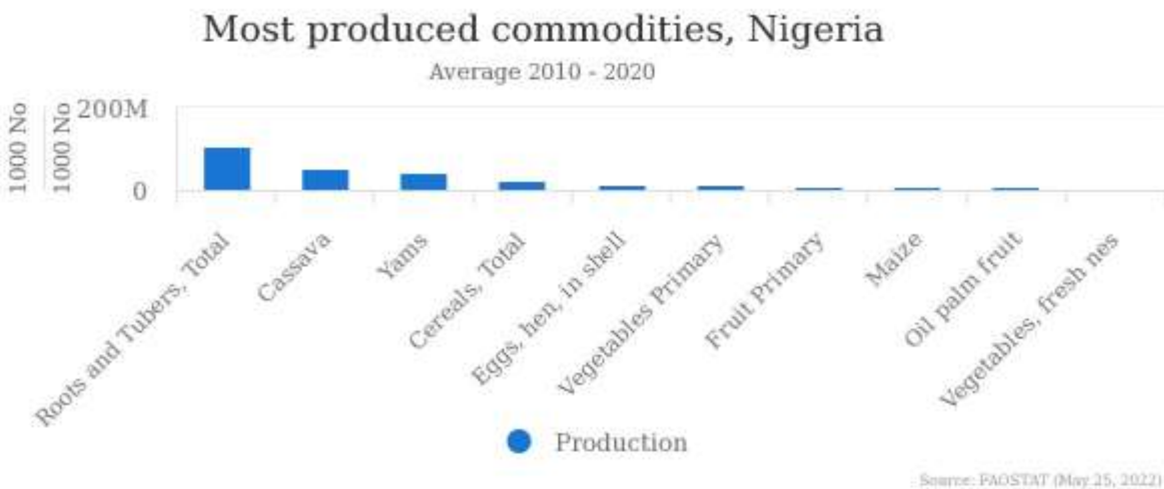

Fig 1.2c Cassava is the most produced commodity crop in Nigeria

Nitrogen fertilizer is the most commonly used nutrient and serves a crucial function in contemporary agriculture, especially in tropical ecosystems. In recent times, its demand has been on the rise because crop yields must be increased to sustain the expanding human population. Notwithstanding the cost, environmental pollution (Wang *et al.*, 2014; Shen *et al*., 2017), and pathogen infection (Huber and Thompson, 2007) challenges posed by nitrogen overuse, the nutrient element whose form is most limiting is nitrogen in tropical regions of the world where cassava is grown (IFDC, 2005; Hartemink, 2006). It is very mobile when applied to the soil, and crops are able to use only a small fraction of applied nitrogen fertilizers; only about half is utilized by crops (Raun and Johnson, 1999). Approximately 50% of fertilizer applied is lost to the environment, as a result of surface runoff, leaching, and volatilization.

Fertilizers of chemical origin usually have low use efficiency, which means that not all of the nutrients given to plants are absorbed (Adesemoye *et al.*, 2009). According to estimates, the overall effectiveness of chemical fertilizer applied to plants is less than 50% for N, lower than 10% for P, and about 40% for K (Baligar *et al.*, 2007). Plant genotypes that efficiently absorb and use applied nutrients save input costs and decrease nutrient losses to ecosystems. Plant interactions with environmental factors cause both intra- and inter-specific variance for mineral nutrient utilization efficiency (NUE) and growth of plants, which is known to be under physiological control and genetic and are further dependent on the interaction of plant and environmental variables. Very little work has been done to understand the variability in nutrient use efficiency that exists in the cassava gene pool. Among the macro-elements, nitrogen is an essential nutrient in crop production and cannot be substituted with any other nutrient element. Nitrogen-deprived plants truncate biomass and leaf elongation (Marschner and Marschner, 2012), retards photosynthetic activities and processes (Gregoriou *et al.,* 2007), reduces the size of chloroplast (Li *et al.*, 2013), and limits the overall plant *growth*. Yet, the majority of nitrogen added to crop systems frequently has little effect on productivity.

According to Borlaug and Dowswell (2005), nutrient-efficient crop genotypes will play a major role in sustaining crop productivity, mainly due to the high cost of inorganic fertilizer inputs and increasing environmental concerns. Breeding initiatives must concentrate on creating cultivars with high NUE. The efficiency of nutrient utilization should be considerably increased by identifying traits like mobilization, absorption, and use of nutrients in plant genotypes (Roberts, 2008). Developing nitrogen-efficient novel cassava varieties through the exploitation of genetic diversity with improved crop genetics and better agronomic practices would aid in increased crop productivity (Sandhu *et al.*, 2021). There are three key components to nitrogen absorption by plants: uptake, assimilation, and remobilization (Han *et al.* 2016), and these processes are governed by several cryptic genetic and physiological mechanisms. The efficiency of nitrogen utilization is defined as the capacity of the cassava genotype to grow, develop, and reproduce in the presence of nitrogen nutritional deficits in the soil (Fritsche-Neto *et al.,* 2010). Nitrogen use efficiency (NUE) is the result of nitrogen uptake efficiency (NUpE) and nitrogen utilization efficiency (NUtE) (Good *et al.,* 2004). Reports have shown that increased NUE has a positive significant correlation with crop biomass and yield (Stanley *et al.*, 2006; Wu *et al.*, 2016). This implies that selection based on NUE can enhance cassava productivity. Kant *et al.* (2011) also claimed that a 1% improvement in NUE may result in annual savings of $1.1 billion. Thus, in order to limit the cost of input, environmental contamination, and loss of plant nutrients, and reduce emissions of greenhouse gases, it is salient to breed cassava varieties with improved nitrogen use efficiency that can respond to low soil nitrogen.

Nitrogen use efficiency (NUE) is an index used to comprehend the connections between total nitrogen input and nitrogen output. Farmers will often apply excess nitrogen despite the high cost of fertilizer and perceive that all nutrients applied would translate to increased yield (Sheriff, 2005). However, not all nutrients applied to the soil are utilized by the crops; hence identification of cassava genotypes with enhanced nutrient use efficiency would save production costs and pollution in the environment associated with nitrogen overdose.

Contemporary approaches that can be adopted in crop improvement include traditional marker-assisted breeding, which involves the genetic mapping of genomic loci linked with the trait of interest in a segregating population or diversity panel and exploiting them upon functional validation in marker-assisted selection. Genome-wide association studies (GWAS) are generally used to study complex polygenic traits and identify QTL regulating variation in quantitative agronomic traits. This approach has been exploited to gain a genetic understanding of the processes associated with NUE-related phenotypes in several crop species (Liu *et al.,* 2016; Morosini *et al.,* 2017; Monostori *et al.*, 2017). However, not many GWAS studies have been applied to the diversity panel of cassava for agronomic traits (Shengkui *et al.,* 2018), and none for NUE-related traits.

In most studies on crops' performances under various treatment conditions, the correlation of traits with respect to nitrogen use efficiency will always show significant interaction with the environment under study, a clear indication that different results could be derivable within the same selection parameter under high or low nitrogen regimes (genetics by environmental interaction), Many studies suggest that selection of genotypes within target environment can be helpful, more especially for low nitrogen regimes (Lammerts van Bueren and Myers, 2011). Plant genomics primarily focuses on discovering the biological roles of genes; it bridges the genotype-phenotype gap; it aids in understanding not just the solitary impact of a gene but also how its genetic and environment interact with one another to modify its activity (Campos-de Quiroz, 2002). Genomics focuses on the science and technology of genome organization by combining three areas of study (Tinker, 2002; Johnson, 2004).

These studies include genetics, which is also defined as the investigation of the particulars of inheritance. The second part, which consists of automated lab equipment for high-output protein analysis (DNA and RNA), depends on the expanding knowledge of the biochemistry of nucleic acids. Lastly, the third area is molecular genetics and information, where information science is used to locate and align gene sequences in order to confirm how genes and gene products interact to construct genetic networks. This field is centered on the convergence of mathematics, statistics, biology, and computer science. In addition to offering methods for predicting phenotypes from gene sequences and related data, bioinformatics also reveals the molecular description of the genetic origins of phenotypes.

In cassava, nitrogen utilization efficiency is a complicated, quantitatively inherited characteristic that contributes to storage root yield. Knowing how quantitative features are inherited would help breeders choose the best breeding strategy. Mating design is a set of guidelines for organizing various regulated crossings as well as a process for creating offspring. Through mating designs, information is provided for evaluating parents' general combining ability (GCA) and specific combining ability (SCA), as well as estimates of genetic parameters and genetic gains (Klein *et al.,* 1973). Low adoption occurs as a result of certain enhanced cultivars not always meeting farmers' needs. According to earlier studies, farmers' demands are not being met when better crop varieties are not adopted widely (Manu-Aduening *et al.*, 2006). Local cultivars are still being grown by farmers because they meet their immediate needs but are often low-yielding and vulnerable to biotic and abiotic stressors (Sam and Dapaah, 2009; Manu-Aduening *et al*., 2007).

Improving the cassava fresh root yield of farmer-preferred varieties and increasing the acceptability or adoption of new cultivars will assist other stakeholders and farmers in increasing productivity and profit (Manu-Aduening *et al.*, 2014). This will necessitate gathering information on farmer preferences for new varieties. Any breeding program must begin by gathering data on farmers' perception of production challenges, preferences, and selection criteria for new genotypes (Efisue *et al*., 2007: Joshi and Bauer, 2006). Contrary to strict on-station breeding, getting farmers to participate in the identification and mitigation of perceived production constraints has led to a more coordinated breeding procedure and a higher success rate (Manu-Aduening *et al.*, 2014).

Finally, involving farmers in the development of varieties speeds up the spread and adoption of such varieties. Nitrogen-efficient cassava genotypes would increase smallholder farmer's income, and preserve the soil environment from nitrogen-based pollution since half of the external nitrogen applied to crop land is usually lost through various pathways to the surrounding environment. Hence developing resilient cassava varieties with improved nitrogen use efficiency should be given priority attention by all stakeholders.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Majority of undernourished people in Africa are found in the sub-Saharan sub region with high levels of poverty, hunger and malnutrition. Potato is the fourth most important staple crop after maize, rice and wheat, and among the oldest crop grown globally. The crop plays a significant role in addressing food and nutrition security in both rural and urban areas, increasing farmer's income and reducing poverty level of the household due to its high yield, excellent food value and early maturity. It is a good source of carbohydrates, proteins, vitamins, minerals, dietary fiber and phytochemicals. The crop provides 75 % more food energy per unit area than wheat and 58 % higher than rice. The protein content in potato is higher than that of animal origin like milk and beef; and has more protein per unit area than wheat and rice. Potato contains 57mg phosphorus, 425mg potassium and 23mg magnesium per 100g of fresh weight. The vitamin C content ranged from 13-30.8 mg per 100g tuber and higher quantities than other vegetables like pumpkin, onion and carrots. Potato has a promising prospect in improving food and nutrition security in both rural and urban areas. Therefore, promoting potato production can alleviate food insecurity, combat micronutrient deficiency, enhance household income and hence reduce poverty level among the farming communities.
Keywords: *Potato, food security, nutrition security, malnutrition*

INTRODUCTION
Potato (*Solanum tuberosum* L.) is believed to have originated from the highlands of Peru and Bolivia (Acquaah, 2012). It is the most popular nutritious vegetable and among the oldest crop grown for food worldwide (Sahair *et al*., 2018; Nityamanjari, 2018; Reddy *et al*., 2018). The crop was rapidly distributed into the world due to its potentials for providing food, preservation and eradication of poverty (Bradshaw and Bonierbale, 2010). Potato is the fourth most important staple crop after maize, rice and wheat, and is consumed by more than a billion people as a staple food worldwide (Zaheer and Akhtar, 2016; CIP, 2014; Nasiruddin *et al*., 2017). It is cultivated in more than 161 countries globally, on an area of 25 million hectares (Tessema *et al*., 2022). The estimated total world production stood at 388.2 million tons, Africa and Nigeria production was estimated at 25,011.800 million tons and 1,284,368 million tons in 2017 respectively (FAO, 2019). In developing of countries of Asia and Africa, increase in potato production is still high due to its importance as a staple food crop (Anonymous, 2016).

The major potato producing areas in Nigeria are located at the highlands of Jos, Plateau State, Mambilla Plateau, Taraba State, Obudu, Cross River State and Biu, Borno State with suitable climatic and edaphic conditions. The crop is mostly grown under rain fed and irrigated conditions, however, recent data revealed that potato can also be grown in some lowland areas of Northern Nigeria under adequate irrigation during the harmattan period. The crop plays a significant role in addressing food security and produce a large amount of food on small area of land (Jansky and Spooner, 2018). Potato is a high potential food security crop with good source of carbohydrates, rich in proteins, vitamins, minerals, dietary fiber and phytochemicals.

The nutrient rich potato can improve food security and health, especially among women and children, thus, reducing mortality rate cause by malnutrition (Kumari *et al*., 2018). Potato is an ideal food for both developed and developing countries due to its ability to be stored for long period of time with minimal technological inputs (Bradeen and Hayes, 2011). Availability of potato 60-120 days after planting as compared to other root and tuber crops confer advantage of double cropping during the rainy season, valuable source of food security and a sustainable source of income for those in production, processing and marketing of the crop. Potato can play a significant role in combating malnutrition which is a major challenges confronting many developing countries where most of the staple food crops are deficient in micronutrients. This current review looks at the contribution of potato in alleviating hunger, malnutrition and poverty in the rural and urban communities in Nigeria.

Contribution of Potato to Food and Nutrition Security

Majority of undernourished people in Africa are found in the Sub-Saharan sub region (FAO, IFAD, WHO, UNICEF, WFP (2020), of which Nigeria is inclusive. Potato is contributing to food and nutrition security of these highlands population through enhancing the quality of the basic diet, thus reducing mortality rate caused by malnutrition, increasing household income as a cash crop and hence reducing poverty levels in both rural and urban areas. Potato potential for higher yield per unit area, short period, and excellent food value is an important option for food security in many developing nations (Semahegn Asredie *et al*., 2015; Tessema *et al*., 2022). It is considered one of the most profitable food crops after rice and maize for the farmer (FAO, 2019). Majeed and Muhammad (2018), reported that potato is consider as one of the major vegetable and predominantly referred to as King vegetable as it produces more dry matter and protein per hectare than major cereal crops (Singha and Ullah, 2020; Storey, 2007). Potato has come to be a basic parts of breakfast, lunch and dinner among rural and urban populations and consumed in various forms like baked, roasted, boiled, fried and or in processed forms like chips, French fry, and potato powder (Nanbol and Timothy Namo, 2019; Farzana *et al*., 2021).

Stevenson *et al*., 2001, highlighted that potato cannot be match up with other food crop, not even soybean for production of food energy and food value per unit of land area. When compared to other potential food crop, potato provides more carbohydrates, proteins, minerals and vitamins per unit area of land (Zaheer and Akhtar, 2016). The crop contains 70-82 % water, 17-29 % dry matter, 11-23% carbohydrates, 0.8-3.0 % protein, 1.1 % mineral and 0.1 % fat (Nityamanjari, 2018). When boiled and eaten with its skin, 150g medium sized potato provides about half of the daily adult requirement of vitamin C, and 10% of the recommended daily intake of fibre (Panigrahi *et al*., 2017; Devaux *et al*., 2020). Kharumnuid *et al*. (2021), reported that there are approximately, 2.05g of protein in a 100 g fresh potato tuber, and provide more protein than maize with nearly twice the calcium when boiled (Panigrahi *et al*., 2017). Starch is the predominant aspect of carbohydrates in potato and supplied most of the energy obtained, and makes up 15-20 % on fresh weight and 60-80 % of the dry matter. Potato has 75 % more food energy per unit area than wheat and 58 % higher than rice (Nanbol and Timothy Namo, 2019).

Protein content in potato is of higher quality, higher than other major roots and tubers, major cereals and moreover, higher that proteins of animal origin like milk and beef (Singh *et al*, 2020). It has 54 % more protein per unit area than wheat and 78 % more than rice (Nanbol and Timothy Namo, 2019). Dereye and Chibuzo (2021) stated potato can provides 7 %, 6 % and 5% of daily energy, and 12%, 11%, and 10% of daily protein requirements for children aged 1-2, 2-3 and 3-5 years respectively. Potato contains minerals such as iron, potassium, phosphorus, and magnesium, and also folate, pantothenic acid, and riboflavin and source of vitamin B_1, B_3 and B_6. (Devaux *et al*., 2020). It is a good sources of iron and folic acid, which are very crucial for formation of red blood cells (Sahair et al., 2018). The crop contains 57mg phosphorus per 100g edible portion, 425mg potassium, and 23mg magnesium per 100g of fresh weight basis (Singh *et al*., 2020). The vitamin C or ascorbic acid content in potato ranged from 13-30.8 mg per 100g tuber (Dereye and Chibuzo, 2021). It contains high quantities of vitamin C than other vegetables like onion, pumpkin, and carrots and rich in dietary fibre which help in lowering cholesterols level, the dietary fibre ranged from 1-2g per 100g of fresh weight (Singh *et al*., 2020).

Potato contains phytochemicals with good medicinal potentials and contributes the highest antioxidant to human diet (Wijesinha and Mouille, 2019). These phytochemicals are known to help in neutralizing cancer cell, reduce blood cholesterol level, heart diseases and eye cataracts (Astley, 2005; Brown and Brown, 2005). Furthermore, potato are also used for the treatment of prostate and breast cancer, and stomach ulcers due to higher antioxidant content (Kumari *et al*., 2018; Ogbuagu *et al*., 2020), and consumption of potato are known to increase milk production in lactating mothers (Ahmed *et al*., 2015). Attributed to its correct balance between protein and calories, potato is considered a good weaning food (Bezabih and Mengistu, 2011). Similarly, Nanbol and Timothy Namo (2019) reported that potato is nutritionally considered to be a well-balanced food crop with good ratio between protein and calories, rich in essential vitamins especially vitamin C, minerals and trace elements, hence, it is a wholesome major food crop that one can live by eating potatoes alone (Singh *et al*., 2020). Potato production in the highlands is constricted to small farm size and its labour requirement is less when compared to other crop like cereals. It is a transitional crop as it's matures earlier, which enable farmers survive the hunger months that occur during the rainy season. Potatoes are consumed in most urban centres of the country, where more than 85% of the biomass are edible, when weigh against other food crops like cereals.

CONCLUSION

Potato has a great potentials for sustainable food supply, in less time and less area. . It is a good source of carbohydrates, protein, vitamins, minerals, dietary fiber and phytochemical and a promising prospect for achieving food and nutrition security in both rural and urban areas. Therefore, promoting potato production can alleviate food insecurity, combat micronutrient deficiency, enhance household income and hence reduce poverty level among the farming communities in the highlands in particular and the country in general.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Field experiments were conducted in 2020 and 2021 cropping seasons in the Teaching and Research Farm, Agricultural Science Department, Alvan Ikoku Federal College of Education, Owerri, Imo State, Nigeria to evaluate the response of watermelon to four rates of pig manure. The investigation was carried out in a Randomized Complete Block Design with three replications. Treatments was composed of pig manure rates of 0, 5, 10, 15 tons per hectare. Parameters studied were number of leaves per plant, vine length per plant, number of fruits harvested per plant and weight of harvested fruits per plant. Data collected were subjected to Analysis of Variance (ANOVA) and significant treatment means were separated using Least Significant Difference (LSD) protocol. Results obtained from the two experiments conducted showed that plants that received application of pig manure at the rate of 15 tons per hectare gave the best performance in all the parameters studied and is therefore to recommended for watermelon cultivation in Owerri, South Eastern Nigeria.
Keywords: *Watermelon, pig manure,*

INTRODUCTION
Watermelon (*Citrullus lanatus*) is a crop with huge economic importance to man (Schippers, 2000). The fresh fruit is relished by many people across the world. It is a nutritious, sweet, thirst-quenching fruit. Watermelon like most vegetables is widely cultivated in the Northern Nigeria but greatly consumed in the Southern Nigeria (Poly-Mbah, 2008, 2012b). Farmers incurred a lot of losses in transporting watermelon fruits from Northern Nigeria where it is produced to Southern Nigeria where it is consumed (Poly-Mbah, 2010a ,2010b and 2012a) This is responsible for the high market price watermelon command in South eastern Nigeria. There is a need for massive watermelon production in the South Eastern Nigeria where it is highly consumed.

Some researchers have published reports on the use of poultry manure for the production of watermelon in South Eastern Nigeria (Enujieke, 2013) but the sustained release of nutrients is a challenge. Hence, the need to investigate the production of watermelon fruits in South Eastern Nigeria using pig manure.

It has been reported that pig manure is effective as a good source of nutrients for sustainable crop production (Enujeke et al, 2021). Research findings have revealed that the application of swine waste (pig manure) at the rate of 20 tonnes/ha could lead to toxic levels of sulphate in crop produced (Mbah et al., 2005). There is a need therefore to determine the pig manure requirement of watermelon in Owerri, South Eastern Nigeria.

MATERIALS AND METHODS
The two experiments were conducted in the Department of Agricultural Education Teaching and Research Farm, Alvan Ikoku Federal College of Education in 2020 and 2021 late session cropping. The site has been under the cultivation of vegetable crops for considerable number of years.

The field experiments were laid out using the Randomized Complete Block Design with three replications. Treatments were four rates of pig manure (0, 5, 10, and 15 tons/ha). Agronomic measurements taken were number of leaves per plant, vine length per plant, number of vine branches/plant number of mature fruits harvested per plant and weight of harvest fruits per plant. Data collected were subjected to Analysis of Variance (ANOVA) test and significant treatment means were separated using the Least Significant Difference (LSD).

RESULTS AND DISCUSSION

Results obtained showed that plants that received 15 tons/ha of pig manure were outstanding in terms of number of leaves/plants (Table 1) vine length/plant (Table 2) at 4, 6, and 8 weeks after planting (Table 1). This confirms the publication made by Aliyu, 2000 who stated that pig manure contains useful proportions of essential and major nutrients that sustains plant growth.

Table 1.- Effects of Pig Manure on Leaf Number at 4,6,8, and Weeks after planting

	2020 4 WAP	2021 4 WAP	2020 6 WAP	2021 6 WAP	2020 8 WAP	2021 8 WAP
T1	10.10	13.53	13.30	25.76	16.10	30.40
T2	16.20	31.63	22.30	33.53	26.50	35.86
T3	21.10	23.30	26.40	34.43	28.30	38.74
T4	25.50	33.96	28.50	39.63	31.10	42.96

LSD	**4 WAP**	**6 WAP**	**8 WAP**
2020	0.30	0.40	0.30
2021	0.52	0.28	0.17

Table 2.- Effects of pig manure on the vine length cm of the watermelon at 4,6 and 8 weeks after planting.

	4 WAP		6 WAP		8 WAP	
	2020	2021	2020	2021	2020	2021
T1	16.32	25.73	31.21	31.73	41.44	61.40
T2	60.38	56.40	117.44	70.30	137.24	148.53
T3	73.98	34.60	131.30	81.83	155.47	165.20
T4	79.96	58.93	162.46	89.73	201.36	187.06

LSD	**4 WAP**	**6WAP**	**8 WAP**
2021	0.5	0.7	0.8
2022	11.02	7.04	14.0

Data obtained on the number of harvestable fruits and weight of harvested fruits showed that the plants that received 15 tons/ha performed best among other treatments (Table 3). This result shows that application of pig manure at the rate of 15 tons/ha not only improved the soil conditions for watermelon establishment but also released adequate nutrient elements for yield enhancement. This finding is in line with reports made by Adekiya and Ojeniyi 2002, Mangila et al., 2008 and Enujeke et al., 2021.

TABLE 3
Effects Of Pig Manure On Fruit Member Per Plant And Fruit Weight (Kg) Per Plant At Harvest

	Fruit Number		Fruit Weight	
	2021	2022	2020	2021
T1	**1**	**1**	**3.31**	**2.13**
T2	**2**	**2**	**6.43**	**5.73**
T3	**3**	**4**	**8.74**	**6.93**
T4	**4**	**6**	**10.07**	**8.0**
LSD	**Fruit number**		**Fruit weight**	
	0.1	**0.15**	**0.3**	**0.2**

CONCLUSION AND RECOMMENDATIONS

The investigation here reported confirmed that the application of pig manure significantly affected all the parameters studied such that the pig manure rate of 15 tons gave the highest values in all the parameters studied and is therefore recommended.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Investigation into health safety of foods served by food vendors on the campuses of Kaduna Polytechnic was carried out. The research is aimed at investigating the safety of food sold by food vendors on how food safety management could be achieved. A total of 16 samples, 4 samples each of the campuses were collected. The samples were subjected to total plate count (enumeration of mesophilic Aerobic Bacteria), coliform count, yeast and mould count and gram staining for the identification of microorganisms isolated. The result of total plate count reveals colony count of $<1.0X10^2$ to 2.7×10^4 with sample CB having the highest. While sample SA and TA showed no growth of mesophilic aerobic bacteria. The result for coliform bacteria indicated no growth for 11 samples while 5 samples were positive for coliform bacteria which ranges from $1.5x10^2$ to 6.5×10^2. The result for yeasts and mould count revealed 13 sample were negative for yeasts and moulds while only 3 recorded growth for yeast and mould which ranges from $<1.0x10^2$ to 1.8×10^3. The isolated organisms were gram stained for possible identification and the result revealed the presence of bacillus species, staphylococcus species streptococci species, coliform species yeast species and mould species respectively. The result reveals that the organisms identified are the common spoilage organisms found in food. Although this study also revealed that most of the vendors had some knowledge of hygiene and safety practices, but they were inadequate. Knowledge insufficiency was presented by 47% and 48% of the respondents who were ignorant of the right temperature to preserve cold foods and the temperature that encourage the growth of bacteria respectively. Therefore, this recommends that, adequate hygiene practice should be carried out daily, foods should be freshly prepared daily and food samples should be subjected to routine laboratory analysis, while training sections are to be enhanced to ensure safety procedures are maintained.

Keywords: Safety of foods, Food vendors, Mesophilic aerobic bacteria, Coliform, Yeast and Mould

INTRODUCTION

Food according to Akintola, (2016) is defined as any substance consumed to provide nutrition support for an organism. Food safety is used as a scientific discipline describing handling, preparation and storage of foods in ways that prevent food-borne illnesses. Ali *et al.* (2011), Arendt (2010) and Evans *et al.* (1998) reported that the street foods are usually sold by vendors or hawkers at street side on cart or on campus small stalls. Street vendors are usually poor, uneducated, lack knowledge of food hygiene and handling, sanitation of the environment, food service, hand washing, source of raw materials and potable water (Khairuzzaman *et al*., 2014). Microbial food borne illness is major health problem associated with street foods, Multi-drug resistant food borne diseases is most common and approximately 30 million people suffer from these illnesses each year in Nigeria (FAO, 2012;Omemu and Aderoju, 2008)

In Tertiary institutions, food safety is affected by the unhygienic handling of foodstuff, health status of food vendors, poor sanitary conditions of markets, absence of adequate waste disposal facilities, use of contaminated water and kitchen equipment and poor food storage. Studies have shown that some food vendors in tertiary institutions engage unsafe hygiene practice (Ferami *et al.,* 2018). Documented reports also indicated that specimen collected from 40 kitchen workers revealed cysts of *Entamoeba histolytica* were isolated in the steel of 23 food producers (Mathee *et al.,* 2008) while salmonella paragraph, the causative agent of Typhoid fever, was also isolated from 3 food handlers (Holtby *et al.,* 2007). Eating away from home, especially in restaurants, has been found to be associated with a significant number of food-borne disease outbreaks in the United States (Gould *et al*., 2013). Therefore, the industry has a role to play in mitigating food-borne' disease outbreaks. Rocourt *et al*. (2003) opined that this can be achieved by addressing food handler related risk factors in these food establishments.

Statement of the Research Problem

Eateries are presently very important in the school and the society as many people eat outside home. It is of utmost importance that every food purchased must be safe for consumption. In spite of the various campaign by the National Food and Drug Agency, various organizations like the World Health Organization, the Federal and State ministries of health on the need for clean food, food safety management is still a challenge among food handlers in the tertiary institutions. In providing a safe food management, there is need for the food centers to practice good hygiene standard.

Objectives of the Study

This study was therefore aimed to investigate health safety of foods served by food vendors on the campuses of Kaduna Polytechnic. The specific objectives of the study are to:

i. To evaluate the level of awareness of food borne pathogens amongst the food vendors.
ii. To ascertain the microbial load of specific organisms found in the food sold in the eateries.
iii. To determine the level of food safety practiced by the food vendors at the eateries of Kaduna Polytechnic.

MATERIALS AND METHODS

The research design adopted for this study was the experimental and survey research design. The study area covered the entirety of the Kaduna Polytechnic four (4) campuses. The population of study comprised of all food vendors including students and staff of Kaduna Polytechnic who were involved in ready to eat food selling business. A multi stage sampling technique was used to select 32 respondents from each of the campuses representing (128) however, only (100) respondents participated fully in the research. A random sampling technique was used to select the food vendors from each campus. A random selection was also made by picking them from the eateries selected following the method of sampling of Fisher *et al.* (1998). The major instruments used for obtaining raw data were a well-structured questionnaire by the researchers and food samples from the vendors. The questionnaire contained 22 questions that were designed to acquire data on food safety management from the selected eateries. The questionnaire was validated at the department of Hospitality and Management Kaduna Polytechnic. Questionnaires were administered personally by the researchers to all the respondents. Freshly cooked food samples were obtained from the vendors, four (4) food samples were collected from each of the campuses making a total of 16 food samples in a mini plastic container to analyze for the safety of which were homogenized and incubated at $37^{o}C$ for 24 hours in the microbiology laboratory for the presence of microorganisms. Plates with identified microbial growth colonies were further isolated to identify specific microorganisms and their microbial load. Data obtained from questionnaire were analyzed using Statistical Package for Social Sciences (SPSS) version 20 and presented using percentage and frequency distribution tables.

RESULTS

A huge number of the respondents (74%) were female with 50% being single. A notable number (45%) of the respondents are between 18 and 25 years of age. Five percent (5%) of the food service staff had no formal education. 12% and 30% respectively had primary and secondary school education. However, more than half 53% of the food service staff had polytechnic and university education. Most 70% of the food service staff acquired their knowledge of food preparation by formal training while few 30% acquired the knowledge through observation. About 4% of the respondents had been in food business for 6 to 10 years; however, only 28% of the respondents had the health certificate to indicate that they have carried out the annual medical checkup while 72% could not present the health certificate.

Table 1. Shows results on the level of awareness of possible food borne pathogens and food borne illnesses amongst the vendors. A remarkable (85%; 60% and 78%) of the food service staff knew that *Salmonella* spp, *Staphylococcus aureaus* and *Vibrio cholera*, respectively are food borne pathogens while 55% of the food service staff did not know whether hepatitis A is a food borne pathogens. 13% disagreed that typhoid can be transmitted through contaminated food and 30% are not aware that abortion in pregnant women can be induced by food borne pathogen. Majority (87%) of the food service staff surveyed know that preparation of food disregarding hygiene rules causes food borne illnesses and (78%) are aware that improper heating of food causes food borne illnesses. The results also revealed the vendors agreed that children, pregnant women, elderly and travelers (91%; 79%; 88% & 78%) respectively were at higher risk of food borne illnesses.

Table 1: Knowledge of food borne pathogens and food borne illnesses.

ITEM	,	TRUE	FALSE	DO NOT KNOW
	Knowledge to possible food borne pathogens			
1.	Salmonella Spp	85	4	11
2.	Staphylococcus Aureus	60	20	20
3.	Hepatitis A	35	10	55

iii.	Elderly/age	88	05	07
iv.	Immune-compromised	58	25	17
v.	Travelers	78	02	20
vi.	Everybody	87	09	04

The results on Table 2. Shows the total plate count for mesophilic aerobic bacteria. The colony forming unit (cfu/g) ranges from No growth to 2.7×10^4 with sample CB (white rice and stew from CBMS) having the highest colony count of 2.7×10^4; followed by sample TC (*eba* and *Ogbono* soup: 2.6×10^3) from CST and sample SB (*Jollof* rice and beef: 2.0×10^3) from CASSS. Others are sample BA (*waina* and *miyan-taushe*: 7.3×10^2) from CES, sample SC (fried rice and beef
; 5.0×10^2) from CASSS. While sample C & CD (cooked beans and stew & *moimoi*) from CBMS had colony forming units $<1.0 \times 10^2$, Sample SA (*semovita* and Ogbono soup from CASSS) and TA (*Jollof* rice and beef from CST) had no growth of bacteria. From the result when compared to WHO and FAO standard of 3.0×10^2, (FAO/WHO, 2022) it can state that sample CB, CA, TC, BD,BC, BA, SC, and SB are above permissible levels of bacteria. Isolated organisms after gram staining discovered the presence of *Bacillus* species, *Staphylococci* species and *Streptococci* species, respectively. These organisms are responsible for food spoilage and food infection.

Table 2a: Analysis on Microbial load and Isolated Organisms

SIN	CODE	SAMPLE NAME	LOCA'I'ION	CFU/g	GRAMS STAINING REACTION	MICROSCOPIC IDENTIFICATION(ORGANISMS ISOLATED)
1	SA	Semovita and Ogbono soup	CASSS	NIL		No Bacteria isolated
2	SB	Jollof'rice and beef	CASSS	2.0×10^3	1.Gram positive rods 2.Gram positive Cocci	1. Bacillus species 2. Staphylococci species
3	SC	Fried rice and beef	CASSS	5.0×10^2	Gram positive rods	Bacillus species
4	SD	Moimoi	CASSS	2.6×10^2	Gram positive rods	Bacillus species
5	BA	Waina and Miyan-taushe	CES	7.3×10^2	1. Gram positive rods 2. Positive Cocci in cluster chain	1. Bacillus species 2. Staphylococci species 3. Streptococci species
6	BB	White rice & stew	CES	1.6×10^2	Gram positive rod	Bacillus species
7	BC	Akpu and Egusi	CES	4.0×10^2	1. Gram positive rod	1. Bacillus species

		soup			2. Gram positive cocci in clusters	2. Staphylococci species
8	BD	Fried rice and beef	CES	4.3 x 10^2	1. positive rod 2. positive cocci	Bacillus species Staphylococci species
9	TA	Jollof rice and beef	CST	NIL		No bacteria isolated
10	TB	FriedPotato/Stew	CST	1.0 x $l0^2$	Gram positive cocci in clusters	Staphylococci species
11	TC	Eba &Ogbono soup	CST	2.6 x 10^3	Gram positive rods	Bacillus species
12	TD	Fried plantain and stew	CST	3.6 x $l0^2$	Gram positive cocci in clusters	Staphylococci species
13	CA	Semovita & Egusi soup	CBMS	1.5 x 10^3	Gram positive rods	Bacillus species
14	CB	White rice & stew	CBMS	2.7 x 10^4	1. Gram positive rods 2. Positive cocci in cluster	1. Bacillus species 2. Staphylococci
15	CC	Cooked beans & stew	CBMS	< 1.0x$l0^2$	Gram positive rods	Bacillus species
16	CD	Moimoi	CBMS	< 1.0x$l0^2$	Gram positive rods	Bacillus species

Table 2b shows the result of total *Coliform* bacteria count. The result indicated that most of the samples had no colony forming unit; however, a considerate number of 5 out of the 16 samples showed the presence of colony forming bacterial ranging from 1.5x 10^2 (the lowest) up to 2.7x10^4 (the highest) for samples TC & CB respectively. The presence of *Coliform* bacteria in food or water is an indication of faecal pollution through direct or remote contamination. Their presence also indicates unhygienic sanitary practices. *Coliform* bacteria are responsible for infantile diarrhea in children.

Table 2b: Coliform Count

S/N	CODE	SAMPLE NAME	LOCATION	CFU/g	GRAM REACTION	MICROSCOPIC ·IDENTIFICATION
1	SA	Semovita and Ogbono soup	CASSS	NIL		No coliform
2	SB	Jollof rice and beef	CASSS	6.5 x 10^2	Gram negative rods	Coliform species
3	SD	Moimoi	CASSS	NIL	--	No coliform
4	BA	Waina and miyan-taushe	CES	2.5 x $l0^2$	Gram negative rods	Coliform species
5	BB	White rice and stew	CES	NIL	--	No coliform

15	CC	Cooked beans and stew	CBMS	NIL	--	No coliform
16	CD	Moimoi	CBMS	NIL	--	"No coliform

A further investigation into the samples for presence of yeast and mould indicated no growth; however, 3 out the 16 samples indicated the presence of microorganism growth with colonies which ranged from total count of (<1.0 x 10^2), (1.1 X 10^2) & (1.8x10^3) for samples BB, BA and BC respectively. An exploration in to food safety knowledge of food service staff as shown in the Table 3. exposed that 47% and 48% of the respondents were ignorant of the right temperature to store cold ready -to-eat food and the temperature that encourage the growth of bacteria respectively. More so, majority of the respondents 72% erroneously stated that contaminated foods always had a change in colour and odour while only 26% of the respondents could tell that clean is not the same as sanitized. Majority of the food service staff are aware of some safety practices as seen in Table 4. However, a notable percentage 20% could not tell if hands and arm jewelries were a source to food contamination. An additional investigation into food safety practice revealed about 10% of the respondents never wash their foods before cooking while about 43% of the food service staffs sometimes prepared their foods 4-6hrs before service.

Table 3: Knowledge of Food Safety

Knowledge of Staff Handling Food		TRUE	FALSE	DON'T KNOW
1.	Cold ready-to-eat food should be conserved at 40°c	45	08	47
2.	Bacteria multiply at approximately 90°c	50	02	48
3.	Contaminated food always have change in colour and odour	72	19	09
4.	Germs/microorganisms are in the skin, mouth, nose, of healthy food	80	15	05
Service staff				
1.	Clean is the same as sanitized	50	26	24
2.	Re-freezing illnesses the frosted. food causes food borne	58	22	20
Food service staff should				
1.	Bath regularly	96	00	04
2.	Wear hair cover/cap when handling food	90	02	08
3.	Wear apron when handling food	88	03	09
4.	Consider hands and arms jewelries as sources of contamination	68	12	20
Food service staff cannot safely handle food				
1.	When they have cold, cough and catarrh	79	17	04
2.	When sick with diarrhea even if hands are washed after trip to toilet	77	15	08
3.	When they have an open wound in the hands	83	02	15
4.	When an open wound in the hands is fully bandaged	43	40	17

DISCUSSION

The result shows that most of the foods produce in most of the ready to eat food vendors were contaminated with mostly bacteria. This could be from the raw materials and the sanitary conditions of the environment which the food were processed. Microorganism live throughout the kitchen and can easily move around by attaching themselves to people, food and equipment. Bacteria may pass from equipment to food which are not properly clean or from food to equipment when not properly sanitized before used. Most of the food contamination are from post contamination were due to mishandling of the food after processing before consumption. This is in agreement with the assertions of

Abdullah and Ismail, (2005). Contamination arises from personal unhygienic, dirty bench surface, on-kept consumption tools. The most important food safety problem is microbial food-borne illness. All those who handle food, including farmers, food producers, individuals who work in markets and food service establishments, and other food preparations, have a responsibility to keep food as safe as possible. As found out in this report, handling and environmental factors are precursor to food contamination. This is in agreement with the reports of Akintola (2016). To keep food safe, people who prepare food should clean hands, food contact surfaces, and fruits and vegetables; separate raw, cooked, and ready-to-eat foods; cook foods to a safe internal temperature; chill perishable food promptly; and defrost food properly. A good protocol for washing fresh fruits and vegetables includes removing and discarding outer leaves, washing produce under clean running water just before cooking or eating, washing under running potable water, scrubbing with a clean brush or with hands, and drying the fruits or vegetables using a clean disposable towel. Free moisture on produce may promote survival and growth of microbial populations. Therefore, drying the food is critical if the item will not be eaten or cooked right away.

There was a lack of knowledge among the food service staff about the critical temperatures of cold ready to eat foods and temperatures at which bacteria multiply. It is evident that most of the food handlers have a good knowledge of the needs to wash hands after some activities; moreover, this knowledge was translated to practice by the surveyed fast food outlets food handlers. This may be attributed to the fact that water and hand washing or toilet facilities are readily available in most of the food outlets surveyed. This assertions are in agreement with the reports Abdullah and Ismail, (2005) as a major cause of foodborne disease outbreaks among populace in cities also as reported by Rocourt *et al*. (2003). These important hygiene measures practiced by most of all the food service staff surveyed was very encouraging. The hands are the important vehicles for the transfer of organisms from feaces, nose, skin or other sites to food. Epidemiological studies of Salmonella Typhi, non Typhi Salmonellae, Campylobacter and Escherichia coli have demonstrated that these organisms can survive on finger tips and other surfaces for varying periods of time and in some cases after hand washing (King *et al.*, 2020).

CONCLUSION

The study involve the assessment of health safety of foods served by food vendors on the campuses of Kaduna Polytechnic. After the results obtained from study, it could be concluded that consumers in Kaduna Polytechnic are prone to food borne infections and food poisoning by consuming the foods. The result also showed the prevalence of some microorganisms found in the food such as Staphylococci species, Bacillus species, Streptococci species, Yeast species, Mould species and Coliform species. The result of this work has proved valuable information about food hygiene and safety practice in Kaduna polytechnic, the level of food hygiene and safety practices by food handlers is not satisfactory, some of the hygiene aspects need to be emphasized.

RECOMMENDATIONS

The researchers encourage the continuous education and training should strengthen food handlers' knowledge in area which seems to be lacking and also improve the status of their food hygiene knowledge, attitude and practice of food safety. Foods should be freshly prepared daily and ore so, food from these vendors should be subjected to laboratory analysis on a routine check to ensure safety measures are met.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Two field trials were conducted in 2014 and 2015 rainy seasons at the research farm of the National Cereal Research Institute Badeggi, Niger State within the Southern Guinea Savanna Agro ecological zone to test the response of soybean as influence by phosphorus level. The treatments were made up of five phosphorus level of 0, 20, 25, 30 and 35 kg/ha and were laid out in Randomized Complete Block Design (RCBD) with four replications. Various growth and yield parameters including plant height, number of leave plant, number of branches plant, leaf area plant, fresh pod yield plant^{-1} and fresh pod yield/ha^{-1}. Data collected were subjected to analysis of Variance (ANOVA) using GENSTAT statistical software (17th edition). Treatment means were compared using the least significant difference (LSD) at 5% level of probability. Result revealed that soybeans responded positively to phosphorus application. Application of 35kg/ha^{-1} of phosphorus levels produces significantly, higher fresh pod yield plant^{-1} and fresh pod yield/ha^{-1} than the rest of treatments whiles the control treatment had the lowest pod yield ha^{-1}
Keywords: *Soybean, Phosphorus Fertilizer, growth and yield.*

INTRODUCTION

Soybean (*Glycine max*) is an important leguminous crop that has great importance in sub-Saharan Africa. This is because of its high grain nutritional contents with 40% protein and 20% oil (Fokadu *et al.,* 2009); that make it an economically important crop for human and animal consumption. Soybean is also very important crop for rotation with cereals like maize and sorghum; because of biological nitrogen fixation that is important in improving soil fertility. Also, the plant is considered as a strategic crop in fighting world's food shortage and malnutrition problems (Thomas, 2004). It has been reported that food aids to displaced persons, malnourished people and HIV/AIDS patients are fortified with soybean derivatives (Thomas, 2004).

Despite the wide range of benefit that soybean could provide to subsistence farmer of sub-Saharan African, its productivity is very low (<2.0 t/ha^{-1}) in many of these countries as compared to more than 2.7 t/ha^{-1}productivity obtained in some developed countries (FAO, 2013). Among the several production constraints responsible for the low productivity of soybean especially in many humid tropical regions are soil acidity and its associated poor soil fertility (Staton, 2012). This is common when the soil pH drops below 5.0. Soybean performs well between the pH range of 6.0 and 7.0 with the optimum pH range of 6.3 and 6.5 for maximum performance, nutrient availability and nitrogen fixation (Jandong *et al.*, 2011). The effect of soil acidity on crop production arises from a combination of several factors, notably Aluminum (AL) toxicity which results from large dissolution of aluminum from clay minerals releasing AL^{3+} into soil solution which is the most important rhizotoxic form of the element (Hockenga *et al.,* 2003). Soybean has been reported to absorbed P fertilizers differently in alkaline soil depending on the pH, soil fertility and the nature of genotype (Fatima and choudhary, 2007). To improve crop production in acidic soils, liming has been used to ameliorate the problem of aluminum toxicity. However, liming the top soil remains a temporary solution due to the subsoil acidity. It has been reported that imbalanced and inadequate nutrition results in poor yield of soybean (Lamptey *et al.,* 2008). Due to fixation of applied P in alkali soils, higher doses of the nutrient are required to satisfy the fixation needs and the requirement of the crop (Lamptey e*t al.,* 2008). The alkali soils are generally poor in fertility and require optimum dose of nutrients for higher productivity (Olowoake, 2022). In many agriculture production systems, phosphorus has been identified as the most efficient essential nutrient after nitrogen (Lamptey *et al*., 2008).

The calcareous soil is wide spread throughout the world, thus the availability of phosphorus in these soil is low due to the high calcium carbonate ($CaCO_3$) content which led to chemical fixation of phosphorous (Elkoca *et al.*, 2010) Therefore objectives of this trial is to determine the effect of phosphorus fertilizer level on growth and yield of soybean.

MATERIALS AND METHODS

The experiment was conducted during 2014 and 2015 rainy season at the Research Farm of the National Cereal Research Institute Badeggi, Niger State within the Southern Guinea Savanna Agro ecological zone of Nigeria ($19^0 45^1$ and $7^0 31^1$). Soil samples were collected at the depth of 0-30cm at the research farm before sowing and the soil samples were analysis for physical and chemical properties following the procedure outlined by Olowoake, 2014). The plot size was 45m ×25m which was cleared and prepared manually. The experiment site was divided into 35 plots. Weeding was carried out at regular interval. The treatment consists of five levels of phosphorus fertilizer (*0, 20, 25, 30 and 35*kg/ha^{-1}) application. The design of the experiment was randomized complete block design and replicated four times. Seeds of Soybean were sown at two seeds per hole. The seed variety used was sources from National Seed Council Abuja and the variety used was TGX 1448-2E.

Data were collected on growth and yield of soybean. The height of five randomly selected plant were measure using meter ruler from the ground level to the tip of the upper most leaf and the average was recorded plant^{-1}. The leaves and branches of five randomly selected crops were counted and the average was recorded plants^{-1}. The length and width of five leaves were randomly selected from five plant were measure and multiplied with 2.325 constant proposed by Osei-yeboah *et al* (1983) to obtain leaf area and the average was recorded. Number of fresh pods was obtained by plucking all the pods of five randomly selected plants and average was recorded plant^{-1}. The harvested fresh pods were converted to hectare by multiplying with number of plant ha^{-1}

Statistical Analysis

All data collected were subjected to analysis of variance (ANOVA) using GENSTAT statistical software (17th edition). Treatment means were compared using the least significant difference (LDS) at 5% level of probability.

RESULTS

Table 1 shows the physical and chemical analysis of the soil used for the trial during the 2014 and 2015 rainy seasons. The soil chemical properties was generally low in organic carbon, total nitrogen, also low in phosphorus level. The electrical conductivity (EC) value of the soil (0.08 and 0.09 ds/m^2) indicated that the soils were not salt affected. From the result (Table1) the soil textural class at the experimental site was sandy loam. The soil was slightly acidic tending to alkaline (5.40 to 6.0) condition in water indicating moderate soil condition for crop production (Kamprath, 2009).

Table 1: Physico-Chemical Properties of Soils from 0-30cm at Experimental Site Badeggi, Niger State. During 2014 and 2015 Rainy Season

Soil properties	2014	2015
Particle size (g/kg)		
Clay	130	100
Silt	150	140
Sand	720	750
Textural class	Sandy Loam	Sandy loam
Chemical properties		
P^H (H_2O;1:2:5w/v)	5.40	6.10
P^H (0.01M $CaCL_2$; 2.5w/v)	6.20	6.60
Exchange Acidity (C mol/kg soil)	0.05	0.06
Electrical conductivity (mg/kg)	0.08	0.09
Bray/P (mg/kg)	6.40	7.55
Organic Carbon (g/kg)	4.10	7.55
Total N(g/kg)	0.18	0.31
Exchangeable Cations (Cmol/kg)		
K (Cmol/kg)	0.17	0.25
Ca (Cmol/kg)	4.15	5.25

Plant Height (cm)

Table 2 shows the effect of phosphorus fertilizer levels on the performance of soybean in 2014 and 2015 rainy season on plant height. There was a significant different ($p<0.05$) among the treatment means due to phosphorus fertilizer levels on plant height. The highest plant height of 39.71cm, 48.36cm was obtain from the phosphorous levels at 35kg ha^{-1} in 2014 and 2015 cropping season. The lowest plant height was recorded (22.33cm), 30.66cm at control where there was no application of phosphorus level in 2014 and 2015 cropping season.

Number of Leaves Plant^{-1}

Table 2 shows response of soybean as influenced by phosphorus fertilizer levels in 2014 and 2015 rainy seasons on number of leaves $plant^{-1}$. This was a significant different ($p< 0.05$) among the treatment means due to phosphorus fertilizer levels on number of leaves $plant^{-1}$ of soybean. The 35kg ha^{-1}recorded highest value of 35.36 and 39.35 in 2014 and 2015 cropping seasons whereas the control had the least value of 21.14cm and 25.29cm in 2014 and 2015 cropping seasons.

Number of Branches Plant^{-1}

Table 2 shows the response of soybean as influenced by phosphorus fertilizer level in 2014 and 2015 rainy seasons on number of branches $plant^{-1}$. There was no significant difference ($p<0.05$) among the treatment means due to phosphorus fertilizer levels on number of branches $plant^{-1}$ of soybean.

Table 2: Effect of Phosphorus Levels on Growth Parameters of Soybean in Badeggi, Niger State.

Treatment	Plant height (cm)		Number of leaves $plant^{-1}$		Number of branches $plant^{-1}$	
Phosphorus rate (kg ha^{-1})	2014	2015	2014	2015	2014	2015
0	22.33 e	30.66 e	21.14 e	25.29 e	14.17 a	16.24a
20	29.38 d	33.38 d	24.35 d	28.28 d	15.33 a	17.37a
25	32.40 c	37.42 c	28.29 c	32.36 c	17.48 a	18.44a
30	36.41 b	41.29 b	31.40 b	36.54 b	19.58 a	20.46a
35	39.71 a	48.36 a	35.36 a	39.35 a	21.28 a	22.48a
SE ±	3.48	3.52	3.32	3.46	3.41	3.50

Means followed by the same letter (s) in a column are not significantly different according to Duncan's Multiple Range Test at 5% levels of probability.

Leaf Area (cm^2) Plant^{-1}

Table 3 shows the response of soybean as influenced by phosphorus fertilizer level in 2014 and 2015 rainy seasons on leaf area $plant^{-1}$. The highest leaf area was recorded at 80kg ha^{-1}phosphorus fertilizer level (43.46), (48.56) in 2014 and 2015 cropping season and the least value was obtained in control plot.

Fresh Pod Yield (g) plant^{-1}

Table 3 also shows the response of soybean as influenced by phosphorus fertilizer levels in 2014 and 2015 rainy season on fresh pod yield $plant^{-1}$. There was a significant difference ($p<0.05$) among the treatment means due to phosphorus combination levels on fresh total shoot yield of soybean. Phosphorus fertilizer level at 35kg ha^{-1}

significantly produced higher mean value over the rest of the treatment, which was followed by 30kg ha^{-1}, followed by 25kg ha^{-1}, followed by 20kg ha^{-1}, and 0kg ha^{-1} which gave the lowest mean value among the treatment.

Table 3: Effect of Phosphorus Levels on Growth Parameters of Soybean in Badeggi, Niger State

Treatment	Leaf area (cm^2)		Fresh pod yield (gm) plant^{-1}		Fresh pod yield (kg) ha^{-1}	
	2014	2015	2014	2015	2014	2015
Phosphorus rate rates (kg ha^{-1})						
0	35.37a	36.34a	43.87e	49.23e	461.37c	570.73c
20	37.53a	38.43a	49.86d	55.86d	573.13c	663.42c
25	39.55	44.36a	55.23c	58.48c	665.25c	779.54c
30	41.33	46.66a	57.22b	61.38b	783.36b	864.63b
35	43.46a	48.56a	59.40a	65.35a	89.72a	970.75a
SE±	3.65	3.68	3.56	3.83	24.44	34.87

Means followed by the same letter (s) in a column are not significantly different according to Duncan's Multiple Range Test at 5% levels of probability.

Fresh Pod Yield (kg) ha^{-1}

Table 3 shows the response of soybean as influenced by phosphorus fertilizer level in 2014 and 2015 rainy seasons on fresh pod yield kg/ha^{-1}. There was a significant difference ($p>0.05$) among the treatment means due to phosphorus combination levels on fresh total yield ha^{-1} of soybean. Phosphorus fertilizer levels at 35kg ha^{-1}significantly produced higher means values over the rest of the treatments which was followed by 30kg ha^{-1}, followed by 25kg ha^{-1}, followed by 20kg ha^{-1}. The least mean values were obtained at 0kg ha^{-1} which was the control plot.

DISCUSSION

Phosphorus application in soybean recorded a significant variation due to varying levels. The soil phosphorus was low but increased significantly with the application of P. phosphorus application increased dry matter accumulation which consequently resulted into translocation of growth and yield traits Mustafa *et al.,* (2004). The increase in phosphorus content in soybean might be attributed to increase in growth resulting into increases in the capacity of plant roots to absorb more of the relatively less mobile phosphorus. This observation is similar to Malik *et al.*, (2006), who observed that application of phosphorus fertilizer up to 70kg P ha^{-1} or more; double the yield of soybean compared with plots testing low in P and with-out P application. This indicate the essentiality of P in soybean mineral nutrition. Chiezey *et al.,* (2013) reported that depending on the nature or fertility stature of the soil, phosphorus is very important and help in mobilization of soil phosphorus which help in plant growth and yield. The entire fresh pod yield improved significantly with P application Malik *et al.,* (2006) reported that plant height is a genetic trait but balance nutrition shows positive effect. Mustafa *et al.,* (2004) reported that P application significantly increased the phosphorus content in soybean shoot yield at harvest. Muhammad *et al.,* (2004) observed that increases in phosphorus content with higher levels help in mobilization of soil phosphorus into available form as a result of action of acid produced by the soil added phosphorus.

CONCLUSION

Application of 35kg ha^{-1} of phosphorus level produced significantly higher fresh pod yield plant^{-1} and fresh pod yield ha^{-1} than the rest of the treatment, while the control treatment produced significantly lower similar traits. Farmers who are into soybean production in Badeggi, Niger State in the Southern Guinea Savannah Agro-ecological zone of Nigeria are advised to used 35kg ha^{-1} of phosphorus levels because it produced significantly higher fresh pod yield plant^{-1} and fresh pod yield ha^{-1} than the other treatments.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Piper guineense seeds, leaves and stems are among the plant parts commonly used as spices and herbs in medicine. This work was carried out to highlight some proximate, phytochemical and minerals composition in the leaves, seeds and the stems of Piper guineense. The healthy parts were selected, air-dried and pulverized for analysis. Result from phytochemical analysis showed that the highest alkaloid content was recorded in Uziza leaves (0.86mg/100g) and stem (0.42mg/100g). Uziza seed had the highest flavonoid content (1.58mg/100g). The highest phenol content was recorded in Uziza stem (0.34mg/100g). The result from mineral composition showed that the highest calcium content was obtained from the leaves (45.02mg/100g), and stem (21.58mg/100g). The highest potassium content was obtained from the stem (10.72mg/100g). While the seed gave the highest sodium content (19.27mg/100g). The stem had the highest zinc content (0.92mg/100g). The results from proximate composition analysis showed that highest ash content was obtained from the leaves (9.19%). The highest crude fiber was recorded in Uziza stem (12.25%). The highest carbohydrate content was obtained from the seed (71.60%), while the highest crude protein content was obtained from the leaves (12.11%). Pearson Correlation result of the phytochemical composition showed that phenol had strong negative and significant correlation with Saponins ($r = -0.829^{**}$) and Flavonoids ($r = -0.716^{*}$). Phenol also had strong positive and significant correlation with Tannins ($r = 0.904^{**}$). Negative and significant correlation was observed between flavonoids and Alkaloids ($r = -0.846^{**}$) and Tannins ($r = -0.932^{**}$).
Keywords: *Piper guineense, phytochemical, anti-nutrients, spice, Uziza*

INTRODUCTION

Piper guineense herb is a West African spice plant commonly called ashanti pepper (Okoye and Ebeledike, 2013), u*ziza* in Igbo and Iyere in Yoruba. The plant is semi-cultivated in Nigeria, where it is found commonly in the southern part (Okwu 2001). It is used as spice for flavoring, seasoning and imparting aroma to food. They can be consumed as vegetable in human meals but have largely become forgotten foods in the modern westernized diet (Craig, 1999). One of the benefits of uziza is primarily due to its antioxidant properties. Free radicals generated by the body cause damage in living system resulting in oxidative stress (Alobi *et al*., 2012). Free radical scavengers (antioxidants) which are in uziza herbs have potentials to prevent many of human chronic and ageing diseases such as cancer, diabetes, heart disease, stroke, malaria, and rheumatoid arthritis (Agbaire, 2011). The seeds are consumed by women after childbirth to enhance uterine contraction for the expulsion of placenta and other remains from the womb (Mbongue *et al.,* 2005), as an anti-asthmatic and to control weight (Morebise *et al*., 2002). These plants are as important today as they were in ancient times for enhancing the flavor and taste of our foods. So many people consume vegetables because of their flavors and taste, and do not concern themselves with their nutritional composition. Ignorance concerning the nutritional properties of different plant parts and presence of some phytochemicals are the major reasons for underutilization of these plant. Therefore, the research findings from this work will enlighten the consumers on the phytochemical and nutrients composition of different plant parts of Uziza plant. The objective of this study is therefore; to compare the phytochemical and nutrients composition of different plant parts of uziza and to examine the relationship between the proximate composition and the phytochemical composition of some Uziza consumed in Nigerian.

MATERIALS AND METHODS

The fresh samples of the leaves, stems and seeds of *Piper guineense* (Uziza) were collected from Obuohia Ibere village in Ikwuano Local Government Area of Abia State, Nigeria. Phenolic compounds were determined by an HPLC method using an Agilent 1100 Series liquid chromatograph (USA) equipped with a UV/DAD detector. Determination of Saponins was done by the double solvent extraction gravimetric method (AOAC, 2005). $\% \, Saponin = \frac{W_2 - W_1}{W}$, Where W = Weight of sample used, W_1= Weight of empty evaporation dish, W_2 = Weight of dish + saponin extract. The tannin contents were determined using Folin Denis Reagent as described by Inyang and Emosairue, (2005). Calcium was determined using the method described by Pearson (1976). Ca (mg/1) = $\frac{T \, x \, M \, x \, E \, x \, 100}{Volume \, of \, sample \, use}$, Where., T = titer value, M = Morality of EDTA, E = Equivalent weight of calcium. The carbohydrates were determined by difference according to Oyenuga (1968) as follows; % Carbohydrates = 100 – (% moisture + % fat + % ash + % protein +% crude fiber). Crude protein was determined using the Kjeldahl method (Adeyeye, 2017). Statistical analysis; Data collected from this study was subjected to Analysis of Variance (ANOVA) test, using Genstat 12 software. Means was separated using least significant different (LSD) at 5% significant level. Pearson Correlation Coefficient used to estimate the linear relationships between the minerals and the phytochemical composition of the plant (Ofori, 1996) was computed using Statistical Package for Social Sciences (SPSS) for windows 2012 version, 21.0.

RESULTS

Phytochemical composition

Result from ANOVA showed that all the traits were highly significant ($P<0.01$). The result from the figure 1 showed that the highest alkaloid content was recorded in Uziza leaves with the value of 0.86mg/100g. This was followed by Uziza stem that had alkaloid content of 0.42mg/100g. Least alkaloid content was obtained from the Uziza seed (0.27mg/100g). However, the highest flavonoid content was recorded in Uziza seed (1.58mg/100g), followed by Uziza stem that had flavonoid content of 0.96mg/100g. Least content of flavonoid was obtained from the leaves (0.76mg/100g) (Fig. 1). The highest phenol content was recorded in the stem (0.34mg/100g). This was followed by the leave that had phenol content of 0.23mg/100g. Least content was obtained from the seed (0.12mg/100g). Similarly, the highest saponin was recorded in Uziza seed with the value of 2.61mg/100g. However, the stem recorded saponin content of 1.39mg/100g. Least saponin was obtained from the leaves (1.32mg/100g). The highest tannin content was recorded in Uziza stem (1.44mg/100g). This was followed by Uziza leaves that had tannin content of 1.28mg/100g (Fig. 1).

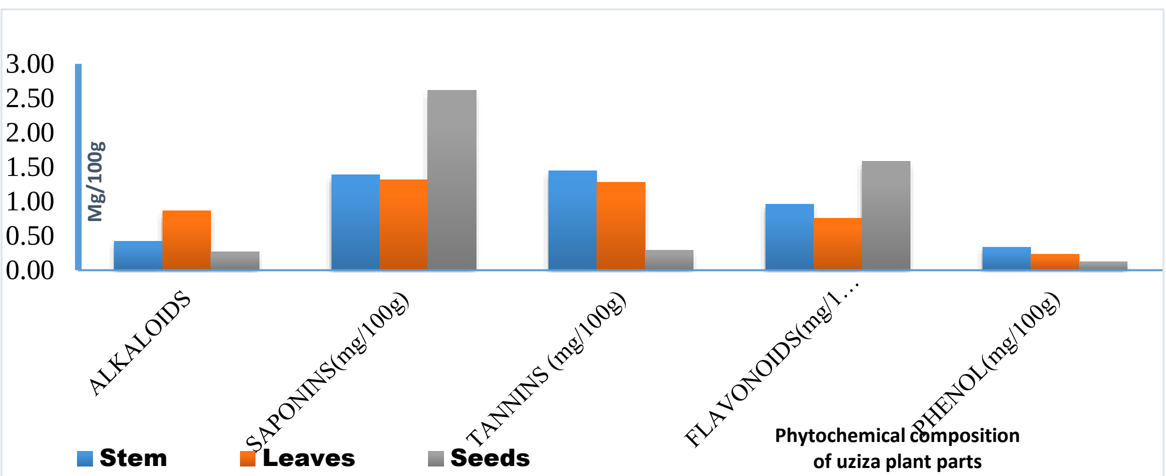

Figure 1: Bar chart of means for phytochemical contents of Uziza plant parts evaluated in Umudike

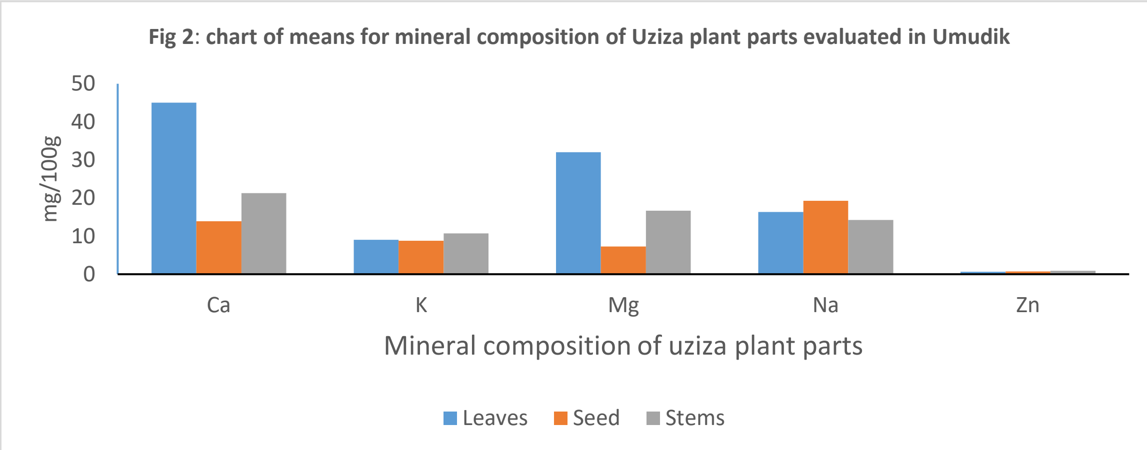
Mineral composition

The mean results showed that the highest calcium content was obtained from the leaves with the value of 45.02mg/100g, followed by stem (21.58mg/100g) and seed (13.87mg/100g). The highest potassium content was obtained from the stem (10.72mg/100g), followed by leaves (9.02mg/100g) and seed (8.80mg/100g). Also the highest magnesium content was obtained from the leaves with the value of 32.07mg/100g. This was followed by stem (16.67mg/100g) and seed (7.24mg/100g). While the highest sodium was obtained from the seed (19.27mg/100g), followed by leaves (16.34mg/100g) and stem (14.21mg/100g). With respect to zinc, the highest content was obtained from the stem with the value of 0.92mg/100g. This was followed by seed (0.73mg/100g) and leave (0.63mg/100g) (Fig. 1).



Proximate composition

Figure 3 presents the proximate composition of Uziza plant parts. Mean results showed that the highest ash content was obtained from the leaves with the value of 9.19%. This was followed by seed (5.69%) and stem (2.91%). The highest crude fiber content was recorded in the stem (12.25%), followed by the leave (10.30%) and the seed (3.46%). The highest carbohydrate content was obtained from the seed with the value of 71.60%. This was followed by stem (69.29%) and leave (57.22%), while the highest crude protein content was obtained from the leaves (12.11%). This was followed by seed (6.89%) and stem (2.74%). However, the highest ether extract content was obtained from the seed (3.61%), followed by the leaves (2.93%) and stem (1.38%). While the highest energy value content was obtained from the seed (364.48kcal/100g). This was followed by leaves (303.74kcal/100g) and stem (300.50kcal/100g). The highest moisture content was obtained from the seed (9.41%), followed by stem (9.28%) and leave (8.91%). Piper guineense stem, seed, and leaf phytochemical analysis provides a good dietary complement and also provides a significant quantity of anti-nutrient alkaloids, tannins, and spaonins that may also offer some health benefits to its consumers. These compounds may also help consumers consume less starchy meals, improve nourishment and protection, and avoid constipation. Above it all, it is also noted that Uziza leaves are affordable vegetables that can contribute to our nutritious values.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study aims to highlight the significance of orange-fleshed sweet potato as a panacea for hidden hunger among rural households in Ebonyi State, Nigeria. It will discuss the nutritional benefits of OFSP, its adaptability to local agricultural conditions, and the impact it can have on alleviating micronutrient deficiencies in the region. Hidden hunger, characterized by deficiencies in essential micronutrients, remains a critical public health concern among rural households in Ebonyi State, Nigeria. The introduction and promotion of orange-fleshed sweet potato in Ebonyi State can significantly contribute to reducing hidden hunger among rural households. By incorporating OFSP into their diets, communities can improve their overall nutritional intake and prevent micronutrient deficiencies. The cultivation and consumption of OFSP may lead to enhanced health outcomes, particularly for vulnerable groups such as pregnant women and young children, positively impacting their growth and development. Additionally, the study highlighted the socio-economic and cultural factors influencing OFSP adoption. Findings suggest that promoting OFSP cultivation and consumption holds great promise in combating hidden hunger, enhancing food security, and improving overall nutritional well-being in rural communities of Ebonyi State, Nigeria. This research contributes vital insights for policymakers and stakeholders seeking effective strategies to combat hidden hunger and promote sustainable nutrition security

Keywords: *Orange Fleshed Sweet potato, panacea, Hidden hunger and rural households*

INTRODUCTION

Hidden hunger, also known as micronutrient deficiency, remains a significant challenge in many developing regions, including Ebonyi State, Nigeria. It refers to the chronic lack of essential vitamins and minerals, such as iron, zinc, and vitamin A, in the diets of individuals and communities. This nutritional deficiency can have severe consequences, particularly for vulnerable groups like pregnant women, children, and the elderly, leading to impaired physical and cognitive development, increased susceptibility to diseases, and overall reduced quality of life. In recent years, increasing attention has been drawn to orange-fleshed sweet potato (OFSP) due to its potential as a sustainable solution to combat hidden hunger (FAO, 2010). FAO (2020), OFSP is a biofortified variety of sweet potato enriched with beta-carotene, a precursor of vitamin A. Its vibrant orange flesh sets it apart from traditional white or yellow-fleshed sweet potatoes, making it a visually appealing and nutrient-dense option for improving the nutritional status of rural households. Amagloh *et al* (2011) , Omoare (2017) Orange-fleshed sweet potatoes are rich sources of beta-carotene, an essential nutrient that the human body can convert into vitamin A. Vitamin A plays a vital role in maintaining healthy vision, immune function, and cell growth. By incorporating OFSP into their diets, rural households can enhance their vitamin A intake, reducing the risk of vitamin A deficiency-related health issues such as night blindness and increased susceptibility to infections (Omoare, 2015, Njoku, 2007). Ebonyi State's rural communities often face challenges related to agriculture, such as limited access to irrigation, unpredictable weather patterns, and soil degradation. Orange-fleshed sweet potatoes have proven to be resilient and adaptable to a range of agro ecological conditions, making them a viable option for smallholder farmers in the region. Their ability to thrive in less fertile soils and their resistance to certain pests and diseases can contribute to increased crop productivity and food security. In recent years, agricultural research and development organizations, along with governmental and non-governmental partners, have undertaken initiatives to promote the cultivation and consumption of orange-fleshed sweet potato in Ebonyi State. These efforts have sought to raise awareness about the nutritional benefits of OFSP, provide training and support to farmers, and integrate OFSP into school feeding programs to reach vulnerable populations effectively. Overall, the unexpected value of OFSP lies in its ability to tackle hidden hunger by providing an abundant, accessible, and nutritious crop that fits well into existing food systems. It's potential to improve nutrition, livelihoods, and food security has led to widespread adoption and recognition as an essential tool in the fight against hidden hunger (Oyediran *et al* 2017, Low *et al* 2010).

This paper therefore reviewed the potentials of orange-fleshed sweet potato as a panacea for hidden hunger among rural households in Ebonyi State, Nigeria. By examining the nutritional benefits of OFSP, its adaptability to local agricultural conditions, and the impact it can have on alleviating micronutrient deficiencies, this study seeks to advocate for greater adoption and integration of OFSP into rural farming systems and diets.

METHODOLOGY

Secondary data was used to elicit information from textbooks, journals, proceedings, guides bulletins and some national dailies.

RESULTS AND DISCUSSION

Orange Fleshed Sweet Potato as a Panacea for Hidden Hunger Transformation

Hidden hunger (micronutrient deficiency), is a persistent issue affecting vulnerable populations worldwide. It arises from a lack of essential vitamins and minerals in diets, particularly in regions where access to diverse and nutritious foods is limited. One innovative and impactful solution to combat hidden hunger is the promotion and adoption of orange-fleshed sweet potato (OFSP). (Endrias *et al*., 2016)

Nutritional Powerhouse: Orange-fleshed sweet potato is a bio-fortified variety enriched with beta-carotene, a precursor to vitamin A. Its vibrant orange color is indicative of its high nutrient content. By incorporating OFSP into diets, particularly in regions with vitamin A deficiency, individuals can improve their nutritional intake and combat related health issues such as night blindness, weakened immune systems, and increased vulnerability to infections. (Kurabachew, 2015)

Vitamin A Delivery: Vitamin A plays a critical role in various physiological functions, including vision, immune function, and growth. OFSP offers an effective and natural means of delivering vitamin A, ensuring a sustained and accessible supply to communities. This transforms OFSP into a powerful tool for improving health outcomes, especially for pregnant women, young children, and those with compromised immune systems. (Hortz *et al*., 2012)

Agricultural Adaptability: OFSP is renowned for its adaptability to diverse agro ecological conditions, making it suitable for cultivation in regions facing challenging agricultural circumstances. Smallholder farmers can benefit from growing OFSP alongside traditional crops, leading to diversified farming practices and enhanced food security. The ability to grow OFSP in poor soil conditions and with minimal water resources empowers farmers to address hidden hunger within their communities sustainably. (Ejigu *et al*., 2022).

Women and Rural Empowerment: In many regions affected by hidden hunger, women bear the primary responsibility for household nutrition and food preparation. By promoting the cultivation and consumption of OFSP, women can become key drivers of change in addressing micronutrient deficiencies. Additionally, OFSP can serve as an income-generating crop for women, empowering them economically and socially. (Abidin *et a*l., 2015)

Climate Resilience: OFSP's ability to thrive under challenging conditions contributes to climate resilience. As climate change impacts agriculture and food systems, the cultivation of resilient crops like OFSP becomes crucial for securing food and nutrition for vulnerable populations. Furthermore, its potential for carbon sequestration can make it an environmentally sustainable option for farming practices. (Wees *et al*., 2015)

Sustainable Food Systems: By promoting OFSP, communities can transition towards sustainable food systems that prioritize nutrition, biodiversity, and resilience. The integration of OFSP into dietary habits and food value chains fosters a culture of diversified nutrition, reducing reliance on monotonous diets and their associated health risks. (Danlo *et al*., 2023).

Policy and Institutional Support: Transforming hidden hunger through OFSP requires supportive policies and institutional frameworks. Governments, international organizations, and local stakeholders can collaborate to provide necessary infrastructure, resources, and technical assistance to promote OFSP cultivation, processing, and consumption.

Challenges of Orange Fleshed Sweet Potato

Awareness and Acceptance: One of the primary challenges is creating awareness about the benefits of OFSP and encouraging its acceptance among the local population. Many people may be unfamiliar with this crop or may have cultural preferences for other staple foods.

Farming and Production: Scaling up the production and availability of OFSP can be challenging. It requires suitable agricultural practices, proper storage, and distribution mechanisms to ensure a consistent and reliable supply throughout the year.

Knowledge and Training: Farmers need access to training and knowledge on best practices for cultivating, storing, and processing OFSP. Lack of information and expertise can hinder successful cultivation and utilization of the crop.

Infrastructure and Market Access: The success of OFSP as a solution for hidden hunger relies on a functional agricultural infrastructure and market access. If farmers face difficulties in transporting their produce to markets or accessing markets with fair prices, they may not be incentivized to grow OFSP.
Socioeconomic Factors: Poverty and limited access to resources can hinder the adoption of new agricultural practices. Farmers may prioritize crops that offer immediate economic benefits over those that address hidden hunger in the long term.
Post-Harvest Losses: Proper storage and processing of OFSP are crucial to preserving its nutritional content. Post-harvest losses due to lack of appropriate storage facilities and processing techniques can diminish the nutritional impact of the crop.
Dietary Diversity: Although OFSP is rich in vitamin A and other nutrients, it should not replace other essential food groups in the diet. Promoting dietary diversity alongside the inclusion of OFSP is essential to address various nutritional deficiencies.
Climate Change and Pests: Climate change can impact agricultural productivity, affecting the availability and quality of OFSP. Additionally, pests and diseases can cause significant crop losses and reduce yields.
Gender Inequality: Women are often key players in agriculture and nutrition, but they may face barriers to access resources and information, limiting their ability to benefit from the introduction of OFSP.

Way Forward in Addressing Hidden Huger with (OFSP)

Addressing hidden hunger among rural households with orange-fleshed sweet potato (OFSP) involves targeted interventions that focus on promoting the cultivation, consumption, and utilization of this nutritious crop. Here are some specific strategies for the way forward:
Promotion and Awareness Campaigns: Launch targeted awareness campaigns about the nutritional benefits of OFSP, emphasizing its high vitamin A content and potential to address hidden hunger. These campaigns can involve community meetings, radio broadcasts, posters, and workshops to reach rural households effectively.
Capacity Building and Training: Provide training and capacity-building programs to rural farmers on best practices for cultivating, storing, and processing OFSP. This can include techniques for soil management, planting, harvesting, and post-harvest handling to minimize losses and preserve nutritional content.
Seed Distribution and Access: Facilitate access to high-quality OFSP planting materials and ensure their availability in rural areas. This can involve establishing community seed banks and promoting the use of disease-resistant and climate-adapted varieties.
Strengthening Value Chains: support the establishment of OFSP value chains that link rural farmers with markets, processors, and consumers. This can improve income opportunities for farmers and ensure a steady supply of OFSP products to consumers.
Nutritional Education: Implement nutrition education programs that teach rural households about the importance of dietary diversity, including the inclusion of OFSP in their regular meals. Demonstrate how OFSP can be incorporated into traditional recipes to enhance their nutritional value.
Processing and Preservation: Encourage the development and adoption of simple and affordable processing techniques for OFSP, such as drying, milling, and making products like flour, snacks, and porridge. This can extend the shelf life of the crop and increase its availability throughout the year.
Community-Based Interventions: Involve local communities in planning and decision-making processes related to OFSP interventions. Community engagement fosters ownership and sustainability of projects.
Gender Sensitivity: Recognize the role of women in agriculture and nutrition and ensure that interventions address their specific needs and challenges. Women often play a crucial role in food production and preparation, making their involvement essential for successful outcomes.
Monitoring and Evaluation: Establish robust monitoring and evaluation systems to assess the impact of OFSP interventions on hidden hunger and nutrition outcomes among rural households. Regular assessments will help identify areas for improvement and ensure the effectiveness of interventions.
Policy Support: Advocate for policies that promote the cultivation and consumption of OFSP among rural households, including incentives for farmers, subsidies for inputs, and integration of OFSP in school feeding programs.

CONCLUSION

In conclusion, hidden hunger, characterized by micronutrient deficiencies despite sufficient caloric intake, remains a persistent challenge in many regions, particularly in developing countries. Addressing this issue requires a multi-faceted approach involving governments, NGOs, international organizations, communities, and individuals. One unexpected but highly effective solution for hidden hunger is the orange-fleshed sweet potato (OFSP). OFSP stands out as a nutritious and versatile crop due to its high beta-carotene content, which addresses vitamin A deficiency, a widespread health concern. Its cultivation adaptability, climate resilience, and integration into local food systems make it accessible and acceptable to diverse communities. Embracing OFSP presents numerous benefits beyond its nutritional value. It supports sustainable agricultural practices, empowers farmers economically, and promotes health and well-being in vulnerable populations. Additionally, it's simple processing and versatility in various food products makes it a valuable resource year-round. However, to fully utilize OFSP's potential as a solution for hidden hunger, challenges must be addressed, such as awareness and acceptance, access to quality planting materials, capacity building, gender sensitivity, and the strengthening of value chains.

By adopting a holistic approaches, including nutrition education, policy support, and collaboration between stakeholders, we can unlock the unexpected potential of orange-fleshed sweet potato to combat hidden hunger. This nutritious crop not only offers a source of essential nutrients but also represents a pathway towards sustainable agriculture, improved livelihoods, and better health outcomes for vulnerable populations. Embracing OFSP is a step towards a healthier, more resilient, and food-secure future for communities worldwide.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
*Field experiment was conducted to evaluate the effect of row spacing and variety on the growth and yield of onion during 2021 rainy season at the Teaching and Research Farm of Federal College of Horticulture Dadinkowa in Yamlatu Deba local government area of Gombe state. Three (3) row spacing (30cm x 10cm, 30cm x 15cm and 30cm x 20cm) were used and two (2) onion Varieties (**V1**`Yar Rumi and **V2** Zobo variety) laid in a Randomized complete Block Design in 3 replications of 5 plots each. The plots size was 2m x 2m (4m^2) with 1m space between the replications and 0.5m between plots. Total number of plots was 15. The results of the research showed that 30x20 cm and variety two were the best on plant height, number of leaves, collar girth, leaf fresh weight and bulb diameter but there were no significant differences on number of leaves and bulb diameter between the varieties. It was therefore suggested that farmers in the study area should adopt 30x20cm spacing and Zobo variety for optimum performance.*

INTRODUCTION
The onion (*Allium cepa* L.) is a vegetable crop grown for its pungent bulbs and flavourful leaves. It belongs to the genus *Allium* of the family *Alliaceae* or *Amaryllidaceae* (Welbaum, 2015). Onion is one of the most important vegetable crops commercially grown in the world. It probably originated from Central Asia between Turkmenistan and Afghanistan where some of its relatives still grow in the wild. Onion from Central Asia, the supposed onion ancestor had probably migrated to the Near East (Bagali *et al.*, 2012). The production of the crop in Northern Guinea Savannah is low when compared to the land area under cultivation by Onion farmers in the area. This could be due poor management practices that has high impact on the crop performance especially selection of varieties with laudable performance, Fertilizer application (forms, rates of application, time of application) and spacing which determine the plant population and quantity of inputs needed (seeds, fertilizer, pesticides), key determinants of cost of production. The study was conducted to determine the most suitable spacing for growth and yield of Onion in the study area and to evaluate the performance of the varieties used.

MATERIALS AND METHOD
The Field experiment was conducted during 2021 rainy seasons at the Teaching and Research Farm of Federal College of Horticulture Dadinkowa in Yamlatu Deba local government area of Gombe state to evaluate the impact of management practices on sustainable onion production in the study area. Three (3) intra-row spacing (30cm x 10cm, 30cm x 15cm and 30cm x 20cm) and two (2) onion Varieties (**V1**`Yar Rumi and **V2** Zobo variety) laid in a Randomized complete Block Design in 3 replications of 5 plots each. The plots size was 2m x 2m (4m^2) with 1m space between the replications and 0.5m between plots. Total number of plots was 15.

Data were collected on plant height, number of leaves, collar girth, and leaf fresh weight at two weeks interval and, bulb diameter at harvest from the five randomly selected plants. The Data collected were subjected to Analysis of variance by Genstat software and means were separated using least significant difference at 5% level of probability.

RESULTS
The results on plant height indicated that 30cmx10 cm recorded the highest mean value at 2 and 4WAT even though there was no significant difference at 2WAT a situation that could be attributed to the closer spacing a condition that encourages competition between the onions stands for space and sunlight. But at 6 and 10WAT the highest value was

recorded by 30cmx20 cm spacing which was the widest spacing used in the research, 30x15 cm at 8WAT had the highest record of number of leaves, the results showed that even though there was no significant difference between the three spacing intervals with the exception of 6 and 10WAT where 30x10 cm performed better, highest values were recorded by the wider spacing at 4, 6 and 8WAT.

Results on collar girth revealed that there was no significant difference between the three-row spacing as recorded in the first sampling period but significant differences were recorded in the subsequent data where 30x20 cm recorded the highest values at 4, 6 and 8WAT while 30x15 cm had the highest at 10WAT.

Leaf fresh weight was higher at wider row spacing (30x20cm) a condition that might be as a result of enough space that supports vigorous growth and low population that made the available nutrients enough for the plant to utilize and build their leaves and sufficient moisture that buffered the water content there increasing their weight and results in higher weight values.

The results on Bulb diameter showed that row spacing significantly influences the bulb size where 30cm x20 cm spacing recorded the highest values. This might be due to the due to the wider space that provided avenue for enlargement of the bulb without tightness and more moisture and nutrients that were at the disposal of the widely spaced onions.

Table 1: Effect of Row Spacing and Variety on the Growth and Yield of Onion (*Allium cepa* L.) in Dadinkowa Gombe State

Treatments	PH	NL	CG	LFW	BD
	63.54	10.99	5.47	43.02	39.42
	64.73	10.91	5.76	44.79	38.60
	65.23	10.91	6.25	45.05	39.68

KEY: PH=plant height, NL=number of Leaves, CG=collar girth, LFW=leaf fresh weight, BD=bulb diameter.

The results on plant height displayed significant variation between these varieties with the exception of first sampling period and, V2 (*Zobo*) recorded the highest values throughout the sampling period. The result on number of leaves showed that no significant differences were observed throughout the sampling period. The results on collar girth showed that *Zobo* (V2) recorded the largest values during the sampling periods. Leaf Fresh weight the result shows significant variation in the performance of the two varieties with regard to fresh weight where *Zobo* (V2) recorded the highest value.

DISCUSSION

This result conformed to the findings (Latif *et al*., 2010) who indicated that the numbers of leaves per plant, bulb weight, foliage dry weight, plant height was highest when the plants were grown at wider spacing of 20cm x 20 cm. There was no marked difference even at period during which the closest spacing had the highest values and this showed that still wider spacing produces highest number of leaves as reported by (Sikder *et al*., 2010); (Latif *et al*., 2010 and Ehizogie *et al*., 2015). This showed that wider spacing provide avenue for enlargement of the onion neck which is also related to the bulb size because of adequate space encourages widening in size in addition to nutrients and moisture availability. This result agreed with the findings of (Brewster, 2010); (Guesh, 2015) who reported that in order to produce large bulbs (>70 mm in diameter) a plant population of between 25 and 50 plants m^2 is required, for medium bulbs (25-50 mm) between 50 and 100 plants m^2 and for small bulbs (<50 mm) more than 100 plants m^2 are required.

This result shows that the Leaf fresh weight was higher at wider row spacing (30x20cm) a condition that might be as a result of enough space that supports vigorous growth and low population and was in agreement with the findings of (Jilani *et al.*, 2010); Sikder *et al*., 2010); Latif *et al*. (2010) and Ehizogie *et al*. (2015) who reported that wider spacing supports growth parameters of onion.

This results conformed to the findings of (Jilani *et al.*, 2010) who stated that although the widest plant spacing (25 cm) produced the maximum leaves per plant, plant height, bulb weight and bulb diameter, but it reduced the yield per plot and total yield.
The result of V2 recorded the highest values was in conformity with the findings of Chala *et al.* (2022) who reported that Plant height was very important ($P < 0.01$) affected by the significant effect of NPS fertilizer levels, varieties and significantly ($P \leq 0.05$) its interaction. The number of leaves shows no significant, this might be due to similarity of the varieties genetically even though it contradicted the findings of Nasha *et al*. (2018) who in his study reported that variety V3 (Agrifound Light Red) recorded a higher mean value of number of leaves per plant than the variety V2 (NHRDF Red-3) at different stages of growth. Varity V1 (NHRDF Red-1) recorded minimum number of leaves at all the stages of the crop growth.
The results shows that V2 recorded the highest collar girth during the throughtout the observation, (Nasha *et al*., 2018) whose research data indicated significant effect of varieties on neck thickness of bulb at harvesting stage. The result shows that the leaf fresh weight was significant and this result was in agreement with the findings of Paul *et al.* (2017) reported that the highest onion fresh weight of 37.15 g was recorded at treatment A3, followed by A2 of 33.18 g, A2 of 29.01 g and A0 of 22.41 g. Results on bulb diameter revealed no significant difference between the two varieties and this might be due genetic makeup of the varieties and the management practices employed. This results contradicted the findings of Nasha *et al*. (2018) Varieties also had significant effect on polar diameter of bulb.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study evaluated the colour intensities of some selected yam varieties using a high throughput Chromameter. The results showed significant differences in the colour intensities of the fresh yam samples evaluated. The L value, which was used to measure lightness or whiteness of the fresh yam samples ranged from 69.993 nm in the head section of sample 11/00873 to 81.225 nm in the middle section of the same tuber while a* value, which measured the red to green pigments ranged from -1.760 nm (Tail section of sample 11/00582) to 2.480 nm (Head section of TDA 291). Values of b* (measure of yellow to blue colour ranges) ranged from 13.955nm in the middle section of sample TDA 291 to 25.643 nm in the head section of 89/02665. The study showed that high-throughput chromameter can be used to assess the colour intensities of fresh yam.*
Keywords: *Colour Intensity, Yam, Chromameter*

INTRODUCTION
Yam, a common name used to describe crops belonging to the genus *Dioscorea* is an annual crop, which belongs to a major staple food crop grown in tropics and sub-tropics for its tubers (Alabi *et al*., 2019). There are many species of yam with different flesh colors, which varies from white to red (Leng *et al*., 2016). However, white yam and yellow yam (*Dioscorea rotundata* and *D. cayenensis*) are the most important and are native to Africa. Yams are consumed in different forms such as boiled, roasted, fried, pounded or processed into flour for other uses (Honfozo *et al*., 2020). However, they undergo colour changes during processing as a result of enzymatic browning by the action of polyphenoloxidase. The colour of yam is measured in intensity and wavelengths depending on the pigments, which may be fat-soluble chlorophylls (green), carotenoids (yellow, orange, and red), water-soluble anthocyanins (red, blue), flavonoids (yellow) or betalains (red) (Barrett *et al*. ,2010). Studies have shown that subjective methods have been used in determination of colors of yam using qualitative descriptive analysis, however, this method does not give the true representation of the yam colours despite the rigors involved in carrying out the evaluation. Colour attribute is important in the consumer acceptance of food (Johannes and Borquez, 2014) and color of food could be determined by their L*, a* and b* values (L* used to measure the lightness of the yam, a* values used to represent the red to green color range and b* values for representing the yellow to blue color range) using Chromameter. It uses a sensor that mimics the function of human eye in sensing colours which are quantified after measuring the three primary colors, which are red, green, and blue in the food (Phatare *et al*, 2013). This method is easier and faster. Therefore, this study aims at evaluating the colour intensities of some selected yam varieties using high throughput Chromameter.

MATERIALS AND METHODS
Fresh 4 African yam varieties harvested from Ezza-mgbo in Ebonyi state were peeled, washed and sliced to 2mm thickness with clean knives. A colorimeter (Konica Minolta CM-3700; Japan) was used to evaluate the colours of the boiled yam sections as well as the fresh-cut yam slices. *L**, *a**, and *b** values at 3 sites on each of the 6 yam slices were measured and their different colour intensities measured. Data generated were expressed as three replications and were subjected to one-way analysis of variance (ANOVA). P values ≤ 0.05 were regarded as significant. All the statistical analysis were performed with SPSS software (version 20).

RESULTS AND DISCUSSION
Table 1 shows the colour intensities of the yam samples.There were significant ($p<0.05$) differences in the colour intensities of the fresh yam samples evaluated. The L* is used to measure the lightness of the yam color (Homaida

and Yang, 2017) in the range of 0−100, where zero represents the darkest (or blackness) and 100, for the whitest color. The L* values ranged from 69.993nm in the head section of sample 11/00873 to 81.225nm in the middle section of the same tuber. Samples with high L* value indicate high brightness. This implies that the middle section of sample 11/00873 was very white in colour while the head section with the lowest L* value had the darkest colour among the yam samples evaluated. The a* values are used to represent the red to green range were red colors have positive values and green colors have negative values. The results obtained showed that a* ranged from -1.760 nm (Tail section of sample 11/00582) to 2.480nm (Head section of TDA 291). Samples with higher positive values of a* showed that they have more red pigments than samples observed in the head section of TDA. All the other sections of the other varieties had negative values indicating the presence of green pigments in the tubers with the tail section of sample 11/00582 having the highest green pigment among all the samples assessed.
The b* values are used to represent the yellow to blue color range where the positive values represent the yellow color and the negative values represent blue colours. Values of b* ranged from 13.955 nm in the middle section of sample TDA 291 to 25.643nm in the head section of 89/02665. This shows that the middle section of the fresh yam sample from TDA 291 had more yellow pigments in its tuber than the other samples evaluated while the head section of 89/02665 tended towards blue colour. The results showed that among the samples evaluated, the middle section of sample 11/00873 and the middle section of sample TDA 291 had brighter colours. This implies that consumers and processors that want to obtain brighter end product such as pounded, boiled yam, yam flour among others should choose from these genotypes that contained few dark pigments in them as it is easy to predict the color quality of their end products from the raw material .

Table 1: Colour intensities of the different sections of fresh yam

GENOTYPE	L*	a*	B*

T	76.688^{d}	-1.140^{bcd}	16.103^{e}

Means with the same superscripts in the same column are not significantly different (P>0.05)
L* = measurement of lightness of yam
a* = values used to represent the red to green color range
b* = values representing the yellow to blue color range

CONCLUSION

The study showed that the different colour intensities of yam genotype could be assessed using a high throughput chromameter, which is easier and faster than the QDA (qualitative descriptive analysis), which is subjective, time consuming and not economical; although, this was used in this study. Breeders can leverage on this study to put more efforts in breeding genotypes that meet end-users preferences.
