Purification of the *Pleurotus ostreatus* into Pure culture

Potato dextrose agar (PDA) medium was prepared by using 39g of potato dextrose agar in a litre of sterile distilled water and was sterilized at 121 ºC for 15 min. The medium was left to cool (45^0c) before 10 ml of the PDA preparation was dispensed into sterile petri dishes and allow to solidify. A small disc of tissue was collected from the culture of *Pleurotus ostreatus* mushroom and transferred onto the sterilized PDA medium under aseptic conditions. This was incubated at 27±2ºC for 8-10 days for sufficient mycelial growth. Pure cultures were obtained by subsequent sub culturing. Test tube containing the 10 ml sterilized PDA were kept in a slanted position and the purified cultures were sub cultured therein. They were later stored in the Regenerator.

Mycelia Inoculation Onto Media

All the four media were aseptically prepared, poured into sterile petri dish and allow to solidify. A flamed and cooled 5mm cork borer was used to pick the purified mushroom and transferred unto all the test media (inoculate). The plates were incubated at 25^0C and observed for 8 days during which the mycelial vegetative growth and mycelial density of ***Pleurotus ostreatus*** were recorded. The mycelial density was rated as described by (Kadiri, 1998) as follows:

+ = Very Scanty mycelial density
2+ = Scanty mycelial density
3+ = Moderate mycelial density
4+ = Abundant mycelial density
5+ = Very abundant mycelial density

The growth rate is given by the formula below:

Growth rate=Colony diameter on the last day (cm) /Number of day's measurement was taken after inoculation. Daily mycelial growth was determined using a ruler across the Petri-dish horizontally. (Kadiri, 1998)

Statistical Analysis

The observations were recorded after one week on the growth length of mycelia and were subjected to SAS Software at 0.05 probability level. CRD design was used with 3 replications under standard laboratory conditions.

RESULTS AND DISCUSSION

Table 1: Growth Rate of *Pleurotus Ostreatus* Mycelia on Different Media for Eight Days

			mm/day					
MEDIA	1	2	3	4	5	6	7	8
PDA	0.20±0.21	0.80±0.21	15.00±0.19	22.00±0.23	25.00±0.15	34.00±0.21	38.00±0.32	39.00±0.37
CMA	0.00±0.19	0.30±0.40	13.00±0.39	17.00±0.27	20.00±0.29	26.00±0.31	32.00±0.30	35.00±0.32
MEA	0.20±0.36	0.70±0.26	10.00±0.31	19.00±0.60	25.00±0.85	35.00±1.65	39.00±1.76	40.00±1.66
DOX	0.00±0.23	0.50±0.36	12.00±0.68	17.00±0.52	22.00±0.52	30.00±0.54	35.00±0.48	38.00±0.33

The results on the growth of *P.ostreatus* mycelia on the four media used are depicted in the Table 1 revealed that when compared the means against standard deviation, all the media had a significant growth from day 2 to day 8 at different levels. It also showed that the highest growth rate after 7 days of incubation was observed in Malt extract agar (MEA) (40.00mm) whereas lowest growth rate was observed on CMA (35.00mm). The effect of media on the radial growth of the fungus was influenced greatly by the kind of media used. Malt extract agar was most favoured by the strains followed by potato dextrose agar and the least CMA with the growth of 35mm. The mycelia growth of *P. ostreatus* on MEA and PDA showed a good mycelia growth from day 2 (0.70 and 0.80mm) respectively. Both Corn meal agar and DOX equally had a poor mycelia growth from day 2 with (0.30 and 0.50mm) respectively.

Table 2: Mycelial Density and Growth Rate of *P.ostreatus* Mycelia in Different *Medium*

S. No	Medium	Average Mycelial Density on 8th Day of Incubation	Growth Rate mm/day
1	Potato dextrose agar	4+	5.6
2	Corn meal agar	1+	5.0
3	Malt extract agar	5+	5.7
4	Czapek dos agar	3+	5.4

The result on mycelia density and growth rate on *P. ostreatus* in (**Table 2**) on the 8th day showed that Malt extract produced the highest mycelial density (5+) and growth rate of (5.7mm/day) followed by PDA media with 4+ and 5.6mm/day being mycelial density and growth rate respectively. On DOX media, mycelial density 3+ and growth rate was 5.4mm/day. The least growth was recorded on CMA media with 1+ as mycelial density and 5.0 mm/day as growth rate. Corn meal agar had a very poor mycelia density according to mycelia density rating while MEA medium proved to be the highest according to the density rating with 5+

Among the four solid growth media, malt extract agar media was found to support fastidious growth of mushroom cultures with the presence of higher amount of carbohydrates particularly maltose, protein and other medium. This is followed by potato dextrose agar medium, Czapek dox agar medium and Corn meal agar medium. Though the mycelial diameter of the mushroom culture in corn meal agar medium was at par with rest of the growth media, but the density of the mycelia was low when compared with the other three media. Thus, malt extract agar medium was found to be an ideal media for growth of these mushroom cultures. Mycological peptone present in the malt agar gives a luxuriant growth with typical morphology and pigmentation. The production of pigments by edible filamentous fungi is gaining attention as a result of the increased interest in natural sources with added functionality in the food, feed, cosmetics, pharmaceutical and textile industries.(Gmoser, *et al*., 2017) Mycelium is an important part for mushroom production as well as for production of several secondary metabolites used for therapeutic purpose. The mycelium growth depends on several factors such as growth media, pH, temperature, nutrient elements and some environmental factors (Calam, 1971). Growth medium is the most important factor because it supplies necessary nutrient for the growth of mushroom mycelium. Different media such as potato dextrose agar, yeast extract agar, malt extract agar, lamberts agar, Czapek dox agar and compost extract agar are mostly used for the growth of mycelium (Pathak, 1998). Gmoser et al, 2017 worked on pigmentation production by edible filamentous fungus and discovered that five factors are particularly important regarding pigment production namely carbon source (glucose and mannose), nitrogen source ($NaNo^3$ or NH_4CL) and trace metals ($Mg^{2+,}Mn^{2+}$ and Zn^{2+}.Malt extract had high source of carbon and protein source which gives it an edge in growth than other media used. Mycelium growth is the best tool to identify necessary nutrients for the production of fruiting bodies as mycelium growth requires short time in comparison with fruiting bodies development Kalmis and Kalyoncu ,(2006).

CONCLUSION

The study showed that Malt extract agar, Potato dextrose agar, Czapek dox agar and Corn meal agar are good in the production of mushroom mycelia as starter culture in the Laboratory but Malt extract agar had higher mycelial density than the other media used. Since mushrooms are good source of bioactive compounds of anticancer, antifungal and anti-diabetic in nature, the mycelia may be used for the large scale production of the compounds as mushrooms are seasonal. To make the bioactive production technology cost effective, present study may be useful in order to obtain more biomass ultimately to have bioactive compounds in hand. Further standardization regarding quantification of substrate as nutritional source for biomass production and its cost economics is required to reach more constructive conclusion.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Heat is a serious production challenge to wheat in Nigeria, sufficient genetic variability is a prerequisite for development of heat tolerant varieties. To adapt and mitigate the adverse effect of heat on wheat, this study was designed with the objective to determine genetic variability in bread wheat for heat tolerance. Ten wheat genotypes obtained from Lake Chad Research Institute was sown at Hadejia sub station, during dry season of 2019 and 2020 (late period, December 25). Agronomic and yield attributes were evaluated at different crop growth stages. Results revealed significant ($p \leq 0.01$) difference among genotypes for days to heading, plant height, grain yield per plot and grain yield per hectare. Results revealed significant variation between the genotypes for the traits measured. Estimates of phenotypic coefficient of variation (PCV) were generally higher than genotypic coefficient of variation (GCV), with lower range indicating that apparent variation for these traits may not only be due to genotypes but also due to the little influence of environment. Likewise, heritability estimates were higher moderate-high for all traits except days to maturity which depicted low of heritability estimate. Mean performance for grain yield indicated that genotype (29526) was the best yielder in 2019 (4.95 Kg/ha), in contrast to observed performance in 2020, genotype (29642) which recorded the highest yield in 2020 (4.77 kg/ha).

INTRODUCTION

Wheat (*Triticum aestivum* L.) is a member of the poaceae family with chromosome number 42 and a self - pollinated crop, it is one of the principal cereal of the world, fulfilling the maximal carbohydrates dietary requirement (Kumar *et al.*, 2013). Wheat contain 70% carbohydrates, 12% water, 2% fat, 12% protein, 1.8% minerals, and 2.2% crude fiber are found in wheat grain kernel. It is also enriched with phosphorus, magnesium, manganese, zinc, selenium, iron, potassium and copper (Liu et al., 2012). Industrially, wheat is utilized for, bio-ethanol production, succinic acid production, like a blend for baked products (bread, cake, crackers, cookies, pastries), pastas (spaghetti, macaroni) as nutritional improvement, for cosmetics, meat substitute, malt, alcohol, dextrose, gluten, neutraceutical/ pharmaceutical products, animal feed and for many more others (Yemsrach *et al.*,2015; William *et al.*, 2021).

Global wheat production stands at 772.30 million metric tons on about 215.90 million hectares (Mha) in 2019 (FAOSTAT, 2019). China is the top producing country in the world in 2019; it accounts for 134.3 m mt (21.9% of the world wheat production (F.A.O, 2020). In Africa, wheat production stands at 27 mt on about 9.8 million hectares, the major producer include Egypt (9.0 mt), Morocco (4.03 mt), Ethiopia (5.3 mt) and Algeria (3.7 mt) (FAO, 2019).

Nigeria production currently hovering around 60,000 tons from 56,080 hectares with an average yield of 1.06 t/ha while demand stands at between 4.5 and 5.0 mt (FAOSTAT, 2019, USDA, 2022). A recent report on wheat production in Nigeria by the National Bureau of Statistics, which conducted a survey that covered the 2020/2021 farming season across 13 states in Nigeria, said wheat production in Nigeria was 36,943.80 tonnes, a decrease of 23 percent from 60,000 tonnes as captured in the Agriculture promotion policy's strategy document of 2016, in that same year demand was put at 4.7 mt. But seven years later, while demand has largely grown, production declined. Nigeria imported wheat worth N1.3 trillion in 2021, an increase of 71% from N756.9 billion in 2020 (Odifa, 2023).

Despite the economic importance of wheat, its production is constraint by abiotic factors, principally high temperature which accounted for about 30% of 50% yield losses in wheat (Oerke *et al*., 1994 and Thilert, 2006) which are increasing in intensity and frequency associated with climate. The optimum temperature for wheat germination is between 20˚C - 22˚C whereas, during the grain development, the mean maximum temperature between 25˚C - 32˚C is considered moderately high and temperature between 35˚C - 40˚C is considered as very high temperature (Bano and Khan, 2021). Thus, it was reported that a rise in temperature of 1˚C in the wheat growing season reduced wheat yield by 3% - 10%.In the present era, the breeding for heat tolerance in wheat is one of the big challenges for breeders. To resolve this problem, there is need for knowledge on the selection of heat tolerant genotypes to respond to changing environments. This study is designed to screen wheat genotypes for development of desirable wheat genotypes for high temperature areas.

MATERIAL AND METHODS

Ten wheat genotypes along with a check were evaluated Randomized Complete Block Design (RCBD) on 3m x 2m late sown at the research farm of Lake Chad Research Institute Hadejia, during dry season of 2019 and 2020 cropping seasons. The experiments were sown using drilling method with three replications, spaced at 30cm between rows. Field management and other agronomic management practices such land preparations, sowing, weeding, fertilizer application, irrigation, harvesting e.t.c were observed based on recommendations. Data were recorded on agronomic traits viz, days to heading, days to maturity, plant height, yield per plant and grain yield per hectare.

Data Collection

Plant height (cm) Plant height was recorded at 12 weeks after sowing. This was obtained by measuring plant from the base to the tip of the plant using metre rule.

Days to 50% heading: Days to 50% heading was recorded as the number of days from planting when 50% of plants in the plot had their head emerged.

Days to maturity: Days to maturity was recorded as the number of days from planting when the plants in the plot had attained physiological maturity.

Grain yield (kg/ha): This was determined by weighing grains from the net plot, divided by net plot area and multiplies by 10,000.

$$\text{Grainyield} = \frac{\text{Seed yield/netplot}}{\textit{Net plot area}} \times 10{,}000$$

Data collected for each character were subjected to analysis of variance (ANOVA) using procedure of general linear model of SAS software 24 version 9.0 and treatment means were tested as significant at 5% probability level and as highly significant at 1% probability level. Mean comparison among genotypes were carried out using LSD at 5% probability levels.

The phenotypic and genotypic coefficient of variation as well as broad sense heritability will be estimated as described by Chaudhrary (2001) and Hallauer *et al*., (1988) as follows:

The genotypic coefficients of variation will be estimated using the formula described by Singh and Chaudhary (1985).

GCV= x 100, Where; GCV= genotypic coefficient of variation, σ_g^2 =estimate of genetic variance, $\overline{X}$ = grand mean of the respective character.

Phenotypic coefficient of variation

PCV= $\frac{\sqrt{\sigma_P^2}}{\bar{x}}$ x 100, Where; PCV= Phenotypic coefficient of variation, c =estimate of genetic variance, $\overline{X}$ = grand mean of the respective character. Using the formula adopted by Allard 26.

$$H_b^2 = \frac{\sigma^2{}_g}{\sigma_p^2} \times 100$$

RESULTS AND DISCUSSION

The results of Analysis of variance (ANOVA) for genetic variability of bread wheat evaluated in Hadejia during 2019/2020 and 2021/2021 irrigated seasons is presented in Table 1 and 2. The results revealed significant ($p \leq 0.05$) difference among genotypes for days to heading, plant height, grain yield per plot and grain yield per hectare in both years. However, significant (($p \leq 0.01$) difference observed for days to heading only for 2019. Furthermore, interaction between genotypes and year revealed significant ($p \leq 0.01$) difference for all traits investigated, except for days to maturity. This study, indicates the existence of variation and possibility of selection for heat tolerance.

Findings by Cheema, *et al.*, 2006, reported significant differences among genotypes for number of productive tillers/plant, spike length, number of spikelets/spike, number of grains/spike, 1000-grain weight and grain yield/plant. In fact the development of any plant breeding programme is dependent upon the existence of genetic variability.

****:** significantly different at (P≤0.05) and (P≤0.01) level of probability, DHH= days to heading, DMA= days to maturity, PHT= plant height, GYD= yield per plot, YLD/ha= grain yield per hectare, SOV= source of variation, Rep=replication, Gen=genotype

Partitioning of variance components and estimate of mean performance evaluated under dry condition at Hadejia is presented in Table 3. Phenotypic coefficient of variation (PCV) were generally higher than Genotypic coefficient variation (GCV) for all traits studied, the range of PCV to GCV was wider for all studied traits, indicating that apparent variation for these traits may not only be due to genotypes but also due to the influence of environment and selection through pure line or single seed descent may be misleading for such traits. This is in accord with those obtained by Gupta and Verma (2000); Wannan *et al.*, (2015) and Shakoor *et al*. (2007) all reported higher value of PCV to GCV in wheat indicating the role of environment in the expression of these traits. Similarly, heritability estimates were higher (>50%) for all traits except for grain yield which depicted low (<50%) value of heritability. The higher estimate of heritability observed indicates that the variation in these traits comes from genetic differences with little contribution from environmental factors. Similar results were also found by Liu and Ma, 1994; Deswal et al., 1996; Yadav et al., 2003; Ansari et al., 2004 and Gupta et al., 2004.

Table 3: Components of variance and Heritability (H_b) of the studied traits Combined.

Traits	σ_g^2	σ_y^2	σ_{gy}^2	σ_p^2	GCV (%)	PCV (%)	H_b (%)
Days to heading	19.21	23.49	31.73	28.00	31.69	46.19	68.61

Grain yield (t/ha)	0.52	3.26	0.16	1.63	16.67	52.33	31.85

Legend: σ_g^2 = Genotypic variance, σ_p^2 = Phenotypic variance, GCV= Genotypic Coefficient of Variation, PCV= Phenotypic Coefficient of Variation, h_n = Narrow-sense Heritability

Estimated mean performance for the studied traits in 2019 and 2020 are presented in Tables 4 and 5. The results indicated that genotypes (29988 and 29823) headed earlier (52 and 53) in 2019 dry sesason, while genotype (Tesfa) recorded the highest (72.33) number of days to flower. However, different trend was observed in 2020, the results indicated that genotypes (Tesfa and 30098) headed earlier (54) days to flower, while genotypes (29988) recorded the highest (71.33) days to flower. Furthermore, genotype (29821) matured earlier (92.676 and 92.33) days in 2019 and 2020 respectively, while Norman and Tesfa are late maturing genotype for 2019 and 2020 respectively. More so, Norman was the tallest genotype for 2019, while genotype (29526) was the tallest in 2020. However, genotype (29988) was the shortest in 2019, while genotype (29642) was the shortest in 2020. Mean performance for grain yield indicated that genotype (29526) was the best yielder in 2019, in contrast to observed performance in 2020, genotype (29642) which recorded the highest yield in 2020.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Using black soldier fly larvae (BSFL) in managing and treatment of biodegradable waste such as kitchen waste is a promising and sustainable way to manage organic waste generated from our home, schools, farm, and industries. At the time of feeding on this waste, the black soldier fly larvae are growing and increasing in its biomass which will serve as feed for livestock such as poultry and fish. Total of 50 larvae weighing 0.10g of 10 days old was inoculated into a plastic of dimension and was fed with kitchen waste (substrate) of 50 g. The number of Black soldier fly larvae dropped from 50 to 37 with weight of 1.3 g while the substrate (50 g) decreased to 18.32g (frass). The proximate and chemical composition analysis results recorded are moisture content 71%, ash content 2.32%, crude protein 18.40%, crude fibre 1.34%, crude fat 2.28% and carbohydrate 4.2%. Among the minerals, calcium had 476.30mg/100g, phosphorus 126.30mg/100g, Potassium 545.80 mg/100g, sodium 65.40 mg/100g, magnesium 124.60mg/100g, iron 5.75 mg/100g, zinc 4.60 mg/100g, copper 0.16 mg/100g, and manganese 0.12 mg/100g respectively. For the vitamins, vitamin B1 had 0.19mg/100g, vitamin B2 1.60mg/100g and vitamin E 1.10mg/100g respectively. The results obtained while feeding the larvae indicated that BSFL has the potential of reducing organic waste to frass which can serve as a biofertilizer. Most of the values of the proximate and chemical composition are related to others found in BSFL fed with other substrates and they fall under the nutrient requirements of most livestock feeds. The proximate, minerals and vitamins composition of BSFL under investigation suggests that BSFL fed with kitchen waste will be a potential and promising feed source for livestock industry.

INTRODUCTION

The black soldier fly (BSF), *Hermetia illucens*, is a valuable insect species whose larvae have many potentials for converting organic waste into compost, and the larvae biomass generated could also be harvested for its protein and fatty acid content Banks *et al*. (2014). The larva feeding behavior also discourages clustering of pest flies (Pest control). The waste generated becomes useful as fertilizer (bio-fertilizer). The residue from black soldier fly larvae (BSFL) decomposition is similar to compost, contains nutrients and organic matter and, when used in agriculture, helps to reduce soil depletion. Solutions of waste disposal are being sought, and some of those proposed (already in practice) are to use the waste palm kernel shells and palm press as biofuel to create steam used in the oil palm mill processes, or the creation of mulch from empty fruit bunches and ash to be reused as fertilizer, both of which lead to self-sufficiency, sustainability and improved net energy balance of the oil palm mills (Abdullah and Sulaiman, 2013, Kamahara *et al*., 2010). According to Ebenebe (2021), Nigeria generates 542.5 million tons of organic waste per annum, and waste is fast becoming a menace in many urban centres. Black soldier fly larvae (BSFL) have large and powerful chewing mouthparts allowing them to shred and devour waste. Kitchen waste is any kind of rubbish produced during your commercial kitchen activities – such as preparing food, cleaning plates and equipment, and dealing with customers' leftovers. Food waste is the main type of kitchen waste, but other products and materials also make up such waste, including packaging, equipment, and more. The study is chosen considering the fact that management of kitchen waste is of great importance from the point of view of a healthy quality of environment. The objective of the study was to evaluate the feasibility of black soldier fly larvae to digest and degrade waste and the utilization of the BSFL as animal feed.

MATERIALS AND METHODS

Collection of material

Kitchen waste material was collected from houses, then sun dried and ground into powder form. This grinded waste material was subjected to aerobic composting to initiate microbial activity. Moisture content was maintained to 60% to 70% and the mixture was kept in a plastic container covered with paper having holes to facilitate aeration in order to get final composted material. The mixture was hand manipulated at regular time intervals and remoistened for sufficient microbial activity.

Collection and Introduction of BSFL

When the temperature became constant and the color of the kitchen waste turned brown to black, it was used as a substrate for feeding BSFL. BSFL was obtained from Entomology division NIFOR. 50 larvae of 10 days old were introduced in a small plastic containers containing about 50 g of substrate.

During the course of investigation, samples was examined at every 48 hours for 21 days of composting

Data collection

Data was collected on initial weight of substrate (g), initial number of BSFL, number of BSFL after, initial weight of BSFL (g), weight of BSFL after (g), and weight if substrate after

Proximate and Chemical Composition Analysis

The BSFL that was reared to pre-pupae with the substrate (kitchen waste) was collected at the end of the experiment and was analyzed for its proximate and chemical composition following the method of AOAC (2010).

RESULTS AND DISCUSSION

Larvae management and composting on BSFL

Plate 1. 0-1 hour of introduction of BSFL.   Plate 2. 24 hours of introducing BSFL

‘

Plate 3. 240 hours of introduction of BSFL.   Plate 4. S400 hours of introduction of BSF

Table 1. Impact of composting on BSFL

Initial weight of substrate (g)	Initial weight of larvae (g)	Initial number of larvae	Final weight of substrate (g)	Final weight of larvae (g)	Final number of larvae
50.00	0.10	50	18.32	1.30	37

As shown on table 1. Substrate weighing 50g was degraded or reduced to 18.32g by the BSFL. The number of BSFL introduced during the experiment reduced to 37 from 50, while the weight of the BSFL increased to 1.30g from initial weight of 0.10g within 21 days of the experiment.

Table 2. Proximate analysis of BSFL fed with kitchen waste for 21 days

S/N	Parameters	BSFL	Units
1	Moisture content	71.30	g/100g
2	Ash content	2.32	g/100g
3	Crude fibre	1.34	g/100g
4	Crude fat	2.28	g/100g
5	Crude Protein	18.40	g/100g
6	Carbohydrate	4.20	g/100g

Table 3. Mineral contents of BSFL fed with Kitchen waste for 21 days

S/N	Minerals	BSFL	Units
1	Potassium (K)	545.80	Mg/100g
2	Sodium (Na)	65.40	Mg/100g
3	Calcium (Ca)	476.30	Mg/100g
4	Magnesium (Mg)	124.60	Mg/100g
5	Phorsphours (P)	126.30	Mg/100g
6	Nitrogen (N)	2.94	Mg/100g
7	Manganese (Mn)	0.12	Mg/100g
8	Iron (Fe)	5.75	Mg/100g
9	Zinc (Zn)	4.60	Mg/100g
9	Copper (Cu)	0.16	Mg/100g

Table 4: Vitamin content of BSFL fed with kitchen waste for 21days

S/N	Vitamins	BSFL	Units
1	B1	0.19	Mg/100g
2	B2	0.60	Mg/100g
3	E	1.01	Mg/100g

The experiment affirmed that black soldier fly larvae have potential to convert organic waste into high value product (bio-fertilizer) and in return the organic waste such as kitchen waste will increase the biomass of the black soldier fly larvae. The larvae possessed the ability to valorized organic waste (kitchen waste) which is a potential benefit for developing countries like Nigeria. This conforms to the work of Nana *et al.* (2018).

The results of the proximate and chemical composition of BSFL in this study is a confirmation of its utilization as an ingredient for animal feeds which has gained considerable interest recently. This observation is similar with the reports of Nyakeri *et al.* (2017), who reported the crude protein, crude fibre, ash content, and fats of wild black soldier fly larvae. He further stated the mineral and vitamin content of wild black soldier fly larvae, which is similar with the findings of this study.

CONCLUSION

The work indicated the possibilities in recycling organic waste such as kitchen materials by using this waste to feed the BSFL. By doing so the BSFL builds its body composition of protein, fat, mineral and other vital nutrients required for feed production. This system could be a sustainable method of organic waste management and a way to provide the livestock industry with nutrients for livestock farming especially now that the cost of grains and soyabean are on the very high side.

However, there is a need to always examine the nutrient content or composition of these waste materials as the quality of substrates may probably influence or determine the growth, nutrient and biomass of the black soldier fly larvae.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Sorghum [Sorghum bicolor (L.) Moench] is the fifth most important cereal crop in the world, and is one of the most widely cultivated cereal in Nigeria. Traditionally, it is grown extensively from the Southern Guinea to the Sahel Savannah of Nigeria, primarily because of its adaptation to varying ecological conditions. The industrial demand for sorghum has grown with several flour mills in the country using it or considering it as a substitute/compliment to wheat. There is also increasing demand for it by malting industries for beverages. These will significantly increase the demand for sorghum in the coming years. The aim of the study was to evaluate the yield stability of selected varieties across the different agro-ecological zones of Nigeria. Ten sorghum genotypes were planted in 7 locations covering the Sahel, Sudan, Northern Guinea, Southern Guinea and derived Savannas agroecological zones in a Randomised Complete Block Design. Eight of these genotypes have been officially released in Nigeria, while two are advanced sorghum lines from ICRISAT germplasm. Analysis of variance for the Additive Main Effect and Multiplicative Interaction (AMMI) model showed significant differences amongst genotypes, environments and interactions between genotypes and environments (P>0.001) for grain yield, genotypes, environments and interactions accounted for 25.5, 48.2 and 5.0% of the sum of squares respectively. This indicated serious contribution of environment in the performance of the genotypes. The study demonstrated that several of the selected sorghum genotypes are adapted to the different locations. These differences can be exploited for cultivation in different agro-ecological zones or at different planting dates in a similar zone.

INTRODUCTION
Sorghum [*Sorghum bicolor* (L.) *Moench*] is the fifth most important cereal crop in the world, and is one of the most widely cultivated cereal in Nigeria. Traditionally, it has been grown extensively from the Southern Guinea to the Sahel Savannah of Nigeria, primarily because of its adaptation to drought. The demand for sorghum has grown appreciably and is expected to increase significantly in the coming years for direct consumption, and industrial demand by flour mills who use it as a substitute/complement to wheatby malting industries for beverages, as well as by livestock feed companies. Although sorghum is an indigenous crop and exceptionally adapted to the region, the yields on farmers' fields are on average low, generally less than 1.5 t/ha despite the potential yields of above 3 tons per hectare (Ajeigbe *et al*., 2018), this is caused mainly by low inputs, poor soil fertility, and the non-availability/low-adoption of improved genotypes or hybrids with significant yield superiority over farmers' landraces. Exploitation of genetic variability is the most important tool in plant breeding, and this has to be inferred by phenotypic expression. The consequences of the phenotypic variation depend largely on the environment. This variation is further complicated by the fact that not all genotypes react in similar ways to the change in environment. If relative performance of genotypes is different in different environments, then Genotype by environment (G × E) interaction becomes a major challenge to crop improvement. G x E interaction is the variation, arising from the lack of correspondence between the genetic and non-genetic effects in multi-location trials. Interactions may involve change in rank order for genotypes between environments and change in the absolute and relative magnitude of the genetic, environmental and phenotypic variances between environments Teressa *et al* (2019). Different statistical models are being used to quantify the genotype by environment interactions including the classical analysis of variance (ANOVA), stability and multivariate analysis. The

additive, multiplicative interaction component (AMMI) model is a hybrid analysis that incorporates both the additive and multiplicative components of the two-way data structure. In this model the additive portion is separated from interaction by analysis of variance (ANOVA) and the multiplicative component is further decomposed by interaction principal component Zobel *et al* (1988). The aim was to evaluate the yield stability of selected sorghum varieties across different agro-ecological zones of Nigeria and identify high yielding, high biomass and stable sorghum genotypes. Therefore, the combined data was also analyzed using AMMI model that further partitions GEI into interaction principal component axis (IPCA) components. Hence, the AMMI model analysis had partitioned the GEI into the first two significant IPCAs. AMMI ANOVA given in Figure 1.

MATERIALS AND METHODS

The study comprised of 10 sorghum genotypes (SAMSORG 42, SAMSORG 45, SAMSORG 47, SAMSORG 48, CSR 01, CSR 02, CSR 03H, CSR 04H, 12KNICSV 418 and Framida) planted in 7 locations (Gambawa, Minjibir, BUK, Zaria, Makurdi, Ilorin, Iseyin) covering the Sahel, Sudan, Northern Guinea, Southern Guinea and derived Savannas agroecological zones of Nigeria. Eight of these genotypes have been officially released in Nigeria, while two are advanced sorghum lines from ICRISAT germplasm. The genotypes were selected to cover different maturity groups and ensure high food and malting quality. Land preparation was carried out by tractor (harrowed and ridged) in Minjibir, BUK, Zaria and Makurdi. At Ilorin and Iseyin trial sites were ploughed and manually ridged while by animal drawn ridger in Gambawa. Planting was done from 22 June – 23 July 2021 and from 23 June to 22 July in 2020. Animal manure was applied at the rate of 2 t/ha after harrowing before ridging in Minjibir and at planting in other locations. NPK (15:15:15) was applied at the rate of 150 kg/ha at planting and 100 kg urea was applied at 3-5 weeks after planting (WAP). The experiments were laid out in a Randomized Complete Block Design (RCBD) with four replications at each location. Each plot was made up of 4 rows, each 5 m long. Row-to row spacing was 75 cm and hill to hill spacing was 30 cm. Seeds (4-6) were sown per hole at a depth of 3-5 cm and thinned to 2 plants per hill at 2 WAP. Weeding was done manually. All the agronomic management practices (thinning, weeding, fertilizer application, pesticide spraying, harvesting, etc.) were applied accordingly. Data on weather (rainfall, minimum, maximum temperatures and humidity) was collected from the nearest weather stations. Days to 50% flowering, days to 80% plant maturity, plant height, grain and stalk yield from two middle rows were collected at harvest and extrapolated to grain and stalk yields. The data was analysed using Genstat statistical software (19th Edition).

RESULTS AND DISCUSSION

Combined analysis of variance (ANOVA) across locations for year, location, grain yield, revealed highly significant variability among the genotypes with significant environment, and genotype by environment interaction effect (Table 1). Significant differences were observed among the genotypes for days to 50% flowering while the mean values for the different genotypes ranged from 69 to 93 days. Genotype FRAMIDA was the earliest to flower (69 days) and followed by CSR 04H (78 days). SAMSORG 47 and CSR 02 had the longest period for flowering (93 days). The genotypes differed significantly in plant height, ranging from 147.0cm to 352.4cm. The highest plant height was recorded in CSR 02 (352.4cm) and CSR 01 (352.2cm). The shortest of 147.0cm was in 12KNICSV 418. Days to maturity ranged from 103 to 128 days with a mean of 118 days, FRAMIDA (103 days) were early maturing and SAMSORG 47 matured last at 128 days, while in Iseyin, genotype FRAMIDA (84 days) is the earlier maturing and SAMSORG 47 (128 days) matured last.

Mean grain yields differ significantly between genotypes in all the locations (Table 2). The lowest grain yield (1447 kg/ha) was obtained in CSR 03H and highest of 2510 kg/ha in CSR 02. Significantly higher mean grain yields were recorded also in CSR 01 (2479 kg/ha), SAMSORG 45 (2285 kg/ha), SAMSOR 42 (2284 kg/ha) and 12KNICSV 418 (2205 kg/ha) higher than the overall mean of the 10 genotypes. Genotypes CSR 03H (1447 kg/ha), FRAMIDA (1827 kg/ha) and CSR 04H (1903 kg/ha) had significantly lower grain yields compared to the grand mean (2113 kg/ha) (Table 3). Stalk yield shows significant different among the genotypes, SAMSORG 42, CSR 01, CSR 02 and SAMSORG 47 recorded the highest stalk yields of 10,230 kg/ha, 9,878 kg/ha, 9,660 kg/ha and 8,443 kg/ha respectively. The earlier maturing genotypes produce less biomass (Table 2) compared to medium maturing genotypes; FRAMIDA (5,317 kg/ha), CSR 03H (5,488 kg/ha) and 12KNICSV 418 (5,510 kg/ha). The Additive Main Effect and Multiplicative Interaction (AMMI) model showed significant differences amongst genotypes, environments and interactions between genotypes and environments ($P>0.001$) (Table 1) for grain yield, genotypes, environments and interactions accounted for 25.5, 48.2 and 5.0% of the sum of squares respectively. This indicated serious contribution of environment in the performance of the genotypes. *The study demonstrated that several of the selected sorghum genotypes are adapted to the different locations. Based on the* AMMI and GGE plot (figure 1), SAMSORG 48, SAMSORG 45, CSR 01, CSR 02 and 12KNICSV 418 are found to be adapted to Ilorin, Gambawa, Iseyin, BUK and Makurdi respectively. Zaria has 2 adapted varieties, SAMSORG 42 and SAMSORG 47. SAMSORG 47 has also found to be good in Ilorin and Makurdi. SAMSORG 45 has found to also be adapted in Minjibir and BUK. In the sudano-Sahelian areas of Gambawa, Minjibir and BUK, SAMSORG 45 is recommended; while SAMSORG 42 and SAMSORG 47 are recommended for northern guinea such as Zaria and Makurdi environs. SAMSORG 47 and SAMSORG 48 are recommended for Ilorin and CSR 01 for Iseyin in the southern guinea and derived savannahs respectively. The high mean square values for locations across the test environments indicating that the test genotypes responded differently across environments. Hence, decision on selecting genotypes need to consider the target environments. Similar findings have been reported by Adugna (2007) and Gasura *et al*., (2015) on multi-environment evaluation of sorghum genotypes. Combined ANOVA determines if GEI is a significant source of variation or not and estimates it but does not provide insight into the patterns of genotypes or environments that give rise to the interaction Samonte *et al*., (2005). The different response of genotypes across the testing environment is considered as a hindrance in selecting and recommending of crops and cause yield fluctuation (Yan and Tinker, 2006).

CONCLUSION

Combined analysis of variance displayed highly significant G x E interaction and variations were significant among the test sites. Selecting genotypes in diversified testing locations and assessing yield stability of sorghum genotypes is quite vital. The AMMI analysis for the additive main effect and multiplicative interaction effect revealed significant difference for genotypes, testing locations and genotype by testing location interaction. The values of the different genotypes for days to 50% flowering and physiological maturity showed significantly different. These differences can be exploited for cultivation in different agro-ecological zones or at different planting dates in a similar zone.

ACKNOWLEDGEMENT

We thank the management of Nigerian Breweries (NB) Plc for the trust and partnership in funding the research. The ICRISAT management were very supportive of the project. We thank partners including Prof Daniel Aba and Mr Ibrahim Juma`are, both of IAR Zaria, Mr Joseph in Iseyin Alhaji Taofiq in Ilorin who provided the fields and assisted in monitoring of crops.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Microbial contamination is a major cause of economic losses in commercial and research plant tissue culture operations. In this study, different chemotherapeutic agents were screened to effectively eliminate both fungal and bacterial contaminants during the in vitro establishment of two selected cassava cultivars (Manihot esculenta Crantz) namely Umucass 36 and Umucass 45, in National Root Crops Research Institute (NRCRI), Umudike Tissue culture/Genetic Transformation laboratory. Chemotherapeutic agents used for the experiment in single and combined treatment in an agar-embedded system were: Antibacterials comprising Ampicillin and Kanamycin at 100mg/L concentration; Fungicides comprising Starinsec® (Imidacloprid 40% + Mancozeb 40%), Nystatin (Phytotech) and Imidazole (Phytotech) at 100mg/L concentration and Plant Protective Mixture™ (PPM) at 2ml/L used as a control. The explants of the cassava cultivars were aseptically established in culture and the results showed that Ampicillin and a combination of Nystatin/Ampicillin compared favorably with PPM in contamination control but outperformed it in the leaf/root proliferation for Umucass 36. On the other hand, PPM and Nystatin/kanamycin treatments gave the best contamination control result for Umucass 45, although other combinations of chemotherapeutic agents showed potentials in being effective in terms of other important traits. The study has provided an alternative effective protocol for establishing clean in vitro cultures of the select cultivars while recommending further research to evaluate possible effect on the genetic fidelity of the varieties.

INTRODUCTION

Microbial contamination is one of the major challenges hampering the application of *in vitro* micropropagation technique (Altan *et al.*, 2010) which could be as a result of explant-borne pathogen or as a laboratory contamination. Various efforts have been made to get rid of microbial contaminants in plant tissue culture (Medjemem *et al.*, 2016). Although surface sterilization of the explant to get rid of epiphytic (surface-living) microorganisms is carried out frequently, there are endophytic (within the tissues) organisms which colonize inside of the living plant tissue and cause contamination of tissue cultures (Cassells, 2012).
A wide range of microorganisms (filamentous fungi, yeasts, bacteria, viruses and viroids) and micro-arthropods (mites and thrips) have been identified as contaminants in plant tissue cultures. Contamination of plant tissue culture by different microorganisms such as bacteria and fungi reduces tissue productivity and results in variable growth, tissue necrosis, reduced shoot proliferation, reduced rooting among other negative effects (Altan *et al.*, 2010).
Several different methods are used to eliminate fungal and bacterial contamination, including the use of antibiotics and fungicides, as well as inactivation by heat and light (Sen *et al.*, 2013). However, these methods can also be injurious to the *in vitro* tissue if not safely applied.
The use of chemotherapeutic agents such as antibiotics in plant tissue culture has been widely reported. Mbah and Wakil (2012) reported that antibiotics used in plant tissue culture should be soluble, stable, unaffected by the components or pH of the medium, lack side effects, broadly active, non-resistance inducing, inexpensive and non-toxic to humans. In other instances, antibiotics effective on isolated organisms cannot be used for treating contaminated plants due to phytotoxicity or poor penetration into tissues (Singh *et al.*, 2020). Although phytotoxicity and development of antibiotic-resistant bacterial populations have restricted the use of antibiotics,

these side effects can be taken care of by the use of combinations of antibiotics at relatively lower concentrations (Yang *et al.*, 2021).

This present study was focused on screening and determining chemotherapeutic agents with the most effective activity against microbial contaminants *in vitro* and evaluating the effect of the chemotherapeutic agents on the growth parameters of the selected cassava cultivars.

MATERIALS AND METHODS

The study was carried out in the National Root Crops Research Institute (NRCRI), Umudike Tissue culture/Genetic Transformation laboratory, Umudike Abia State, Nigeria.

Two pro-vitamin A cassava cultivars (Umucass 36 and Umucass 45) were selected for this study due to the persistent microbial contamination incidence associated with their *in vitro* establishment and importance to genetic transformation activities. The planting materials were obtained from the experimental farm at National Root Crops Research institute at three months after planting (3MAP) and established *in vitro* culture.MS medium (1962) was prepared (Murashige and Skoog, 1962) using 3% sucrose (w/v) and 0.8% (w/v) agar) in 250ml capacity glass jar. Chemotherapeutics used for the experiment were: Antibiotics- Ampicillin and Kanamycin (Phytotech, USA) at 100mg/L concentration; Fungicides- Starinsec® (Imidacloprid 40% + Mancozeb 40%), Nystatin (Phytotech), Imidazole (Phytotech) at 100mg/L concentration. Plant Protective Mixture™ (PPM) at 2ml/L was used as a positive control and zero additive (NONE) for negative control.

Surface sterilized nodal explants were initiated into 50ml MS medium primed with the chemotherapeutics in single and combined forms as denoted below:

T1= Starinsec; T2= Nystatin; T3= Imidazole; T4=Ampicillin; T5= Kanamycin; T6= Starinsec/Ampicillin; T7= Starinsec/Kanamycin; T8= Nystatin/Ampicillin; T9= Nystatin/Kanamycin;T10=Starinsec/Ampicillin/Kanamycin; T11=Nystatin/Ampicillin/Kanamycin; T12=PPM; T13= None (zero additive).

Surface sterilization was carried out aseptically using the following sterilants; 10% sodium hypochlorite, 70% ethanol and 20% (w/v) benomyl fungicide. The labelled culture bottles were sealed and incubated at a temperature of 26 ± 2ºC for 16 hour photoperiod and 8 h darkness at light intensity of 2000-3000 lux in the growth chamber.

Cultures were observed weekly (for a 4-6week cycle) for visual signs of microbial contamination and data on growth parameters (number of leaves, roots, vigour) were collected at 4weeks. Each experimental unit was replicated three times in a completely randomized design (CRD) and the experiment was repeated twice. The means of data collected were subjected to analysis of variance (ANOVA) at 0.05% level of significance using R-Software and descriptive statistics.

RESULTS AND DISCUSSION

A summary of treatment means showing the effect on number of leaves, roots and vigour of Umucass 36 and Umucass 45 are highlighted in **Table 1.** The treatment effect on contamination (**Figure 1**) showed that Ampicillin (T4), Starinsec/Ampicillin (T6), Starinsec/Kanamycin (T7), Nystatin/Ampicillin (T8) were comparable with the positive control [PPM] in their performance for Umucass 36 at 100% contamination control; while Nystatin/Kanamycin (T9) compared with the positive control at 100% for Umucass 45. Fang and Hsu (2012) reported that aminoglycosides antibiotics such as kanamycin have been specifically found effective against *in vitro* phytopathogens as corroborated by this study.

For leaves/shoot proliferation, there was a significant effect of treatment on genotype/cultivar (**Figure 2**); Umucass 36 had the highest mean number of leaves (3) for the treatment effect with Ampicillin (T4) which agreed with Mineykina *et al.* (2020) who reported on the effectiveness of beta-lactam antibiotics (cefotaxime and ampicillin) as not only antimicrobial in their activity but also growth-enhancing in the microspore embryogenesis of *Brassia* spp. This trend was not followed by the Umucass 45 cultivar that had its highest mean number of leaves (4.0) with the negative control and Starinsec/Kanamycin (T7) as second highest (3.5).

For rooting in Umucass 36, Ampicillin (T4), Starinsec/Ampicillin (T6) and Nystatin/Ampicillin (T8) among others outperformed the positive control (PPM) which conformed with the findings of Mineykina *et al.* (2020) but was not observed for Umucass 45 which had highest rooting with PPM (**Figure 3**).

The vigour of both cultivars were significantly affected by the treatments with Ampicillin (T4) & Nystatin/Ampicillin (T8) outperforming that of the positive control (PPM) (**Figure 4**).

Comparatively for all parameters evaluated, Ampicillin (T4) and Nystatin/Ampicillin (T8) outperformed the positive control (PPM) for Umucass 36; for Umucass 45, positive control (PPM) in conformity with the findings of Leão *et al.* (2020) and Nystatin/kanamycin (T9) performed at 100% contamination control (**Figure 5)**.

CONCLUSION AND RECOMMENDATIONS

Umucass 36 and 45 are important genetic transformation candidates not just due to their high Pro Vitamin A content, also due to their high compatibility and susceptibility to the manipulation protocols. A microbial contamination elimination protocol using Ampicillin and a combination of Nystatin/Ampicillin in an agar-embedding system gave clean cultures without compromising the leaf/root proliferation of Umucass 36. Although, PPM and Nystatin/kanamycin treatments gave the best contamination control result for Umucass 45, other combinations of chemotherapeutic agents showed potentials in being effective in terms of other important traits. It was also observed that PPM^{TM} can be used for long term conservation of the select cultivars while using these cost-effective chemotherapeutic agents in their *in vitro* establishment for genetic transformation that requires growth proliferation within a short cycle of 3-4 weeks.

However, it is recommended that a further step of genetic fidelity testing is carried out on the target cultivars to investigate somaclonal variation that may be induced by the use of these agents at the investigated concentration (100mg/L). Other alternatives such as botanicals with antimicrobial properties should be tested across different cultivars of interest.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Sweet sorghum (Sorghum bicolor (L.) Moech) is a type of cultivated sorghum and has been recognized widely as potential alternative source of bio-fuel because of its high fermentable sugar content in the stalk. A substantial variation of brix content and related traits is rarely known to exist in sweet sorghum. The objective of the studies were to estimate the extent of heritability in some cultivated genotypes of sweet sorghum. The experiment consisted of three crosses from six generation (P_1, P_2, F_1, F_2, BC_1P_1 ,BC_2P_2). Nineteen traits were evaluated on six generations during two seasons(wet and dry). The phenotypic coefficient of variation (PCV) was greater than the genotypic coefficient of variation (GCV) for most of the traits studied in all the locations indicating high environmental influence amongst all the genotypes across the locations except 264.45 of grain yield and 531.49 of panicle weight(wet) and 703.25 of grain yield, 704.30 grain yield(dry). While high broad sense heritability was recorded (98.15) for number of leaves (wet season), high narrow sense heritability(75.15) for number of leaves. However, high genetic advance was recorded in only the dry season (33.67) of brix content at milk stage, was observed across all the location indicating the selection prospects for further breeding. The PCV ranged from 5.13 for panicle weight to 264.45 of grain yield while the GCV ranged from 2.31 for fresh biomass to 91.65 of number of leaves at Bauchi. While at Zaria wet season PVC ranged from 7.81 for panicle weight to 531.49 of grain yield. GCV ranged from 1.49 for fresh juice weigth to 120.49 for number of leaves. However, at Bauchi dry season PCV varied from 7.64 of panicle weight to 703.25 of grain yield, whereas GCV varied from 2.26 of fresh volume (ml) to 54.00 of stem diameter (mm). while at Zaria dry season PVC ranged from 8.57 of panicle weight to 704.30 for grain yield, and the GCV ranged from 4.83 of leaf length to 74.66 of stem diameter. The heritability (Hbs) estimates were 2.29 for panicle weight to 98.15 for number of leaves, with GA of 33.67% for brix content at milk stage at Bauchi wet season whereas, Hns estimates varied from 1.21 for panicle weight, 58.76% of leaves length, 5.17% for days to fifty per cent heading, 94.19% for panicle weight , 0.03% for brix content at maturity to 75.43% for number of leaves with GA of 25.25% in Zaria. Based on the results of the study, it concluded that, selection for brix content should be delayed in early generations and improved using recurrent selection approach.

Keywords: *GCV, PCV, Heritability.*

INTRODUCTION

Sorghum [*Sorghum bicolor* (L.) Moench) is a tropical C4 grass noted for its versatility, wide adaptation to temperate climates Hatamipour,, & Jahanshah, 2015, and improved water-use efficiency relative to other grasses Olukoya, & Aichele, (2015). “Sweet sorghum” refers to a specific ideotype that has high biomass and juicy stems with high concentrations of sugar (Serna-Saldívar, & Heredia-Olea, 2012). Sucrose concentrations in sweet sorghum increase rapidly after flowering, and harvest is usually performed at the dough stage of grain filling, around 30 d after anthesis. Historically, sweet sorghum has been used for small-scale U.S. syrup production, but there is growing interest in its use as a bioenergy crop. In climates where sugarcane (*Saccharum officinarum* L.) is widely grown, a complementary sugarcane–sweet sorghum harvesting system could potentially extend the harvest window an additional 3 to 4 month (Ranggi *et a*l, 2016).

Sweet sorghum sugar yields are considerably lower than those of sugarcane. However, sweet sorghum is an annual diploid crop that has received relatively little breeding attention, suggesting that rapid genetic improvement may be possible. Physiological mechanisms underlying sugar accumulation in sweet sorghum are not well understood. Like sugarcane, sweet sorghum accumulates sucrose in stem parenchyma cells, but phloem loading and the timing of sucrose accumulation both appear to differ between the two species. In sugarcane, sucrose transfer in mature internodes is predominantly symplasmic, with sugars loaded into the phloem via plasmodesmata (Rutto, Xu, & Kering, 2013) , whereas in sorghum, sucrose transfer is symplasmic in growing internodes but apoplastic in mature internodes. Kalpande, & Unche,(2014) reported that sweet sorghum sugar accumulation increases rapidly after panicle emergence, once internode elongation has ceased. Other studies suggest that the timing of sucrose accumulation is similar in sweet sorghum and sugarcane, beginning while stem elongation is still occurring (Sami et al., 2013). Some of these contradictory findings might result from the use of photoperiod sensitive (PS) versus photoperiod-insensitive (PI) sorghum genotypes. In PI genotypes or PS genotypes grown under short days, internode maturation is generally coincident with flowering, whereas in PS genotypes grown under long days, flowering is delayed relative to internode maturation, and sugar levels at anthesis are considerably higher Almodares & Hadi, (2009). Overall, the data suggest that sugar accumulation is dependent on internode maturation rather than flowering, but for practical purposes sugar accumulation before flowering is limited to the lower internodes of PS genotypes grown under long days. Genetic mechanisms underlying sugar hyper accumulation in sweet sorghum are unknown. However, sugar yield and its component phenotypes, Brix and juice volume, appear to be quantitative traits in sorghum with significant environmental and genotype-by-environment effects Oyier et al., (2017). The economic superiority is contributed by characters such as stalk yield, stalk sugar content (Brix %), stalk juice extractability, content of non-reducing and reducing sugars and grain yield Li, & Dale, (2010). The sugar content in the juice extracted from sweet sorghum stalks varies from 16-23%. Sweet sorghum is best suited for ethanol production because of its higher fermentable sugar content in the stalk compared to sugarcane (Reddy & Ramesh, 2005). Ethanol production has become an important new market for grain sorghum due to the classification of grain sorghum as an advanced biofuel feedstock in the 2008 Farm Bill. According to the World Agricultural Supply and Demand Estimate report ethanol production will account for 26 percent of domestic grain sorghum usage Li.,(2014).

MATERIALS AND METHODS

The experimental materials consisted of three selected crosses from NCII mating based on their sugar/brix content. The three crosses are: IS23525 x KSV15, NRS005 x SAMSORG45, and SAMSORG44 x NRS003.Each cross in 2018 was advanced to F_2, BC_1P_1 and BC_2P_2. The non-segregating generations of each of the three crosses (P_1,P_2 and F_1) along with the segregating generation(F_2, BCP_1 and BCP_2) was evaluated during the dry season of 2018 in a Randomized Complete Block design at two locations, IAR Samaru farm and ATBU farm in Bauchi, with 3 replications at each location. Plot size for non-segregating generation will be 5rows of 5mlong with inter and intra row spacing of 0.25m x 0.65m respectively, and for the segregating generation, plot size will be measure 12rows of 5m long with same intra and inter-row spacing as in non-segregating generation. Standard cultural practice for sorghum production will be as described by IAR will be followed throughout the growing condition. Ten competitive plants of parental lines and F_1S and 25 plant of F_2S, BC_1P_1 and BC_2P_2 per replication was randomly be selected for data collections.The knowledge of the genetic make-up of complex quantitative traits and the magnitude of genetic variability that exist among available germplasm are important for breeding of high sugar content genotype(Rao *et al.*, 2013).

RESULTS AND DISCUSSION

Phenotypic and genotypic coefficient of variation were estimated on nineteen traits on six generation (P_1, P_2, F_1 non segregation population) (F_2, BC_1,BC_2 segregation population)) for three crosses in Bauchi wet season and showed PVC ranged from 5.13 of panicle weight to 264.45 of grain yield, while GCV were range from 2.31 of fresh biomass to 84.80% of stem diameter. High heritability were observed in all the traits except in days to fifty per cent flowering,grain yield, Hbs ranged from 31.21 of panicle weight to 48.62 of plant height. Moderate broad sense heritability were observed in all the traits except panicle weight, grain yield. All the traits showed low genetics advance except in brix content at milk 33.67%.While in Zaria wet the PVC ranged from 7.81 for panicle weight to 531.49 for grain yield while the GCV ranged from 1.49 for fresh juice volume to 120.69 of number of leaves. The PCV were higher than GCVs. The broad sense heritability (Hbs) estimates ranged from 5.17 of days to heading to 92.31 of number of leaves. Broad sense heritability ranged from 0.02 of brix content at maturity to 83.78 of panicle weight. The high heritability estimates for days to maturity and plant height suggest that these traits are likely to respond to direct selection. Zou *et al.*, (2011) reported similar estimates of heritability for these traits. The high heritability obtained for most of the traits is in agreement with the findings of (Olukoye *et al,.2015*). Low Hns was observed in all measured traits except plant height, number of leaves number of internode, stem diameter, fresh biomass, fresh juice weight, brix content at dough stage that was moderate. Narrow sense heritability (Hns) were ranged from 2.01 of number of inter node to 74.80 of days to heading. Moderate narrow sense heritability was observed in all the traits except fresh biomass, leave length. All the traits showed low GA estimates of 0.18 for leave length to 19.68 moderate of brix content at dough stage. The effectiveness of selection for any character depends not only on the extent of genetic variability but also on the extent to which such traits can be transferable from one generation to the next.

Heritability estimates (expressed in %) in broad sense (Hbs) and narrow sense (Hns) and phenotypic and genotypic Coefficient of Variability (PCV) and (GCV), Genetic Advance (GA) were estimated on nineteen traits for six generation (P_1,P_2, F_1, non-segregation population and F_2, BC_1,BC_2) for three crosses of dry season (Bauchi and Zaria). The results were presented in Tables 2. The PCV ranged from 7.64 for panicle weight to 176.78 for hundred seed weight while the GCV ranged from 2.27 for fresh juice weight to 91.80 for brix content at milk stage. In all the traits PCVs were higher than the also Zou *et al.*, (2011) reported similar estimates of heritabilit . The heritability (Hbs) estimates ranged from 8.58 for leave length to 91.80 for number of internode. High heritability was observed for all the traits except fresh juice weight that was moderate (17.86) and leaves length that showed low Hbs (8.58). Narrow sense heritability (Hns) ranged from 6.95 for leaves length to 62.01 for brix content at dough. High Hns was observed for all the traits being >20% with exception of stem diameter, hundred seed weight, grain yield and fresh juice weight which were moderate and plant height (7.28), FJV (8.19) and leaves length (6.95) which were low. The genetic advance was classified as suggested by Johnson *et al*., (1955) (<10%) low, 10-20% moderate and >20% high. The GA ranged from 0.20 for leaves length to 5.93 for fresh juice volume. All the traits showed low GA estimates. All the traits showed low GA estimates except in brix content at dough stage 19.68% indicated moderate genetic advance. While in Zaria Dry the PVC ranged from 8.57 for panicle weight to 794.30 for grain yield while the GCV ranged from 2.70 for plant height to 74.66 of stem diameter.. The PCV were higher than GCVs. The heritability (Hbs) estimates ranged from 13.53 for leave length to 80.40 of days to flowering. High broad sense heritability was observed for all the traits except fresh biomass, fresh juice weight, brix content at dough stage that was moderate. Narrow sense heritability (Hns) were ranged from 2.01 of number of internode to 74.80 of days to heading. Moderate narrow sense heritability was. Observed in all the traits except fresh biomass, leave length. All the traits showed low GA estimates of 0.18 for leave length to 19..68 moderate of brix content at dough stage .

RECOMMENDATION AND CONCLUSIONS.

To accomplish any breeding program depends upon the genetic variation in the materials at hand. The greater the genetic variability, the higher would be the heritability, hence the better the chances of success to be achieved through proper selection. In this study most of the traits showed high heritability indicating the possibility of positive response to selection. This indicates the likelihood of transferring the heritable components from parents to offspring during breeding process. The Transgresive sergeants identified in this study could be improved by pedigree or recurrent selection favourable alleles for the improvement of brix component traits

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Strigolactones, a new group of phytohormones, are reported chemical cues that trigger the germination of Striga. A pot experiment was conducted to investigate the impact of synthetic strigolactone (GR24 at 0.1 mg L^{-1}) and exudates of maize genotype (at 0, 2, 4, 6 mg L^{-1}) on nine crosses of seven parents including: three inbred lines; TZSTR 190, TZSTR 193, TZEI 114 and three open pollinated varieties; SAMMAZ 14, SAMMAZ 16, SAMMAZ 17 and SUWAN and two check varieties GWG 111 and 5005 with different reaction to Striga infestation were selected to identify strigolactones production in maize genotypes using LC/MS/MS analytical procedure as well as their stimulation of Striga seed germination in a germination assay. The results of the LC/MS/MS showed that only two genotypes namely SUWAN X SAMMAZ 17 and Check GWG111 produced a detectable amount of the compound as that of the standard GR24 (m/z 321. However, when subjected to 4 different concentrations (0mg/L, 2mg/L, 4mg/L and 6mg/L) of the root extracts showed GR24 at 6mg/mL and 4mg/mL gave the highest Striga seeds germination of 68.83 and 47.00 respectively, while TZSTR 190 at 2mg/mL had the least Striga seeds germination of 19.33. It is suggested that Striga germination depends on maize genotype and concentration of the strigolactone and the use of LC/MS/MS analytical procedure to study the level of concentration in which GR24 and exudates from maize genotypes could play a vital to identify tolerant genotypes is extremely imperative and can open novel horizons for future investigations in the management of the parasitic plant.
Keywords: *Striga, LC-MS-MS, Germination Assay, Strigolactone, GR24, Open Pollinated Varieties,*

INTRODUCTION
The root obligate hemiparasite *Striga hermonthica* is one of the major global biotic threats to agriculture in sub-Saharan Africa, causing severe yield losses of cereals. The germination of *Striga* seeds relies on host-released signaling molecules, mainly strigolactones (SLs). Many seed germination stimulants have been extracted and identified in parasitic weeds host and non-host plant (Li et al., 2020; Sato et al., 2014). Among the germination stimulants of parasitic weeds in host plants are three distinctive classes of compounds which include, dihydroquinones, strigolactones, and sesquiterpene lactones (Li et al., 2020).

Maize plant produces at least two strigolactones, strigol and sorgolactone (Sato et al., 2014). Jamil et al., (2011) in their work reported some common SLs like sorgomol and 5-deoxystrigol and some yet to be named putative SLs, SL1 and SL2 with molecular mass of 348 and 376, respectively in maize. However, recent studies by Charnikhova et al., (2017) have shown the presence of seven unidentified SLs and 2 new structures were identified in maize.

Strigolactones produced by individual plant are usually unstable and very low in concentration for isolation and characterization using ODS-HPLC separation (Sato et al., 2014). Recovery in a culture filtrate using this method is put at as low as 2 % there by making it unfit for low strigolactones producing plant like maize. However, the use of a simple and fast analytical tool known as HPLC-tandem mass spectrometry (LC/MS/MS) has been reported for adequate identification, isolation, characterization and quantification of biomolecules in samples (Ismail et al., 2019; Jamil *et al*., 2011; Motmainna *et al.*, 2021; Peixoto Araujo *et al.*, 2020).

The objective of this present study is to identify the presence of strigolactones in some selected hybrids of maize identified with high, low and moderate *Striga* infestation in potted glass house experiment as well as their parents using LC/MS/MS. The study also examines the relationship between the strigolactones production and *Striga* seed germination stimulation in maize.

MATERIALS

Planting material

A pot experiment was conducted in a glass-house of Ladang 15 (2°59'05.7"N, 101°44'02.9"E, 30 m above average sea level) at the Agricultural Research Park, Institute of Tropical agriculture and Food Security, Universiti Putra Malaysia. Maize seeds of nine crosses and their reciprocals hybrids out of 42 hybrids derived from 7 x 7 diallel single cross, their seven parents and two check varieties with different reaction to *Striga* infestation were tested . The crosses and their reciprocals selected include: recip. SUWAN x SAMMAZ 16, cross SAMMAZ 14 X SUWAN, TZRST 190 x TZSTR 193; TZSTR 190 x SAMMAZ 14, SAMMAZ 17 x TZSTR 190 and SAMMAZ 14 x TZSTR 193, SUWAN x TZSTR 193, SUWAN x SAMMAZ 17, SAMMAZ 16 X TZSTR 190, the parents, TZSTR 190, TZSTR 192, TZEI 114, SAMMAZ 14, SAMMAZ 16, SAMMAZ 17 and SUWAN and the check varieties 5005 and GWG 111. The seeds of maize and *Striga* used in the experiment were supplied by International Institute for Tropical Agriculture, Ibadan, Nigeria and green W Seed company.

Exudate extraction procedure and sample preparation for LC-ESI-MS/MS

The exudate extraction was carried out at Weed Science Laboratory of Department of Crop Science, Faculty of Agriculture, Central Laboratory and Physiology Laboratory of Institute of Tropical Agriculture and Food Security, University Putra Malaysia. Seeds from Eleven hybrids, their parents and two check varieties of maize were sterilized in 70 % ethanol (EtOH) for 2 minutes and then 1% sodium hypochlorite (NaOCl) for 5 minutes. The seeds were thoroughly rinsed using distilled water. The seed were germinated in petri dishes with moistened filter paper for 7 days at 28°C in the dark (Plate 1A). Ten germinated seedlings from each variety were transferred into Nalgene (115ml filter units and 0.8 micromillimeter pore) with 2 cm glass wool fibre in the filter unit and moistened with 5 ml half strength Hoagland's nutrient solution as culture medium (Plate 1 B&C). The culture medium in each filter were removed by suction and replace with a fresh solution at two days interval for three weeks. The set up were placed under inflorescence illumination at 25 ± 1 °C temperatures. The exudates were collected by washing the filter with 150 ml of sterile water after 24 hours and fresh sterile water added. The collected root exudates were extracted 3 times with 100 % LCMS GRADE acetone and stored in -20°C. The acetone extracts were combined and washed using 0.2M of K_2HPO (pH 8.4), dried over anhydrous $MgSO_4$, stored in -80°C and later concentrated using Freeze dryer. 4 µg/mL solution of the freeze-dried acetone extracts from each sample were prepared using 55 % LCMS GRADE methanol, vortexed and filtered through 0.2 µm spin columns into sterile glass vials for LC-QTOF-MS/MS analysis.

Under a sterile condition, *Striga* seeds surface were sterilized in 2% Sodium hypochlorite containing 0.02% (v/v) Tween20 for 5min and rinsed thoroughly with distilled water. The seeds were dried for 30 mins in a laminar air flow cabinet. Approximately 100-150 seeds were spread on a glass fibre filter paper (GFFP) disc (9cm diameter) and placed in sterilized petri dishes (9cm diameter) and covered with Whatman filter paper as described by Jamil et al., (2011) & Jamil et al., (2018). The set up were wetted with 2.7ml of distilled water, sealed with parafilm and incubated in darkness at 28^{o}C for 12days. The set ups were checked regularly and water added when necessary. After preconditioning, 1g of the preconditioned seeds were dissolved in 99ml of distilled water (1:99) and 100µl were pipetted into petri dishes containing folded tissue papers.
LC-ESI-MS/MS analysis was carried out on the root extracts of the eighteen genotypes of maize by measuring 2 µg/mL samples from sub-section and GR24 standard. Thermo Scientific Ultimate 3000^{TM} Q Exactive^{TM} Hybrid Quadrupole Orbitrap mass spectrometer with an ESI attached to a UHPLC binary pump autosampler (Macherey-Nagel, Düren, Germany). Separation was performed using Water Acquity UPLC^{TM} BEH a C18 reversed-phase column (100 x 2.1 mm, 1.9 µm) (Ireland). The mobile phase was A-0.1% formic Acid in water B- 0.1% formic acid in Methanol) with flow rate of 0.5ml/min and injection volume of 5ul and PDA range of 190-600nm. 0-11 minutes: 95% A: 5% B, 12–15 minutes: 10% A: 90% B, 15–17 minutes: 95% A and 5% B. It remained isocratic 20 minutes at: 95% A: 5% B. The injection volume was 5 µL. The mass acquisition data was operated at both negative and positive switch modes, with a voltage of 4.0 kV, capillary temperature 350°C, sheath gas flow rate 80 arbitrary units, and a scan range m/z 150 to 2000 respectively. Data acquisition was performed using Xcalibre 2.2. SP 1.48 (Thermo Fisher Inc) software.
Four different concentrations: 0µg/mL (Blank 55% methanol) as negative control, 2µg/mL, 4µg/mL and 6µg/mL of freeze-dried acetone extracts from each sample and GR24 standard (positive control) were prepared in 55% Methanol. 10 µL of each sample solution were pipetted into each petri-dish containing *Striga* seeds in triplicates arranged in a factorial completely randomized design CRD, sealed using paraffin to maintain moist condition and incubated in the dark at room temperature (25 ± 1 ^{o}C) for 5 days.
Number of germinated *Striga* seedling at 5 days after incubation was recorded.
The data collected were subjected to analysis of variance and the mean separated using Fisher's Least Significant Difference (LSD) at 5% significance difference.

Plate 1: Picture showing Strigolactone extraction process

RESULTS AND DISCUSSION
LC/MS Analysis of samples
The LC/MS analysis on the standard showed the value of GR24 to be m/z 321.07 on the full scan (Fig A). The ms/ms fragment showed fragments at m/z 321, m/z 224 and m/z 11 at 3.95 retention time. This agrees with the report of Rial et al., (2018). The only genotypes that showed same compounds as the standard at 3.95 retention time are hybrid recip. SUWAN X SAMMAZ 17 and Check GWG 111. The full ms scan of hybrid recip. SUWAN X SAMMAZ 17 and Check GWG 111 as well as the ms/ms fragments of m/z 321, m/z 224 and m/z 11 is shown in figure B and C. This result is also in agreement with the report of Rial et al., (2018).

Analysis of variance for *Striga* seed germination at 5 days

The analysis of variance for mean squares of *Striga* seed germination at 5 days for first and second season are presented in appendices 29-30. The combined analysis results for *Striga* seed germination assay arranged in a two factorial design is presented in Table 2.

The mean squares from the analysis of variance in a combined season as well as the mean interaction of treatment x concentration of the methanol-based root extract from 27 maize genotypes and analog synthetic Standard GR24 in a *Striga* seed germination assay is presented in Table 2 and 3.

Result in Table 2 shows that the effects of treatment, concentration and their interactions on germination of *Striga* seeds were highly significant. This indicates that the germination of *Striga* seeds is dependent on the treatment (genotypes) and the concentration of strigolactones in the root extracts formulation. This is in line with the findings of Mohemed et al., (2018) & Motmainna et al., (2021). Also, the combine analysis shows a highly significant

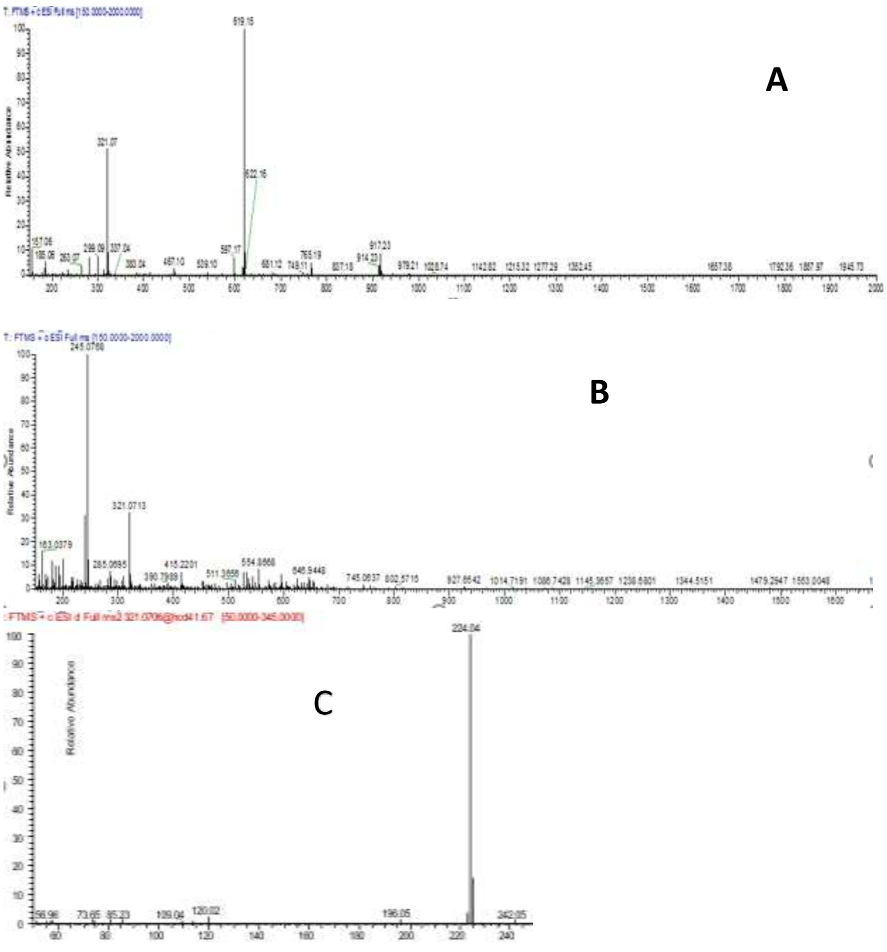

Figure.1: LC-MS analysis showing peak for the of Strigolactone in sample MS/MS fragmentation of Standard Strigolactone GR24 (A) and Strigolactone in hybrid recip. SUWAN X SAMMAZ 17 (B).and Check GWG 111 (C)

Table 1: Analysis of variance for *Striga* germination at 5days after treatment in combined Season

Source of variation	df	MS
Season	1	363.15**
Treatment	27	825.71**
concentration	3	24450.82**
Treatment x season	27	159.86**
Treatment x conc.	81	142.23**
Treatment x season x conc.	84	34.42**
Error	224	
Total	335	

**highly significant at p=0.001

Difference in the seasons. This could be as a result of increase in the duration of *Striga* seeds conditioning. The longer the period of pre-conditioning, the higher the viability or germination of *Striga* seeds. This is in in line with the work reported by Charnikhova et al., (2017) & Jamil et al., (2011).

The mean interactions between treatment and extracts concentration on *Striga* seed germination as shown in Table 3 indicates that GR24 at 6mg/mL and 4mg/mL have the highest *Striga* seed germination of 68.83 and 47.00 respectively (Plate 3A),

followed by check GWG111 (43.67) at 6mg/mL (Plate 3E) and parent TZSTR 193 (43.17) at 6mg/mL (Plate 3D).While TZSTR 190 at 2mg/mL had the least *Striga* seeds germination of 19.33 (Plate 3C), however, there was no significant difference with the control at concentration of 2mg/mL (Plate 3B). This was followed by SUWAN X SAMMAZ 14 (3.33), TZSTR 193 X TZSTR 190 (3.50) and TZSTR 193 X SAMMAZ 14 (3.67) at concentration 2mg/mL. The overall mean showed that GR24 has the highest numbers of germinated *Striga* seeds of 34.96 which was significantly different from the TZSTR 193 which has the second highest *Striga* seed germination of 24.17. this was closely followed by Check GWG 111 (20.29), SUWAN (18.67), SUWAN X TZSTR 193 (18.67) while TZSTR 190 has the least overall *Striga* seed germination of 7.25 (Plate 3C), followed by TZEI 114 X TZSTR 190 with 7.79, TZSTR 193 x SAMMAZ 14 (8.13) and SUWAN x SAMMAZ 14 (8.59). However, there was no significant different between the two genotypes with the least in the overall *Striga* seed germination.

The result also shows that increase in concentration of the root extract solution across all genotypes and Standard GR24 gave a corresponding increase in *Striga* seed germination except TZSTR 190 at 0mg/L and 2mg/L, TZSTR 193 and SUWAN X TZSTR 193 at 4mg/L and 6mg/L respectively, as well as SAMMAZ 16 X SUWAN at 2mg/l and 4mg/L.

It is interesting to note that there was significant difference in the *Striga* seeds germination between most crosses and their reciprocals, indicating that there could be reciprocal or maternal effects in the inheritance of strigolactones production by the maize plants. This further validates the result of obtained in the *Striga* infestation reaction potted experiment as presented in chapter five which is indicated significance in reciprocal and maternal effect in *Striga* count at 7 and 10 weeks after planting. This is in line with the reports of Adetimirin et al., (2000).

CONCLUSION

All root extract exudates from 27 different genotypes used in this present study were carefully examined by LC/MS/MS for the presence GR24 (M/z 321), only two of the genotypes namely SUWAN X SAMMAZ 17 and Check GWG111 produced a detectable amount of the compound under the conditions used in this study. However, they all stimulated the germination of *Striga* seeds in various degrees at different concentrations of the root extract solution in a germination assay conducted. This shows that either they amount produced by the other genotypes were too minute to be detected or other forms of strigolactones were present in the root. It may be concluded that different genotypes produce different mixtures of stimulant and at different concentration which could be very low for detection by the procedure used in this study. However, further studies using different higher concentrations of the root extracts in an LC/MS/MS analysis should be conducted, in order to allow for identification of stimulants present in samples.

Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Information on combining ability facilitates efficient utilization of genetic materials in a breeding program. Selection of suitable breeding-lines is desirable in crop improvement and requires complete knowledge about the nature of gene action involved in the inheritance of quantitative and quality traits. Gene action of grain yield and quality traits in maize (Zea mays L.) was studied through crossing 8 parental lines in half diallel mating design (griffing method II model I). The parents and the 28 progenies were laid out in randomized complete block design (RCBD) with three replications. The result combined of analysis of variance revealed significant (p<0.05) variation among the genotypes and the parent TZSTR190 was the best combine for major yield contributing characters including plant height, ear length, number of rows per cob, grain yield, starch content and protein content. The GCA: SCA ratio and GCA x Env, SCA x Env Specific combining ability estimates showed that desirable SCA effects in Crosses TZSTR190 x TZSTR193 and TZSTR166 x TZSTR 193 for all traits studied except ear height and number of rows per ear. Gene action analysis revealed preponderance of both additive and non-additive genes for yield and quality traits. Therefore, for varietal improvement, these crosses could be useful towards enhancing maize yield and quality.
Keywords: *Maize, Gene action, General and specific combining ability, grain yield and quality traits*

INTRODUCTION
Maize (*Zea mays* L.) occupies a prestigious place in world agriculture. It is a Miracle crop in view of its widespread usage as human food, animal feeding and industry (Keskin *et al*., 2005). Maize can be grown over diverse geographical environments compared with other crops. The identification of parental inbred lines that perform superior hybrids is the most costly and time consuming phase in maize hybrid development. Per se performance of maize inbred lines does not predict the performance of maize hybrids for grain yield (Hallauer and Miranda, 1988) predictors of single cross hybrids value or heterosis between parental inbred lines could therefore increase the efficiency of hybrid breeding programs (Betran *et al*., 2003). Plant breeders and geneticists often use diallel mating design to obtain genetic information about a trait of interest from a fixed or randomly chosen set of parental lines (Murray *et al.*, 2003).

The combing ability analysis is an important method to know gene actions and it is frequently used by crop breeders to choose the parents with high general combining ability GCA) and hybrids with high specific combining ability (SCA) effects (Yingzhong, 1999). Beside gene effects, breeders would also like to know how much of the variation in a crop is genetic and to what extent this variation is heritable because efficiency of selection mainly depends on additive genetic variance influence, the environment and interaction between genotype and environment (Haron *et al*., 2014). Large genotype x environment effects tends to be viewed as problematic in breeding because the lack of a predictable response hinders progress from selection (Dudley and Moll, 1969).

The knowledge on the genetic system controlling the quantitative and qualitative traits is important for formulating an efficient selection program through the use of a suitable mating design (Arti and Sonia, 2015). The information about the relative contribution of components of variation viz; additive and non-additive is essential for effective crop important program (Azhar and Ajmal, 1999). In order to apply an optimum breeding strategy of targeted qualitative and quantitative trait, a genetic analysis of the traits needs to be performed. Diallel mating design has been used extensively by several researchers to measure gene action for yield and yield component of maize (Mahdi *et al.*, 2010). Several workers studied gene action on the yield and yield attributes and determined that additive and non-additive variance components are important in the genetic control of yield and its associated traits in maize (Haron *et al*., 2014, Gideon *et al*; 2017). The present investigation was therefore, undertaken to study the estimates of general and specific combining ability and gene action in maize for yield components and quality traits.

MATERIALS AND METHODS

Eight maize inbred lines viz: TZSTR166, TZEI114, TZEI80, TZEI88, TZSTR190, TZSTR193, TZSTR115 and TZEI25were chosen based on their performance for yield and reaction to *Striga* in this study to represent an amount of genetic diversity of various agronomic traits. They were crossed in the raining season of 2015 at the University of Agriculture Research field, Makurdi in half diallel to give 28 crosses excluding reciprocals. The parents and their 28 F_1 hybrids were evaluated using RCBD with three replication in 2016 at 2 environments; the research farm of University of Agriculture, Makurdi and the research station of College of Agriculture, Science and Technology Lafia Lat 8º 32'N and 8º 32ºE) above sea level, Nasarawa State. At both environments, the parents and their progenies were sown in three-row plots of 3 x 1.5m. Two seeds were sown at inter-row spacing of 0.75m within intra row spacing of 0.50m and were later thinned to one plant per hill at two weeks after sowing (WAS) to obtain a population of 53, 333 plants per hectare. At four weeks after sowing (WAS); the plots were hoemanually weeded to keep the trial free from weeds. Supplementary hoe weeding was carried out at eight weeks after sowing. A compound fertilizer (NPK 15:15:15) was applied at the rate of 30kg/hectare three weeks after sowing while urea was applied at the rate of 20kg/hectare after first weeding (6WAS). Data were collected from both environments on days from emergence to silking, days from emergence to maturity, plant and ear height (cm), ear length (cm), number of rows per ear, number of kernels per ear, seed yield per hectare (kg), starch content and protein content. Data collected at both environments were subjected to analysis using Griffing (1956) method II model I (fixed effects). Both general and specific combining abilities (gca and sca were computed using SAS Procedure (1999) for the parents and hybrids respectively. At the statistical model for RCBD and that of diallel method II model I to be provided as a guide for the analysis.

RESULTS AND DISCUSSIONS

An important step in a breeding programme is to adopt a suitable breeding strategy for the purposeful management of generated variability which largely depends upon type of gene action in the population for the traits under genetic improvement (Sprague, 1966). A knowledge of gene action helps to set an appropriate breeding strategy to accumulate fixable genes through selection. Genetic improvement in seed yield has been the priority of breeders. Genetic analysis helps in identifying traits for improvement of yield potential (Arti and Sonia, 2015).

Results of combined ANOVA across environment revealed that environment effects were significantly ($P<0.01$) different for all the traits measured (Table 1). This indicates that the lines do not perform the same across environments for most of the traits. Other authors inferred that environmental effects were significant for days from emergence to silking, plant height (Mickelson *et al.*, 2001, Abimiku, *et al.*, 2020) number of kernels per row (Vidal Martinez *et al*., 2001) and grain yield (Doerkben *et al.*, 2003). Genotype x environmental interaction effects were significantly ($p<0.05$)for all the traits except for Number of rows per ear suggesting that the genotypes performed differently for these across the two environments and specific genotype could be selected for different environment.

Non-significant genotype x environment interaction effects indicated that selection for days from emergence to silking, ear length and grain yield at one environment might be effective for a broad range of environments. Genotypes x environment interaction effects were significant for other traits, suggesting that genotypes did not perform same in the environments (Table 1). Some researchers have reported genotype x environment interaction effects for days from emergence to silking, plant height (Mickelson *et al*., 2001) number of rows per ear, ear length and grain yield (Doerksen *et al*., 2003; Mickelson *et al*., 2001).

Genetic variability of genotypes was significant for all traits. Therefore, the genotype sum of squares was partitioned into GCA and SCA (Table 1). Haron *et al.* (2014, Abimiku, *et al.*, 2020) similarly revealed that genotype effects were significantly ($p<0.05$) different for all the traits measured which showed that these genotypes perform differently across both environments. The results also showed that both general combing ability (GCA) and specific combining ability (SCA) was highly significant ($P<0.01$) for all the traits, indicating the importance of both additive gene action is important in the inheritance of these traits (Table 1).GCA x environment interaction effects were significant for all traits except days from emergence to silking and plant height while SCA x environment interaction effects were significant for all traits except ear length and grain yield. This indicate that hybrids performed the same across both environments in yield.

Estimate of Genetic Components of Variances:

The nature of gene action has been inferred from the estimates of GCA and SCA variances. The estimates of combining ability variances (σ^2gca and σ^2sca) and the ratio of δ^2A/δ^2_D is presented in Table 2. In this study plant height, ear height, ear length, number of row per ear number of kernels per row and grain yield showed non-additive gene effects, indicating preponderance of non-additive gene effects for inheritance of these traits. This predominance of SCA

variance denotes that non additive genetic effect were largely influencing the expression of the traits, hence heterosis could be exploited for can be exploited in producing high performing hybrids. These results were in agreement with the report of other researchers about predominance of non-additive genetic effects for plant height and ear height (Alam *et al*., 2008) ear length and number of rows per ear (Saeed *et al*., 2000), number of kernels per row (Srdic *et al*., 2007) and grain yield (Srdic *et al*., 2007). In contrast to this result other researchers indicated predominance of additive genetic effects for plant height (Vacaro *et al*., 2002), number of rows per ear (Srdic *et al*., 2007) number of kernels per row (Saeed *et al*., 2000) and grain yield (Ojo *et al*., 2007) days to emergence to silking and days to harvest traits showed additive genetic effect indicating additive genetic effects was more important than non-additive genetic effect in controlling the inheritance of these traits.
In the present investigation, the comparative estimates of σ^2sca, σ^2gca, σ^2A, σ^2D and σ^2A/σ^2D revealed that non-additive gene action is controlling the expression of ear length, number of rows per ear and grain yield per plant. The traits viz; plant height, ear height, days to emergence to silking and days to harvest duration are controlled by additive gene action as the ratio δ^2A/δ^2D is greater than unity hence pedigree selection could be exploited for these traits. These results are in conformity to findings of Mahdi *et al.* (2011) and Kumar *et al* (2014). However, contradictory reports are also available in literature with respect to gene action studies which can be due to different genetic material used in the present study. Since both additive and non-additive variances were found to be important in the genetic control of all quantitative and qualitative traits in this study, the use of population improvement method in the form of diallel selective mating or mass selection with concurrent random mating may lead to release of new maize varieties with higher yields.
Estimates of general combining ability for various traits have been presented in Table 3. The estimates of GCA effects exhibited that the parent TZSTR190 was the best general combiner for most traits studied i.e. days to silking, ear length, number of rows per cob, grain yield, starch content and protein content. This parent is most suitable for good yield performance at both environments.).. TZSTR 166 exhibited desirable GCA effects for plant height, ear length, number of rows per cob, grain yield, starch content and protein content Therefore this parent could be used extensively in hybrid program to increase maize yield with quality similar to the investigation reported for the following characters i.e. plant height (Vacaro *et al*; 2002) number of rows per cob (Rodrigues and da Silva, 2002).
High positive estimates of specific combining ability (SCA) in absolute values, indicates that hybrid performance is relatively superior to parent. In the selection of parental lines used to produce hybrids, the effect of SCA analyzed in isolated way has a limiting value. Therefore other parameters should be considered such as the average of hybrids and GCA of the respective parent lines (Dhasarathan *et*, *al*., 2015). Thus, superior hybrid combinations, which are important for breeding, are involved with at least one parental line that has the most favorable effects of GCA (Cruz and Regazz, 1997). Therefore it is possible to analyze the 2 hybrids that showed high performance for most of the yield quality and quantitative traits such as TZ5TR166 x TZ5TR190 and TZ81Z190x TZSTR190 (Table 4.)
The maize yield in the hybrid TZSTR190 x TZSTR193 is associated with high effects of GCA of both parental lines. Therefore, in this case, the high productivity is not due to dominant genetic effects of inbreds but to additive effect. In the TZSTR190 x TZSTR193 hybrid, it is associated with one of the highest effects of the GCA of the TZSTR190 inbred with one of the highest effects of the estimated SCA – since TZSTR193 inbred showed lower GCA. In this case, the participation of SCA is significant for hybrid yield, contributing almost to the GCA from both inbreds, regarding the dominance and epistasis effect (Gardner, 1963). However, hybrids TZSTR166 x TZSTR190 and TZSTR166 x TZSTR193 both exhibited high SCA for grain yield, plant height, ear length starch content and protein content, while TZSTR190 x TZSTR193 showed highest SCA for starch content and protein content. About seven hybrids exhibited higher mean performance and SCA effects of maize yield. In respect of maize yield superiority, it is decided by its quality. Therefore, crosses TZSTR190 x TZSTR193 and TZSTR166 x TZSTR193 recorded the highest mean and SCA effects for yield and quality traits. This present study revealed that most of the yield and quality traits include, plant heights, ear length, number of rows per cob, starch content and protein contents are governed by both additive and non-additive genes.

CONCLUSION

Sufficient genetic variability was generated for yield and related traits after crossing eight diverse inbreds of maize in half-daillel planting design. TZSTR190 and TZSTR193 were the best among parents as they showed desirable mean and GCA effects for most yield and its contributing traits and yield and quality traits respectively. Therefore, these parents could be used extensively in hybrid breeding program with the view to increase maize yield with quality. However, based on mean and SCA effects, two hybrids TZSTR166 x TZSTR193 and TZSTR190 x TZSTR193 proved to be the best to increase yield with better quality. For varietal improvement, these hybrids could also be used for exploiting promising recombinants and it could be useful to increase maize grain yield and quality.

Table 1: Combined analysis of different traits of maize based on Griffing method 2 model 1 model 8 x 8 diallel cross evaluated at -Makurdi and Lafia in 2019

Traits	source of varieties	Days from emergence to silking	Days from emergence to maturity	Plant height (cm)	Ear heights (cm)	Ear length (cm)	Number of rows per ear	Number of kernel per row	Grain yield of (per plant)

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cassava is an important staple food that has boost food security and income generation over the years. It is an all purpose crop that is used traditionally and industrially. It is a remarkably known foreign exchange commodity. Processing cassava into flouris a means of adding value and expanding the use of the root crop. Cassava breeders have achieved genetic gains in improving cassava for most key agronomic attributes, but there is low adoption of these released varieties by farmers. There is the need to in cooperate food quality attributes into breeding programs so farmers, food and industrial processors can explore the potentials of these varieties Ten (10) cassava genotypes at Uniform Yield Trial (UYT) stage were harvested from NRCRI cassava programe experimental field Five (5) Kg each of the fresh roots of the different cassava clones were washed peeled grated/dewatered and processed into high quality cassava flour (HQCF). Three (3kg) of each genotype was cut into chips, dried at 50^0c and milled for laboratory analysis. The fresh roots were analysed for dry matter, crude fibre, Amylose, Amylopectin, starch and sugar content while HQCF of the genotypes were analysed for pH and total titrable acity(TTA) . The result was collected and analysed using the right statistical package. The result of the analysis obtained at UYT stage; shows the genotypes NR18059, NR16002, NR180019 and NR10018 had good chemical properties and potential attributes for confectioneries other industrial application.
Keywords: *Chemical properties, Genotypes, Amylose, pH and Total titrable acidity*

INTRODUCTION

Cassava is an important staple food that has boost food security and income generation over the years. It is an all purpose crop that is used traditionally and industrially. It is a remarkably known foreign exchange commodity. Processing cassava into flouris a means of adding value and expanding the use of the root crop. Cassava flour has been partially used to replace wheat flour in the food and plywood industries (Amoa-Awua et.al 2014,Dhingra and Jood, 2004). High quality cassava flour (HQCF) is a promising market that has gained popularity in West Africa over the past few years (Kamala et al. 2012). Cassava breeders have achieved genetic gains in improving cassava for most key agronomic attributes (Bechoff et al., 2018). The need to in cooperate food quality attributes into breeding programs has become imperative considering the low adoption of the released improved varieties by farmers, food and industrial processors respectively. Evaluating cassava varieties for different food and industrial purposes may be achieved through understanding the chemical properties of the fresh roots and their flour.

MATERIALS AND METHODS

Eight (8) cassava genotypes at Uniform yield trial (UYT) stage and two checks (TME419 and UMUCASS 46) were harvested from the experimental field of the National Roots Crops Research Institute (NRCRI) . Five (5) Kg fresh roots of the different cassava clones were washed, peeled, grated, dewatered and processed into high quality cassava flour (HCQF). 3kg of each genotype was cut into chips, dried at 50^0C and milled for laboratory analysis. The fresh roots were analyzed for dry matter and crude fibre content using the method of AOAC (2000). Amylose and Amylopectin were analysed using the method of Idowu *et al*. (2013). Starch and sugar content were determined by the spectrophotometry methods described by AOAC(2005). The PH of HQCF samples from the different genotypes were also determined using a pH meter (Model HI 98129, Hanna Instrument, Italia) The percent titrable acidity was determined following the method of FAO (2005). The result was collected and analysed using SPSS statistical package.

RESULT AND DISCUSSION

The Dry matter content ranged from 15.08 to 43.00. NR16002 had the highest dry matter content (43.00) while NR18058 had the least dry matter content , There was no significant difference($P<0.05$) between NR16002, NR18001 and NR18059. Dry matter contents relates to good cooking habit and storage quality.(Eleazu and Eleazu 2012) .The crude fibre value ranges from 0.32 to 3.27. NR18053 had the highest crude fiber content. There was no significant difference ($P>0.05$) in NR16002, UMUCASS 46, NR18059, and NR18007. The amylose content ranged from 11.35. to 25.83 with no significant difference($P>0.05$) between NR18043 and UMUCASS 46 and NR18008 and NR180018. The amylopectin content ranged from 74.17 to 88.65. There was significant difference ($p<0.05$) among all genotypes except NR18043 and UMUCASS 46, so also in NR18007 and NR180018. The starch content ranged from 23.72 to 78.51. There were no significant ($P>0.05$) between NR16002 and NR180018. The sugar content ranged from 8.86 to 16.54 with all values significantly different from each other.

The pH is an indicator of the quality of the flour, the values ranged from (5.45-6.28). There was no significant difference ($P<0.05$) in samples (NR180019 and NR180018) The pH values are less acidic. flour with pH of ≤ 4 will have a characteristics sour taste and this is not desirable in bakery products (Apea Bah *et al.*, 2011).The total titrable acid value ranged from (0.40-1.22%) were within range of value stated by National standard specification of (1.0%).

CONCLUSION

From the result of the analysis obtained at UYT stage; using rank summation index Genotypes NR18059, NR16002, NR180019 and NR10018 have good chemical properties and potential attributes for confectioneries and industrial applications.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The demand gap between the breeder's crops and the consumer's choice has become a concern and necessity for adoption of improved varieties. Molecular approach has proven to be very useful in detecting solutions to complex quantitative traits driven by polygenic loci. Ability of cassava to ret (soften) fast for "fufu" processing is one of such complex traits that drives the adoption of improve varieties. In order to understand the region of the cassava genome responsible for retting ability, a molecular approach was applied using genome-wide association analysis (GWAS). One hundred and fifty-five genotypes laid in an alpha lattice design at the Experimental site of the National Root Crops Research Institute, Umudike were used for the association study. Data were collected on retting parameters using the standard operating procedure (SOP) method. The result showed low to moderate heritability estimates for the traits and significant (P<0.05) variation among the performances of the genotypes. The correlation analysis showed positive and significant coefficient of 70% between the dry matter content and firmness (penetrometer reading), while there was also a 60% positive and significant relationship between dry matter content and the retting index (fufu yield).The GWAS result indicated significant SNP markers on chromosome 2 and 10 for firmness of the root and on chromosome 16 for control of peel loss. The following vicinity functional candidate genes: LOC122723098, MANES_02G00400v8, MANES_10G043300v8, and MANES_16G013800v8 were further recognized to regulate biosynthesis of secondary metabolites for accumulation of starch and defense. Second year evaluation is in progress to further validate the result.

Keywords: *Cassava, retting ability, genome-wide association, fufu. Molecular.*

INTRODUCTION

Fufu is one of the many products that may be made from cassava, a crop that is very adaptable. A common food item made from cassava root via the retting technique is fufu, which is fermented cassava mash. Traditional fermentation of cassava that happens naturally while the roots are soaked and causes the roots to soften is known as "retting." According to Ampe *et al.* (1994), it is a crucial stage in the preparation of the majority of traditional foods made from cassava in central and West African nations. So, according to Wakem (2012), one of the key characteristics influencing consumer preference is the cassava root's ability to rotten. Similar to other food qualities, retting ability is complicated and impacted by both inherited and environmental variables. However, the role played by each component in the process of retting as well as the physiological (biophysical and biochemical) underpinnings of the root that control this qualitative feature are yet unclear Shengkui et al., (2018). Due to the lack of physiological markers on retting ability, it is challenging to incorporate this quality feature earlier in breeding programs and marker-assisted selection. As a result, the quality attributes of cassava hybrid cultivars fall short of end-user requirements and are hardly ever used. Further research is necessary, nevertheless, to determine the precise process behind these traits. Through the selection of suitable genotypes and desired phenotypic features to identify desirable functional genes or regions, molecular marker-assisted breeding is a practical method to investigate numerous advantageous allele variations Balyejusa, *et al.*, (2007). In this study, we attempt to evaluate the genetic diversity and identify the quantitative trait loci (QTL) of cassava for retting ability through the GWAS-SNP controlled by biophysical indicators associated with cassava retting of contrasted cassava varieties.

MATERIALS AND METHODS

Study area, experimental design and methods: The experiment was carried out in the experimental site of the National Root Crops Research Institute (NRCRI), Umudike. One hundred and fifty five (155) diverse cassava genotypes were established in a randomized incomplete block design (RIBD) with 2 replications.. Fresh cassava roots were processed from these genotypes into *fufu* using the validated RTBfoods standard operating protocol (SOP) for sensory characterization of *fufu* (https://doi.org/10.18167/agritrop/00595). Retting ability was also evaluated using the standard operating procedures developed within RTBfoods project**.** Instrumental firmness of 155 cassava genotypes was also measured with a handheld Penetrometer of 3.5mm diameter cylindrical probe (FHP-802 model) through fermentation time (0, 24, 48 and 72h). A total of ten (10) repeated measurement samples were taken on each genotype by measuring the proximal and distal parts of five randomly selected cassava roots per genotype through fermentation time. The turbidity of the fermented liquor was also measured in the lab using a BOSCH UV-VIS spectrophotometer (752N model). An aliquot of the fermenting liquor per fermenting vessel in two replicates was poured into a cuvette, and the transmittance was measured at 650nm.

Gene Annotation: The position of the highly significant SNP markers were explored by subjecting them to fine mapping and BLAST search on National Center for Biotechnology Information (NCBI) Genome Viewer v6.0 to annotate genomic regions and detect the nearby putative candidate genes associated with storage root formation and bulking. Putative genes within the significant SNP region were searched with respect to the significant SNPs position flanking right and left the position.

Data collections and Statistical analysis: Data were collected on the dry matter content and peel loss of the fresh root of the cassava. The methods used also entail data on the fufu yield, penetrometer readings, pH-value, turbidity and chaff loss of the fermented cassava root. A derivative summation retting index was calculated using the coefficient of the correlation of the traits to the yield by using this formula below:

Retting Index $= (X_1*W_1) + (X_2*W_2) + \ldots + (X_n*W_n)$

Where X_1, X_2, X_n *= the value of the traits under consideration, while* W_1, W_2, W_n *= economic weight with respect to the values from coefficient of correlation.*

Data were subject to analysis of variance to extract the variance components using GenSTAT v12 edition. The genome wide association study was carried out using the bioconductor package in R statistical software.

RESULTS AND DISCUSSION

Phenotypic variations and correlations of the Retting traits and Index:

The result of the analysis of variance (ANOVA) in Table 1 recorded significant ($P<0.001$) genotypic variance for all the traits indicating substantial phenotypic variance for breeders to make selection. The results also indicated that the effect of genotypes by environment interactions was not significant ($P>0.05$).

There is moderate heritability estimates observed for **penetrometer** and **turbidity (**0.653 and 0.572 respectively) from the instrumental evaluation and low heritability estimates observed for the manual (hardness: 0.279) and visual (foaming ability: 0.390; water visibility: 0.328) evaluations. The traits accompanied with moderate genetic variability confirmed that these traits are moderately genetically controlled and, selection for improvement would likely be successful. This showed that the phenotypic variance of the retting traits were better evaluated using the instrument for moderate to high genetic variation which is consistent with report by Gowda *et al.* (2015). High heritability estimates is an indication that selection of these traits should result in significant gains in cassava germplasm improvement Okogbenin *et al.* (2013).

The result of the Figure 1 showed the association of the retting traits and the index value. The results of the correlation show that strong positive and significant correlations ($P<0.001$) was observed between the bulking index and the different bulking traits like dry matter content ($r = 0.83$), and fufu yield ($r = 0.83$), but slight positive and significant correlation ($p<0.05$) with pH ($r = 0.48$). Fufu yield showed strong positive and significant correlation ($p<0.001$) with dry matter content ($r = 0.69$). The correlation of the retting index with the turbidity showed a strong negative and significant correlation ($r = -0.51$, $p<0.001$). Studies on correlation enable breeders to understand the mutual relationship among traits and indirectly consider related traits that are useful for selection, which could improve genetic values (Falconer and Mackay, 1996).

Relationship of the significant SNP marker across the retting traits: A total of three significant SNP markers passed the Bonferroni significance threshold shown in Figure 2 and 3. GWAS identified two significant SNP markers (S2_525353 and S10_4463009) for the firmness of cassava root on chromosome 2 and 10 respectively, while one significant SNP markers (S16_ 1363504) for the peel loss on chromosome 16. No significant SNP markers were observed for retting index, fufu yield and DMC. The genetic/allelic effect unit of the single SNP to the phenotypic variation was also estimated across the traits (Table 3).

Candidate Gene Annotations: Table 4 showed the number of the SNP markers related to the number of functional genes. The result recorded a total of five putative functional genes closest to the three significant SNPs of which two putative functional genes (LOC122723098 and MANES_02G00400v8) for the SNPs S2_525353 has a known gene description of mRNA-mavicyanin-like; one functional gene (MANES_10G043300v8) for the SNP marker S10_4463009 has mRNA-hypothetical protein description and two putative functional genes (MANES_16G013800v8 and LOC110603951) for the SNP marker S16_1363504 with a known gene description of Cysteine-rich receptor-like protein kinase. This putative gene (MANES_16G013800v8 and LOC110603951) were discovered to control Cysteine-rich receptor-like kinases (CRKs) which are transmembrane proteins that bind to the calcium ion to regulate stress-signaling in plant root (Quezada, *et al.,* 2019). Some of these genes have been previously identified as regulating and controlling root growth, development, and stress response in sweetpotato and related crops by Bararyenya *et al.,* (2020) and Kusaba *et al*., (2013). But this is the first time these genes were identified for retting traits.

				LOC122723098	mRNA-mavicyanin-like
				MANES_02G00400v8	mRNA-hypothetical protein
S10_4463009	10	4463009	Hardness	MANES_10G043300v8	mRNA-hypothetical protein
				MANES_16G013800v8	Cysteine-rich receptor-like protein kinase
				LOC110603951	Uncharacterized protein

CONCLUSION

The findings in the study showed significant genetic variations and broad sense heritability of moderate estimates for the retting traits. The SNP markers S2_ 525353 and S10_ 4463009 were found to be significant for firmness while S16_ 1363504 was found significant for peel loss. The following putative genes (LOC122723098, MANES_02G00400v8 and MANES_10G043300v8) were discovered to control mavicyanin-like protein which is related to glycoprotein isolated from zucchini peelings.

This putative gene (MANES_16G013800v8 and LOC110603951) were discovered to control Cysteine-rich receptor-like kinases (CRKs) which are transmembrane proteins that bind to the calcium ion to regulate stress-signaling in plant root.

The second year genomic studies is currently on going for the validation of this study.

ACKNOWLEDGEMENTS

We appreciate the support of the staff of National Root Crops Research Institute (NRCRI), Umudike and the International Institute for Tropical Agriculture (IITA), Ibadan.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The need to identify cassava genotypes that meet the needs of the end-users is of great importance. A hand-held penetrometer was used to characterize 17 cassava genotypes harvested from the NRCRI Umudike UYT population and 4 varieties identified as fufu processor preferred genotypes into three main contrasting groups (high, intermediate and low retting rate) according to the rate of softening. The result showed that more genotypes retted intermediately and very few of the genotypes had low retting. This implies that a hand-held penetrometer can be used to determine the retting ability of cassava genotypes and classify them into different categories.
Keywords: *Cassava, hand-held penetrometer, retting*

INTRODUCTION
The cassava retting process is a traditional fermentation that occurs spontaneously during root soaking leading to a root's softening. It has also been reported that varietal differences have a significant influence on the extent of retting of cassava roots (Nanda et al., 1996). The degree of root softening determines the easy separation of the water-insoluble material which ultimately determines the yield of wet *fufu* mash and textural properties of fufu; traits of primary interest to *fufu* processors and consumers (Umeh et al., 2014). With the increasing demand for food due to the rapid population growth in many developing countries, local processors have resorted to the addition of various chemical substances such as kerosene, trona and common wire nails to water for the steeping of the roots to accelerate. There is therefore need for research institutes to breed and release cassava varieties that meet the needs of the end-user. However, no standard approach has been developed to be used by breeders to screen and identify genotypes that have good retting ability within the breeding population. This study aims to present the hand-held penetrometer as a mid-throughput technique for classifying or characterizing the retting ability of cassava genotypes at the early stages of breeding.

MATERIALS AND METHOD
Sample Preparation
17 different cassava genotypes from regional UYT and 4 varieties identified as fufu processor preferred genotypes were used for the retting ability studies.4kg weight of uniform-sized (medium-sized root) freshly harvested cassava roots were weighed from each genotype. The roots were peeled and 3kg of each peeled genotype was weighed into the fermenting vessel of uniform size. An equal volume of water (5 litres) was poured into each fermenting vessel containing the roots and was allowed to stand for 72 hours.

Penetration test using hand-held Penetrometer
The SOP for Determination of the Firmness of Cassava Genotypes during Retting using the Hand-held Penetrometer developed by Chijioke et al. (2023) was used. Retting progression was monitored daily by Penetration test using a hand-held penetrometer to evaluate softness. 2 penetration readings on opposite sides of five (5) randomly selected roots/genotypes were taken resulting in 10 penetration readings per genotype to evaluate firmness.

RESULTS AND DISCUSSION
Table 1 shows the retting progression concerning genotype. The result of the penetrometer data shows that retting ability is genotype-dependent. The table shows the clustering of the genotypes into 3 contrasting groups, indicating differences in the retting ability of the genotypes evaluated. More genotypes retted immediately and this includes 2 of the preferred genotypes (Nwaocha and TMEB419), followed by the high retting ones. Genotypes that had between 75-100% are classified as high retting genotypes. Some of them include NR15C1aF24P001, NR15C1aF25P001, TMS14F1306P0015 and NR15C1aF3P017. These genotypes are among those processors will

wish to adopt because they ret faster, take a shorter time to be processed and as such reduce the use of chemicals. The genotypes that had between 20-30% are low-retting genotypes. They take a longer time to ferment and won't be easily adopted by processors. This result shows that a handheld penetrometer can be used as a technique to identify cassava genotypes that have good retting ability and determine the level of firmness of crops as validated by English et al., (2022). Breeders are therefore encouraged to adopt this in screening for cassava genotypes that meet the needs of fufu processors and indigenous foods that require softening of roots.

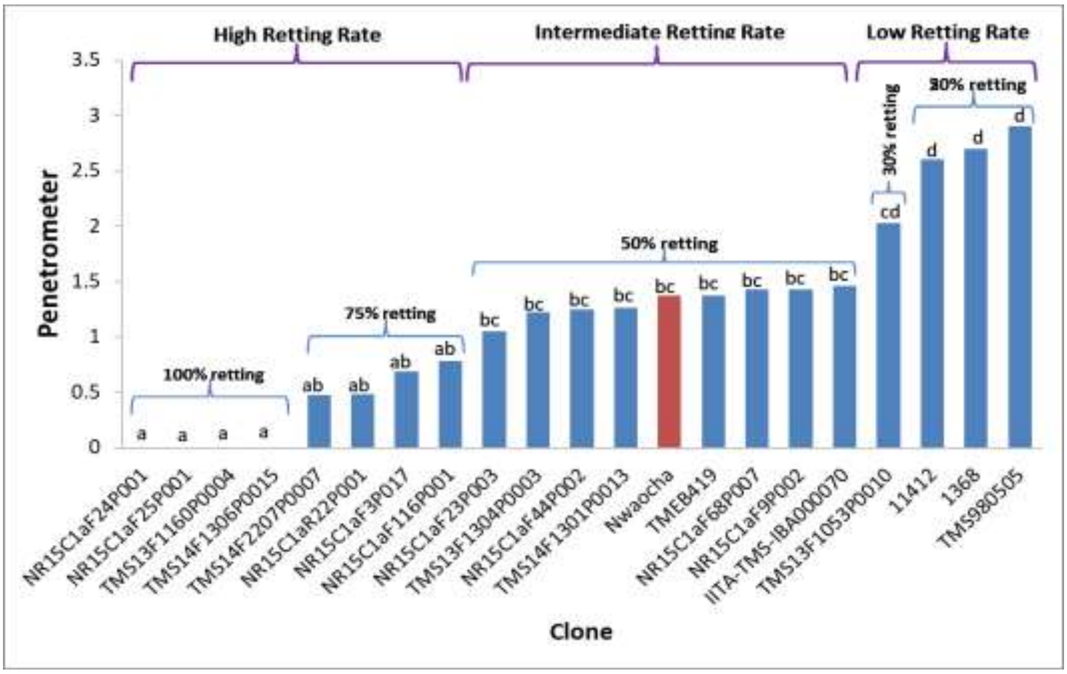

Fig. 1: Retting Progression concerning Genotypes

CONCLUSION

In conclusion, the hand-held penetrometer may be useful in discriminating between cassava genotypes as fast, intermediate or slow retting for fufu processing operations.

ABSTRACT
Despite the economic importance of yam on lives of the people, yam faces a number of constraints that significantly reduce its potential to support rural development and meet consumers needs as an affordable nutritional product: amongst the constraints, is the availability of enough planting materials. The aim of this study is to produce ware yams in alternative soil mediums like sacks, jute bags, plastic containers and baco bags. Three yam cultivars namely: Alumaco, Hembakwase and Nwopoko were planted in Baco sacks filled with top soil. Each cultivar treated with Mancozeb and benlate (a soil insecticide and fungicide) before planting. The experiment was laid out as randomized complete block design in 6 Baco sacks/plot of 3.6m x 1m and replicated 3 times. Weeding was carried out at 4WAP, 8WAP, and 12WAP. Fertilizer N:P: K 15:15:15 was applied at the rate of 400kg/ha at 8wap. Trellis method of yam staking was carried out. Data were collected on the following: Stand count at harvest, Number of ware yams harvested, Number of seed yams, Weight/plot (kg/tons/ha) and Pests incidence. The data collected were subjected to ANOVA and significant treatment means were separated using LSD under GenStat statistical software. The result showed that there is no significant (P>0.05) difference among the different media of planting used which means that ware yams could be produced using sacks, jute bags or baco bags where land is a limiting factor. It also showed that cost of weeding could also be reduced when yams are grown in such containers. Space could as well be conserved. To get good tuber size of yam, its planting materials must be planted on a fertile medium. It is therefore recommended that due of the time and energy involved in land clearance and construction of ridges and heaps for yam planting, other energy and time saving strategy like the use of unperforated cement sacks with topsoil, dried grasses, organic manure and topsoil should be practiced and used.
Keywords: *Yam, production space management, ware yam.*

INTRODUCTION
The productivity of yam (*Dioscorea* spp.), a vegetatively propagated crop, which is cultivated for its underground edible tubers, is a very important food and income source for millions of producers, processors and consumers in West Africa. About 48mt of yams are produced annually in this sub region on 4mha of land. Nigeria is the largest producer of yams in the world contributing to two-thirds of the global yam production each year (NBS, 2013). About 32% of the population depends on yams for food and income security. Yam is the first most valuable food and agricultural commodity in Nigeria for the year 2012 (FAOSTAT, 2014); it is also integral to the socio-cultural life in this sub region. With the advancement in agriculture, various types of protected cultivation practices suitable for a specific type of agro-climatic zone have emerged. Among these protective cultivation practices, poly green house, net house, shade house, plastic tunnel, polythene bags etc. are very useful for crop production. This technology can be adopted by the rural youth for more income per unit of land. The improvement in economy of farmers with the decreasing land holding is also possible through the protected cultivation by increasing production per unit area Yam cultivation is under increasing pressure due to scarcity of planting materials, preasure on land use for agriculture, shortening of fallows, reduction in soil fertility, pests and disease build-up and rapid urbanization in most of the yam producing areas (Manyong *et al*., 2011). As a result of rapid urbanization which has claimed most agricultural lands, efforts should be geared towards producing yams using other alternative medium other than direct planting to the land (Katung *et al*., 2006). The specific objective of the study is to produce ware yams in alternative soil mediums like sacks, jute bags, plastic containers and baco bags.

MATERIALS AND METHODS
Plant materials and Experiment Design
Three yam cultivars namely: *Alumaco, Hembakwase and Nwopoko* were planted in Baco sacks filled with top soil. Each cultivar treated with Mancozeb and benlate (a soil insecticide and fungicide) before planting. The experiment was laid out as randomized complete block design (RCBD) in 6 Baco sacks/plot of 3.6m x 1m and

replicated 3 times. Weeding was carried out at 4WAP, 8WAP, and 12WAP. Fertilizer N:P:K 15:15:15 was applied at the rate of 400kg/ha at 8wap. Trellis method of yam staking was carried out. Data were collected on the following: Stand count at harvest, Number of ware yams harvested, Number of seed yams, Weight/plot in kg/tons/ha and Pests incidence . Location and period of experiment is necessary.

Data analysis

The data collected were subjected to ANOVA and significant treatment means were separated using LSD using GenSTAT statistical software.

RESULTS AND DISCUSSION

In 2011 and 2012, there was no significant difference in the mean stand count (Table 1). The mean number of ware yam in both 2011 and 2012 did not show any statistical difference. cross check your dates there was no significant difference among the treatments tested statistically within the two cropping seasons (Tables 1). However, closer observation indicated significant difference in weight among the treatment means in 2012. Treatment 1(*Alumaco*) gave the highest yield of 7.00t/h, followed by treatments 2 (*Hembamkwase*) with 4.80t/h and 3 (*Nwopoko*) with 3.67t/h respectively, However, .*Hembamkwase* and *Nwopoko* did not differ in their yields in 2011 and 2012 cropping season, there was no significant difference on the mean number of pest attack but , there was high significant difference observed in the mean number of Nematode attack(Table 2).The nematode infestation was attributed to the unsterilized soil used in the study. Similar increase in growth rate at closer spacing were noticed and reported by Rajewar *et al*. (1981) in tomato, This confirms results obtained by Sandri *et al*. (2002) , Ogbomo and Egharevba (2009) Agarwal and Zakwan (2011) in tomato, as well as Choudhary and Singh (2006)] in capsicum . The findings corroborate similar results by Busari *et al*. (2008), as well as Michael and Reid (2018), who submitted that application. inorganic manures in form of fertilizers produced the highest level of growth and yield in crops.

Crosscheck the period of experiment.

Table 2: Mean on Pest attack on the preliminary trial on space management for ware yam production in 2011

Treatments	Cricket	Nematode
Alumaco	0.00	4.00
Hembamkwase	0.67	5.33
Nwopoko	0.33	3.00
Means	0.33	4.11
LSD(0.05)	1.309	0.756

CONCLUSION

Ware yams could be produced using sacks, jute bags or baco bags where land is a limiting factor. Cost of weeding could also be reduced when yams are grown in such containers .Space could as well be conserved. To get good tuber size of yam, its planting materials must be planted on a fertile medium. Because of the time and energy involved in land clearance and construction of ridges and heaps for yam planting, other energy and time saving strategy like the use of unperforated cement sacks with topsoil, dried grasses, organic manure and topsoil should be sought for.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Field trials were carried out at the Teaching and Research Farm of Federal University of Technology Gidan Kwano Minna, Niger State, Nigeria during 2011 and 2012 wet seasons to investigate the susceptibility of maize varieties to periods of weed interference in southern guinea savannah zone of Nigeria. The influence of varieties on the response of maize to period of weed interference was laid out in split plot design and replicated three times. The highest crop establishment percentage during 2011 wet season was observed with 2008-DTMAYSTR (77.54) and the least was Oba-98 (66.92); while during 2012 EVDTY 2000 recorded the highest value (75.02) while Oba-98 still was observe to have the least value (73.16) of the parameter through with a minimized difference with the other varieties Sammaz-13 (73.41) and 2008-DTMAYSTR (73.75). The average crop establishment percentage in 2011 was 72.92 while in 2012 it was 73.83; therefore, during 2011 the variety 2008-DTMAYSTR established best while EVDTY-2000 was best established in 2012. Among the varieties tested, 2008-DTMAYSTR was observed to have the highest average grain yield of 4.00T/ha followed by EVDT Y-2000 with an average yield of 3.40T/ha, Oba-98 3.32T/ha and Sammaz-13 3.27T/ha. The effect of variety on crop height was statistically significant at 9WAS and at harvest in 2011 and 2012 only and not the combined. The combined data revealed that the hybrid variety Oba-98 recorded the highest value of cob weight and highest weight was recorded by the Oba-98. The weed free throughout cob weight was 40.71% and 34.82% higher than the weed infested plot during 2011 and 2012 respectively. Effect of period of weed interference was significant in cob length and seed production was significant 100% seeds weight throughout the period of study. Initial weed infestation for 6 WAS only was comparable to initial weed free period for 12 WAS and till harvest. Similar to what was obtainable with the grain yield, initial weed infestation for 3WAS only did not significantly differ from plot kept weed free throughout the period of study.

Keywords: *Cob length, Cob weight, Maize varieties, Periods of weed interference, yield components***.**

INTRODUCTION
Maize is a member of the grass family, Poacea. It is the most widely adapted and was the most important cereal in the world in 2008 with production of 826.2million metric tonnes followed by rice and wheat (FAO, 2010).United States Of America was the largest producer which accounted for 37.2% of the world's total, followed by China and Brazil that accounted for 20.1% and 7.1% respectively (FAO, 2010). Africa produced 6.7% of the world's total from 29.3million hectares. Nigeria produced 7.5 million metric tonnes which represents 0.9% of the world's total in 2008; it ranks second after South Africa in the African continent.

Maize production in Nigeria was initially restricted mainly to the forest zone but the production has now expanded to the savannah where it accounts for over 70% of the production in the country (Uyovbisere *et al.*, 2001). Kassam *et al.*, 1975 attributed the higher production of the crop in the savannah to more favourable production conditions which includes solar radiation intensities, lower night temperature and low incidence of diseases and pests. Maize was introduced into Nigeria probably in the 15th century by Portuguese (Osagie and Eka, 1998). The country`s maize crop covers about 1million hectare out of 9 million hectares it occupied in Africa (Hartman, 1985). Maize is a cereal plant that produces grains that can be cooked, roasted, fried, ground, pounded or crushed to prepare various food items like pap, tuwo, gwate, donkunu and a host of others (Abdur Rahman and Kolawole, 2006).

Hoeing is the cultural method adopted for weed control in cereals of which maize is inclusive in the southern guinea savannah zone. It is labourious, slow, expensive and only feasible on a small holding (Lagoke.1988; Adeosun, 1990). Some weeds especially those that have close resemblance with the maize crop at the young stage e.g. *Andropogongayanus* may however escape weeding; these will compete maize seriously and will cause reduction in yield considerably. Hoe weeding is beneficial to the maize crop because it tends to improve aeration in the soil environment. For the hoe weeding to be successful, Proper timing and frequency of weeding are necessary. The broad objective of this study is to assess four maize varieties to ten periods of weed interference.

MATERIALS AND METHODS

Field trials were conducted during the raining season of 2011 and 2012 on the research farm of the Federal University of Technology Gidankwano Minna (situated on Longitude 6.23^{0}E, Lattitude9.37^{0}N and altitude of 1475m above sea level) in the Southern Guinea Savannah zone in Niger State of Nigeria. The treatments were laid out split plot design. These were made into maize varieties (early, extra early and a late maturing or hybrid) and ten periods of weed interference. One set of the interference treatment, plots were kept initially weed free for 3, 6, 9 and 12 weeks after sowing (WAS) maize and subsequently left not weeded. In the other set of treatments, plots were left unwedded for 3, 6, 9 and 12 WAS but were left weed free until harvest. Two control treatments were maintained in which one plot was weed free while the other plot weed infested until harvest in both cases for the purpose of comparison. The treatment consisted of 2 early maize variety one extra early variety and one hybrid. The plot size was 1800m^2 with ten rows separated at 50cm. four crop varieties of maize were used, Oba 98 hybrid maize matures in 100-120 days and is excellent drought escape variety, its grain is white in colour and it is labelled as $V_{1,}$ SAMMAZ 13 (Extra early variety) maize matures in less than 80 days and is excellent drought escape variety, its grain is yellow in colour and labelled as V_2, EVDT – Y2000 (Early variety) striga tolerant, matures in less than 90 days drought tolerant and can be grown in soils that have low Nitrogen. Its grain is yellow in colour labelled as $V_{3,}$ 2008 DTMAYSTR (Extra early variety) striga tolerant, matures in less than 90 days drought tolerant and can be grown in soils that have low Nitrogen. Its grain is yellow in colour it is labelled as $V_{4.}$ These shall be obtained from the seed production unit of the Institute for Agricultural Research Ahmadu Bello University Zaria.

The experimental area was cleared, ridged and spaced at 75cm. The field was marked out into plots and replications. Each split plot had six ridges with a measurement of 4m x 3.75m. There was a total of 120 split plots on the field separated by an unplanted border of 50cm. The seeds were sown manually at the rate of 3 seeds per hole along the ridges using an intra-rows spacing of 50cm. The plants were thinned to 2 plants per stand at ten days after planting. Cultural weeding using hoe was carried out at 3, 6, 9 and 12 WAS for both cultivation season of 2011 and 2012. Basal application of fertilizer using NPK 15-15-15 was done after 2 WAS at 600g/plot and top dressed with urea after 4-5 WAS at the rate of 200g/plot by banding method.

The observations and data collection was done on crop establishment and grain yield ha^{-1} (tons) and was statistically analyzed.

RESULTS

Crop establishment: The effect of variety and period of weed interference on maize crop establishment percentage at harvest during 2011 & 2012 wet seasons is presented in Table 1. Variety did not significantly affect crop establishment in 2012 but in 2011 and the combined. Variety 2008-DTMAYSTR exhibited higher establishment percent than Oba-98 in both years and the combined (Table 1). Period of weed interference significantly affected crop establishment percentage in both years, and the combined (Table 1).The percentage establishment was observed to decrease as plots were kept unweeded after 6WAS, till harvest during 2011 and after 3WAS till harvest in 2012 wet seasons and combined. Conversely the percentage crop establishment was observed to increase to a maximum value when plots were kept weed- free initially from 3WAS till harvest. The crop establishment percentage was observed to be higher during 2012 wet season than 2011. However, keeping the crop initially weed infested for 3WAS did not differ significantly from those kept weed free for 12WAS. In 2011 and combined and those kept weed free till harvest in 2012 (Table 1), There was no significant interaction between the variety and period of weed interference in crop establishment throughout the period of study.

Table 1 Effects of Variety and periods of Weed- interference on percentage crop establishment at harvest at Gidan kwano for 2011 and 2012 wet seasons

Treatment	Crop establishment at harvest 2011	2012	combined

1 Week after sowing.
2. Means followed by the same letter (s) / are not significantly different at 5% level of probability (DMRT)
3 NS Non significant
4 Treatment not applied.

Table 2 result shows that the effect of variety on grain yield was significant only in 2011. Variety 2008-DTMA-YSTR was observed to have the highest grain yield in 2011 with a value of 3.77t/ha (Table 2) followed by Sammaz-13(2.71t/ha), next is EVDT Y-2000 (2.57t/ha) and Oba-98(2.25t/ha) had the least grain yield value during the 2011 wet season. Although not significant the yield in 2012 was more than that of 2011.
Period of weed interference significantly affected grain yield throughout periods of the study and the combine. The grain yield was observed to decrease as plots were kept initially weed infested from 3WAS till harvest during 2011 and 2012 wet seasons and the combined. As the plots were initially kept weed free the grain yield was observed to increase from a minimum value of 1.69t/ha 2.73t/ha and 2.36t/ha respectively for 2011, 2012 are combined to a maximum value of 3.87t/ha 6.47t/ha and 5.17t/ha respectively from 2011, 2012 and combined (Table 2) hence showing that weeds interfere or deplete nutrients from the soil rendering it unavailable to crop plants. Weed infestation for 3WAS did not significantly affect the grain yield throughout the study and the combined compared with weed free from 9WAS and till harvest. However infestation beyond 6WAS drastically reduced the grain yield compared with the initial weed free periods from 9WAS till harvest. Similarly initial weed free period for 3 weeks only did not differ significantly from plots kept weedy throughout the period of study.

Table 2 Effect of Variety and Periods of weed- interference on grain yield at Gidan Kwano for 2011 and 2012 wet seasons.

1WAS - week after sowing.
2. Means followed by the same letter (s) / are not significantly different at 5% level of probability (DMRT)
3 NS non-significant

Treatment Interaction shows that the result of the combined analysis showed that maximum grain yield was obtained with plots kept weed free from 6WAS and till harvest with 2008-DTMAYSTR as well as the least grain yields on weed infested plot till harvest with Sammaz-13 during 2011 wet season. This clearly showed the variation in the ability of the varieties to compete with weed and to produce an acceptable grain yield. Although the maize variety EVDTY-2000 when kept weed free for 6WAS had comparable crop vigour to the maximum while Oba-98 kept weed infested for only 6WAS had the least comparable vigour score. This might be due to the fact that crops kept weed free had the benefits of utilizing both underground and above ground nutrients. Ayeni and Duke (2011), earlier reported that good crop vigour influence and enhance good development of the photosynthetic capacity, prior to tasselling initiation and grain filling in maize crop as a result of better utilization of available growth resources in the absence of weeds.

DISCUSSION

Weed infestation throughout the crop life-cycle decreased the yield of maize variety Oba-98 by 65 and 50% in 2011 and subsequently other yield parameters were observed to reduce. Similar yield reductions between 50 and 87% of maize due to uncontrolled weeds throughout the crop life-cycle was reported by (Kunjo, 2011). Period of weed interference also had significant effect on crop vigour score at 9WAS during 2012 wet season. Keeping plots weed free till 9WAS and beyond produced more vigorous crops, while keeping crops weed infested and beyond for similar periods, produced less vigorous crops. This might be due to the competition for growth factors between the maize and the weeds in the weed infested plots as reported by IITA (2007). Plant height was significantly affected at 9WAS and at harvest for both years. While keeping plots weed free till 9WAS and beyond produced taller crops, the converse is the case when plots are weed infested for the same period. Carson (2010) stated that when maize crops are kept weed infested for 9WAS and beyond their heights significantly decrease. Other yield parameters such as maize cob weight, cob length and weight of 100 seeds were all significantly affected by period of weed interference. Weed infestation from 6WAS and till harvest significantly decreases these yield parameters. In the study, uncontrolled weeds throughout the life cycle of maize varieties resulted in grain yield loss of 59.43% and 72.33% respectively for 2011 and 2012 wet seasons compared to maximum obtained with weed free plots throughout the study. Weed infestation for 3WAS only did not significantly affect grain yield of maize in 2011 compared with initial weed free plots at 9WAS while weed infestation for 3WAS only was comparable to initial weed free plots up to 9WAS.
It is apparent that once the crop was kept weed free for 12WAS subsequent weed infestation until harvest did not cause any significant reduction in maize grain yield in the four varieties. Contrary to earlier reports, weeds infestation for first 3WAS caused significant reduction in maize grain yield, even though it did not have adverse effect on crop growth as reflected in crop vigour score, crop height and weed dry matter production. The yield depression by weed infestation for 3WAS may be attributed to rapid weed growth and its high infestation within 3WAS during the growing season. This was apparent in the weed cover score at 9WAS and beyond. Weed infestation with crop until 12WAS resulted in significantly lower crop vigour score and grain yield compared infestation for 3WAS. Subsequent weed removal until 12WAS did not prevent reduction in grain yield compared with weed infestation until harvest. Weed dry matter production was higher during 2011 than 2012.

CONCLUSION

A significant maize grain yield reductions were recorded when weeds were associated with maize varieties for 6WAS and more. In the study, uncontrolled weeds throughout the life cycle of maize varieties resulted in grain yield loss of 59.43% and 72.33% respectively during 2011 and 2012 wet seasons compared to maximum obtained with weed free plots throughout the study. Weed infestation for 3WAS only did not significantly affect grain yield of maize in 2011 compared with initial weed free plots while weed infestation for 3WAS only was comparable to initial weed free plots up to 9WAS.

RECOMMENDATION

It is recommended that a weed free period of 21-42days after planting is required for an acceptable maize grain yield with 2008-DTMAYSTR and EVDTY-2000.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The paper aims to examine the historical significance of crop rotation as an agricultural practice, particularly in Nigeria, and elucidate its potential benefits in mitigating soil erosion, enhancing water utilization efficiency, and sustaining high crop yields. Crop rotation, a time-honored agricultural practice celebrated for its historical yield advantages, entails cultivating a variety of crop types sequentially within the same area over successive seasons. Nigeria, steeped in agricultural tradition, has embraced rotation cropping systems for numerous years. Given the pronounced climatic and soil diversities across different Nigerian regions, cropping practices exhibit considerable variations. The investigation into the impacts of legume-cereal crop rotation on crop yields boasts a long-standing history, with contemporary literature supporting the assertion that soybean-corn crop rotation yields increased grain production and represents an avenue for sustainable agriculture. Comprehending alterations in soil physical, chemical, and biological characteristics is paramount for elucidating the mechanisms responsible for both the direct and indirect effects of crop rotation on grain yields, along with its environmental benefits. This paper undertakes the task of assembling and synthesizing existing literature pertaining to diverse legume-cereal crop rotation studies conducted across various agroecological regions of Nigeria. The attainment of sustainable production and the effective implementation of legume-cereal crop rotations in a site-specific context hinge on an array of factors. These factors encompass crop composition, varietal selection, conservation tillage practices, and integrated pest and weed management approaches, necessitating collaborative efforts across multiple disciplines and sectors. Consequently, the introduction and adoption of new cropping systems and technologies must undergo rigorous testing under site-specific conditions and gradual dissemination, transitioning from initial demonstration plots to wider regional adoption.

Keywords: *Crop rotation, legume-cereal, sustainable agriculture, Nigeria, soil properties, site-specific adoption*.

INTRODUCTION

Crop rotation involves cultivating a variety of crop species successively on the same piece of land, as highlighted by several authors (Yates, 1954; Shen and Liu, 1983). This stands in contrast to intercropping, where multiple crops are grown simultaneously on the same land, as noted by Stinner and Blair (1990), or continuous monoculture, which entails repetitive cultivation of a single species on the same land, as described by Power (1990). Extensive research has consistently demonstrated the efficacy of crop rotation in mitigating soil erosion, enhancing water utilization efficiency, and sustaining high crop yields, as emphasized by Zhu et al. (1994) and Li et al. (2000).

In the context of this chapter, we place particular emphasis on the primary forms of crop rotation practiced in Nigeria, with a specific focus on legume-cereal crop rotations. Crop rotation may involve the sequential cultivation of two or more crops over multiple growing seasons. For instance, a two-crop rotation, such as alternating between Maize (Zea mays) and soybean (Glycine max) or guinea corn (Sorghum bicolor) and peanut (Arachis hypogaea) in alternating years, exploits the leguminous crop to supply complementary inorganic nitrogen to the soil for subsequent crops. Legumes have long been recognized as "soil-building crops" due to their ability to significantly enhance the biological, physical, and chemical properties of the soil when cultivated. Therefore, from an agricultural standpoint, it is sensible to intersperse them with cereals and other nitrogen-demanding crops. The positive effects of crop rotation on crop yields have been consistently reported by numerous scientists over the years, as evidenced by Bullock (1992), Carsky et al. (1997), Fan et al. (2012), Kelley et al. (2003), and Yusuf et al. (2009). In the legume-cereal rotation system, this beneficial effect is attributed to the availability of additional nitrogen (N) resulting from biological nitrogen fixation and other rotational influences, as discussed by Sanginga et al. (2002). Legume-cereal rotation enhances soil nutrient content, with legumes possessing root nodules that harbor nitrogen-fixing bacteria called rhizobia, as pointed out by Danga et al. (2009). The inclusion of grain legumes in rotation with annual cereal crops contributes to the overall nitrogen pool in the soil and enhances cereal yields.

Crop rotation systems optimize the utilization of soil resources, including nutrients, water, and biodiversity, by cyclically switching between different crops over consecutive years, capitalizing on their varying characteristics. This approach not only fosters crop production and land utilization efficiency, as advocated by Bullock (1992), but also offers farmers a means to maintain continuous field productivity, reducing the need for chemical fertilizers. Furthermore, crop rotation has the added benefit of diversifying the geographical distribution of crops. The objective of this review paper is to comprehensively assess and synthesize existing literature on the practice of legume-cereal crop rotation, with a specific focus on its impact on crop yields, soil properties, and sustainability in diverse agroecological regions of Nigeria.

Crop Rotational as a Sustainable Agricultural Practice

Crop rotation is a time-tested agricultural practice with a history deeply rooted in sustainable agriculture (Yates, 1954). This age-old technique involves systematically altering the types of crops cultivated on the same land over consecutive growing seasons. Its primary objective is to maximize soil resources, minimize soil depletion, and mitigate disease buildup, making it a cornerstone of sustainable farming.

Yates (1954) underscores the historical importance of crop rotation as a means to enhance soil health and agricultural sustainability. This practice has been honed over centuries to optimize crop yields while preserving the long-term productivity of the land. It involves strategic planning to ensure that the crops selected for rotation complement each other in terms of nutrient requirements and pest management.

In Nigeria, an agriculturally rich nation deeply entrenched in farming traditions, crop rotation has evolved over the years to suit the diverse agroecological regions (Shen and Liu, 1983). Nigeria's agricultural history is characterized by a tapestry of innovative farming practices, many of which emphasize sustainable land management and food production. The country's agricultural landscape spans a wide range of climatic zones and soil types, resulting in a plethora of cropping practices across different regions.

Shen and Liu (1983) discuss the adaptation of crop rotation practices to Nigeria's diverse agroecological regions, highlighting the nation's commitment to optimizing agricultural sustainability. These adaptations have been crucial in addressing the unique challenges posed by the country's multifaceted agricultural sector.

Research studies consistently affirm the positive impact of legume-cereal crop rotations on critical aspects of agriculture, including crop yields, soil properties, and overall sustainability (Bullock, 1992; Carsky *et al*., 1997; Fan *et al.*, 2012). This positive effect is primarily attributed to the nitrogen-fixing capacity of legumes, which enrich the soil with essential nutrients through their symbiotic relationship with nitrogen-fixing bacteria known as rhizobia (Sanginga *et al*., 2002).

Bullock (1992), in their research, provides evidence of the significant improvements in crop yields achieved through legume-cereal crop rotations, supporting the notion of enhanced agricultural sustainability. Carsky et al. (1997) delve into the impact of legume-cereal rotations on crop yields, particularly in the context of West Africa, shedding light on the practical benefits of this practice.

Fan et al. (2012) conduct a study on sustainable crop rotations, emphasizing the role of legume-cereal rotations in improving soil fertility and, by extension, crop sustainability. Furthermore, legume-cereal crop rotations have been shown to conserve soil structure and organic matter, contributing to overall soil health (Kelley *et al*., 2003). This dual benefit not only bolsters crop production but also aligns with the principles of sustainable agriculture by reducing soil erosion and preserving the long-term productivity of farming systems.

Mitigating Soil Erosion and Enhancing Water Use Efficiency

Crop rotation's role in mitigating soil erosion is well-established, as evidenced by Zhu et al. (1994), who recognize its pivotal role in sustainable agriculture. Soil erosion, characterized by the loss of topsoil due to natural forces like wind and water, poses a grave threat to soil fertility and overall agricultural productivity. Nigeria, with its diverse climate and soil types, necessitates an adaptable and region-specific approach to cropping practices, as highlighted by Li *et al*. (2000). In Nigeria's agricultural landscape, characterized by varying agroecological zones experiencing diverse rainfall patterns and soil characteristics, the significance of crop rotation in controlling soil erosion becomes paramount.

Crop rotation effectively reduces soil erosion in Nigeria through several well-documented mechanisms:

Root Structure and Soil Stability

Crop rotation with a mix of deep-rooted and shallow-rooted crops, such as legumes with robust root systems, enhances soil stability. Deep-rooted crops create channels in the soil that facilitate water infiltration and reduce surface runoff, as noted by Hargrove (2001).

Residue Cover

Crop residues left on the field post-harvest act as a protective cover against soil erosion. By varying crops in rotation, the quantity and quality of residue cover can be optimized, aiding in the reduction of erosion rates, as highlighted by Mann (1986).

Diverse Canopy Architecture

Crop rotation often involves cultivating crops with varying canopy structures. Tall crops can intercept rainfall and reduce the impact of water droplets on the soil surface, a crucial factor in erosion mitigation, as discussed by Zhang et al. (2002).

Soil Microbial Activity

Crop rotation influences soil microbial communities, with different crops releasing distinct exudates and root exudates that impact soil structure and microbial activity. These microbial communities play a vital role in stabilizing soil aggregates and minimizing erosion, as explored by Hartmann et al. (2015).

These empirical studies collectively emphasize how crop rotation, tailored to Nigeria's diverse agroecological characteristics, serves as a powerful tool in combating soil erosion, safeguarding soil fertility, and optimizing water use efficiency. This approach not only ensures the long-term sustainability of agricultural lands but also aligns with sustainable farming practices.

Mechanisms of Positive Effects and Role of Crop Composition and Varietal Selection

One of the fundamental mechanisms underlying the positive impacts of legume-cereal crop rotation is nitrogen fixation by legumes. Numerous empirical studies confirm the substantial contribution of legumes to soil nitrogen levels. For example, a study by Sanginga *et al.* (2002) conducted in West Africa demonstrated that grain legumes in rotation with cereals significantly increased the total nitrogen pool in the soil, consequently benefiting cereal crop yields. Changes in soil physical, chemical, and biological properties resulting from legume-cereal crop rotations have been widely documented. Danga et al. (2009) conducted research highlighting the improvement in soil health due to crop rotation. Their study revealed that legumes, with their root nodules housing nitrogen-fixing rhizobia bacteria, positively influence soil microbial communities, which, in turn, enhance nutrient cycling and soil structure.

Empirical studies have underscored the significance of crop combinations in crop rotation systems. For instance, research by Carsky et al. (1997) in West Africa explored the impact of specific legume-cereal combinations on crop productivity. They found that certain combinations, such as cowpea and maize, had synergistic effects on soil fertility and crop yields, emphasizing the importance of strategic crop composition within rotations. Varied crop varieties within the same species can exhibit different growth patterns, disease resistance, and adaptability to local conditions. A study by Fan et al. (2012) in North China Plain assessed the impact of varietal selection in wheat-maize rotations. They discovered that the choice of wheat and maize varieties significantly influenced yield outcomes and nutrient utilization efficiency. This empirical evidence underscores the importance of selecting crop varieties tailored to specific agroecological zones.

Conservation Tillage and Integrated Pest Management (IPM)

Empirical studies have consistently shown the benefits of conservation tillage practices within legume-cereal rotation systems. Research by Derpsch et al. (2010) conducted in various countries, including Nigeria, demonstrated that no-tillage and reduced tillage practices help improve soil structure, moisture retention, and reduce erosion. Such practices, when integrated into crop rotations, contribute to both higher yields and enhanced environmental sustainability. In addition to conservation tillage, Integrated Pest management (IPM) strategies are integral to sustainable crop rotation systems. A study by Ogunlade et al. (2017) in Nigeria's maize-legume cropping system highlighted the effectiveness of IPM in controlling pests and reducing the need for chemical pesticides. By strategically incorporating pest-resistant crop varieties and biological control methods, IPM contributes to higher crop yields and reduced environmental impact.

The importance of site-specific testing in crop rotation systems has been well-documented. A study by Ndiiri et al. (2016) in Kenya emphasized the significance of adapting cropping systems to local conditions. Their research revealed that site-specific testing and tailored crop selection led to increased yields and enhanced sustainability. This empirical evidence underscores the need to consider agroecological factors when implementing crop rotations. Every site-specific testing in crop rotation should be succeeded by Technology dissemination. Gradual technology dissemination is crucial for the successful adoption of crop rotation practices. An investigation by Akinseye et al. (2016) in Nigeria emphasized the importance of extending successful practices beyond demonstration plots to wider regional adoption. Their study demonstrated that farmer-to-farmer knowledge sharing and community-based extension services were effective in disseminating crop rotation techniques, leading to increased yields and sustainability.

CONCLUSION

Crop rotation, a time-honored agricultural practice, plays a pivotal role in sustainable agriculture, as highlighted by a wealth of empirical research spanning several decades. This practice involves the systematic rotation of different crop species on the same land over successive seasons, with the primary goal of optimizing soil resources, minimizing soil depletion, and mitigating disease buildup. In this context, we placed particular emphasis on legume-cereal crop rotations in Nigeria. In conclusion, crop rotation, particularly legume-cereal crop rotations, stands as a cornerstone of sustainable agricultural practices in Nigeria and beyond. Empirical research consistently validates its efficacy in improving crop yields, enhancing soil health, and mitigating environmental challenges. Implementing and further refining these practices in diverse agroecological regions is essential for ensuring food security, preserving soil fertility, and fostering sustainable agriculture in the face of evolving agricultural landscapes and global challenges.

RECOMMENDATIONS

Based on the empirical evidence presented regarding the significance of crop rotation, particularly legume-cereal crop rotations, in sustainable agriculture, the following recommendations are proposed:

I. There is need to collaborate with government agencies, agricultural extension services, and NGOs to raise awareness among farmers about the benefits of crop rotation.
II. Conduct training programs, workshops, and educational campaigns to disseminate knowledge and best practices.
III. Motivate farmers to develop site-specific crop rotation plans tailored to their region's agroecological characteristics. This should consider factors such as local climate, soil types, and prevalent crop diseases to optimize rotations.
IV. Invest in research initiatives focused on refining crop rotation systems, particularly those involving legume-cereal combinations.
V. There is need to promote the integration of IPM strategies into crop rotation systems. This includes identifying pest-resistant crop varieties, implementing biological control methods, and reducing reliance on chemical pesticides to minimize environmental impact.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The continuous cultivation of land has led to a decline in soil fertility, which poses a significant challenge of food insecurity in developing countries. To assess this issue, a study was conducted to evaluate the physical and chemical properties of soil samples collected from two profiles. The results showed low levels of organic carbon (ranging from 0.80 to 9.20 g kg^{-1}), available nitrogen (ranging from 0.10 to 1.15 g kg^{-1}), and available phosphorus (ranging from 2.98 to 5.95 mg kg^{-1}). The soil samples were moderate to slightly acid, with pH values ranging from 4.60 to 6.40. In addition the cation exchange capacity of the soil was found to be medium, ranging from 5.70 to 9.60cmol kg^{-1}. Furthermore, the Exchangeable Sodium Percentage (ESP) indicated that the soil quality was excellent. From the result of this study it is evident that the nutrient status of the orchard soils is inadequate. The following management practices are suggested, the application of organic manure, nitrogenous and phosphorus fertilizers. These practices will help improve the soil's nutrient content and fertility status, ultimately contributing to robust agricultural productivity and addressing the problem of food insecurity in developing countries.
Keywords: *Soil profile, Exchangeable Sodium Percentage (ESP), orchard, nutrient status.*

INTRODUCTION
Fertility status of soil plays a crucial role in orchard plantation. When crops are continuously cultivated in an orchard, the fertility status of the soil can improve within the root zone depth, considering that lime and phosphorus have limited mobility while potassium moves slowly. Sofo *et al*. (2020) submitted that in many orchard soils, soil biodiversity and the ecosystem services it provides are under threat from a range of natural and man-made drivers. Kurešová *et al*. (2019) highlighted the importance of understanding the nutrient status of orchard; therefore, assessing soil fertility is a fundamental tool for making sustainable decisions regarding soil nutrient management. This evaluation involves measuring the availability of essential nutrients for plants and estimating the soil's capacity to provide a continuous supply of nutrients to crops. Soil properties exhibit spatial and temporal variations, ranging from individual fields to larger regional scales, influenced by both intrinsic factors (e.g., soil parent materials) and extrinsic factors (e.g., soil management practices, fertilization, and crop rotation). Soil fertility significantly impacts crop yield and productivity, with nutrient deficiencies being a major constraint to soil sustainability and productivity (Kumar *et al*., 2020). Despite continuous cultivation, little attention has been given to maintaining soil fertility in the soils of the Institute for Agricultural Research (IAR) orchard. In addition the locally available data on soil fertility status are insufficient. Therefore, the objective of this research is to investigate the current fertility status of the orchard soil.

METHODOLOGY
The Study area
This research was conducted at the orchard of the Institute for Agricultural Research (IAR) in Samaru, Kaduna State, Nigeria. The experiment site is situated at coordinates 11° 10.37.0'N latitude and 7° 37.88.1'E longitude, with an altitude of 698 meters above sea level. The location falls within the northern guinea savanna ecological zone of Nigeria. The climate in this region is classified as sub-humid tropical, characterized by distinct wet and dry seasons. The orchard covers an area of 6.41 hectares and cultivates a variety of fruits and agricultural crops. Among the fruit trees grown in the orchard are guava, mango, cashew, grapevine, pawpaw, coconut, apple, oil palm, jackfruit, avocado pear, custard apple, kola nut, cocoa, coffee, orange, banana, and others.

Fruit trees, when properly planted with suitable soil and other considerations, can live for many years in an orchard (Ahmet, 2009). The orchard also includes other fruit trees like apple, oil palm, and cocoa, which are not the primary focus of the Institute. This demonstrates the Institute's commitment to conducting broader research (Shobayo *et al*., 2019). The orchard is well-organized and divided into sections for the nursery and permanent plots dedicated to specific tree species.

Field Observation

Two profile pits were randomly excavated within IAR horticultural orchard, and a total of seven soil samples were gathered from genetic layers of the soil to assess its characteristics. In addition, bulk soil samples were obtained from each genetic layer for further analysis in the laboratory. Core samples were extracted to determine the bulk density.

Laboratory analysis

The bulk soil samples collected from each layer were subjected to a series of procedures. First, they were air dried and then ground and sieved to eliminate particles larger than 2 mm in diameter. The resulting material, consisting of particles smaller than 2 mm, was used for laboratory analysis. The core method, as outlined by Blake and Hartge (1986), was employed to determine the bulk density. The hydrometer method, described by Gee and Or (2002), was utilized to analyse the particle size distribution. Soil reaction, or pH, was determined in a water solution with a soil-to-solution ratio of 1:2.5, using a Pye Unicam model 290 MK pH meter (Agbenin, 2005). To measure organic carbon, the acid dichromate wet oxidation method by Walkley and Black, as described by Nelson and Sommers (1986), was employed. The Macro Kjedahl method (Bremmer and Mulvaney, 1982) was used to determine total nitrogen content. Available phosphorus was assessed using the Bray-1 method outlined by Bray and Kurtz (1945). Exchangeable acidity was determined using the method described by Thomas (1982). Exchangeable bases (calcium, magnesium, potassium, and sodium) and cation exchange capacity (CEC) were determined using a neutral (pH 7.0) ammonium acetate (NH4OAc) solution, as described by Anderson and Ingram (1993). Base saturation (BS) was calculated by dividing the sum of exchangeable bases (Ca, Mg, K, and Na) by the CEC. The exchangeable sodium percentage (ESP) was calculated as the proportion of CEC occupied by sodium cations.

RESULTS AND DISCUSSION

Table 1 showed that the sand fraction dominates the mineral composition of the orchard soils. This can be attributed to the parent material, which is rich in quartz minerals, an essential component of granite (Shobayo *et al*., 2019). In addition, biological activities, clay migration through eluviation and illuviation, and surface erosion by runoff, either individually or in combination, contribute to the sorting of soil materials, thus influencing the sand content (Aliyu, 2023). The distribution of silt content in the soils appears to be irregular (Table 1). Previous studies by Shobayo *et al*. (2019) and Jimoh *et al*. (2022) in the Savanna region of Northern Nigeria have suggested that the irregularity in silt content can be influenced by Harmattan dust. Clay content tends to increase irregularly within soil depth, often exhibiting higher values in the subsurface horizons. This increase can be attributed to illuviation and pedoturbation processes (Aliyu, 2023).The bulk density values presented in Table 1 fall within the critical range of 1.4 to 1.65 Mg m^{-3} for clayey soil, as indicated by Donahue *et al*. (1990). These values suggest that the soils are suitable for plant growth and facilitate root penetration.

Table 1: Physical properties of the soils of IAR Horticultural orchard

Horizon	Depth cm	Sand g kg^{-1}	Silt	Clay	Textural class	Bulk Density (g/cm^3)
Pedon 1

The chemical characteristics of the soils in the IAR orchard are presented in Table 2. The soil reaction was found to be moderate to slightly acid. Aliyu (2023) suggests that this acidity may be attributed to both the chemical nature of the underlying parent materials and the limited leaching of soluble salts in the soil. The mean pH value (6.04) is slightly higher than values reported by other researchers (Shobayo, 2010; Aliyu *et al*., 2016) in the northern guinea savanna. This difference could be attributed to reduce leaching caused by the presence of tree canopies and branches, which diminish the impact of raindrops. The organic carbon content in the soils ranged from 6.80 to 9.20 g kg^{-1}, indicating a low rating according to Soil Survey Staff (1993) criteria. The decrease in organic carbon content with depth can be attributed to the influence of biomass on the surface horizons. Similarly, the total nitrogen content was rated as low, suggesting rapid organic matter mineralization in the savanna soils. The available phosphorus content was also low, with significant quantities found only in the surface soil. The values remained below the thresholds for low, moderate, and high levels (6, 6-12, and >12, respectively). The exchangeable bases in the soils were generally low to medium, with calcium and magnesium being the predominant basic cations. Similar observations have been made for tropical soils in general (Aliyu, 2023).

The exchangeable acidity (EA) was rated as low, indicating the absence of aluminium toxicity in the orchard soils. The highest exchangeable acidity values were found in the surface horizons and decreased with increasing soil depth. The moderate cation exchange capacity (CEC) of the soils can be attributed to the mixed mineralogy of the clay minerals (Shobayo *et al*., 2019). While organic matter typically influences CEC, the low organic content observed in terms of carbon, nitrogen, and phosphorus suggests that the CEC values may not be solely associated with organic matter contribution. Base saturation in the orchard soils was rated as low, falling within the range of 19.24 to 37.85%. According to FAO (1999), soils with base saturation above 50% are considered fertile, while those below 50% are classified as infertile. Based on this classification, the soils in the orchard are generally infertile. The exchangeable sodium percentage (ESP) values were below the critical limit of 15% for sodicity, according to Brady and Weil (2002), indicating that sodicity is not a problem in the orchard soils. Furthermore, the ESP values were less than 20%, falling under the excellent category, which is indicative of a fertile soil status.

CONCLUSION

In conclusion, the analysis of the orchard soils in IAR reveals several important findings. The dominant mineral composition is sand, which can be attributed to the presence of quartz minerals in the parent material. The bulk density values indicate that the soils are suitable for plant growth and root penetration. The moderately to slightly acidic soil reaction is influenced by the chemical nature of the parent materials and limited leaching of soluble salts. The presence of tree canopies and branches may contribute to reduced leaching, resulting in slightly higher pH values compared to other studies in the region. The organic carbon content is rated as low, decreasing with depth due to the influence of biomass on the surface horizons. Similarly, the total nitrogen and available phosphorus contents are low, suggesting rapid organic matter mineralization and limited phosphorus availability. The exchangeable bases in the soils are generally low to medium, with calcium and magnesium being the predominant cations. The absence of aluminum toxicity is indicated by the low exchangeable acidity values. The moderate cation exchange capacity is influenced by the mixed mineralogy of the clay minerals. The soils in the orchard are classified as infertile based on their low base saturation values. However, sodicity is not a problem, as the exchangeable sodium percentage remains below critical limits.

Overall, the findings suggest that the orchard soils require amendments to improve fertility and nutrient availability for optimal plant growth. This could include organic matter additions, phosphorus fertilization, and the application of appropriate soil amendments to enhance cation exchange capacity and base saturation. Further research and management strategies can be implemented to address the specific needs of the orchard soils, promoting healthy and productive plant growth.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was to investigate the soil fertility status in Ohaji-Egbema of Imo state, southeast Nigeria. Five (5) typical soil samples were collected at 0–30 cm depth from three distinct land uses: oil palm plantations, cassava farms, and fallow land. Bulk density was determined using core samplers. After air drying, the samples were sieved through 2 mm mesh, and routine laboratory analyses were performed. ANOVA was used to analyze the data, and the means were divided using the least significant difference at the probability threshold of (p = 0.05). The mean sand fraction in cassava farms ranged from 886 g kg^{-1} to 952 g kg^{-1}, and the mean silt and clay contents ranged from 32 g kg^{-1} (fallow and oil palm) to 52 g kg^{-1} (cassava), respectively. The bulk density of the soils ranged from 1.04 to 1.12 g/cm^{-3}; however, there was no significant difference in the mean bulk density of the soils (p=0.05). Chemical analysis of the soil of the study area revealed a mean pH range of 5.84 in fallow land to 6.49 in cassava soil. The pH levels of the various land use types did not significantly differ, according to the results (p = 0.05). The organic carbon and matter range was 0.97-1.19 and 1.67-2.05 g/kg, respectively. The nutrient index and fertility rating results suggested that the study area had generally low fertility rates.
Keywords: *Critical limits, nutrient index, soil suitability, land use types, soil fertility*

INTRODUCTION
Agricultural use of floodplain soils has increased significantly recently in most developing nations, particularly in Africa, including Nigeria (Akpan *et al.*, 2017). Farmers go to flooded areas for their activities because they are known to be very fertile for farming. Water and nutrients are available for sustainable crop growth in these areas (Eshett, 1990). In Nigeria, about 4.62 million hectares of land space are characterized for wetland and rice cultivation, and only 11.25% of these lands are being used worldwide (Olaleye *et al.*, 2001). Floodplain soil is essential to agricultural production as it is known to have a considerable reserve of available nutrients for the utilization of crops, especially rice (Akpan-Idiok and Ogbaji, 2013).
Many researchers have employed nutrient ratios in plant tissue to diagnose mineral nutrient deficiencies in crops (Sumner, 1978). Ca/Mg, K/Mg, K/Ca, N/P, and (Ca+Mg)/K are some regularly seen ratios in the literature and are usually a reflection of some recognized nutritional antagonism. (Olaleye *et al.*, 2009; Obasi *et al.*, 2016). When the cations calcium (Ca), magnesium (Mg), potassium (K), and hydrogen (H) occupied the cation exchange sites in the exact percentages of 65%, 10%, 5%, and 20%, respectively, soil productivity was discovered to be ideal for certain crops. They calculated cation equivalent ratios of Ca:Mg 6.5:1, Ca:K 13:1, and Mg:K 2:1 using these saturation percentages. Graham (1959) later revised the saturation percentages to be 65-85% Ca, 6-12% Mg, and 2-5% K. Graham's percentage ranges are the current figures for the Basic Cation Saturation Ratio hypothesis. Loide (2002) recommended 10-20:1 (Ca/Mg) and 3:1 (K/Mg) ratios for optimum yield and productivity of crops. Many basic cation saturation ratio interpretations, however, continue to be done using the precise cation ratios of 6.5:1, 13:1, and 2:1, rather than interpreting a range of ratios that could be created from Graham's percentages, Ca:Mg 5.4:1-14:1, Ca:K 13:1 - 42.5, and Mg:K 1.2:1 - 6:1.
Many studies on soil fertility focus on managing nutrients to improve crop production. The fertility status and properties of soils of the floodplain have not been adequately investigated and evaluated in most parts of the country, especially in South-Eastern Nigeria, where some works have been done on the fertility status of the floodplain (Nkwopara *et al.*, 2019). Also, Onwudike *et al.* (2016) studied the fertility status of selected soils in

Mbaise, Imo State, Southeastern Nigeria, using the nutrient index method. However, there needs to be more information on the fertility status of soils of the floodplain, especially in the Ohaji/Egbema area Owerri of Imo State. Therefore, this study aimed to investigate the nutrient status of floodplain soils under three land use types in southeastern Nigeria's Ohaji/Egbema location.

MATERIALS AND METHODS

The study was conducted at Ohaji-Egbema in Owerri, Imo State, Southeast Nigeria. Ohaji lies between Latitude 5^{o} 19^{1} and 5^{o} 32^{1} N and between Longitude 6^{o} 45^{1} and 6^{o} 59^{1} E. Orajaka (1975) reported that Ohaji-Egbema soils are formed from a parent material primarily known to be Coastal plain sand, otherwise known as Benin formation and had instead been classified as Alfisols or Ultisols (Obasi *et al.*, 2015). Ohaji Egbema, located in the humid tropical rainforest region, has a mean monthly temperature of about 27^{o}C and a mean annual rainfall of about 1700-2400mm. The area has a bimodal rainfall distribution with peaks in July and September and a short break in August, known as the August break (NIMET, 2020). The dominant socio-economic activity in Ohaji-Egbema is agriculture dominated with food crops such as yam *(Dioscorea* spp), cassava *(Manihot* spp*)*, Fluted pumpkin *(Tefeira ocedentalis)*, and maize *(Zea maiz)*, all at a substantial level**.**

Field study

The study was conducted on a floodplain of three different agricultural land use types.; 2-year continuously cultivated cassava farmland, fallow land (secondary forest), and oil plantations were randomly selected for the study. Soil auger was used to collect soil samples from each land use type at 0-30cm depth. Five (5) soil samples were collected from each land use type at an equal distance of 5 meters apart. A total of 15 soil surface samples were collected. A core sampler collected soil samples for soil bulk density determination. Soils collected were bagged, transported to the laboratory, air-dried at room temperature, crushed, and sieved using a 2 mm mesh sieve for analysis.

Laboratory Analyses

Fertility evaluation

The fertility status of the soils was determined using the elemental ratios; Ca:Mg ratio was determined by dividing the value of exchangeable Calcium by the value of exchangeable Magnesium. C: N ratio was determined by dividing the organic carbon value by the total Nitrogen value. K: Mg ratio was determined by dividing the exchangeable potassium value by the exchangeable magnesium value. **Sodium Adsorption ratio (SAR):** this was determined using the equation as follows: SAR = $\frac{(Na^{+})}{(\frac{(Ca^{2+})+(mg^{2+})}{2})^{\frac{1}{2}}}$ While Na^{+}, Ca^{2+}, and Mg^{2+} are concentrations of sodium, calcium and magnesium ions in millimoles (mmol) of charge per liter.

Exchangeable Sodium Percentage (ESP): this was obtained using the equation below;

ESP = $\frac{exchangeNa^{+}}{ECEC}$ X $\frac{100}{1}$ Where ECEC = Effective cation exchange capacity.

Aluminum saturation: this was calculated as follows; Al sat = $\frac{Al^{3+}}{ECEC}$ X $\frac{100}{1}$

Statistical Analysis

Data collected were subjected to Analysis of Variance (ANOVA), and significant means were separated using Least Significant Difference (LSD) at a 0.05 probability level (Wahua 1999). The relationship among soil properties was determined using correlation analysis and scattered diagrams.

RESULTS AND DISCUSSION

Physical Properties of the Studied Locations

The results of selected soil physical properties of the study location are shown in Table 1 Particle size distribution was dominated by the sand fractions. The mean sand content ranged from 886-952g/kg. From the results, the sand contents of the soils differed significantly (p=0.05), with fallow land having the highest mean. Similarly, significantly different (p=0.05) was recorded in the silt and clay contents of the varying land use types, which ranged from 16-22g/kg and 32-52g/kg in the land use types of fallow land, cassava farm and oil palm plantation respectively. But fallow and oil palm have the same clay. However, the soils of the cassava farm had significantly the highest silt and clay contents. The geology of the area could explain the high percentage of sand seen in all land use schemes. The area's geology includes coasted plain sands with sandy soils spread across a large area of land (Akamigbo and Ukaegbu, 2003). Bulk density ranged from 0.91-1.25 g/cm^3 for fallow land,1.08 –1.19 g/cm^3 cassava farm, and 0.96 – 1.16 g/cm^3 in oil palm plantation. According to the mean values, Cassava farms had the most significant bulk density among the land use patterns evaluated. The bulk density result is consistent with Osuji *et al.* (2011) observations on soils in South Eastern Nigeria. Total porosity (TP) ranged from 52-65% in fallow land, 55-59% in cassava farms, and 56-63% in oil palm plantations. The mean values of the TP indicated that the oil palm plantation had the highest (60.20%) while the cassava farm had the least (57.60%). From the soil's Total porosity results, the soils are dominated by a high sand fraction with high total porosity and moisture content. These soils, therefore, require proper management practices that could improve the soil's physical qualities.

Moisture Content (MC) ranged from 94.25 – 98.25% in fallow land, 91.82– 95.49% in cassava farm, 95.38 – 96.54% in cassava cultivated land in 11.33-13.02% in oil palm plantation. The mean Moisture Content values showed that fallow land had the most significant (96.79%) and cassava farm had the lowest (94.25%). The high MC value of the Fallow land could be attributed to the poorly drained nature of the soil and the area's flooded status, which can be remedied with a sufficient drainage system. Depending on the textural class, land use system, soil structure, and vegetation, moisture content differs amongst land use types. The findings are consistent with Brady and Weil (2007) claim that soil physical parameters and quality influence soil moisture content. The silt clay ratio (SCR) ranged in land use categories from 0.31 to 1.25, 0.09 to 2.5, and 0.31 to 1.25 in fallow land, cassava farmed land, and oil palm plantation order. The SCR values of the investigated land use types are consistent with the findings of Hassan *et al.* (2016), who reported that SCR values less than one (1) suggested that the soils are significantly eroded and possess a ferrallitic character from a pedological perspective.

Table 1: The means of the soil physical properties of the study location

Land used	Sand gkg-1	Silt gkg-1	Clay gkg-1	TC	BD gcm-3	TP %	MC %	SCR
Fallow	952	16.0	32.0	S	1.09	58.40	96.79	0.50
Cassava	886	42.0	52.0	S	1.12	57.60	94.25	1.12
Oil palm	946	22.0	32.0	S	1.04	60.20	96.29	0.69
LSD(0.05)	2.83	2.64	3.03	S	0.18	6.68	0.820	1.57

S = sandy, TC – Textural Class, BD = Bulk density, TP= total porosity, MC = Moisture Content, LSD = Least Significant Difference

Soil chemical properties under different land use types

The chemical characteristics of the soil (Table 2) revealed that the analyzed soil of the land use types was generally acidic. The mean pH value of the three land use types ranged from moderately acidic (5.84) in fallow land and oil palm plantation to slightly acidic (6.49) in cassava farms (FAO 2004). Acidic situations in diverse land use types could be linked to heavy leaching caused by excessive tropical rainfall (IITA, 1995; Ojanuga and Lekwa, 2005). The average organic carbon content of the examined land use types was 0.97%, 1.19%, and 1.01% for fallow land, cassava farmland, and oil palm plantation, respectively. When compared to FDALR values (<4%), the organic carbon concentration of the examined land use types was low (1985). The mean organic matter content of the examined land use systems was (1.67%, 2.05%, and 1.74%) for fallow land, cassava farmland, and oil palm plantation, respectively. Compared to FAO rates (2-4%), the O.M content of the analyzed land use systems was low (2004). The findings show that the organic carbon levels of the four land use categories evaluated coincided with the findings of Ufot *et al.* (2016) of soils under vegetative cover in southeastern Nigeria.

The change in TN could be due to a significant buildup of organic material on the surface horizon, the rate of decomposition, and the rate of illuviation and illuviation. Several researchers' findings in soils with comparable agroecology (Hassan *et al.*, 2016; Chude *et al.*, 2011; Ufot *et al.*, 2016) corroborate the findings. Total nitrogen mean ranged (0.12%, 0.13%, and 0.12%) for fallow land, cassava farmland, and oil palm plantation, respectively, in the analyzed land use systems. The mean levels of T.N in all land use types were less than the threshold value of (0.15%) for Nigerian soils (FDALR, 1985, Chude *et al.*, 2011). Low N concentrations in soils could be attributed to quick mineralization of soil organic matter and severe leaching caused by heavy tropical rainfall (Howeler, 2002; Ojanuga and Lekwa, 2005). On the fallow ground, cassava agricultural land, and oil palm plantation, the available phosphorus had mean values of 1.92 mg/kg, 2.83 mg/kg, and 3.99 mg/kg, respectively. The FDALR grade (<6, <5) indicated that the available phosphorus in all of the land use systems investigated was low (1985). The low accessible phosphorus value could be owing to a high sorption reaction. Low accessible phosphorus levels have been ascribed to soil weathering, clay type, severe leaching, rainfall, and absorption reaction by soil elements (Hillocks, 2002). The effects of fixation and erosion might also contribute to a decrease in accessible P. The available phosphorus increased with increasing soil organic matter and cation exchangeable capacity under diverse land use regimes.

The exchangeable bases values revealed that Sodium (Na), Potassium (K), and Magnesium (Mg) levels in the fallow land were low when compared to Calcium (Ca) levels. On cassava farmland, potassium (K) and magnesium (Mg) have equivalent means. Ca, Mg, K, and Na mean values are (2.80 cmol/kg, 1.08 cmol/kg, 0.80 cmol/kg, and 0.94 cmol/kg) for oil palm plantation land, (3.46 cmol/kg, 1.18 cmol/kg, 1.18 cmol/kg, and 0.79 cmol/kg) for cassava farmland, and (3.28 cmol/kg, 0.98 cmol/kg. Exchangeable bases readings revealed that Sodium (Na), Potassium (K), and Magnesium (Mg) levels were low in comparison to Calcium (Ca) levels in fallow land. Potassium (K) and magnesium (Mg) have equal mean values on cassava farmland. Ca, Mg, K, and Na mean values are (2.80 cmol/kg, 1.08 cmol/kg, 0.80 cmol/kg, and 0.94 cmol/kg) for oil palm plantation land, (3.46 cmol/kg, 1.18 cmol/kg, 1.18 cmol/kg, and 0.79 cmol/kg) for cassava farmland, and (3.28 cmol/kg, 0.98 cmol/kg.

Low organic matter and high weathering could explain the low amount of ECEC in the terrain types (Akamigbo and Asadu, 1983). In all land use types, the ECEC increased unevenly with soil depth. The percentage base saturation (%BS) for fallow land, cassava farmland, and oil palm plantation land use types was (90.54-94.84%), (85.02-91.72%), and (84.10-93.80%), respectively, according to the results of the soil chemical characteristics under diverse land use types. According to FAO assessments, the percentage base saturation mean suggested that all land use types were high (2004). The percentage BS results show that primary cation dominates cation exchange capacity in all land use types. The fallow land use type had the highest mean value (92.52%), and the cassava farmland use system had the lowest (89.90%) among the land use kinds. The findings on percentage base saturation of the analyzed land use systems contradict Igbokwe's (1990) work on soil fertility and land use patterns in Nigeria's eastern states. Nevertheless, parent material, weathering rate, and global climate change may have contributed to the variation shown by the findings (Onweremadu *et al*., 2011, Wang et al., 2001).

Table 2: Means of Soil chemical properties of the study location

Land used	pH	Org Carbon %	Org. Matter %	Total N %	Avail P Mg/kg	Ca	Mg	K	Na Cmolkg^{-1}	H	Al	TEB	TEA	ECEC	BS %

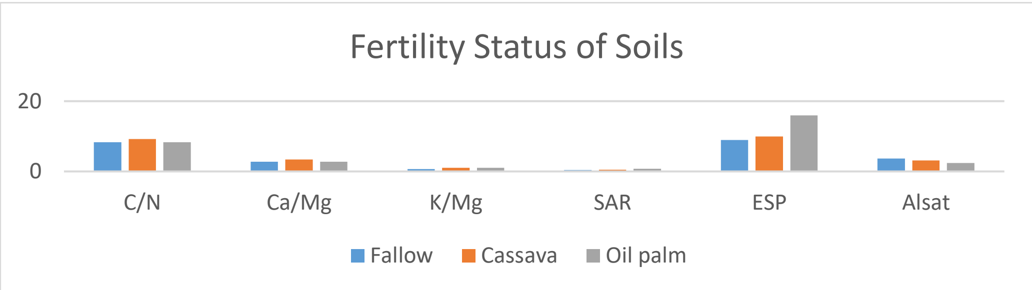
Some fertility indicators of soils in the study area

The results in Fig. 1, which shows some fertility ratios, indicated that all the elemental ratios are not significant. In all land use classifications, the median of C:N ratios indicated fertile, ranging from 8.29 to 9.21. When the C: N ratio is between 1 and 15, fast mineralization and N release occurs, making N accessible for plant uptake. The lower the C: N ratio, the faster nitrogen is released into the soil for immediate crop utilization. (Watson *et al.*, 2002). A C: N ratio > 35 results in microbial immobilization. Ca: Mg showed that fallow land and palm plantation were unfertile with means of 2.80 and 2.78, respectively. According to Johnstone (2011), the Ca: Mg ratio in fertile soils is typically in the range of 3:1-7:1. Landon (1991) also said that a Ca: Mg ratio less than 3:1 indicates infertile soils. Except for barren land, which had a mean of 0.70, the K:Mg values suggested fertile land. It has been reported that ideal K: Mg ratio in fertile soils is in the range of 0.2-.0.35 and the K: Mg ratio greater than 2:1 may inhibit the uptake of Mg (Udo *et al*., 2009). Sodium adsorption ratio (SAR) indicated fertile land use types with means of 0.37, 0.51 and 0.73 in the fallow land, Cassava farm land and oil palm plantation respectively. When the sodium adsorption ratio (SAR) is >13, the soil contains sufficient sodium to interfere with the growth of most crop plants, meaning its infertile (Brady and Weil, 2010). The ESP of the fallow land and Cassava farm is fertile while oil palm plantation is infertile with the mean of 15.96. If exchangeable sodium percentage (ESP) is >15 it is associated with severely deteriorated soil physical properties and pH values of 8.5 and above, making the soil infertile.



ALSAT = Aluminum Saturation, ESP = Exchangeable Sodium Percentage, SAR = Sodium Adsorption Ratio.
Fig. 1: Mean of Some fertility indicators of soils in the study area

CONCLUSION

The particle size distribution demonstrated that sand dominated other soil fractions across the three land use categories tested. When compared to other land use types, Cassava farm land had a high bulk density. Overall porosity was high, with the greatest mean seen in oil palm plantations. The moisture content was high, with fallow land having the most moisture. All lansd use types had low levels of organic carbon, organic matter, accessible phosphorus, and total nitrogen. The exchangeable cation ranges from low to high, but the effective cation exchange capacity was low. The percentage of base saturation was very high. C/N elemental ratios indicated fertile in all land use types, Ca/Mg indicated unfertile in fallow land and palm plantation, K/Mg indicated infertile in fallow land, and SAR indicated fertile in all land use types. Yet, as compared to the critical level (0.6 mg/kg), the zinc content in the research area was quite low. This shortage is caused by the organic carbon level of study area. The copper concentration of the study area differed significantly. Despite the fact that the copper concentration was below the threshold limit of 0.2 mg/kg. This shortage can be linked to the high sand content of the study area, which restricts the available copper content in the soils. Generally, iron, copper, and zinc were all found to be below the critical limits in the soils of Ohaji-Egbema for the three land use categories, which can be attributed to the leaching effect of the floodplain soil.

This study investigated the soil fertility status of Ohaji-Egbema in Imo state, southeastern Nigeria, across three distinct land use types: oil palm plantations, cassava farms, and fallow land. The analysis revealed variations in soil texture, with cassava farms exhibiting higher sand content and clay-silt composition than other land use types. Bulk density showed minor fluctuations across the sites. While pH levels differed slightly among land use types, they remained within an acceptable range. Organic carbon and matter content varied within relatively narrow limits. However, overall nutrient indices and fertility ratings indicated a prevailing condition of low fertility across the study area. These findings underscore the importance of implementing targeted soil management practices to enhance fertility and sustain productivity across diverse land use contexts in this region. Further research could explore specific soil improvement strategies tailored to each land use type for more effective and sustainable agricultural practices.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An experiment was carried out at the Research Farm of Oyo State College of Agriculture and Technology, Igboora, Oyo State. The research objective was to assess the effect of Cow dung (CD), and Pig manure (PGM) on soil properties and yield of Okra. The experimental design was a Randomized Complete Block Design (RCBD), replicated five times. The treatments used in the study were; Control (CO), 5 t/ha (CD and PGM) and 10 t/ha (CD and PGM). Data were collected on yield components and subjected to Analysis of Variance (ANOVA). Application of Cow-dung and pig manure significantly influenced ($p<0.05$). Number of harvested pods, fresh and weight of dry pods were significantly ($p<0.05$) higher compared to control. The result indicated that application of 5 t/ha (CD and PGM) significantly ($p<0.05$) improved okra performance. Conversely, CD and PGM at $10tha^{-1}$ did not result in corresponding increase in the growth and yield of Okra. Also, the results showed that the addition of CD and PGM significantly ($p<0.05$) improved some soil chemical properties (pH, total N, available P, Organic matter and cation exchange capacity). Thus, application of CD and PGM at 5 tha^{-1} is recommended for use to improve soil fertility status for sustainable Okra production in the study area.
Keywords: *Pig manure: Cow dung; Okra,*

INTRODUCTION
Okra (*Abelmoschus esculentus* [L], is a valued vegetable in different parts of Nigeria, mainly for its delicious fruits. It can be consumed alone or in combination with other foods. Nutritionally the dry seed has been considered the richest part of the crop (Adelakun, *et al.*, 2009). The crop occupies about 1.5 million hectares of the arable land in Nigeria (IFA, 1992). Its world production as fresh fruit vegetable has been estimated at 1.7 million t/year (Schippers, 2000). However, Okra cultivation is affected by low yield, partly because of low soil fertility.
Recently, farm yard manure recycling is one of the main options adopted in agriculture because of its richness in plant nutrients, especially N and P (Bello, *et al.*, 2017). Similarly, the application of organic manures had been found to have higher comparative economic advantage over the use of inorganic fertilizer. Manure is relatively cheap when compared with mineral fertilizers. Thus, it is a better option of improving soil fertility status with minimum effect on the soil properties,
Bello *et al.*, (2019) observed that in households where crop and livestock production are integrated, farmyard manure and their compost are valuable sources of amendments for improving soil fertility and sustaining crop production, especially in the sandy loam soils such as found in some locations of Oyo State, South-west Nigeria (Bello and Adejuyigbe, 2012).
In view of the constraints associated with fertilizer usage in tropical agriculture (unaffordability due to high prices), more small farmers in Africa may consider the adoption of organic manure (cow-dung and pig manure), on soil properties and Okra yield.

MATERIALS AND METHODS
The study was conducted at the Teaching and Research Farm, Oyo State College of Agriculture and Technology, Igboora, located in the Derived Savanna Zone, Nigeria. The region has two prominent rainy periods ranging from 1000 to 1600 mm of annual rainfall and temperature between 22^{o}C to 38^{o}C. Okra seeds (var. Lady's finger) were obtained from National Horticulture Research Institute, (NIHORT), Ibadan, Oyo state, Nigeria.
Experimental site was manually ploughed and harrowed, and demarcated into plots of 1.5 x 1 m dimension. The soils of the experimental site were randomly sampled at depths of 0-30 cm before and after planting using auger.

The soil samples were bulked, air-dried and sieved through 2 mm mesh and analyzed for selected physical and chemical properties (pH taken in a 1:25 solution of 10 g air-dried soil + 25ml distilled water or 1MKCL solution). Texture was determined by pipette method. Samples were fractionated using Vanluwe *et al.*, (1998) method. The Olsen-P method was used to determine available phosphorus concentrations in the soils. Percentage total nitrogen was measured by the Kjeldahl digestion method, while the Amato method was used to measure percentage total soil carbon (Amato, 1983).

Treatments used were: control (Co), Piggery manure (PGM), applied at 5 t/ha and 10 t/ha (CD and PGM) respectively,. The experimental design was a Randomized Complete Block Design (RCBD) replicated three times. Each plot measured 3 m x 3 m. The manures were first subjected to routine laboratory analysis to determine their nutrient status and applied a week before planting to hasten decomposition and enhance nutrient use efficiency by the testcrop. The manures were worked into the soil with the aid of small African hand-held hoes, while the Okra seeds were planted a week after by drilling. Okra seeds were planted at 0.25 m within rows and 0. 5 m between rows and the seedlings were thinned to one plant per hill two weeks after planting (WAP). Weeding was carried out regularly by hand pulling up to 6 WAP.

RESULT AND DISCUSSION

The result of the soil analysis carried out before planting is presented in table 1. The results showed that the soil was sandy loam in texture, with high proportions of sand (75.4 %), likely to cause basic cations (Ca, K, Na and Mg), to easily leach. The soil was slightly acidic in pH (6.6), low in organic carbon, total nitrogen and available P. The low organic carbon and organic matter content of the soil could be as a result of the sandy loam texture of the study soils. Also, the low nutrient content of the soil could be attributed to continuous cropping and increased land use (Mafongaya *et al.*, 2003). Thus, the low soil OC, N, P, K, Mg content and its acidic status justify the need for the application of goat and Cow-dung manure (Table 1).

Table 1: Pre-Soil properties of the experimental site and chemical properties of the manures

Parameters	Value	Pig-manure	Cow-dung manure
Physical characteristics

Table 2: Effect of Cow-dung and Pig manure on number of harvested pods, fresh and dry weight of pods of Okra

Treatments	Number of Pods	Fresh weight of Pods	Dry weight of Pods
Control	32.66e	0.56e	0.18d
Pgm5t/ha	75.56dc	0.86cd	0.22c
Pgm 10t/ha	110.60b	1.25b	0.27b
CD 5t/ha	86.20c	0.97c	0.24c
CD 10t/ha	126.16a	1.36a	0.29a

Means followed by the same letter in the columns are not significantly different at 5% level of probability by DMRT.

Pgm – Pig manure, CD – Cow-dung manure.

Table 2, indicated that the application of cow dung and poultry manure) significantly ($p<0.05$), increased number of pods, fresh weight of pods and the dry weight of pods respectively. The highest number of pods, fresh weight of pod and dry weight of pods was obtained at 5 t/ha (CD and PGM) followed by 10 t/ha (CD and PGM). The use of 5 t/ha (CD and PGM), produced higher yield than 10 t/ha (CD and PGM). This increase in Okra yield associated with increased in the rate of CD and PGM is consistent with the observation of Bello *et al.*, (2018).

Table 3: Soil properties of the experimental site after harvesting

Parameter	Control	PGM 5t/ha	PGM 10t/ha	CD 5t/ha	CD 10t/ha
Physical characteristics					
Sand %	75.4	74.70	70.40	75.00	71.00

P (mgkg-1)	18.6	27.48	22.53	27.10	19.39
Ca (cmolkg-1)	0.42	5.26	7.66	2.06	4.46
Mg ,,	1.4	4.93	6.13	1.33	3.73
K ,,	0.57	1.05	0.71	0.71	1.01
Na ,,	0.53	0.54	0.88	0.49	0.93

Addition of cow-dung and poultry manures enhanced the improvement in soil chemical properties, (pH, total N, available P, Organic matter, exchangeable cations and cation exchange capacity was improved), (Table 3). Application of cow dung and pig manure could be used for soil management as it improves soil nutrient status and enhanced the sustainable production of crops. The observed result corroborates the findings of Sanni and Adenubi, (2015) who reported that application of pig and goat manure is recommended for sustainable Okra production. The results obtained showed that okra responded well to the application 5 t/ha (CD and PGM) than the use of 10 t/ha (CD and PGM), (improved soil organic matter and nutrient availability), hence enhancedyield. The application of 5 t/ha (CD and PGM) is therefore, recommended for optimum production of okra and restoration of soil fertility.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACTS
Field experiments was conducted at Faculty of Agriculture research farm Lafia in 2020 and 2021 rainy season. These comprised of two plant spacing (35 x 75 and 40 x 75 cm), fertilizer applications (NPK at the rate of 0, 30 and 60 kg ha^{-1}), and weed control methods, using herbicides (pre-S-Methalachlor®, post-Fusillade®, hoe weeding [at 3 and 6 weeks after planting (WAP)] and weed check (control). The experiments was laid out in a split-split plot design replicated three times. The field experiment results of 2020 and 2021 indicated that fertilizer application of NPK 15:15:15 applied at the rate of 60 kg ha^{-1} recorded the highest growth parameters and yield followed by 30 kgha^{-1} fertilizer application supplemented with the application of pre-emergence herbicide of S-Metolachlor followed by hoe weeding at 6 (WAP) with plant spacing of 40 x 75 cm which gave the highest yield 6.78 tons ha^{-1} and 7.70 tons ha^{-1} and the 30 kgha^{-1} fertilizer application recorded 6.08 tons ha^{-1} and 6.30 tons ha^{-1}, during 2020 and 2021 season respectively. The results showed that both growth and yield performance of sweet potato were better with weed control method using pre-S-Metolachlor within 4 -10 days after planting (DAP) with the application of 60 kg ha^{-1} of fertilizer NPK 15:15:15 should be adopted .
Keywords: *Sweet potato, herbicides (pre-S-Metolachlor, post-Fusillade®), fertilizer rates, spacing, hoe weeding*.

INTRODUCTION
Sweet potato (*Ipomoea batatas* [L.] Lam) is one of the major staple food and perennial crops cultivated as an annual crop which serves as the most important food security promoting root crop in the world, especially in sub-Sahara Africa (Low *et al.*, 2009). The family is made up of 45 genera and 100 species. The crop is reported to have originated from Central America in about 300 BC and later introduce into Europe between 15th -20th Century. The first introduced sweet potato into Nigeria was in the late 1694 to 1698 through the early activities of Portuguese and Spanish explorer, respectively (Mbanaso, 2010). The crop was introduced by Portuguese Seafarers into Western Mediterranean Europe, Africa, India and parts of South-east Asia (Jia, 2013). Sweet potato grows at temperature between 20°C and 24°C with annual rainfall of 100 mm to 700 mm with optimal soil pH between 5 and 7 (Roullier *et al.*, 2013).

Sweet potato serves as main food crop of the tropical and subtropical areas and therefore people of rural and urban region can benefit from its nutritional advantage by enhancing their production and increasing consumption of sweet potato (Wariboko and Ogidi, 2014).

Planting on mounds and ridges are methods to peculiar to traditional peasant sweet potato production (Wubanechi, 2014). It is suggested to make the mounds 30 cm high to 40 cm wide at the base. If using a mechanical digger at harvest time it is important to match the width of the mound with the digger mouth and the higher the ridges the greater the yield of sweet potato (Bhuiyan *et al*., 2006).

Proper use of fertilizer on sweet potato production can be increased substantially. Fertilization of soil is one of the main factors to increase the yield of crops, it helps in accumulation of mineralization and humification of fertilizer when added to the soil and the plant potential can be determined by the amount of fertilizers introduced to the soil (Kolozie, 2006).

Weeds are controlled by hand weeding, hoeing and tilling between the rows by means of physical energy through implements, either manual or power operated, It has been suggested that, the use of herbicides may be a suitable alternative for managing the weeds as well as increasing the yield and ensuring the efficient use of fertilizer (Singh *et al.,* 2019). The objectives of this study was to determine sweet potato growth and yield performance to fertilizer application, plant spacing and weed control method using the herbicides pre and post emergence plus hoe weeding.

MATERIALS AND METHODS

The field experiment was conducted at the research farm Faculty of Agriculture Shabu- Lafia Campus of Nasarawa state University Keffi, situated at Latitude N 8°33' 49" Longitude E 8°33'1", with an altitude of 168.47 m above sea level (asl) (Jayeoba, 2013) during the 2020 and 2021 rainy seasons.The experimental design was a Split-split plot. The treatments consist of two plant spacings (35x75cm and 40x75cm) giving planting densities of 21,428 and 18,750 plants ha^{-1}, respectively). Laid in the main plot; two NPK (30 and 60 kgha^{-1}) and untreated control (0 kgNha^{-1}) were placed in the sub-plot and weed control methods of Pre-emergence of S-metolachlor® (Dual Gold; Syngenta) of 1160 g a.i. ha^{-1} at 4 days after planting (DAP) followed by hoe weeding at 6 WAP; Post-emergence of Fluazifop-p-butyl (Fusilade-forte®) of 450 g a.i. ha^{-1} at 2 weeks after planting (WAP) followed by hoe weeding at 6 WAP, Hoe-weeding at 3 and 6 WAP and a weedy check (control)], laid in the sub-sub plots thus, giving a 24 treatment combinations. The treatments were replicated three times to form seventy-two (72) plots. The gross plot size was 4 x 4 m (16 m^2), while the net plot size was 2 x 2 m (4 m^2). An alley of 1 m was used to separate each plot from each other and the replications (blocks). The field experiment study data collected was analyzed using ANOVA by GENSTAT software, version 13. The means were separated using Fischer's Least Significance Difference (F-LSD) at 5 % level of probability.

RESULTS

The result of Table 1 shows that the spacing with the plots of (40 x 75 cm) recorded high number of nodes (44.80) compare with the plot spacing of 35 x 75 cm (44.00) but no significantly difference during the second seasons. The number of nodes similarly were significantly higher with the application of 60 kg ha^{-1} of NPK fertilizer along sides with the application of of S-metolachlor and hoe weeding at 3 and 6 WAP compared to weedy check plots that recorded significantly lower number of nodes (36.16 and 34.80) throughout the period of observation of the both seasons.

The treatments showed that the effect of interaction on number of nodes throughout the period of observation in both years recorded not significant,

The Table 2 shows that the weed dry weight was significantly influenced by weed control treatments as observed in Table 2. For both seasons (2020 and 2021), only the plots sprayed with S-metolachlor (0.84 and 0.20) followed by 6 WAP hoe weeding, Fluozifop-P-butyl (Fusilade®) (1.55 and 1.24) followed by 6 WAP hoe weeding and hoe-weeded at 3 and 6 WAP produced lower (0.91 and 0.71) compared to the season-long weedy check (5.36 and 3.83) for both seasons throughout the period of observations. The vine dry matter recorded higher weight (6.66 and 4.45) with the fertilizer application of 60 kg ha^{-1} followed by 30 kg ha^{-1} (5.04 and 3.33) compared to plots treatment with zero fertilizer application (3.30 and 2.06) throughout the period of observations for both seasons (2020 and 2021).

The highest weed densities (6.25) were observed on the spacing 40 x 75 cm at 28 DAP at first season and compared to the spacing of 30 x 75 cm (5.33) at 28DAP of weed count. There was no significant differences between the spacing of 35 x 75cm and the spacing of 40 x 75cm on weed density except at 28 DAP after the fertilizer application during the first season (2020).

The interaction effects on weight of vine dry matter at 2021 growing season shows significant.

Interaction between Fertilizer Application Rates Weed Control Methods on Weight Vine Dry Matter during 2021 Season of Field Experiment: The interaction for fertilizer application rates and weed control methods was significant (P≤0.05) for sweet potato vine dry matter weight for 2021 cropping season. The highest weight of vine dry matter recorded was 5.30 in plots treatment of weed control with S-metolachlor and 6 WAP, with the fertilizer application NPK 15:15:15 of 60 kg ha^{-1} at both years (Table 3).

Table 3. Interaction between Fertilizer Rates and Weed Control Methods of Vine Dry Matter in Sweet Potato Production in 2020

Fertilizer (Kg)	Weed Control Vine Dry Matter 2021 S-metolachlor	Fusilade	Hoe Weeding	Control
0	2.18	2.18	2.38	1.48
30	3.42	3.20	3.75	2.75
60	5.30	4.30	5.23	2.97
LSD	0.56			

Table 4 shows that stand count had significant (P≤0.05) differences effect among the treatments. Plots treated with fertilizer applications of 60kg ha-1 recorded the highest stand count compared to no fertilizer application plots. Plot treatment of weed control (weedy check) had the lowest (78.44 and 71.94) stand count throughout the two seasons years of field research.

The number of tubers, weight of tubers per plant and the yield of sweet potato is as depicted in the results showed the influence of the application of fertilizer rates of NPK 15:15:15 of 30 and 60 kg ha^{-1} compared to plots with no fertilizer application and weed control of pre-emergence with S-metolachlor alongside with hoe weeding of 6 WAP and post emergence application with hoe weeding of 6 WAP compared to plots treatment with 0 kg application. The plots with 60 kg ha^{-1} fertilizer application with S-metolachlor and hoe 6 WAP had the highest number of tubers, weight of tubers and highest record of yield ha^{-1} (tons) at both season 2020 and 2021 (2.40 and 3.56, 0.65 and 1.05, and 6.68and 7.70). The second season had highest number of tubers, tubers weight and yield ha^{-1} (tons) compared to the first year field experiment. The plot with 0 kg ha^{-1} alongside side with weedy check had lowest number of tuber plant, tubers weight and yield ha^{-1} (tons).
There was no significant effect of interaction on tuber per plant, tubers weight and yield ha^{-1} (tons) between other factors in both year.

DISCUSSION

The results from the analysis of variance shows that, increase in plant spacing increased the population of large–sized tubers. The plots with spacing of 40 x 75 cm recorded higher yield (6.31). This observation is in line with the report of Arega *et al*. (2018) that the maximum weight production of tuber with wider plant spacing were due to the optimum number of nodes production with lesser competition for resources between plants compared to closer plant spacing. The application fertilizer at the rate of 60 kg ha^{-1} in combination with application of s-metalochlor and hoe weeding of 3 and 6 WAP, significantly increased numbers of nodes at 12 WAP (65.30 and 51.62). These are in agreement with the assertions of Dapaah *et al.* (2004) who emphasized that the application of nitrogen, phosphorus and potassium influenced growth and yield of sweet potato significantly. Hoe weeding was used at 3 and 6 WAP. This weed control method was effective in reducing weeds interference with sweet potato giving chance for maximum growth parameters and yield. Plots treated with pre-emergence, post-emergence and supplemented with hoe weeding and that where hoe weeding was carried out, showed high growth and yield parameters throughout the two seasons when compared to the control. This is in agreement with the assertions of Adigun and Lagoke (2003) that the use of traditional manual weeding is the most popular method of weed control among the sweet potato farmers in Nigeria.

CONCLUSION

The field experiments shows that the growth and yield of sweet potato were better with the application of 30 and 60 kg ha^{-1} of fertilizer application of NPK 15:15:15 with the wide plant spacing of 40 x 75cm followed by the weed method control of S-metolachlor for pre-emergence application carried out from 4 -10 DAP and post-emergence herbicides of Fluzifop-p-butyl (Fusilade®) applied at14 DAP followed by hoe weeding at 6 WAP. Hoe weeding at 3 and 6 WAP was one of the effective weed control methods but a tedious process

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Knowledge of soil physical and chemical variability and relationship amongst soil properties is important for the evaluation of agricultural land management practice. The study was to characterize the detailed survey of the chemical soil properties variability along a toposequence of teaching and research farm, Oyo State College of Agriculture and Technology. The objective of this study is to provide invaluable information on soil variability along three topographic position, aimed at evaluating the potentials of the soil, which could assist in better management for crop production system. Different in chemical soil properties in three topographic positions (crest, lower slope and valley bottom) and 5 depths were observed on many soil properties important to crop growth. Soil profiles were described and sampled for chemical analysis. The results showed that there are various degree of variability in the chemical properties of soil in the study area. Crop residue management, construction of contour bonds and mixed cropping system are therefore suggested for sustainable exploration of land resources for crop production especially in different micro-topography area.
Keywords: *Topographic, position, growth, variability, terracing and depths*.

INTRODUCTION
Soil form a three dimensional continuum on the landscape and thus, do not exist in isolation but are organized within the landscape (Gerrard 1981; Hall, 1983). The one great constant concerning soil is their variability. Anyone who works intimately with soil soon realized that soils are anything but uniform. It is well known that soil properties vary in vertical and lateral directions and that such variation follows a systematic change (Wilding and Drees, 1983) as a function of the landscape position, the soil forming factors and/or management practices (Beckett and Webster, 1971). One can say that soils variability are the products of the five soil formation factors and as a consequence, of continuous changes over the earth's surface.
Soil variability can be as a result of the interaction among the various factors, which are topography, parent materials, climate, soil physical and chemical processes, biological activities, soil age and cropping system and tillage practices. Where there are large differences, the land cannot usually be managed in the same way, more variation can be tolerated within an area that is extensively managed (e.g. in pastoral use) than in one that is intensively managed (e.g. for irrigated agriculture).
Variability is an important feature in the identification of soil properties related to crop production, irrigation scheduling, land drainage, land reclamation, run off and pollution, ground water contamination, liquid waste disposal from municipal, industries and so on. Some of them are known and can be described, many others are unknown. Soil variability thus seems random. Nevertheless, our task is to reveal at least some of these factors, and use the knowledge to design agricultural management practices that would be both environmental friendly and highly productive otherwise known as precision agriculture. A major motivation for research in soil variability is the need to make the best use of land, water and energy resources possible. Thus, this work focuses on the study of soil variability that can serve as important features in the identification of soil properties relatives to crop production, irrigation scheduling, land drainage and land reclamation as related to Oyo State College of Agriculture and Technology Teaching and Research Farm Igboora, Oyo State.

MATERIALS AND METHODS

The study was conducted on a three major toposequence at the Oyo State College of Agriculture and Technology Teaching and Research Farm, Igboora, located in Ibarapa Central Local Government Area of Oyo State Nigeria. It is located between 7° 15' to 7° 33' North, and 3° 56' to 3° 57' East. The high relative humidity favours the cultivation of crops such as a cowpea, maize, millet, cassava and yam. Igboora falls in the derived savanna agro-ecological zone of Nigeria; the area is characterized by adequate rainfall that spread for about seven months (mid-march – September) and dry period (October – May).

The study field has a total area of Ten hectares (10ha), the whole landscape was divided to three topographic positions for the purpose of this work, which are the summit or crest, lower slope and the valley bottom.

Transverse were cut and spaced at 50m apart at each delineated unit and points of observation were fixed at the intersection of the perpendicularly running transects, after this, soil with similar characteristics were grouped together as same mapping unit. Three soil profile pits were located and dug (1.5M x 1.5M x 2.0M) to represent each of the identified delineations (topographic positions) on the field. Altogether, a total of fifteen samples were collected from the three pits. The sample were air dried crushed and sieved to separate the fine earth fraction $\geq$ 2mm from coarser fragments using ceramic mortar and pestle with a 2mm sieve. Particle size analysis was determined using the modified Bouyoucous hydrometer method. Soil pH was determined in three suspension, using the procedure of pH in water, calcium chloride and potassium chloride. The available phosphorus was extracted with Olsen method (Emteryd, 1989) while exchangeable cations (Ca, Mg and K) were determined by flame photometry (Jackson, 1982).

The set of data from laboratory was analyzed statistically using Descriptive analysis for Mean (X), Standard deviation (SD) and coefficient of variation (CV) to find the level of variability. While critical level / range for some soil nutrient where used to determine the critical value/range. Correlation and regression analysis were done using SAS 2009 version. The variability of each property was measured by the coefficient of variation (CV) express as percentage. The higher the CV the more variable the properties.

RESULTS AND DISCUSSIONS

The soil reaction plays an important role in determining the solubility and reactively of soil elements such as Aluminium (Al), Manganes (Mn) and Cadium (Cd). The critical values for all the element is presented in table 1. The results of soil pH determined in a 1:2.5 soil to water and potassium chloride (KCl) suspension showed in coefficient of variation (CV) of 7.02% pedon-1, 10.52% pedon-2 and 7.22% pedon-3, table 2. This indicate that variability did occur within the three position on the same piece of land. This could be attributed to the type of vegetation cover and pattern of cropping system at the study area. Good tillage practice such as, pulverization of soil enhances microbial decomposition of organic matter and provides favourable conditions for microbial action. However, the total nitrogen was above the critical value /range according to rating by Sobulo and Osiname (1985). Available phosphorus of the studied pedons had Cv of 15.83% for pedon-1, 20.76% for pedon-2 and 14.26% for pedon-3; According to Adeoye and Agboola (1985) the available phosphorus of pedon-3 is below the critical range. With this result the lower available P at certain points on the top sequence could be due to some losses through plant uptake. Pedon and Krueger (1980), observed that some test for phosphorus and potassium had cyclic variation with season and that the degree of this variation increase with an increase in the rate of K and P fertilizer application. Available phosphorus was below critical level range as observed by Adeoye and Agboola (1985). Calcium increase with increase in organic matter and this explains the higher range of calcium observed in all pedons. However, the high variation shown by calcium could have been attributed to formation of calcium complexes which is still the effect of high soil organic matter. The exchangeable calcium was above critical level range as observed by Agboola and Corey (1973). The available iron CV in the studied pedons were 18.43, 10.37 and 18.87% respectively. The higher value of available iron in pedon-3 was attributed to high pH value which help indissolubility of more iron. According to Adeoye (1986) the value of the iron were all above the critical value/range. The available copper (Cu) had CV of 17.40, 23.24 and 11.09% respectively. The available manganese of the three pedons had CV of 14.60, 15.53 and 11.07% respectively, table 2. The highest value of manganese at pedon-2 could be attributed to lower slope that help to reduce the mobilization of Mg with water movement. The results of some soil chemical properties along top sequence in Teaching and Research Farm of Oyo State College of Agriculture and Technology, Igboora study site shows a complexity in variation. Soil pH, Ca and P where least variable while T.O.C, TN, K, Mg, Fe and Cu were variable. This must be taken into consideration for further stratification. The various soil region existing may require different management system for the same or different crops because of the basic differences in their characteristics. From the result obtained in the study, transfer of management methods adopted can be done for the slope of the upper regions but not for the lower region or the valley bottom.

Table 1: Critical Level/Range for some Soil Nutrients.

Element	Critical value/Range	Source
Total N (g/Kg)	15 – 20	Sobulo and Osiname (1985)
Available P (mg/Kg)	10 – 15	Adeoye and Agboola (1985)
Exchangeable k (Cmol/Kg)	0.01 – 0.15	Adeoye (1985)
Exchangeable Ca (Cmol/Kg)	2.0 – 2.6	Agboola *et al*., (1975)
Organic matter (g/Kg)	26	Sobulo and Osiname (1985)
Organic carbon (g/Kg)	15	Sobulo (1985)
ECEC (Cmol/Kg)	5	Adeoye and Agboola (1985)
Available Fe (mg/Kg)	5	Adeoye (1985)
Available Cu (mg/Kg)	1.9	Aderonmu (1988)
Available Zn (mg/Kg)	5 – 10	Adeoye and Agboola (1985)

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A pot experiment on 'Effect of micro – size biochar on remediation of heavy metal polluted dumpsite soil' was conducted to assess the use of micro – size biochar for remediation of heavy metals. The experiment consisted of three rice husk micro – size (1.00, 1.50 and 2.00mm) as treatments. The experiment was laid out in completely randomized design (CRD) in the screen house and replicated three times. Data was collected on the heavy metals before treatment application and after harvesting of test crop (Maize) and the result analyzed using GENSTAT. The result revealed that, dumpsite soil studied was contaminated with heavy metals. The largest quantity of heavy metal present was Zinc (4.749 mg/kg); followed by Mercury (2.556 mg/kg); Manganese (2.108 mg/kg); Chromium (1.111 mg/kg); Iron (1.044 mg/kg); Nickel (0.192 mg/kg); Cupper (0.156 mg/kg); Lead (0.117 mg/kg) and the lowest was Cadmium (0.051 mg/kg). The heavy metals in the dumpsite soil is presented in ascending order of concentration as: Cd < Pb < Cu < Ni < Fe < Cr < Mn < Hg < Zn. Application of 2mm size nano-sized biochar adsorbed the lowest amount of heavy metals: Zinc (0.01mg/kg); Mercury (0.01mg/kg); Manganese (0.01mg/kg); Chromium (0.01mg/kg); Iron (0.01mg/kg); Nickel (0.01mg/kg); Cupper (0.02 mg/kg); Lead (0.02 mg/kg) and Cadmium (0.01 mg/kg). It can be concluded that the dumpsite soil contained heavy metals in ascending order of concentration as: Cd < Pb < Cu < Ni < Fe < Cr < Mn < Hg < Zn and 1mm size of micro-size biochar adsorbed high concentration of these heavy metals in the dumpsite soil.

INTRODUCTION

Remediation of heavy metal polluted soils is usually carried out by conventional practices; which include excavation and land filling. This is usually not feasible on large scale, because these techniques are cost-prohibitive and environmentally disruptive (Arthur *et. al.,* 2005). However, recent studies by these scientists (**Beesley *et.al,* 2011;** Ndor *et.al,* 2016a; Noreen and Abd-Elsalam, 2021), reported that soil amendment with biochar reduced the bioavailability of a wide range of heavy metals, potentially reclaiming contaminated soils for agricultural use. Biochar is a solid carbonized product obtained from biomass feedstock such as agricultural waste and other lignocellulosic materials by the controlled process of thermal decomposition in the absence (pyrolysis) or limited oxygen (Lehmann and Joseph 2015). In recent years, carbon nano-materials have been developed as powerful tools; due to their unique characteristics and number of applications in various areas like: energy, materials science, agriculture and the environment. Nanobiochar technology may result in production of carbon-based nano-materials known as nano-biochar; which serve as advanced nanostructured biochar that have come up with the sustainable solutions for a range of soil problems of modern era (Lateef *et al.,* 2019). Nanobiochar is nanosized biochar material with better physical, chemical and surface properties. Therefore, the decreasing particle size in micro range (10–600 μm) of biochar always led to increased available sites for adsorption, thus resulting in better adsorption capacity (Lonappan *et al.,* 2016). Further reduction in size of biochar particles to nano-size was reported by Naghdi *et al.,* (2019) to enhance its properties of higher surface to volume ratio, increased surface energy, increased adsorption potential and consequently biological effectiveness. Hence, nanobiochar is trending these days as it amalgamates the advantages of nanotechnology with biochar technology. Therefore, the objective of the study is to assess the use of micro – size biochar for remediation of heavy metals on dumpsite soil in Nasarawa State

MATERIALS AND METHODS

Experimental Site

The experiment was conducted during the rainy season of 2022 at the screen house of College of Agriculture, Science and Technology, Nasarawa State. The study area falls within southern guinea savanna agroecological zone of Nigeria. Rainfall period is usually from March – October and the average monthly rainfall figures of 350 mm. The months of July and August usually record heavy rainfall. The daily maximum temperature ranges from 20.0°C– 38.5°C and daily minimum ranges between 18.7°C–28.2°C. The months of February to early April are the months that have the highest maximum temperature; while the lowest maximum temperature are recorded in December and January because of the prevailing cold harmattan wind from the northern part of the country at this period. The relative humidity rises from April to a maximum of about 75- 90 percent in July (NIMET 2022).

Treatment and Experimental Design

The pot experiment consisted of three rice husk micro – sized biochar (1.00, 1.50 and 2.00mm) laid out in completely randomized design (CRD) and replicated three times.

Soil Sample Collection/Preparation

The dumpsite soil was collected at a depth of 0-20cm in the month of April, 2022 at an old abandoned dumpsite in Al-makura street in sabon-pegi Lafia; Nasarawa state. This period was chosen for sample collection because rain had not started, so infiltration is restricted. Due to the fact that soils vary intrinsically, soil samples were obtained through random sampling in three different spots on the same dumpsite, bulked together to form a composite sample. The composite sample was air dried in the laboratory and sieved through a 2 mm mesh.

Soil Analysis

The composite soil sample was analyzed for heavy metal before maize was planted. Soil samples were again collected after the harvest of maize cobs from each of the treatments for analysis. 100g from each soil sample in the 9 buckets were transferred into different 250 ml standard flask, diluted with 50 ml of 2M HNO_3 and then heated in the sand bath for about 3 hours at a temperature of 900 C to 1000 C. The digested solution was evaporated to near dryness and allowed to cool to room temperature. It was then filtered into standard flask, diluted to 100 ml with distilled water and shaken vigorously. Subsequently, it was poured into 120 ml plastic bottle prior to aspiration into the Atomic Absorption Spectrophotometer (Perkin Elmer) to determine the metals. Settings and operational conditions were followed with respect to the manufacturer's guidelines.

Production of rice husk micro - size biochar

Rice husk was collected from Lafia rice mill for the production of parent biochar. An improvised kiln was constructed using an empty drum that was perforated but had a cover. The rice husk material was poured inside the drum to half full, then ignited inside the drum. More rice husk material was added, the drum lid was covered to encourage slow burning and the content in the drum was consistently stirred to enhance uniformity of burning. After 3-4 hours the content of drum was poured out, the fire quenched with water (by sprinkling water on the hot char) and dried in the sun for 2 days (Ndor *et al.*, 2016). Then, the bulk parent biochar produced using rice husk is mechanically ground using pestle and mortar; then sieved into micro-size biochar using different sizes of the sieve according to the treatments.

Pot Experiment

A total of nine plastic buckets were filled with 5kg of the sieved composite dumpsite soil. After filling the plastic bucket with dumpsite soil, treatments were incorporated into the plastic bucket. Sammaize 15 variety of maize was used as test crop.

Data Collection

The following heavy metals (Cd, Pb, Cu, Ni, Fe, Cr, Mn, Hg and Zn) were analyzed before sowing and after harvesting of the test crop (maize).

Data Analysis

The data collected were subjected to analysis of variance using GENSTAT, and where there is a significant difference; the means were separated using F-LSD at 5% probability level.

RESULTS

Concentration of heavy Metals in Dumpsite soil

The result in Table 1 showed that the dumpsite soil studied was contaminated with heavy metals. The largest quantity of heavy metal present was Zinc (4.749 mg/kg); followed by Mercury (2.556 mg/kg); Manganese (2.108 mg/kg); Chromium (1.111 mg/kg); Iron (1.044 mg/kg); Nickel (0.192 mg/kg); Cupper (0.156 mg/kg); Lead (0.117 mg/kg) and the lowest was Cadmium (0.051 mg/kg). The heavy metals in the dumpsite soil is hereby presented in ascending order of concentration as: Cd < Pb < Cu < Ni < Fe < Cr < Mn < Hg < Zn.

Table 1: Concentration of heavy metals in dumpsite soil

Heavy metal (mg/kg)	WHO Standard	Mean	Mini	Maxi	SD	SE	%CV
Cd	0.8	0.051	0.002	0.280	0.047	0.008	92.137
Cu	36	0.156	0.056	0.282	0.063	0.010	40.421
Cr	100	1.111	0.001	2.498	0.623	0.100	56.081

Hg	NA	2.556	1.710	4.194	0.906	0.145	35.421
Mn	NA	2.108	1.170	3.064	0.561	0.090	26.604
Ni	35	0.192	0.030	0.720	0.231	0.041	76.252
Pb	85	0.117	0.001	0.560	0.091	0.015	78.021
Zn	50	4.749	3.683	5.127	0.385	0.062	80.104

Effect of micro-size rice husk biochar on remediation of heavy metal in the dumpsite soil

The result in Table 2 showed a significant ($p< 0.05$) decreased in bioavailability of all the heavy metals assessed in dumpsite soil after the harvest of test crop. Application of 1mm sizes of micro-size biochar adsorbed higher concentration of cadmium, copper, manganese, nickel and zinc in the dumpsite soil; and this is statistically at par with the application of 1.5mm size micro-size biochar. However, application of 2mm size micro-size biochar adsorbed the lowest amount of heavy metals: Zinc (0.01mg/kg); Mercury (0.01mg/kg); Manganese (0.01mg/kg); Chromium (0.01mg/kg); Iron (0.01mg/kg); Nickel (0.01mg/kg); Cupper (0.02 mg/kg); Lead (0.02 mg/kg) and Cadmium (0.01 mg/kg).

Table 2: Effect of Nano-sized biochar and rates of application on remediation of heavy metal in dumpsite soil after harvest of maize

Treatments Nano biochar	Cd	Cu	Cr	Fe	Hg (mg/kg)	Mn	Ni	Pb	Zn
Size (mm)									
1.00	0.07	0.17	1.23	1.24	3.08	2.42	0.08	0.16	4.91

LSD(0.05)	0.01	0.02	0.01	0.01	0.01	0.10	0.01	0.02	0.01

DISCUSSION

The dumpsite soil used for this study was really contaminate with heavy metal. This result is in agreement with the findings of other earlier works like Esakku *et al.* (2003), who reported that heavy metals were always the major concerns at municipal dumpsites. Also, Umoh and Etim (2013) who worked on soils from dumpsites within Ikot-Ekpene in Akwa-Ibom State, Nigeria discovered that the increased in the concentration of the heavy metals in the soils from the areas could be attributed to different sources like: automobile exhaust fumes, dry cell batteries, sewage effluents, runoff from other solid wastes garbage. Finally, Asawalam and Eke (2006) and Njoku and Ayoka (2007) also investigated the trace metal concentrations and heavy metal pollutants from dump soils in Owerri, Nigeria observed that though these heavy metal concentrations fell below the critical permissible concentration level, it seems that their persistence in dumpsite soils may lead to increased uptake of these heavy metals by plants.

The positive response of micro – size biochar to remediation of various heavy metals in dumpsite soil in this study corroborates with the findings of Ma *et al.* (2019) who reported that nanobiochar exhibited outstanding adsorption capability owing to its unique characteristics. Hence, nanobiochar has been considered to be a promising agent for bioremediation of a wide variety of contaminants in the soil. Also, Liu *et al.* (2020) who worked on remediation of cadmium contaminated soil using micro size biochar reported a significant decreased in bioavailability of Cd in the soil. It has also been proven by several other researchers (Yu *et al.*, 2015; Wang *et al.*, 2015 and Wang *et al.*, 2018) that nanobiochar contain huge capacity to remove major heavy metal contaminants including arsenic, lead, copper, chromium, cadmium etc in the soil.

CONCLUSION

In conclusions, this study revealed that the dumpsite soil contained heavy metals in ascending order of concentration as: Cd < Pb < Cu < Ni < Fe < Cr < Mn < Hg < Zn. Then, 1mm size of micro-size biochar adsorbed high concentration of these heavy metal (cadmium, copper, manganese, nickel and zinc) in the dumpsite soil after harvest of the test crop.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This research study focused on comparative economic analysis of rice production under irrigation and rain-fed systems in Yobe State, Nigeria. Primary data were collected from Eighty (80) respondents with the use of well structured questionnaire. Data were analysed using gross margin analysis, and stochastic production frontier model. The result revealed that gross margin realized by the irrigated and rain-fed farmers were ₦137,189.90 and ₦355,625.64 respectively. The net profit obtained by irrigated farmers was ₦76,979.79, while rain-fed farmers realized ₦327,892.66 with gross margin ratios of 0.44 and 0.77 respectively. Also, the estimates of the factors influencing the total output of rice production among the farmers under irrigated and rain- fed systems showed that seed, farm size, fertilizer, chemical, family and hired labour are statistically significant at different level. Furthermore, the study shows that rice farmers under both systems were faced with the following constraints; high cost of transport, lack of storage facilities, inadequate finance, bad roads, excessive rainfall, flooding and high cost of inputs. The research concluded that rice production is profitable though irrigated system is more viable. The study recommended that extension services should be intensified to improve technical know-how and capacity of the rice farmers.
Keywords: *Comparative, Rice, Production, Stochastic, Nigeria*.

INTRODUCTION
Rice (*oryza sativa*) is the staple food in Nigeria that is produce and consumed in all regions in the country. With the growing population in Nigeria, rice production is strategic as it plays a key role in the provision of food and employment as well as enhances every famer's income and food security (Adeleye *et al*., 2020). Nigerian is the highest consumer of rice in West Africa and highest producer in Africa as well as one of the leading importers of rice in the world (Soullier *et al*., 2020). This was due to continuous increase in population, preference of people, change in income, urbanization that has made the demand to grow at geometric proportion. The amount of land available for rice production in Nigeria was reported to be about 6 million hectare of land but only 3.2 million hectares were used for rice production, producing about 3.7 million tons of rice per year while the total demand for rice in 2018 was about 6.4 million tons (FAOSTAT, 2018). This implies that the land area for rice production is not totally covered by cultivation which means that only half of the specified land is under cultivation. The deficits of over 2.8 million tons of rice were being imported to Nigeria.

Rice production as a major source of employment and nutritional support to household and the nation with attendance issues should not be neglected. Efforts have been directed on various researches aimed at addressing rice production and sufficiency at different researches in Yobe State. Some of which include resource used efficiency of rice production (Madaki *et al*, 2022), effect of importation ban on rice production, women participation in rice production, environmental impacts on rice production (Bukar et al, 2021) ,effect of malaria on crop production in Yobe State (Madaki, 2017), among others. Little or no attempt has been made on comparative analysis of rain fed and irrigation system of rice production in the State. Hence, the research work intends to carry out comparative analysis of rain fed and irrigated rice production in Yobe State. The specific objectives are to;

(i) compare costs and returns of rice production under irrigation and rain-fed system in the study area,

(ii) determine the factors influencing technical efficiency of rice farmers under irrigation and rain-fed systems in the study area,

METHODOLOGY

Yobe State lies on coordinate latitude 12°, 00N and longitude 11° 30E with an estimated area of 45,502 km². The total population according to the census 2006 was 2,321,399 and it was estimated to be about 4,000, 000 in 2021 (NPC, 2022). A multi-stage sampling procedure was employed for the study. The sample matrix is shown in Table 1 below. Primary data were collected and used for this study. Primary data were obtained through administration of well-structured questionnaire that was administered by the researcher and with the help of extension officers and well-trained enumerators. Data were analyzed using gross margin analysis, and stochastic production frontier model.

Table 1:Sampling Frame and Sample Size of Rice Farmers in the Study Area

S/N	LGA's	Wards	Sample Frame		Proportion		Sample Size		Total Sample

Source: Field Survey, 2022.

Gross margin Model (GM) is stated thus.

$$GM = TR - TVC \dots\dots (1)$$

$$GM = \sum_{i=1}^{n} P_i Q_i - \sum_{i=1}^{n} P_j X_j \dots\dots (2)$$

Where, GM = Gross Margin (₦/ha);
TR= Total Revenue from the sales of rice harvested under irrigation and rain fed systems (₦);
TVC= Total Variable Cost (₦).
P_i = Price of rice in (₦/Kg)
Q_i = Total quantity of rice produced under irrigation and rain fed system (Kg/ha)
P_j= Price of Input (₦/Kg)
X_j = Quantity of Input Used (Kg/ha).

Stochastic Production Frontier Model.

This study applied stochastic production frontier function model developed by Sanusi et *al*., (2022). It is stated thus;

$$Y_i = f(X_i, \beta)\epsilon, i = 1, \dots, N \dots\dots\dots\dots (5)$$

Where
The Stochastic Frontier Model is stated thus

$$Y_i = F(X_i, \beta) + \epsilon_i \dots\dots\dots\dots\dots\dots\dots\dots (6)$$

$$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, V - U_i) \dots\dots\dots (7)$$

$$LnY_i = \beta_0 + \sum_{i=1}^{6} \beta_i LnX_i + \cdots \beta_n LnX_n + V - U_i \dots\dots\dots\dots\dots\dots\dots (8)$$

The explicit function is stated thus:

$$LnY_i = \beta_0 + \beta_1 LnX_1 + \beta_2 LnX_2 + \beta_3 LnX_3 + \beta_4 LnX_4 + \beta_5 LnX_5 + \beta_6 LnX_6 + V_i - U_i. (9)$$

Where,
LnY_i = Output of rice (Kg)
X_1= Seed Input (Kg)
X_2= Farm Size (Hectares)
X_3= Quantity of Fertilizer NPK(Kg)
X_4= Agrochemical Inputs (Litres)

X_5 = Family Labour Input (Mandays)
X_6 =Hired Labour (Mandays)
β_0 = Constant Term
$\beta_1 - \beta_6$ = Parameters to be estimated
Ln =natural log
Vi =error term
The Technical Inefficiency Component of the Stochastic Frontier model is stated thus:

$$U_i = \alpha_0 + \alpha_1 Z_1 + \alpha_2 Z_2 + \alpha_3 Z_3 + \alpha_4 Z_4 + \alpha_5 Z_5 + \alpha_6 Z_6 + \alpha_7 Z_7 + \alpha_8 Z_8 + \alpha_9 Z_9 \alpha_{10} Z_{10} \alpha_{11} Z_{11} \dots\dots\dots\dots\dots\dots (10)$$

Where,

$$U_i = Technical\ Inefficiency\ Component$$

Z_1= Age of Farmers (Years)
Z_2= Education Level of Farmers (Years).
Z_3= Household Size (Number)
Z_4= Farm Experience (years)
Z_5= Non-Farm Income (Naira)
Z_6= Amount of Credit (Naira)
Z_7 =Frequency of Extension contact (number of contact per day)
Z_8= Access to Price Information (1, Yes;0, Otherwises)
Z_9 = Total Revenue from sales of rice produce (Naira)
Z_{10} = Unit Price of rice (Naira/kg)
Z_{11} = Membership of Cooperative Association (1, Yes;0, Otherwise)
α_0 = Constant Term
$\alpha_1 - \alpha_{11}$ = Regression Coefficients
This was used to achieve specific objectives two (ii) which is to determine the technical efficiency of rice farmers under irrigation and rain-fed systems.

RESULTS AND DISCUSSION

Costs and Returns of Rice Production under Irrigated and Rain-fed System among Farmers in the Study Area

The analysis of costs and returns involved in rice production under irrigated and rain-fed system among farmers in the study area as presented in Table 2. The study revealed that, the total variable cost incurred by rice farmers under irrigated system was ₦127,347.66, while the total variable cost incurred by rice farmers under rain-fed system was ₦105,001.28, the variable cost 68% and 79% out of the total cost of rice production under irrigated and rain-fed systems respectively. This result is in agreement with Akinbode (2013), who reported that the total variable costs (TVC) dominated the production cost of rice farmers, with 84.43% of the total production cost, while total fixed cost (TFC) explained the remaining 15.57% of the total production cost in rice production under irrigation system. Estimated cost of family labour has the highest value out of the variable cost in both irrigated and rain -fed systems with a percentage of 28% for irrigated system and 56% for rain fed system respectively. This is in line with the findings of Oloyede *et al*., (2021) who reported that family labour costs rated highest with total of 68.92%, this is followed by hired labour cost, which rated 59.25%.

Estimates of the Factors Influencing Technical efficiencies of Output of Rice Production among Sampled Farmers under Irrigated and Rain-fed Systems in the Study

The results of the maximum Likelihood estimates (MLE) of the parameters of the stochastic frontier production function and technical efficiency and inefficiency component for rice farmers under irrigated and rain-fed systems (Table 3). The estimate of gamma is a measure of the level of the inefficiency in the various parameters and its values ranges from 0 to 1. Gamma estimates was 0.30 and 0.0022 indicating the presence of technical inefficiencies among irrigated and rain-fed systems among rice farmers in the study area. This result can be interpreted that 30% and.0.22% of the random variations in the output of rice among farmers under irrigated and rain- fed systems was due to differences in technical inefficiencies. The estimated coefficient of chemical usage among irrigated and rain fed system were 0.7705 and -0.3556 and are positively and negatively statistically significant at (P<0.01) and (P<0.10) respectively. This implies that a percentage increase in quantity of chemical applied to rice by farmers under irrigated system will result in 77% increase in the total output of rice production among farmers under irrigated system and -10% decreases in technical inefficiency in ran fed farmers.

CONCLUSION

The study concluded that rice farming under irrigated and rain-fed system in the study area was a profitable enterprise. The farmers were more into rain-fed system of rice farming than irrigation farming, because of the high cost of investment capital on equipment's and lack of technical know-how and skills. Rain-fed rice production is more profitable in rainy season, while irrigation production is more profitable in dry season in the study area. Further the studied concluded that seed input and hired labour are significant factors of efficiency on irrigated farms while farm size is a significant factor in rain fed. Inefficiency factors of common to both irrigated and rain fed include level of education, household size and cooperative association. The demand for rice is applicable to both seasons; therefore, increased production is necessary throughout the year to meet up with demand of the citizenry in the study area and beyond. Based on the findings emanating from the research, the study recommends as follows;

(i) There should be efforts aimed at reduction in inefficiency level of the rice farmers through extension services training, and capacity building to improve their technical know-how. This will enhance efficiency in production..

(ii) Government and non-governmental organizations should enhance infrastructural facilities in the rural areas. This will curb the high cost of transportation owning to poor road networks.

Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Determinants to intensity of fertilizer use by yam farmers in Anambra State, Nigeria was studied. 120 respondents were selected or the study using multistage random sampling technique. Primary data were obtained using questionnaire and oral interview. Percentages responses and ordinary least squares were used to analyze the objectives of the study. Compound fertilizer was the most important fertilizer used in the study area. Also, educational level, household size and membership of organization were the determinants to intensity to fertilizer use in the area. The need to enhance the farmers' access to educational programmes and as well, encourage farmers to form or join cooperatives were recommended
Keyword: *Determinants, Intensity, Fertilizer use, Yam farmers*

INTRODUCTION
Sub-Saharan Africa faces huge food supply challenges due to among others declining yields associated with continuously declining soil fertility (Amanze, Eze, and Eze, 2010). Among the crops grown by the smallholder farmers in the region is yam. It is one of the principal tuber crops in the Nigeria economy, in terms of land under cultivation and in the volume and value of production (Ume Kaine and Ochiaka 2020). Yam is one of the major staple food in Nigeria and has potential for livestock feed and industrial starch production (FAO, 2020). Nigeria is the largest producer of yam in the world (67% of global output), with an annual production of 44.1 million tonnes (IITA, 2020). To improve food security, farmers use inorganic fertilizers in compensating for soil nutrients loss caused by intensive cultivation practices, soil erosion and among others (Kelly, 2006).
Despite the fertilizer subsidy by the Anambra State government in order to boost fertilizer technology adoption by farmers to enhance their crop productivity, empirical studies show that the intensity of use of this soil amendment in recent time is not encouraging. For instance, according to Amanze, Eze and Eze, (2010) fertilizer use rate among farmers in the Nigeria was far below the 200 kg/ha recommended by Food Agriculture Organization (FAO) for the sub- Sahara African countries. Therefore, following the current situations of low growth rate of arable crop outputs, rapid population growth and unintended objective from the highly publicized fertilizer subsidy programme in the state; there is need to identify the factors impeding optimum used of fertilizer among yam farmers in the State. Specifically, the objectives of the study are to, describe the socioeconomic characteristics of respondents, identify types of fertilizer and determine factors that affect fertilizer use intensity among respondents in the study area.

MATERIALS AND METHODS
The study is carried out in Anambra State of Nigeria. Anambra State is located between latitude $5^0$38 'N and $6^0$47 'E of Equator and longitude $6^0$36 'N and $7^0$21 'E of Greenwich Meridian. The state is bounded in the East by Enugu State, in the West by Delta State, in the South by Imo State and in the North by Kogi State. Anambra State has projected population figure of 6,317,840 million people (NPC, 2023).The non-agricultural activities involved by Anambra people are trading, vulcanizing, barbing and tailoring

Sampling Technique and Sample Size
A multi-stage random sampling technique was used to select Local Government Area (LGA), towns and processors. In the first stage, twelve LGA were purposively selected out of seventeen. The selection was based on intensity of yam production. In the second stage, ten towns were randomly selected from each LGA. These brought to a total of one hundred and twenty towns. In the third stage, one yam famer was selected from each towns from

the lists of farmers provided by the extension agent residing in the towns. This brought to a total of one hundred and twenty yam farmers for detailed study.

Method of Data Collection

Structured questionnaires and informal or oral interview were used to collect primary data.

Method of Data Analysis

Fertilizer use intensity (FUI) as defined by Olayide, Arega and Ikpi., (2009) was described as follows:

$$FUI = \frac{\text{Quantity of fertilizer used by } i_{th} \text{ farmer measured in Kg}}{\text{Area of land cultivated by } i_{th} \text{ farmer measured in hectare}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

The Logit regression model is used to determine factors influencing fertilizer use intensity among yam farmers in the study area. This is mathematically stated thus:

$L1 = In [p1/1\text{-}p] = \beta o + \beta 1X1 + \beta 2X2 + \beta 3X3 + \beta 4X4 + \beta 5X5 + \beta 6X6 \ldots\ldots\ldots\ldots \beta nXn \ldots\ldots(2)$

Where Pi = 1 if respondent had high intensity of fertilizer use, Pi = 0 if respondent had low intensity. .

This could be represented explicitly as

$Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8, X_9, X_{10}, X_{11} + e) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(3)$

X_1 = age of a farmer (years), X_2 = years of formal education of farmers (years), X_3 = household size of farmer (number), X_4 = off farm income by farmers (1=Yes and 0 otherwise), X_5 = purpose of crop grown by farmer (1= commercial crop, 0 = otherwise), x6 = perceived price of fertilizer by farmers (1= high price and 0= low price), X_7 = distance to fertilizer selling point (1 = far, 0= otherwise), U = stochastic error term.

RESULTS AND DISCUSSION

Table 1 Distribution of respondents according to socioeconomic characteristics

Age		
20 – 40	45	37.5
41 – 72	75	62.5
Household Size		
1- 10	80	66.67
11 – 20	40	33.33
Farm Size		
Less than 2ha	48	40
Above 2 ha	72	60
Educational Level(Years)

Organization membership		
Yes	54	45
No	66	55
Distance to fertilizer selling point		
Far	68	56.67
Near	52	43.33

Source: Field Survey, 2018

Table 1shows that most farmers (37.5%) were below 40years of age, while 62.5 % were above 40 years. Aged people are very conservative to engage in committing substantial resources, especially costlier ones like fertilizer in farming for fear of failure (Olayide, *et al;* 2009). More so, 66.67% of the sampled farmers had household size of 1– 10 people, while 33.33% had 11 persons and above. Household head with large dependents members may not be able to have money to procure as much fertilizer that could be needed in his farming activities, thus underutilizing the resource (Chnu and Tsuji, 2004). Table 1 shows that 73.33% of the sampled farmers had formal education, while 26.67% had no formal education. The higher the educational attainment of the farmer, the high propensity of harnessing the benefits of the use of improved inputs such as fertilizer in crop production. As well, most (60%) of the sampled farmers had farm size ranging from above 2 hectares, while 40% had less than 2 hectares. Empirical studies show that farmer with large farm holdings has high intensity in fertilizer use than their counterpart with small farms (Ume; *et al;* 2020). Also, 66.67% of the respondents perceived price of fertilizer to be high, whereas, 33.33% do not. The higher the cost of fertilizer, the lower the intensity of fertilizer use and vice versa (Amanze; *et al;* 2010) More so, 56.67% of the respondents reported that distance to source of the fertilizer was barrier to intensity of fertilizer use. The high price of fertilizer coupled with high transport fares from procuring point could determine the intensity of its (fertilizer) use. Additionally, most (28.33%) respondents grow yam for subsistence, while 7.67% grow for commercial purpose. When farmers grow for commercial purpose, the use intensity of fertilizer is higher than for subsistence. More so 45% of the respondents were members of social organization such as cooperative, while55% were not. Cooperative members, for instance through interaction among themselves could boost their intensity of fertilizer use (Ume, Uloh, Nnadozie, and Nnaji, 2020).

Table 2.Types of Fertilizer used by the farmers.

Variable	Frequency	Percentage
Compound Fertilizer	102	85
Muriate fertilizer	24	20
Single super phosphate	15	12.5
Urea	12	10
Commercial fertilizer	54	45

*Multiple Responses.
Source, Field Survey, 2022

Most (85%) of the respondents used compound fertilizer, which could be inform of complete(Contains Nitrogen, Phosphorus and Potassium.(NPK) and balanced fertilizers (contain equal nutrient amounts, such as a 10-10-10) for high crop output (IITA 2020). The least (10%), was urea fertilizer. Urea has intrinsic quality of providing nitrogen at the lowest cost, has NPK ratio of 46-0-0 and may be mixed with other fertilizers or may be applied alone, hygroscopic in nature and highly soluble in water (FAO 2020).

Source; Field Survey, 2022
***, **, * are significant levels at 1.0%, 5.0% and 10.0% respectively. NB. PCG = Purpose of crop grown, PPF = Perceived price of fertilizer, DFSP = Distance to fertilizer selling point

The coefficient of age of farmer had negative relationship with intensity of fertilizer use. The negative sign identity of the coefficient of age could be related to conservative attitude of aged farmers to adoption of technology, hence could affect their intensity of such technology use (Chinu and Tsuji, 2004). Additional, the educational level coefficient was positive and significant to fertilizer use intensity. Educational status of the farmer enhances his /her judicious use of resource, fertilizer use intensity inclusive in order to boost their farm outputs and as well to conserve possible degradation of the environment as result of the resource use (Ume, *et al;*2020). Also, the coefficient of household size was positive and significant at 1% probability level. Household heads with large family size are more proxy of using cheap family labour to enhance fertilizer use intensity in their farms compare to those with small household members (Ume, Kaine and Ochiaka 2020). More so, the coefficient of organization was positive and significant at 5% probability level. Farmers that are members of organization using have easy access to agricultural information, training, credit and other production inputs, hence enhances their rate of fertilizer use (IITA 2020) As well, the perceived prices of fertilizer coefficient had negative relationship with intensity of fertilizer use and significant at 10%. The sign identify of the coefficient could be related to the fact that farmers restore to minimal fertilizer application compare to standard requirement, leading to meagre crop yield (Kelly, 2006).

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A multi-locational field experiment was conducted during the cropping seasons of 2022 at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University, Keffi Shabu-Lafia Campus and at the National Cereals Research Institute Baddegi Niger state, Kusotachi experimental site to study the influence of planting method, weed management and timing application on growth and yield on rice. The experiment was a 2 x 6 x 2 factorial combination of two planting methods (pregerminated seeds and transplanting), six methods of weed control (Weedy check, Hoe weeding at 3 and 6 WAS, cyhalofop-butyl + MCPA, quinclorac + pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim) and two timing (Lafia and Badeggi) laid out in a Randomized Complete Block Design (RCBD) with three replications. Planting method was assigned to main plot, location was allocated to the sub plot and weed management was assigned to the sub-sub plot. The results obtained in both locations showed that, the plots with early and late application of MCPA consistently produced higher growth, yield and yield attributes of rice. The number of tillers per plant have the highest record in Lafia location while Badeggi location, recorded the tallest plants, and highest grain yield. The use of transplanting method recorded the optimum growth, yield and yield attributes of rice. Applications of early and late MCPA herbicide recorded increased growth, yield and yield attributes of rice. Therefore, it is recommended that farmers should adopt the integration of transplanting method of planting rice with early and late applications of MCPA in both locations for improved growth; yield and yield of rice.

INTRODUCTION
Rice (*Oryza sativa* L.) is a primary food crop cultivated widely over 161 million hectares in more than 100 countries across the globe (FAOSTAT, 2020). Globally, rice ranks third after wheat and maize in terms of production (Ejebe, 2013). It is cultivated on almost 11 % of the earth's cultivated land area and a wide number of ecosystems (Oluwaseyi *et al.*, 2016). China and India share 28 % and 22 % respectively of the total global rice production.

Rice constitutes major staple foods in many parts of the world. It supply more of carbohydrates, proteins, fats and also minerals vital needed for survival and healthy life (Ejebe, 2013). Rice supplies about 21 % of the total calories needed per day in human and it is a source of income to more than 100 million household around the world. it stands out as the major food crop for about a half of human race and consumption of rice its growing faster than that of any other staple in Africa and the world at large, simply because it has become a convenient food for the growing world population (Oluwaseyi *et al.*, 2016). All over the world, 26 % and 50 % increase is demanded in rice production to meet the needs of growing human population by 2035 and 2050 respectively (Rao *et al.*, 2017).

In Nigeria, the demand for rice assumed a regular increase for the past decades compared to sorghum and millet which fluctuate annually. Rice demand annually in Nigeria was estimated to about 5 million metric tons while local production around 2.21 million metric tons and about 2.79 million metric tons imported to bridge the gaps (NRDS, 2009). Weed being one of major pests in agriculture, having ability to compete with crops for nutrients through rapid growth and development.

In paddy field, weeds available nutrients uptake, compete with rice plants for water, light and space. Under adverse conditions, weeds negatively affect leaf architecture, plant developmental pattern, plant growth cycle, tillering ability, as well as yield and yield attributes of rice (Materu *et al.*, 2018). Transplanting is the most common method of planting rice, while dibbling and broadcasting are reported to be picking-up gradually (Gill *et al*., 2014). Akhgari *et al*. (2011) defined dibbling (direct seeding) of rice as the process of establishing a rice crop from seeds sown in the field rather than by transplanting rice seedlings from the nursery, it assist rice farmers to have a reduced production cost. Poor weed management also responsible for reduction in rice yield depending on weed type and their infestation (Neog *et al.,* 2015). Good weed management program is essential throughout the growing period of crops to overcome various types of weeds challenges. Manual control of weeds is not a quick method thus, requires lot of time and labour. Herbicides offer easy, economical and quick control of weeds if applied in proper dose and at proper stage of crop growth (Bhullar *et al.,* 2018). Among all measures taking in rice weed control, chemical weed control is commonly used to overcome weeds infestation and it is reliable, easy, quick, time saving, and cost effective.

There is no or little attention given by the rice growers in Nigeria on the use of metsulforun methyl, cyhalofop-butyl + MCPA, quinclorac pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim herbicides in controlling of weed in rice production due to paucity of information about the herbicides. However, this study is aiming at evaluating the effects of these herbicides application under various timing (early and late) and planting methods (pre-germinated seed and transplanting) on rice production. The objective of this study therefore is to determine the effect of location, planting methods and weed management on weed control, growth and yield of lowland rice.

MATERIALS AND METHODS

The field experiment was conducted at two locations during 2023 cropping seasons at the Teaching and Research Farm (Latitude 08.33^{0}N, Longitude 08.33^{0}E) of the Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University Keffi, Nasarawa State, Jayeoba, 2013. And at National Cereals Research Institute (NCRI) Baddeji, Niger State at experimental site Kusotachi latitude 9°3'24.58"N, Longitude 6°8'36.31"E) Ojohomon *et al*., 2006.

The experiment is a 2 x 6 x 2 factorial combination of two planting methods (pregerminated seeds and transplanting), six methods of weed control (Weedy check, Hoe weeding at 3 and 6 WAS, cyhalofop-butyl + MCPA, quinclorac + pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim) and two location (Lafia and Badeggi) arranged in a randomized complete block design (RCBD) replicated three times. The gross plot size was 3 m x 4 m (12 m^2) while the net plot size was 1.5 m x 4m (6 m^2).

The field was cleared using a land preparation herbicide (Glyphosate a.i 360g/L) at 3 L/ha. The soil was ploughed and the site was marked into plots and replications. One meter unplanted boarder were maintained between plots, while 0.5 m unplanted boarder was maintained between each replication.The nursery was prepared in dry soil conditions on 3 by 4 m wide seed bed, was filled with top most soil to a height of 10 cm level. A layer of half burned paddy husk was distributed on the nursery bed to facilitate uprooting. 80 kg/ha of seed was used for the sowing covered with mulch, watering the beds at regular basis (morning and evening). Transplanting of vigorous healthy seedlings where done after 14-21days of germination. Five pre-germinated seeds where sown (direct seeding) and thinned to two plants per stand. For transplanting method, 14-21 days old seedlings wastransplanted from nursery bed to permanent field. One seedling per hole at a space of 20 cm by 20cm between and within the plant where maintained. Same plant spacing for transplanting was maintained for pre-germinated seed planting methods. Seed rate of 80 kg/ha where used for pre-germinated seeds while 40 kg/ha for transplanting. Fertilizer application wasdone using side placement in all the plots at the rate of 46 kg P_2O_5/ha and 64 kg N /ha. Phosphorus in the form of single super phosphate (SSP) was applied at the time of sowing and transplanting. Whereas, N in the form of UREA was applied in three splits (one third during sowing and transplanting and the remaining two third was apply in two splits at 4 and 8 WAS

The data collected included plant height tip at 4, 6, 8, 10 and 12 WAS, numbers of tillers from the tagged plants was counted and the mean recorded at 4, 6, 8, 10 and 12 WAS. The five randomly selected tagged plants from each plot where used for periodic observation during the crop growth periods at 4, 6, 8, 10 and 12 WAS. The net plot where harvested manually, grain collected, dried to 13.5% moisture content, and weight recorded. This was determined by weighing grains from the net plot, divided by net area and multiply by 10,000.

$$\text{Grain yield} = \frac{\text{Seed yield per net plot}}{\text{Net plot area}} \times 10{,}000$$

The data collected where subjected to analysis of variances (ANOVA) using SAS statistical software (version 2020) while Least Significant Difference (LSD) was used to separate treatment means at 5 % level of probability.

RESULTS AND DISCUSSION

The plant height differed significantly at 4, 6, 8, 10 and 12 weeks after sowing (WAS) for rice with respect to location, planting method and weed management as shown in (Table 1) below. Generally, Badeggi location consistently produced the tallest plants than Lafia location which consistently recorded the shortest plants throughout the sampling periods in this study.

Planting method had a significant effect on plant height at 10 and 12 WAS in this study. The use of Transplanting consistently produced significantly tallest plants than the Dribbling method which consistently produced the shortest plants.

Weed management had a significant effect on plant height of rice throughout the sampling periods of the study. The weedy check, early and late applications of Cyhalofop + MCPA produced statistically similar tallest plants than the other weed controls which recorded similar shortest plants at 4 WAS. At 6 WAS, early application of Metsulforun methyl, produced significantly taller plants which was not statistically different from weedy check, early application of Cyhalofop + MCPA and early application of Pretilachlor + Pyribenzoxium compared with late application of MCPA which recorded the shortest plants. At 8 WAS, weedy check recorded the tallest plants statistically similar with 2 HW at (3 + 6 WAS), early and late applications of Metsulforun methyl, early and late applications of Cyhalofop butyl + MCPA and early application of Pretilachlor + Pyribenzoxium while late application of Pretilachlor + Pyribenzoxium recorded the shortest plants. At 10 WAS, the use of 2 HW at (3 + 6 WAS), early applications of Metsulforun methyl and late application of Pretilachlor + Pyribenzoxium produced significantly similar tallest plants than all the other weed controls compared with early and late applications of MCPA which recorded statistically similar shortest plants. At 12 WAS, late application of Pretilachlor + Pyribenzoxium produced significantly taller plants than all the other weed controls compared with late applications of Cyhalofop butyl + MCPA which produced the shortest plants.

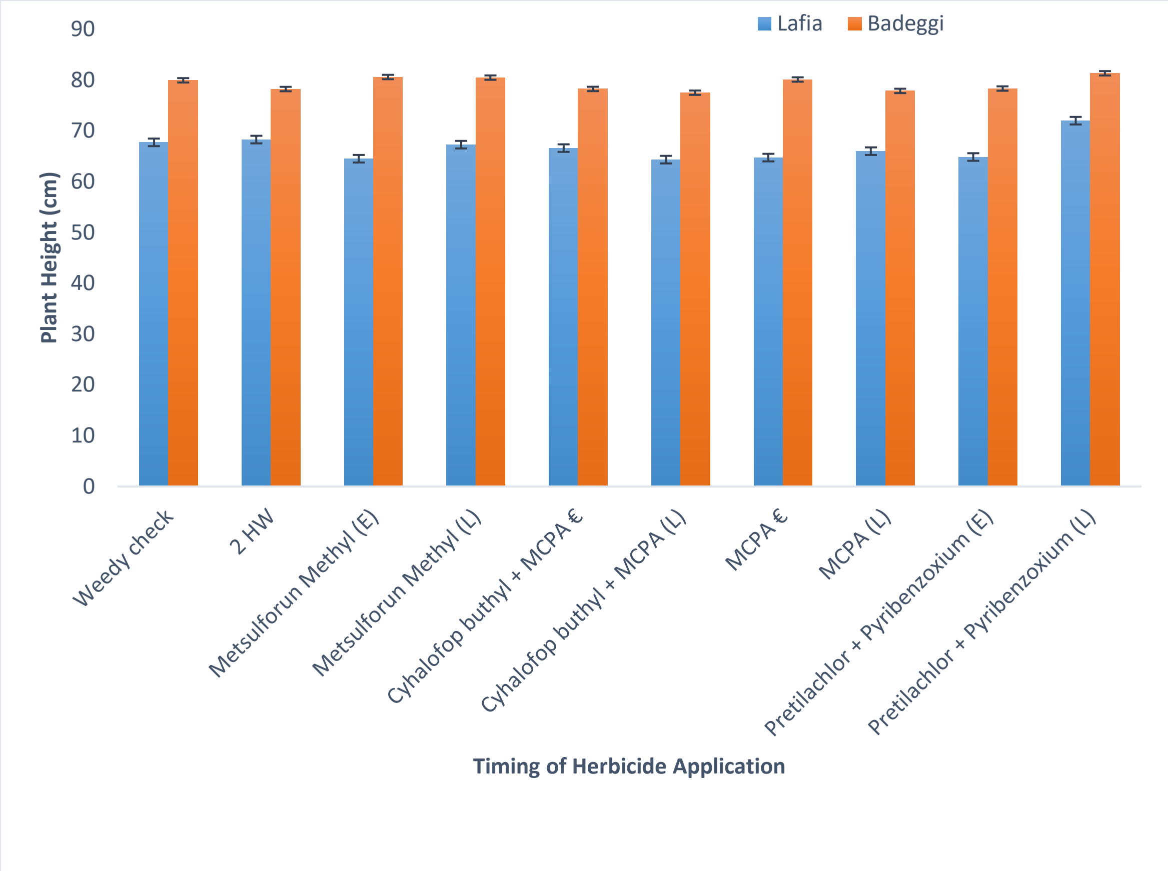
Figure 1: Below show the interaction between location, planting method and weed control on plant height at 12 WAS were significant. The combination of Badeggi location, transplanting method and early application of MCPA significantly produced the tallest plants than all the other combinations compared with the combination of Lafia location, dibbling method and late application of Metsulforun methyl recorded the shortest plants.



The effect of location, planting method and weed control on number of tillers per plant of rice at 6 - 12 WAS is shown in Table 2 below. Location affected number of tillers significantly, such that, Lafia location consistently produced significantly highest number of tillers than Badeggi location which consistently recorded the lowest number of tillers per plant.

Number of tillers per plant was significantly different among the planting methods at 10 and 12 WAS only in this study. The use of Transplanting method produced significantly highest number of tillers per plant than dibbling method which produced the lowest number of tillers per plant.

Weed management had a significant effect on number of tillers per plant at 6 - 12 WAS in this study. At 6 WAS, late application of MCPA significantly produced the highest number of tillers per plant than all the other weed controls compared with late application of Pretilachlor + Pyribenzoxium which produced the lowest number of tillers per plant. At 8 - 12 WAS, early application of MCPA consistently recorded the highest number of tillers per plant than all the other weed controls compared with the weedy check which consistently recorded the lowest number of tillers per plant which was statistically not different with 2 HW at (3 + 6) and early application of Cyhalofop butyl + MCPA at 10 WAS.

The effect of location, planting method and weed management on grain yield of rice at is presented in Table 2. Location differed significantly on grain yield, such that, Badeggi location produced significantly highest grain yield than Lafia location which had the lowest grain yield. Planting method had a significant effect on grain yield of rice. The use of transplanting method significantly recorded the highest grain yield than dibbling method which gave the lowest grain yield in this study. Weed management also affected grain yield of rice significantly, such that, the application of early and late MCPA gave statistically similar highest grain yield than all the other weed managements compared with the weed check which recorded the lowest grain yield in this study.

DISCUSSION

The tallest plants and highest grain yield recorded at Badeggi location may be due to the productivity of soil of the location and the suitability of the weather conditions of the study area which supported the utilization of growth factors (water, nutrients and solar radiation) and hence the production of optimum growth, yield and yield attributes of rice in this study.

The tallest plants, highest number of tillers and grain yield produced by transplanting method could be attributed to the specific distance between the plants and the competition between plants were minimum and deep penetration of roots resulting in efficient nutrient uptake and good plant growth. Also, transplanted rice seedlings have a 'head start' over germinating weed seedlings, leading to competitive control of weeds. This result is in line with the work of (Yakubu., 2013) who reported maximum plant height in transplanted rice due to the reason that plants were at specific distance and the competition between the plants were minimum and deep penetration of roots resulting in efficient nutrient uptake and good plant growth.

The shortest plants, lowest number of tillers per plant and grain yield produced by the weedy check as compared with plots with weed management may be due to the effectiveness of the herbicide which lead to the inhibition of weed seeds in the soil and killing of the weed seedlings already emerged in rice fields in this study. Anwar *et al*. (2013) reported that among the herbicides, Propanil/Thiobencarb and Cyhalofop butyl + Bensulfuron caused no visible injury to rice plant, while Pretilachlor/Safener, Bispyribac Sodium, and Bentazon/MCPA showed slight phytotoxicity to rice. Pytotoxicity of Pretilachlor/Safener was characterized by minor reduction in plant height and slight leaf chlorosis as observed at 7DAA. Khan *et al*. (2014) reported that the best performance of Triasulfuron herbicides can be attributed to the best control of weeds which reduced weed competition and enable increased flow of nutrients towards the grains and ultimately increased the grain yield.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Well Water samples were collected from three sampling areas at different sampling points at the mechanic villages at Apir, North Bank and New Garage in Makurdi metropolis for heavy metals specifically Iron (Fe), Zinc (Zn), Copper (Cu), Silver (Ag), Manganese (Mn), Lead (Pb), Chromium (Cr), Cadmium (Cd), Arsenic (As) and Mercury (Hg). The samples were analyzed using pH meter and Atomic Absorption Spectrophotometer (AAS). The data were compared with the World Health Organization (WHO) standards. The results showed that the concentration in mg/L of all the heavy metals were found within the maximum allowable limits of WHO, with the exception of Cadmium at all the locations where they were found to have concentrations above the WHO's standards in most of the wells investigated. The results also showed that the mechanic activities at these three (3) areas are responsible for the concentrations of these heavy metals. Therefore, the water in the areas studied especially at the Apir Mechanic Village is not safe for both human purposes.
***Keywords:** Heavy metals, Underground water, Pollution, Mechanic activities, Health.*

INTRODUCTION
Water is ranked among the most remarkable compounds owing to its unique physical and chemical properties and importance for biological activities of living organisms. Water, a universal solvent which makes up about 70% of man's body is one of the most commonly available natural resources of man. (Talabi *et al*., 2020). For water with its innumerable physical, chemical and biological properties to meet the demands and vital functions for human, plants and animals, has to satisfy a number of quality requirements. A good water quality, therefore, is one that meets the WHO's set standards and standards set by other water regulatory bodies. The quality of water varies greatly from diverse sources which include surface, rain and underground. The quality of these water bodies vary depending on the location and environmental factors (Adetunde *et al*, 2011). Heavy metals on the other hand can be defined as "metals with densities that are five times heavier than water and are formed naturally from the terrestrial environments, and are found in rocks, plants, soils and sediments" (Talabi *et al.,* 2020;,Orobator et al.,2020).WHO (2011) define heavy metals as metallic elements with an atomic weight > 40. Heavy metals are non-degradable and indestructible hence their presence in the earth's crust poses a consistent environmental contamination. Ukah *et al.,* (2019) opined that their excessive accumulation in the body is a big threat to human health. Pollution caused by heavy metals has been considered as a serious environmental health problem as a result of its toxicity even at low concentration, persistence, and bioaccumulation ability (Olagunju *et al*., 2020).. Once the water bodies and the environment are contaminated with excess heavy metals, health risks and hazards are inevitable (Ukah *et al.,* 2019). To avoid diseases caused by heavy metals to the existing pandemic rampaging Nigeria and the world at large, it is important to check the status of water (underground water in this case) intermittently, for monitoring and prevention of further outbreak and health hazards. This research works was aimed at evaluating heavy metals pollution in well water caused by mechanic activities and its consequent implication on health of makurdi dwellers and compare the results with WHO set standards for heavy metals.

METHODOLOGY
Materials
Soil samples
HNO3
HCl
Weighing balance
Atomic Absorption Spectrophotometer

Kjeldal apparatus
Metals e.g. Fe, Zn, Cu, Hg, Ag, Mn, Pb, Cr, Cd, and As.

METHODS

The research began with a preliminary investigation of Makurdi metropolis in order to understand the area under study and the mechanic activities taking place there. The study area was then divided into three areas namely: Apir, North Bank, and the New-garage mechanic areas. Then, a survey of water samples from dug wells were carried out around the three mechanic villages. At the Apir mechanic area, five (5) dug wells were discovered within the distance of 120 m. At the North Bank area, five (5) wells were found at the same approximate distance of 30m apart. At the New garage, three wells were found within the distance of 60m. A total of 13 water samples were collected in a labeled plastic swam water bottles, one from each sampling area. The depth of the wells, colour of water and pH of the waters were all taken..

Laboratory Analysis of the Heavy Metals

Digestion of the samples was carried out using Kjeldahl apparatus at temperature of 100°C and a mixture of HNO_3 and HCl in a ratio of 3:1 added to the beaker containing 0.5g of the samples. The concentrations of the heavy metals from each of the filtered samples were determined using Atomic Absorption Spectrophotometer (AAS).

Data Analysis

The data obtained were compared to the World Health Organization (WHO) set Standards.

RESULTS AND DISCUSSION

The results of the analysis carried out are represented in Table 1, 2 and 3 as shown below:

Table 1: Results showing the concentrations of heavy metals at Apir

DISCUSSION

The concentration of the chemical properties of underground water for 11 samples (4 at Apir, 4 at North Bank and 3 at New garage areas of Makurdi metropolis) are represented in Table 1, 2 and 3 as shown above. Table 4 represents the World Health Organization (WHO) maximum allowable limit recommended for heavy metals in water sources, which is used as a tool for comparing the data obtained in this work. The pH of all the water samples analyzed were found to be in a range of 6.5-8.0. These values are all within the WHO recommended standard of 6.5-8.5 (WHO, 2015). It was observed that, the concentrations of the heavy metals with exception of Pb and Cu at Apir and Cr at New garage were found to decrease steadily with increasing distance away from the mechanic sites. However, the concentrations with exception of cadmium were all within the maximum allowable limits of WHO (WHO, 2015). Zinc recorded the highest concentrations at all the three places though within the maximum allowable limits. At the Apir mechanic village, the concentration of Zinc was 2.684mg/L, which was the highest of all. The concentrations of Zn at both Apir and North Bank decreases with increase in distance away from the mechanic villages. However, they were all within the maximum limits of 3.0 standards set by WHO (WHO, 2015).

CONCLUSION

From the results of the analysis carried out, it is observed that, of all the concentrations of the heavy metals studied at the three areas, the Apir mechanic village recorded the highest concentration values of cadmium, which is above the maximum allowable limit set up by the World Health Organization (WHO) in drinking water. This may be attributed to the high or large scale mechanic activities taken place at this area particularly electroplating where they are used as solders for joining metals. With exception of cadmium, all the heavy metals investigated have concentrations within the maximum permissible limit set up by WHO. Moreover, the concentrations of all the heavy metals analyzed, cadmium inclusive decreased with increase distance as one moves away from the mechanic sites. As a result of this, we can generally conclude that the mechanics activities at these places are largely responsible for the concentrations of these heavy metals in ground water. With cadmium and zinc showing higher concentrations, at these three places it can be inferred that the waters in these places are not safe for drinking and even for agricultural purposes.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The most limiting factor in vegetable production is water, the quality and amount of water play an important role in the growth and yield of vegetables. This study was carried out with the aim to investigate the effects of different irrigation water sources on the growth and yield of Amaranthus cruentus. The experiment was set up in a randomized complete block design, carried out in four locations in Ibadan which lies in the forest agro-ecological zone of Nigeria. Water used for irrigation were borehole water which serve as the control and river water at the different locations. Ten plants were randomly selected from each plot and tagged for data collection on plant height (cm), stem diameter (cm), number of leaves, leaf area (cm^2) and leaf yield (kg/ha). Data collected were subjected to analysis of variance (ANOVA) and significant means were separated using the least significant difference at a 5% probability level. Plant height of amaranth at early stage (3 and 4 weeks after planting) were not significantly different from one another at the various locations but as growth advanced to 5 WAP, amaranth planted at NIHORT Upland (42.56 cm) was significantly taller than those cultivated in Akilapa (26.82 cm) and NIHORT Lowland (30.57 cm) but not significantly different from those planted at Babalegba (36.36 cm). Leaf yield of A. cruentus grown at different locations with different sources of irrigation water varied significantly across the four locations, amaranth cultivated in upland of NIHORT had significantly higher leaf yield (22.3t/ha), followed by leaf yield of amaranth grown at Babalegba which had 17t/ha while those planted at lowland of NIHORT and Akilapa produced leaf yield of 9.1t/ha and 6.1t/ha respectively. In conclusion, growth and yield of A. cruentus varied with irrigation water sources.

Keywords: *Irrigation water, Amaranthus cruentus, water quality, vegetable, growth and yield,*

INTRODUCTION
Amaranth is a leafy vegetable that is commonly grown in the tropics and is one of the most significant leafy vegetables in Africa and Asia's lowlands (Andreas *et al.,* 2011). It is a nutritious vegetable rich in calcium, iron, protein, vitamins A, C, and K, riboflavin (B2), niacin (B3), vitamin B6, and folate (B9). Amaranth is a fast-growing annual plant that can be easily grown in home gardens and on a commercial scale. *Amaranthus cruentus* belongs to the family Amaranthaceae, it contains a lot of genetic variation in terms of plant form (erect to prostrate), plant height, number of inflorescences (one to many), seed color, protein content, seed yield, pest and disease resistance, and adaptation to soil type, pH, climate, rainfall, and day length (Kulakow, 1990). Amaranth is a plant that thrives in arid conditions. Amaranth seeds sprout best in soil temperatures between 18^{0}C and 25^{0}C, and they thrive best at air temperatures above 25^{0}C. At temperatures below 18^{0}C, the growth stops. Amaranthus may grow in a variety of soil types and moisture levels, it has been observed to thrive in loamy, sandy-loam, or silty-loamy soils with good water holding capacity and a pH range of 4.5 to 8.0 (National Research Council, 1984; Palada and Chang, 2003).

Various parts of the plant have been utilized for a variety of reasons, including food, feed, ornamentals, sacraments and traditional medical treatments. The commercialization of indigenous green-leaf vegetables supports the local economy in addition to playing an essential role in African diets (Lenne and Ward, 2010) and it is an integral component of traditional African medicine (Padulosi *et al.,* 2013). Amaranthus leaves have a high nutrient value, ranging from 4 to 6 g of protein, 0.2 to 0.6 g of fat, and 4 to 7 g of carbohydrates per 100 g of fresh leaves (Uusikua *et al.,* 2010) and are known to be high in micronutrients and vitamins, particularly chlorine, copper, iron, manganese, sodium, vitamin A, vitamin C, and vitamin B-12 (Mnkeni, 2005). Amaranthus seeds have a protein content of 12.5 to 17.6% (Teutonico and Knorr, 1985) with significantly higher levels of lysine (0.73 to 0.84 percent of total protein content) and sulfur-containing amino acids (methionine and cysteine) than other cereal grains (Railey, 1993; Lehmann, 1996; Petr *et al.,* 2003), and thus have the potential to improve the world food situation as an alternative.

Water is a major limiting factor in agricultural productivity, and crop water requirements must be met in order for the crop to grow and yield optimally. According to Musa (2001), the overall unreliability and unpredictability in the temporal and spatial distribution, as well as lack of rainfall, frequent droughts, and rapid population expansion, have all conspired to make irrigation an important part of Nigeria's food security strategy. Most Leafy vegetables benefit from frequent irrigation throughout the season. In Nigeria, the production of *Amaranthus cruentus* has increased through irrigation farming system due to the increase in population and demand for the crop. The most limiting factor in vegetable production is water; the quality and amount of water play an important role in the growth and yield of vegetables. Increase in demand for vegetables keeps rising as a result of an increase in population which cannot be efficiently addressed by rain-fed agriculture. The irrigation farming system has gained attention in Nigeria in the production of vegetables but the quality of water used for irrigation is not considered by local farmers. Most sources of water used for irrigation are polluted which are detrimental to the soil, plant, and human. The objective of this study was therefore to investigate the effects of different sources of irrigation water on growth and yield of *Amaranthus cruentus*.

MATERIALS AND METHOD

The experiments were carried out in four different locations within Ibadan metropolis:

1. Babalegba" along Sanngo - Eleyele Road (Long. 7.522^{0}N and Lat. 3.316^{0}E),
2. Akilapa along All saint's College Road (Long. 7.797^{0}N and Lat. 3.771^{0}E),
3. NIHORT Lowland (Long. 7.443^{0}N and Lat. 3.037^{0}E) and
4. NIHORT Upland (Long. 7.639^{0}N and Lat. 3.365^{0}E).

The experiment was conducted at Vegetable Research Farm of NIHORT, Ibadan, Oyo state and other locations were around NIHORT in dry season of 2022. The sites lies within the Rain-forest agro-ecological zone of Nigeria. The soil is dominated by Alfisols, the monthly rainfall distribution pattern for Ibadan is bimodal with peaks in June and September. Annual rainfall ranges from 1250 mm and 1500 mm spanning eight months (March to October) with dry spell in August.

The study was a one factor experiment laid out in a randomized completely block design (RCBD) in three replications. The treatments consist of four locations which served as different sources of irrigation water, flowing river close to the experimental sites was used to irrigate the field at Akilapa, Babalegba and NIHORT lowland while borehole water was used to irrigate experimental site at NIHORT upland. Seeds of *Amaranths cruentus* obtained from NIHORT were drilled in rows of 40 cm apart on seed bed of 3 m × 3 m in each location Water from each location was used to irrigate the plants daily at the rate of 8 l/m^2 (Grubben, 2004) Soil samples were collected from each sites using a soil auger at a depth of 0 - 15 cm. The soil was air-dried and sieved using a 2 mm sieve. The sieved soil samples, water used for irrigation at each site and plant samples after harvesting were taken to the laboratory for analysis to determine both their physical and chemical properties. Ten plants were randomly selected from each plot and tagged for data collection on growth and yield of the crop commencing from three weeks after planting weekly intervals for 3 weeks. Data collected on plant height (cm), stem diameter (cm), number of leaves, petiole length (cm), leaf area (cm^2) which was determined by measuring the length and width of the leaf and was calculated using 0.5 (Length x width) Pearcy *et al.* (1989) and leaf yield (kg/ha) were subjected to analysis of variance (ANOVA) using SAS software (1990), and significant means were separated using the least significant difference at a 5% probability level.

RESULT AND DISCUSSION

The soil textural class, physical and chemical properties of the soil of each location where the experiment was carried out as shown in Table 1 revealed the textural class of the soil in the different locations to be loamy soil. Result of heavy metal concentration present in water used for irrigating the amaranth cultivated in the four locations. The heavy metals in the water used for irrigation in the different locations were within the permissible level as recommended by WHO (1996) except for that of Babalegba which was high in the lead (Pb) (Table 2). Fig. 1 showed that plant height of amaranth at 3 and 4 weeks after planting (WAP) were not significantly different from one another at the various locations but at 5 WAP, amaranth planted at NIHORT Upland (42.56 cm) was significantly taller than those cultivated in Akilapa (26.82 cm) and NIHORT Lowland (30.57 cm) but not significantly different from those planted at Babalegba (36.36 cm). In line with the findings of this study, researchers have reported that plant height of amaranth is not significantly affected by the location of cultivation or the type of irrigation water used, especially at early stages of growth (Muhammad *et al.*, 2017; Adekiya *et al.*, 2020). However, at 5 WAP, amaranth cultivated in NIHORT Upland was significantly taller than those cultivated in Akilapa and NIHORT Lowland, indicating that growth of amaranth may be influenced by the location and type of irrigation water used at later stages of growth. This corroborates the result of Adekiya *et al.* (2020) who observed a significant effect of irrigation water on height of amaranth at 5 WAP.

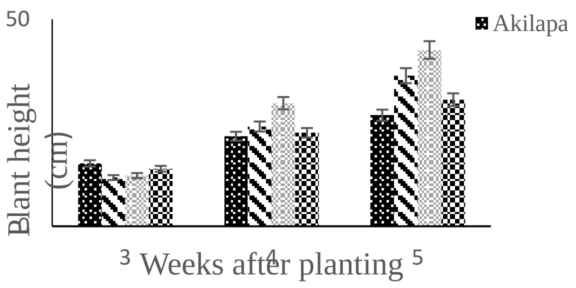

Fig. 1: Plant height (cm)

Fig. 2: Number of leaves

Number of leaves of amaranth cultivated in the four locations as influenced by different river sources of irrigation water presented in Fig. 2 showed that there was no significant difference in the number of leaves produced by amaranth cultivated in all the four locations at 3 WAP but as growth advanced to 4 WAP, number of leaves of amaranth grown in NIHORT Upland (17) was significantly higher than those cultivated in other locations. Meanwhile, amaranth grown at NIHORT lowland produced the least number of leaves (11.6) though not significantly different from that of Akilapa (11.9). At 5 WAP, amaranth grown at NIHORT upland still produced the highest number of leaves (25) but not significantly different from that of Babalegba (21.46) while Amaranth cultivated in Akilapa has the least number of leaves (13.8), which suggests that the low percentage of Organic Carbon (0.87%) and Nitrogen (0.1%) in that location might be responsible for this poor growth and development of *A. cruentus*. As reported by Qiang *et al*. (2014) that Nitrogen is one of the major elements for plants growth and metabolism.

Result of the study showed that there was significant effect of the different sources of irrigation water on the leaf area of amaranth. At 3WAP, amaranth grown in both Upland and lowland of NIHORT and Akilapa were comparable to each other in terms of leaf area (13.34 cm^2, 13.52 cm^2 and 11.16 cm^2, respectively), while amaranth cultivated in Babalegba produced the least leaf area of 8.33cm^2. The same trend was also observed at 4 WAP where no significant difference was observed in the leaf area of amaranth cultivated in both upland and lowland of NIHORT and Akilapa (30.48, 21.52 and 24.12 cm^2, respectively) with that of Babalegba having the least leaf area (16.85 cm^2). At 5 WAP, there was no significant difference in the leaf area of amaranth cultivated in NIHORT upland (31.48 cm^2), NIHORT Lowland (27.18 cm^2), and Babalegba (26.15cm^2). However, amaranth in these three locations had significantly wider leaves than those cultivated in Akilapa which had the least leaf area of 14.996 cm^2 (Fig. 3). The leaf area of *A. cruentus* cultivated in NIHORT Upland, NIHORT lowland, and Akilapa was significantly wider than that of Babalegba. This suggests that the irrigation water quality in Babalegba may not be optimal for the growth and development of *A. cruentus* which is accordance with the finding of Adekiya *et al*. (2020) that water quality can have an impact on leaf area in amaranth.

The results of stem diameter of amaranth planted in four different locations grown with different sources of irrigation water as shown in Fig. 4 revealed that significant difference existed in the stem diameter of amaranth throughout the growth stages of the amaranth. At 3 and 4 WAP, amaranth grown in upland of NIHORT had the highest stem diameter (0.76 and 0.96 cm, respectively) while no significant difference existed in the stem diameter of amaranth planted in other three locations. At 5 WAP, amaranth planted in upland of NIHORT still had the highest stem diameter (0.99 cm) but not significantly from those planted at lowland of NHORT (0.72 cm). Leaf yield of *A. cruentus* grown at different locations with different sources of irrigation water varied significantly across the four locations, amaranth cultivated in upland of NIHORT had significantly higher leaf yield (22.3t/ha), followed by leaf yield of amaranth grown at Babalegba which had 17t/ha while those planted at lowland of NIHORT and Akilapa produced leaf yield of 9.1t/ha and 6.1t/ha respectively (Fig. 5). The leaf yield of *A. cruentus* varied significantly across the four locations, these differences could be attributed to various factors such as the soil type, the quality of irrigation water, and the level of heavy metal contamination in the soil. The higher yield of *A. cruentus* in NIHORT Upland could be due to the favorable soil condition which provided the necessary nutrients for the growth and development of the plant (Olowoake and Ojo, 2014).

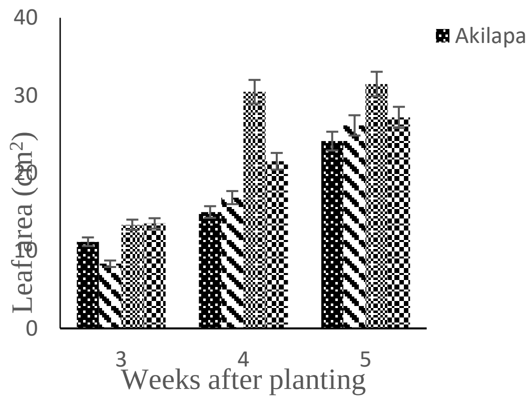

Fig. 3: Leaf area (cm^2)

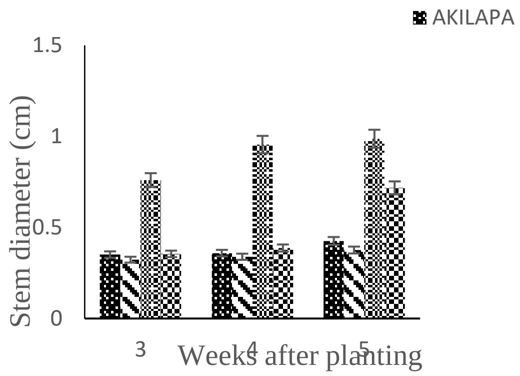

Fig. 4: stem diameter (cm)

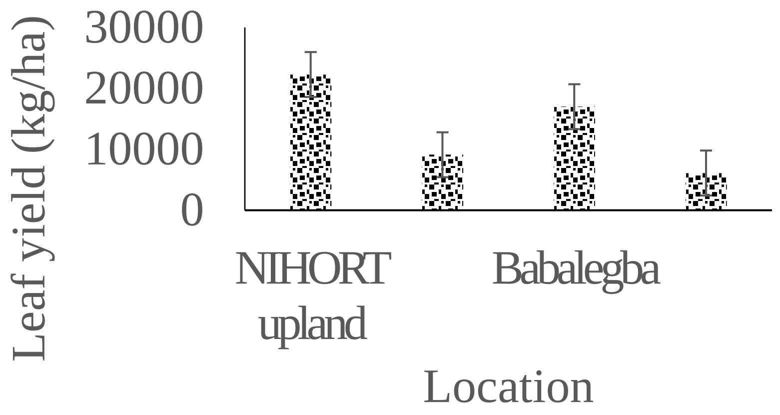

Figure 5: Yield (kg/ha) of amaranth grown in different locations with different sources of irrigation water

CONCLUSION

The study revealed that growth and yield of *Amaranthus cruentus* were significantly influenced by location and irrigation water source. Differences in soil fertility and irrigation water sources possibly enhanced growth and yield of amaranth.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
UMUSPO/3, BUTTERMILK and TIS 87/0087 Sweetpotato varieties selected from screen house of Sweetpotato in NRCRI were surfaced sterilized and planted in different substrates of Klasmann (K), Soyabean husk (S), Coco peat (C), Rice husk (R) and in selected combination. The vigour rate, survival rate and growth rate were measured as indicators to evaluate the performance of the different varieties of sweetpotato in different substrates application. The experiment was a 3 by 6 Factorial design laid out in Randomized Complete Block Design (RCBD) with 18 treatments and three replicates. The data collected from the experiment were subjected to analysis of variance (ANOVA) using the R software package. The results indicate that for all the three Sweetpotato varieties, C and combination of both K, S and C have significant effect ($p<0.05$) compared to combination of K and R, and R and S respectively on the Growth rate (UMUSPO/3-C, 3.306, combination of K, S and C, 2.861, K and R, 0.361, R and S, 0.194, BUTTERMILK- C, 2.306, combination of both K,S and C, 1.417, K and R, 0.472, R and S, 0.417 and TIS 87/0087- C, 2.778, combination of both K, S and C, 2.639, K and R, 0.67, R and S, 0.194). Similar effects were observed for the Survival rate (UMUSPO/3-C, 3.472, combination of K, S and C, 3.250, K and R, 0.444, R and S, 0.250 BUTTERMILK- C, 2.611, combination of both K,S and C, 2.444, K and R, 0.361, R and S, 0.361 and TIS 87/0087- C, 3.417, combination of both K, S and C, 3.167, K and R, 0.361, R and S, 0.167), and Vigour (UMUSPO/3-C, 3.389, combination of K, S and C, 2.639, K and R, 0.444, R and S, 0.444 BUTTERMILK- C, 2.250, combination of both K,S and C, 2.833, K and R, 0.361, R and S, 0.556 and TIS 87/0087- C, 2.861, combination of both K, S and C, 3.222, K and R, 0.472, R and S, 0.444). This suggests that Coco peat and Soyabean husk can serve as possible alternatives and supplements for Klasmann in Semi Autotrophic Hydroponic techniques (SAH) in order to save cost.
Keywords: *Sweetpotato, Klasmann, Soyabean husk, Coco peat, Rice husk, semi-autotrophic hydroponic*

INTRODUCTION
Sweetpotato (*Ipomoea batatas* Lam.) is an important tuber crop grown in over 120 countries in the world, on about 8 million hectares of land, and with a total annual production of about 92 million tons with a yield of 114 ton ha (FAO, 2018). The crop grows in a wide range of soils but prefers moderately fertile, well –drained, deep, light or medium textured soils, with pH ranging from 4.5 to 7.0 (Abidin *et al*., 2017; Makini *et al*., 2018). Sweetpotato is considered a food security crop in sub-Sahara Africa due its fast growing period with low input requirements. Most products are derived from roots, while the vegetative parts can be utilized as vegetable and feed for livestock (Lebot, 2009). Inadequate availability of quality Sweetpotato vines limits the utilization of improved and new varieties. Farmers are faced with the challenge of obtaining clean planting material and in the right quantity. Despite the many advantages, Sweetpotato is still susceptible to biotic and abiotic stresses that hinder its production. Semi-Autotrophic Hydroponics (SAH) is a technology targeted at mass propagation of virus – free plants of tissue culture. It is an easy to adapt technique suitable for commercial seed multiplication and production. It involves the use of modified soil, which holds plant roots in planting pots with little water. With this technology farmers will have easy access to new varieties once they are developed. However, the cost of SAH substrate (Klasmann) is expensive. Therefore, the objectives of our study are to identify and determine the efficacy of locally-sourced substrates as alternatives to the expensive Klassman, to develop composite formulations of the different substrates and to evaluate the locally available substrate in a 50:50 or equal combinations with Klassman.

MATERIALS AND METHODS
The experiment was carried out in semi autotrophic hydroponic (SAH) at the NRCRI Umudike on Latitude 5.5°N, 7.5°E, South-East region of Nigeria at altitude 1800m (mean sea level). Three Sweetpotato varieties namely

UMUSPO/3, BUTTERMILK and TIS 87/0087 were selected from the screenhouse of Sweetpotato in NRCRI, surfaced sterilized by washing in running, followed in Benlate liquid fungicide, 70% ethanol and finally rinsed with distilled water, and planted in a bucket containing air dried river sand with substrate which have been autoclaved at 121Psi for 30 minutes. The experiment was set in a 3 by 6 Factorial design laid out in Randomized Complete Block Design (RCBD) with 18 treatments and three replicates.
The Growth rate, Survival rate and Vigour were measured to determine the performance of the three Sweet potato varieties on different level of substrates application. Data collected from the experiment was subjected to analysis of variance (ANOVA) using the R software package.

RESULTS AND DISCUSSION

Growth rate from fig 1 revealed UMUSPO/3-C, 3.306, combination of K, S and C, 2.861, K and R, 0.361, R and S, 0.194, BUTTERMILK- C, 2.306, combination of both K,S and C, 1.417, K and R, 0.472, R and S, 0.417 and TIS 87/0087- C, 2.778, combination of both K, S and C, 2.639, K and R, 0.67, R and S, 0.194). The results showed that the effect of substrates on the growth rate of Sweetpotato has significant ($p<0.05$) difference with significant positive effect found in Coco peat and combination of both Klasmann, Coco peat and Soya bean husk while the least effect occurs for combination of both Klasmannand Rice, and Rice husk and Soya bean husk.
Similar effects were observed for the Survival rate as showed in fig 2 (UMUSPO/3-C, 3.472, combination of K, S and C, 3.250, K and R, 0.444, R and S, 0.250 BUTTERMILK- C, 2.611, combination of both K,S and C, 2.444, K and R, 0.361, R and S, 0.361 and TIS 87/0087- C, 3.417, combination of both K, S and C, 3.167, K and R, 0.361, R and S, 0.167). There was significant difference between Klasmann and other substrates on the survival rate of Sweetpotato. This suggested that Coco peat and combination of both Klasmann, Soyabean husk and Cocoa peat could be used in placed of Klasmann for survival rate.
From Fig. 3, the result of the Vigour (UMUSPO/3-C, 3.389, combination of K, S and C, 2.639, K and R, 0.444, R and S, 0.444 BUTTERMILK- C, 2.250, combination of both K,S and C, 2.833, K and R, 0.361, R and S, 0.556 and TIS 87/0087- C, 2.861, combination of both K, S and C, 3.222, K and R, 0.472, R and S, 0.444) showed that there was significant difference among the substrates. These results were similar with that obtained by Ritter *et al.* 2001 but further research should be carried out to validate these preliminary findings.

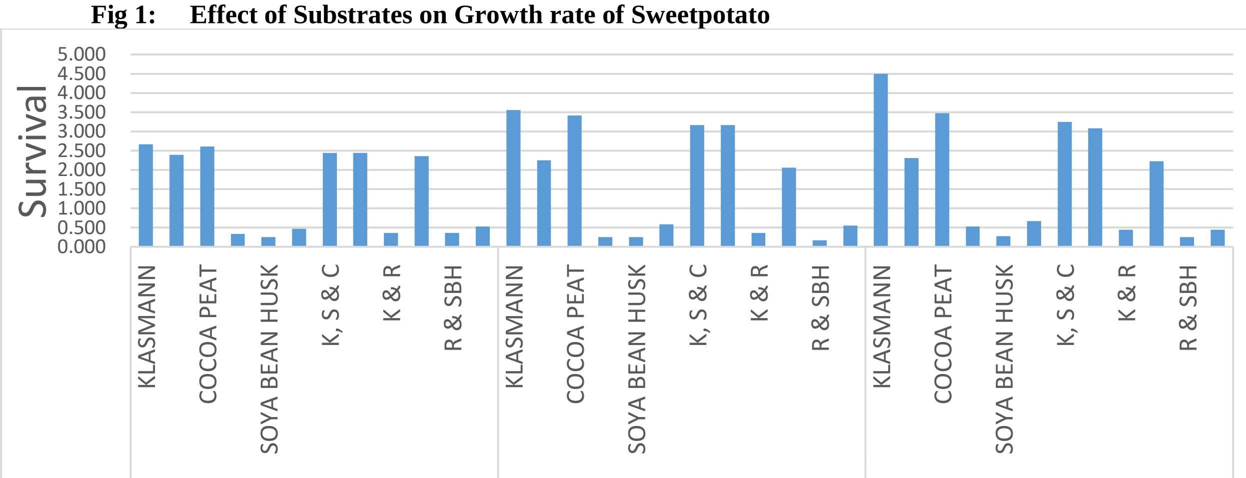

Fig 2: Effect of Substrates on survival rate of Sweetpotato

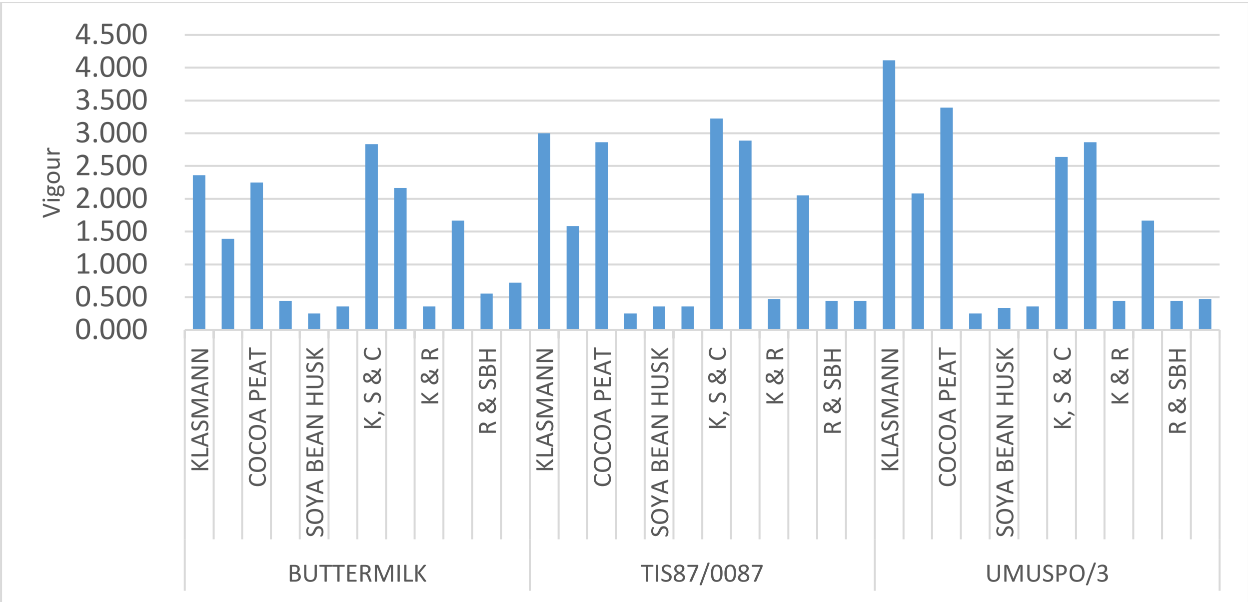

Fig 3: Effect of Substrates on Vigour rate of Sweetpotato

Table 1: **Analysis of variance (ANOVA) of culture (Sweetpotato vines) growth rate, survival rate and vigour rate to variation in Sweetpotato varieties and SAH substrates**

Sources of variation	Df	Growth rate	Survival rate	Vigour
SUBSTRATE	11	1.228***	16.008***	12.339***
GENOTYPE	2	10.947***	0.803**	0.713**
SUBSTRATE:GENOTYPE	21	0.327**	0.314*	0.352***
Residuals	72	0.144	0.158	0.128

CONCLUSION

Based on this study on evaluation of low-cost semi-autotrophic hydroponic substitutes for sweetpotato production, it can be concluded that Coco peat and Soyabean husk can serve as alternatives as well as supplements for Klasmann, to reduce cost of seed multiplication using Semi Autotrophic Hydroponic techniques (SAH).

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study compared early growth of Khaya senegalensis as a fodder crop using organic and inorganic fertilizers. Khaya senegalensis seeds were collected and planted in polythene pots using different treatments; Cow dung, Nitrogen and control. The experiment was laid in a completely Randomized Design (CRD) each treatment consist of 16 replicates. Growth parameters measured include; stem height (cm), number of leaf production, collar diameter (cm) and leaf area (cm^2). Data collected were subjected to a one way analysis of variance (ANOVA) and Fishers Least Significant Difference (LSD). Results show that seedling treated with Nitrogen had the highest mean number of leaf production and leaf area with values (13.16) and ($39.44cm^2$) respectively while seedling treated with cow dung had the highest mean stem height (17.07cm) and collar diameter (1.044cm). Results showed no significant difference ($p<0.05$) in stem height, collar diameter and leaf area. However, there was a significant difference ($p<0.05$) in the number of leaf produced. In conclusion, the research revealed that all treatments applied were valuable sources of fertilizer for growth of Khaya senegalensis as a fodder. Both organic and inorganic fertilizers greatly improved growth performance of treated plants over the control. Seedlings treated with Nitrogen demonstrated better growth attributes in terms of foliage production while seedlings treated with cow dung showed greater performance in stem increment which both results indicated Khaya senegalensis as means for fodder crop which is useful to both domestic and wild animals. It is recommended that, either Organic or Inorganic fertilizers can be adopted as a treatment when raising Khaya senegalensis seedlings for fodder crop production.

Keyword: *Khaya senegalensis, Organic and Inorganic fertilizer and growth parameters*

INTRODUCTION
African mahogany (*Khaya senegalensis*) is one of the best known and more frequently used species of forest stands in African and some parts of West Africa (Areolo *et al.*, 2001) e.g Benin, Burkina Faso, Cameroon, Central Africa Republic, Chad, Ivory coast, Gabon, Ghana, Gambia, Mali, Niger, Nigeria, Senegal, Togo, etc. Mahogany and other Meliaceae of Celdrela genus are the backbone of the forest industry in West Africa and the main source of income for large number of people in rural communities (Areolo *et al.*, 2001). The tree is medium sized which can grow up to 15-30cm in height and 1m in diameter. The tree is characterized by leaves arranged in spiral formation clustered at the end of branches. Flowers are sweet scented, fruits changes from gray to black when ripening. Seedlings develop taproot system in deeper soil. Tree may reach a height of 10cm after two to three months with roots about 23cm long. Under normal condition, initial growth is slow, seedlings being 12cm to 23cm tall after two years. Early growth may be much faster (Ayeni, 2011). In Nigeria *Khaya senegalensis* is called Madachi, Oganwa, Ono and Haa in Hausa, Yoruba, Igbo and Tiv languages respectively.
Fodder is an agricultural term for animal feed, *Khaya senegalensis* is a fodder crop which is highly used by both domestic and wild animals as feed. Shoots or sprouts especially tender twigs and stem of woody plants with their leaves, flowers, fruits or pods are raised, managed for livestock feeds. These fodders are also grown to provide nutritional needs of animals. Babayemi and Bamikole (2006) opined that fodder is an important component of

ruminant diet and nutrition for grazing animals in areas where few or are not available (Van *et al*., 2005). Fodder trees are used for livestock production during shortage in pasture especially in terms of extreme climatic conditions such as drought (Franzel *et al.,* 2014; Balehegn *et al.,* 2015). There has been increasing interest in fodder trees and their potentials to help the rural poor as they have a positive effect on milk production in livestock and hence local income generation (Chakeredza *et al.,* 2007; Place *et al.,* 2009). Incorporating this type of trees e.g. *Khaya senegalensis* into agro-silvopastoral systems can also contribute to environmental rehabilitation, improving soil fertility (Moreno and Obrador, 2007). Indigenous fodder trees are multipurpose and provide multiple benefits and services (e.g food, fibre, medicine, fire-wood, etc.) (Balehegn and Eniang, 2009).

Elevitch and Wilkinson (2000) pointed out that fodder trees and shrubs have several application and uses and hence they serves as good sources of Shade, Wind shelter, Life fence, Improved fallow and pasture, Mulch, Bee forage, Human food, Fuel wood, Timber, Fiber resins, Dyes, Tannins, Medicine, Fertility enhancement, Soil stabilization, Beauty, Oxygen, Wildlife habitat, Increases self-sufficiency, Nutrients cycling, Farm diversity etc. Fodder is harvested in the natural environments though (i) Selective cutting of leafy parts, flowers and fruit of shrub and trees. (ii) Pruning of shrubs and trees which are suitable for livestock. (iii) Pollarding of tree crowns (Osemeobo, 2006).

Fertilization with organic and inorganic fertilizer to nursery or forest seedlings is one of the most crucial factors with a positive effect on seedling quality, performance and establishment (Aluko *et al*., 2014). Inadequate management of nursery soil can result in depletion of soil fertility and corresponding reduction in seedlings growth. However, efficient supply of nutrients in proper proportion leads to efficient growth and development of seedlings (Rafiqul *et al*., 2004). Organic fertilizer (cow dung) is rich in microbial diversity, containing different species of bacteria, protozoa and yeast (Randhawa and Kullar, 2011). Inorganic fertilizer (Nitrogen) is an essential aspect of cropping system and these include soil productivity, soil fertility, plant nutrition and qualitative crop yield. The availability of this nutrients to plant contributes to growth and yield. Deficiency of mineral element to plant is evident to poor yield (Raines, 2011). Nitrogen is outstanding among other nutrients; it is required in larger quantities by most crops (Margues *et al.,* 2006). Maintaining adequate fertility of forest nursery soils is of paramount importance to ensure production of high quality planting stock.

METHODOLOGY

The study was conducted at the Nursery unit of the Department of Forestry and Wildlife Management of Modibbo Adama University Yola located between Latitudes; 9^0 20' 32"N and 9^0 20' 36''N and Longitudes; 12^0 30' 18''E and 12^0 30' 21''E. Adamawa State falls under the Sudan, Southern and Guinea Savannah types of vegetation and it experiences distinct dry and wet seasons with temperature ranges from 27^0Cto 40ºC and relative humidity vary with seasons ranges from 20-80% (Adebayo and Tukur, 2010). The wet or rainy season lasts from April to October, and is characterized by single maxima in August and September. During this season, the moisture laden south west trade wind from the Atlantic Ocean blows over the area. Seventy percent of the total rainfall in the area falls within four months of May-September (Adebayo, 2020).

STUDY DESIGN

The experiment was arranged in a Completely Randomized Design (CRD) with three (3) treatments and sixteen (16) replicates. Stem diameter (mm), seedlings height (cm), leaf production and leaf area (cm^2) was assessed. Data were collected every week for a period of (10) weeks on Stem height increment, collar diameter increment, number of leaf production and leaf area. Stem height measurement was taken via the vertical distance from the ground level to the top of each seedling using a measuring rule. Collar diameter was obtained by measuring the diameter at collar points of the seedlings using veneer caliper. While number of leaves on each seedlings was obtained by counting. Finally leaf area was estimated by randomly selecting a leaf from each replicate and determined its area using graph method

Procedure

Fresh seeds of *Khaya senegalensis* seeds were collected from a standing mother tree. Materials used were air dried decomposed Cow dung and River sand were collected from the Nursery section. Materials such as Polythene bags and Inorganic fertilizer (Nitrogen) were obtained from the local market. Top soil was collected few meters beside the nursery in the university compound. Potting mixture was done in the Nursery. The first treatment had a potting mixture of Top soil, River sand and Cow dung at a ratio of 3:2:1. The second treatment had a potting mixture of Top soil and River sand at a ratio of 3:2 of which 0.5g of Inorganic fertilizer (Nitrogen) was added after germination. The third treatment was Control with a potting mixture of Top soil and River sand at a ratio of 3:2 respectively. These treatments were filled into separate polythene pots of 23cm height and 10cm in diameter. Seeds was treated in cold water for 12hours and sown directly into the filled polythene bags. Watering was done twice a day (morning and evening). Other Nursery operations such as weeding were carried out as required throughout the experiment. Measurement commenced a week after the application of Inorganic fertilizer.

Data Analysis

Data collected was analyzed using a one way analysis of variance (ANOVA). Fishers Least Significant Difference was used for the mean separation.

RESULTS AND DISCUSSIONS

Stem height increment

The mean stem height increment recorded from *Khaya senegalensis* seedlings with cow dung, Nitrogen and control, taken at weekly interval for ten weeks is shown in the (Table 1). Mean stem height increment after weeks was highest in seedlings treatment with cow dung (17.07cm) followed by seedling treated with Nitrogen (17.05cm) then the control (16.76cm). ANOVA results in (Table 5) showed that there was no significant difference among treatments.

Number of Leaf Production

The mean number of leaf production by *khaya senegalensis* seedlings treated with cow dung, Nitrogen and control, taken at weekly interval for ten weeks is shown in (Table 2). Mean number of leaf production after ten weeks was highest in seedlings treated with Nitrogen (13.16) followed by seedlings of the control (12.04) and seedlings treated with cow dung (10.07). ANOVA results (Table 5) showed a significant difference among the treatments ($p<0.05$). LSD conducted showed that there was a significant difference between Nitrogen and cow dung as well as control (Table 6).

Collar diameter increment

The mean value of collar diameter of *khaya senegalensis* seedlings with cow dung, Nitrogen and control taken at weekly interval for ten weeks is shown in (Table 3). Mean collar diameter after ten weeks was smallest in control with value (0.996cm) followed by seedlings treated with Nitrogen (1.043cm) and was highest in seedlings treated with cow dung (1.044cm). ANOVA result (Table 5) indicated that there was no significant difference among treatments.

Leaf area

The mean value of leaf area of *khaya senegalensis* seedlings with cow dung, Nitrogen and control measured after ten weeks is shown in (Table 4). The mean leaf area after ten weeks was highest in seedlings treated with Nitrogen (39.44cm^2) followed by seedlings treated with cow dung (38.40cm^2) and least in seedlings of the control (35.57cm^2). ANOVA results (Table 5) showed that there was no significant difference among the treatments.

DISCUSSION

The increment of stem height, collar diameter, number of leaves and leaf area of *Khaya senegalensis* seedlings used as a fodder crop due to potting mixture treated with cow dung, Nitrogen and control showed variations in the growth parameters measured. Seedlings grown on cow dung, Nitrogen and control responded differently with regards to the height ($p>0.05$). The result showed that treatments have no significant effects on the seedlings height. This implies that there could be no need for different treatment when raising fodder crop e.g *Khaya senegalensis* with regards to stem height. The result on stem height increment agrees with the study of (Arnold, 2004), who reported that organic fertilizer gradually release more nutrients to species over a longer time which enable fodder crops to develop for consumption unlike inorganic fertilizer which release nutrient within shorter period for seedling growth.

Application of cow dung and Nitrogen in relation to control responded differently with regards to leaf production ($p>0.05$). The result showed that there is a significant difference between Nitrogen and cow dung. *Khaya senegalensis* seedlings used as a fodder crop treated with Nitrogen recorded highest mean number of leaves. This showed the essential of Nitrogen in vegetative growth of crops. Seedling treated with cow dung recorded the least number of leaves and leaf spot disease was also observed. This may be due to high dose of cow dung and some other inherent chemicals such as Phosphorus since excess absorption of Phosphorus can affect regular functioning of organs in trees, shrubs, herbs, fodder etc. This result is in conformity with the study of (Saka *et al.*, 2008) who reported that seedlings treated with cow dung had the least mean number of leaves. This indicated that the species which are used as a fodder can be best raised with Nitrogen.

Results of the potting mixture which is treated with Nitrogen, cow dung and control responded differently ($p<0.05$) with regards to collar diameter of *Khaya senegalensis* seedlings. The result indicated that the various treatments did not significantly increase collar diameter of fodder crop (*Khaya senegalensis* seedlings). Seedlings treated with cow dung had the highest mean stem diameter compared to Nitrogen and control seedlings. Collar diameter showed a better response to cow dung in the initial development phase. Stem diameter is one of the important parameter to estimate survival of seedlings after planting of forest species. This result agrees with (Afonso *et al*., 2017). However, the result implies that there could be no need for application of fertilizer when raising *Khaya senegalensis* seedling in terms of stem height, this may be due to organic manure which may contain recalcitrant element which affect the growth and development.

Based on the treatments, variation in leaf area of *Khaya senegalensis* seedlings, Nitrogen had the best mean leaf area ($p<0.05$). Results showed that various treatments did not significantly increase leaf area. Seedlings treated with Nitrogen had the best mean leaf area. This could also be as a result of comparatively higher Nitrogen concentration in potting mixture treated with Nitrogen which is more of enhancement in the vegetative growth of seedlings.

CONCLUSION

From the results of this study, it is revealed that all treatments applied were valuable sources of fertilizer for the growth of *Khaya senegalensis.* They greatly improved growth performance of plants over the control. Seedlings treated with Nitrogen demonstrated better growth for large fodder production and leaf area compared to cow dung. However, seedlings treated with cow dung showed better growth rate in terms of stem height and collar diameter. The results also attest that *Khaya senegalensis* can be grown for successful plantation establishment for the growing of fodder crop which can be utilized using both organic and inorganic fertilizer based on the objective or focus of management. Organic fertilizer performed better in terms of stem growth while inorganic fertilizer proved to be better in foliage production.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Field trials were conducted at Institute for Agricultural Research, Samaru, and Irrigation Research Station, Kadawa in the northern Guinea and Sudan Savanna ecological zones of Nigeria respectively, during the 2021 wet season. Treatments consisted of three lowland rice varieties (FARO 44, FARO 52, and FARO 57), three planting methods (dibbling, drilling and broadcasting) and four rates of NPK and Agric-Zyme 3X organic liquid fertilizers (0:0:0 kg NPKha^{-1} + 3.0 lha^{-1}, 60:30:30 kg NPKha^{-1}+1.5lha^{-1}, 60:30:30 kg NPKha^{-1} + 3.0 lha^{-1} and 120:60:60 kg NPKha^{-1} + 0 lha^{-1}). The trials were replicated three times, in a factorial arrangement using split plot arrangement. Fertilizer rates and planting methods were the main plots and rice variety as subplot. FARO 44 recorded shorter plants heights and higher net assimilation rates, but took fewer days to 50 % flowering than FAROs 52 and 57. Effect of planting methods was generally not significant on rice, however, broadcasting recorded higher leaf area index, while dibbling recorded higher paddy yield. Application of 120: 60: 60 NPK kg ha^{-1} alone out-performed other fertilizer management methods followed by 120: 60: 60 NPK kg ha^{-1} +1.5 l ha^{-1} Agric-Zyme 3X in all parameters alone. In conclusion, FARO 57 variety out-performed other varieties used in the study, Drilling method and application of 120: 60: 60 NPK kg ha^{-1} alone were better for growth, yield and grain quality of lowland rice in the study areas.

Keywords: *Growth Response, Lowland Rice, Variety, Planting method and Fertilizer management*

INTRODUCTION
Rice (*Oryza Sativa*) is a staple food in many countries of Africa and other parts of the world. Imolehin and Wada, (2000) reported that rice is the second most important cereal in the world in terms of production, after wheat. West Africa accounts for 64.2 % and 61.9 % of total rice production and consumption respectively in sub-Saharan Africa, with Nigeria ranking first in both production and consumption (Imolehin and Wada, 2000**)**. Nigeria is currently the largest rice producing country in Africa. Traditional rice varieties are tall, have a long growth and maturation periods (5-6 months) and low yields (1.5-2.0 t ha^{-1}) tons per hectare. Improved varieties are shorter (less than 50 cm) and are more responsive to fertilization with short growth duration and higher yields (3.5-5 t ha^{-1}), (Mohammed, 2016). Improper sowing techniques usually affects yield potentials of the rice crop. Sowing of improved varieties using appropriate methods of seeding could produce a fast growing and uniform crops with higher yields which could compete weeds more efficiently (Kawure *et al.*, 2018). This study was therefore, conducted to identify suitable varieties and appropriate planting methods and fertilizer management in rice.

MATERIALS AND METHODS
Field trials were conducted at the Institute for Agricultural Research, Samaru, in the Northern Guinea and Sudan Savanna ecological zones of Nigeria, during 2021 wet season. Treatments consisted of three lowland varieties (FARO 44, FARO 52, and FARO 57), four rates of combined NPK and Agric zyme 3X organic liquid fertilizers (0:0:0 kg ha^{1} plus 3lha^{-1}, 60:30:30 kg NPKha^{-1}plus 1.5lha^{-1}, 60:30:30 kg NPKha^{-1} plus 3lha^{-1} and 120:60:60 kg NPKha^{-1} plus 0lha^{-1}), and three planting method (dibbling, drilling and broadcasting). These studies were designed as Randomized Complete Block Designs, laid out in split plots arrangements with fertilizer rates and planting methods as main plot and lowland rice varieties as sub plots. Gross and net plot sizes were 3.0 m x 4.0 m (12 m^2) and 2 m x3 m (6 m^2) respectively. The treatments were replicated three times. The experimental site was harrowed twice to obtain a fine tilth and marked out into plots (basins) and replicates Each main plot was separated by 1 m pathway, the sub-plot by 0.5 m. Seeds were sown according to treatments. Dibbling, at 20 cm inter and intra row spacings using 60 kg ha^{-1} seed rate, while seeds were drilled in grooves 2-3 cm deep at 20 cm spacings using 80

kg ha^{-1} seed rate. Seeds were manually sown at at 100 kg ha^{-1} and covered lightly with soil. The crop was harvested at maturity when the entire plants turned yellowish or golden brown, using sharp locally made handheld sickles. Harvested plants were threshed. Growth data were collected on plant height (cm), leaf area index, net assimilation rate, days to 50 % flowering at 3, 6, 9 and 12 weeks after sowing effective grain-filling period and paddy yield.

RESULTS AND DISCUSSION

Details of physical and chemical properties of the soil taken at the experimental sites (Samaru and Kadawa) at a depth of 0-30 cm in 2021 wet seasons are shown in Table 1. The soils were identified as loamy and sandy loam for Samaru and Kadawa respectively. In both locations, soil pH were slightly acidic (pH of 5.67 and 6.25), moderate in organic carbon (14.62 and 16.85 gkg^{-1}), and total nitrogen (1.68 and 1.95 gkg^{-1}) respectively, and low in available phosphorus (14.20 and 16.10 mgkg^{-1}). Exchangeable cations were low (K = 0.16 and 0.19 cmolkg^{-1}, mg 0.58 and 0.62 cmolkg^{-1}, Ca 3.02 and 3.55 cmolkg^{-1}, Na 0.25 and 0.27 cmolkg^{-1}, Al^{+++}+ H^{+} 0.8 and 0.6 and low CEC 4.81 5.25 cmolkg^{-1} respectively, were moderate for both locations, in the 2021 wet season. Chandrasekaran *et al*. (2007) reported that rice can be grown successfully on a variety of soils, the most important requirement been its ability to hold moisture. Plant height of lowland rice varieties as influenced by planting methods and fertilizer management at Samaru and Kadawa, did not differ significantly (Table 2). However, at Samaru, application of 120: 60: 60 NPK kg ha^{-1} + 0 Agric-Zyme 3X l ha^{-1} recorded taller ($p< 0.05$) plants followed by combined application of 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha^{-1} while application of 3 Agric-Zyme 3X l ha^{-1} alone recorded shortest ($p< 0.05$) plant heights. At Kadawa application of 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha^{-1} recorded taller plant height, but was statistically similar with 120: 60: 60 NPK kg ha^{-1} + 0 Agric-Zyme 3X l ha^{-1} and 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha^{-1}. Similarly, application of 3 Agric-Zyme 3X l ha^{-1} alone recorded shorter plants and was also statistically similar with 120: 60: 60 NPK kg ha^{-1} + 0 Agric-Zyme 3X l ha^{-1} and 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha^{-1}. Varietal variations and effect of planting methods were not significant ($p< 0.05$) on leaf area index at both locations. Effect of fertilizer management on leaf area index (LAI) was significant across locations and seasons. At Samaru application of 120: 60: 60 NPK kg ha^{-1} recorded higher leaf area index, followed by 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha-^{1} and 60: 30: 30 NPK kg ha^{-1} + 3.0 Agric-Zyme 3X l ha-^{1} which were statistically similar ($p< 0.05$) and 3.0 Agric-Zyme 3X l ha-^{1} alone recorded lower leaf area index. At Kadawa, application of 60: 30: 30 NPK kg ha^{-1} + 1.5 Agric-Zyme 3X l ha-^{1} and 60: 30: 30 NPK kg ha^{-1} + 3 Agric-

Zyme 3X l ha-^{1} and 120: 60: 60 NPK kg ha^{-1} alone were statistically similar and recorded higher leaf area index, while 3 Agric-Zyme 3X l ha-^{1} recorded lower leaf area index. The three varieties did not differ significantly ($p< 0.05$) in their leaf area indices in both locations while both drilling and dibbling recorded similar but lower indices than broadcasting at Samaru only (Table 2). Application of 120:60:60 kg ha^{-1}NPK alone recorded highest ($p< 0.05$) leaf area index in both locations followed by combined application of NPK and Agric-Zyme 3X (Samaru) and Agric-Zyme 3X alone (Kadawa). FAROs 44 and 57 recorded similar and higher ($p< 0.05$) net assimilation rates than FARO 52 at Samaru. However, FARO 52 variety was also statistically similar ($p < 0.05$) with FARO 57. Planting method had no significant effect on net assimilation rates at both locations. At both Samaru and Kadawa, application of 120:60:60 kg ha^{-1} NPK alone or 60:30:30 with 1.5 l ha^{-1} Agric-Zyme 3X registered statistically similar ($p < 0.05$) and higher net assimilation rates than other fertilizer management rates. FARO 44 took shorter ($p < 0.05$) days to attain 50 % flowering followed by FARO 52, while FARO 57 took relatively longer ($p < 0.05$) days to flower. Paddy yields of three varieties were statistically similar ($p < 0.05$) at both locations, while dibbling, followed by broadcasting out-yielded drilling in paddy at Kadawa. Application of Agric-Zyme 3X alone at Samaru recorded least ($p < 0.05$) paddy yield than other fertilizer management methods. Similar trend was observed at Kadawa. Treatments interactions on all parameters assessed were not significant. The contrasting varietal responses (largely non-significant) observed on growth parameters and paddy yield is supported by Islam *et al.*, (2010), who reported that varieties with longer growth duration produced higher grain yields than varieties with shorter growth duration. Usman *et. Al.*, (2022) reported that FARO 44, is an early maturing variety. This conforms with these findings, while Fasina and Adeyanju, (2006) reported that FARO 52 was a medium maturing rice variety. Djomo *et al.*, (2017) observed that application of N-P-K fertilizer increased growth parameters such as height. They recorded higher leaf area index, ant this agrees with Gala *et al.*, (2011), who reported that increasing amount of NPK improved considerably, the vegetative growth of rice. The larger the leaf area of a plant the more the photosynthetic area and consequently, the output. Wu *et al*. (1998) reported similar results on increasing rates of N, P, and K fertilizers favoured vigorous growth of the rice plant. Higher number of tillers gave more panicles consequently translating to higher paddy yields.

CONCLUSION

In conclusion, FARO 57 variety out-performed other varieties, drilling method and application of 120: 60: 60 NPK kg ha^{-1} alone were better for growth, yield and grain quality of lowland rice in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A field trial was conducted in the 2015 and 2016 cropping season to determine the performance of Sesamum indicum L. (Beniseed) on the growth and yield of sesame at two planting methods at Lafia-Nasarawa state. The planting methods were broadcasting and dibbling, at 3 different levels (10 cm x 10 cm, 20 cm x 20 cm ,and 30 cm x 30 cm). At the growth stages of sesame broadcasted plots had spindle stems and were taller but plants on the dibbling plots had comparatively wider or thicker stems. However, at harvest the plants in the dibbled plots produced significantly higher (p<0.05) seed yield and higher 1000 seed weight per plot than the sesame plants on the broadcasted plots.
Keywords: *Sesame, planting methods, broadcasting, dibbling*

INTRODUCTION
Sesame belongs to the Family Pedaliaceae and is one of the most ancient seed and oil seed crops known to man. It was a major oil seed crop in the ancient world due to easiness of extraction, stability, and resistance to drought. It is cultivated in almost all tropical and sub-tropical African and Asian countries, mainly for its highly nutritious and edible seeds. In Nigeria , it is cultivated in the dry, Northern and Southern Guinea, Sudan and Sahel savannah zones. Sesame has diverse usages and contains 42 – 45 % oil , 20 % protein and 14 – 20 % carbohydrate (Bari , 2004).

Despite the nutritional and socio-economic roles played by sesame, the crop is still facing constraints in terms of application of agronomic practices (correct planting pattern and fertilizer rates that will enable the farmers have better growth and yield of the crop). Presently, the crop is planted by merely broadcasting the seeds on the field, and this appears not to be a good method of planting.

With the socio-economic and nutritional roles played by sesame in Nigeria, sesame it is important to determine more appropriate planting methods that may ensure earlier and better emergence than merely broadcasting seeds on the field as currently practiced in the major sesame producing areas of Nigeria . In Nasarawa state, the only method of planting used by farmers is broadcasting. This and other factors could be responsible for the low yield of sesame. Therefore, to have higher yield of this crop, the application of better planting methods is imperative.

MATERIALS AND METHODS
The field trial was carried out at the Teaching and Research Farm of College of Agriculture Lafia-Nasarawa State, during the wet seasons of 2015 and 2016, in the Southern Guinea Savannah zone of Nigeria. Data on rainfall distribution, maximum and minimum temperatures and relative humidity of the study area for the two years were obtained from the Nigerian Meteorological Agency (NIMET) of the Federal Ministry of Aviation, Lafia office. The soil of the area has been classified to be sandy loam and characterised by low N, P and K as shown in the soil textural and chemical analyses - table 1.

The experimental design used was Randomised Complete Block Design (RCBD), replicated three times. Treatments consisted of two planting methods of broadcasting and dibbling at 3 levels (10 cm x 10 cm , 20 cm x 20 cm and 30 cm x 30 cm). Plots were first cleared and then, harrowed. The area was then mapped out into plots of 9 m^2 each. The plots were arranged side by side in rows of three blocks with each row having 4 plots. The space between blocks was 1 m apart, while the space between plots within a block was 50 cm. Sesame seed variety E8 was got from the Seed Store of Nasarawa state Agricultural Development Programme, Lafia.

The seeds were then sown at a depth of 3-4cm and seeds uniformly spaced and spread on the broadcast plots. The sesame seedlings on the spaced treatments were thinned to 3 plants per stand after 3 weeks of sowing. Weed, pest and disease control and other agronomic practices were applied at 4 weeks after sowing. Five sampled plants were randomly chosen from each plot and tagged for data collection. From the five tagged plants, growth parameters (plant height and stem diameter), were taken fortnightly, while yield parameters (seed yield per treatment and 1000 seed weight per treatment) were recorded. Analysis of variance (ANOVA) was carried out to test for significance between treatment means using F-test as described by Snedecor and Cochran (1967). Where significant differences occurred, Fisher's least significance difference (F-LSD), was used to separate means.

Table 1: Physical and chemical analyses of soil before planting Soil properties at 0 - 30cm depth.

Soil properties	Value
Physical composition

Mg (mol/kg)	1.45
Ca (mol/kg)	2.21
Na (mol/kg)	0.85
CEC (mol/kg)	4.67

RESULTS AND DISCUSSION:

Table 2 below shows the effect of planting methods on growth and height on sesame in 2015 and 2016 seasons. During the 2-year period of research, broadcasting method of planting sesame produced plants that were significantly ($p<0.05$) taller than those planted by dibbling particularly at 12 WAS (76.60 cm). This indicated that sesame planted by broadcasting grew taller with spindle stems than those planted by dibbling. This result also showed that planting sesame at closer spacing and broadcasting leads to production of taller plants due to competition for space, sunlight.

Plant Height (cm)

Table 2: Effect of planting methods on growth height of sesame in 2015 and 2016 rainy seasons

	Plant height (WAS)									
Planting methods	**4**		**6**		**8**		**10**		**12**	
	2015	2016	2015	2016	2015	2016	2015	2016	2015	2016
Broadcasting	8.72	8.04	22.0	21.9	56.10	59.70	72.77	72.31	74.40	84.60
Dibbling

20 cm x 20 cm	9.59	8.21	23.69	21.20	46.24	33.90	44.45	43.90	46.45	43.90
30 cm x 30 cm	10.13	8.54	24.97	19.66	49.66	31.50	51.75	38.40	58.85	40.80
LSD (0.05)	1.53		3.30		7.82		2.12		5.22	

Table 3 shows effect of planting methods on stem diameter of sesame in 2015 and 2016. Broadcasting produced sesame plants with spindle stems. Dibbling. All the 3 levels of dibbling produced sesame plants with significantly ($p<0.05$) wider or fatter stem diameter than in broadcasting. This result tallies with that by Umar Bako, (2014) who reported that under wider spacing (30 cm x 45 cm or 30 cm x 60 cm). and that with wider spacing, the were less populated with little or no etiolation was experienced by plants in such plots .

At 12 week, sesame planted by dibbling at a spacing of 20 cm x 20 cm gave plants with significantly ($p<0.05$) wider diameter than those planted at 10 cm x 10 cm apart. Also in 2016, at 12 weeks, spacing at 30 cm x 30 cm produced plants whose stem diameter that were statistically similar ($p<0.05$) with those planted at 20 cm x 20 cm.

Table 3: Effects of planting method on the stem diameter of sesame for 2015 and 2016 rainy seasons

Planting methods	Stem Diameter (WAS) 4		6		8		10		12	
	2015	2016	2015	2016	2015	2016	2015	2016	2015	2016

Sesame Seed Yield per Treatment(g):

Table 4 below shows effect of broadcasting and levels of dibbling on the growth and yield of sesame, in 2015 and 2016 growing seasons, The mean seed yield produced per plot by broadcasting method were 3088.52 g and 3098.20 g respectively. Comparatively, the seed yield of sesame planted at 10 cm x 10 cm was significantly higher (p<0.05) than those produced by broadcasting in both years. There was significant differences (p<0.05), between yields of all the 3 levels of dibbling and the yields obtained from broadcasting. Dibbling was significantly higher (p<0.05) than that of broadcasting. This result is in harmony with Akbar, *et al.*, (2001) who worked on 2 varieties of sesame (Punjab—89 and TS -3) and concluded that their seed yields were significantly influenced by planting pattern in both varieties. Also, Arunachalam (2010), reported gradual reduction in seed yield of sesame from 279 kg to 184 kg /ha with increase in plant population from200,000 to 400,000 plants per hectare.

Table 4: Effect of planting methods on Seed yield of sesame per treatment for the 2015 and 2016 wet seasons.

Planting method	Year	
Broadcasting	2015	2016
	3088.52	3098.20
Dibbling		
10 cm x 10 cm	3175.93	3361.30
20 cm x 20 cm	3185.19	3465.01
30 cm x 30 cm	3193.52	3470.20
LSD (0.05)	37.7	37.40

One Thousand Sesame Seed Weight(g):

Table 5 shows the effects of broadcasting and 3 levels of dibbling on 1000 seed weight of sesame. The 1000 seed weight for sesame planted by broadcasting is 2.88 g and 3.04 g respectively. However, the 1000 seed weight produced by sesame at all the 3 levels of dibbling in 2015 was significantly higher (p<0.05), than that of broadcasting. In 2016 , the 1000 seed weight produced by sesame at 20 cm x 20 cm and 30 cm x 30 cm apart were significantly higher (p<0.05), than that produced by broadcasting. This result is also in harmony with that reported by Akbar *et al.*, (2010), who reported that 1000 seed weight was significantly affected by planting patterns.

Table 5: Effect of planting methods on 1000 sesame seed weight for 2015 and 2016 wet seasons

Planting method	Year	
Broadcasting	2.88	3.04
Dibbling		
10 cm x 10 cm	3.81	4.01
20 cm x 20 cm	3.82	4.90
30 cm x 30 cm	3.83	4.95
LSD (0.05)	0.09	1.02

CONCLUSION AND RECOMMENDATION:

The result of this two-year research has shown that sesame planted by dibbling performed better than that by broadcasting. It is therefore, recommended that dibbling be used in planting sesame to optimise yield and consequently, income.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Afield experiment was carried out in the rain forest zone of Nigeria at Akwa Ibom State University Teaching and Research Farm, Obio Akpa Campus in April 2021, to assess effect of varying rates of cattle dung on growth and yield of Turmeric (Curcuma longa L.). The experimental design was a Randomized Complete Block Design, comprising five (5), treatments replicated four times. The treatments (rates of cattle dung) were 1.0, 2.0, 3.0, 4.00 and control (0 t/ha). Data were collected for growth and yield parameters and subjected to analysis of variance. Significant means were separated using Fisher's least significant differences at 5 % level of probability. Results indicated significant differences (p<0.05) on turmeric height (cm), number of leaves/plants, leaf area at 2, 4, 6 months after planting (MAP), number of rhizomes/plant, number of tillers/plant, tiller lengths and weight of rhizomes (t/ha) respectively. Application of 4.0 t/ha of cattle dung, gave statistically higher (p<0.05) values on plant height, number of leaves/plant and leaf area at 2, 4, 6 MAP. The least values (p<0.05) were obtained at 1.0 t/ha when and control. With 4.0 t/ha application of cattle dung, number of rhizomes/plant (5.75), number of tillers/plant (5.92), length of tillers (25.41 cm) and the yield (18.44 t/ha) were higher (p<0.05) compared with the control (2.24, 2.43, 17.20 cm, 6.75 t/ha..
Keywords: *Turmeric, rhizomes, tillers, cattle dung.*

INTRODUCTION
Turmeric (*Curcuma longa* L.) is an important and common spice crop used for many years (Chattopadhyay *et al.*, 2004; Kikusawa and Reid, 2007). It was first used as a dye and then later for its supposed properties in folk medicine (NCCIH, 2012). The plant grows up to 1 m with a short stem, tufted leaf with yellow flowers between 10-15 cm in length (Udoh *et al.*, 2005). The rhizomes are yellowish-brown with a dull orange interior that looks bright yellow when powdered (Jajji, 2012). It contains appreciable quantities of proteins (6.3 %) lipids (5.1 %), carbohydrates (69.4 %) and fibre (2.6 %). Turmeric is rich in minerals like phosphorus, calcium, iron and vitamin A (Udoh *et al.*, 2005). Among spice crops, turmeric is popular and used on a large number of food items (Rachman *et al.*, 2010; Ishimine *et al.*, 2003). It also shows anti-bacterial, anti-fungal, anti-ulcer and anti-cancer effect. It can be grown on different types of soils, but it thrives best in well-drained, fertile, sandy and loamy soils with a pH range of 4.5-7.5. It cannot stand water stagnation or alkalinity (Akpan *et al.*, 2021).
Cattle dung (cow pats, cow pies or cow manure) is a waste product of bovine animal species. These species include domestic cattle, bison and water buffalo. Cattle dung is the undigested residue of plant matter which has passed through the animal's gut and the resultant faecal matter is rich in minerals. Cattle dung manure is presumed to be an excellent fertilizer, rich in organic matter (contains about 3 % nitrogen, 2 % phosphorus and 1% potassium (N.P.K 3-2-1, high levels of ammonia and potentially dangerous pathogens, hence the recommended bagging or composting prior to its use as cow manure or fertilizer. It can improve soil moisture-holding capacity when mixed with the soil and further improves aeration helping to break-up compacted soil (Ummul, 2021). The objective of this study was to evaluate the effect of cattle dung application on the growth and yield of turmeric in the rain forest zone of Nigeria.

MATERIALS AND METHODS
The research was conducted at the Akwa Ibom State University Teaching and Research Farm Obio Akpa Campus in Oruk Anam Local Government Area, Akwa Ibom State in Nigeria. The experimental design was a Randomized Complete Block (RCBD), with five treatments (cow dung at 1.0, 2.0, 3.0, 4.00 and 0 t/ha), and three replications.

Each plot measured 3 x 4 m with 1 m alleyways, with an area measured 23 x 16 m. Deep ploughing were made in beds of 15 cm height spaced 1 m apart. Planting was done with carefully preserved and selected rhizomes using an Africa hand-held hand hoe at spacing of 50 x 50 cm and covered. The cattle-dung manure was sun cured for about 3 days, pulverized before application and applied uniformly in band at sixty days after planting. Weeds were removed manually at intervals of 60, 90 and 120 days after planting, while harvesting of the rhizomes was done at 8 MAP when the leaves turned yellow and dried. Harvested turmeric rhizomes were cleaned of soil, mud and other extraneous matter. The following growth and yield parameters were collected: height, number of leaves per plant and leaf area for the growth parameters. Number of rhizomes/plant, number of tillers/plant, length of tillers and weight of rhizomes (t/ha) were collected for as yield parameters. All data were subjected to analysis of variance (ANOVA). Significant means were separated using Fisher's Least Significant Difference.

RESULTS

The effect of different rates of cattle dung application on the plant height of turmeric is shown in Table 1. The result showed significant differences ($p<0.05$) on height of plant at 2, 4, 6 months after planting (MAP) . With increase in the tonnage of cow droppings application, there was a corresponding increase in the growth parameter such as plant height. At 2, 4 and 6 MAP, higher values of plant height (33.52, 52.50 and 60.25 cm respectively) were recorded with 4.0 t/ha treatment. This was followed by 3.0 t/ha (27.09, 48.91 and 55.92 cm). The least values were obtained at 1.0 t/ha.

Table 2 shows the effect of different rates of cattle dung application on number of leaves of turmeric plant. Result indicated significant differences ($p<0.05$) in that 4.0 t/ha, gave higher number ($p<0.05$) of leaves (6.20, 24.61, 27.13) at 2, 4, 6 MAP respectively. This was followed by 3.0 t/ha (6.01, 22.17 and 24.06) at 2, 4, 6 MAP.

Table 3 shows effect of different rates of cattle dung application on the leaf area of turmeric. Results indicated that at 2, 4 and 6 MAP, higher ($p<0.05$) values (63.72, 197.01 and 201.43 cm^2) were obtained for the 4.0 t/ha. At 3.0 t/ha, values of 58.31, 196.30 and 199.47 cm^2 were obtained at 2, 4 and 6 MAP respectively. The least value 46.30, 107.50 and 122.51 cm^2 were obtained with 1.0 tonne/ha in comparison to the control treatment (34.61, 81.72 and 93.22 cm^2).

Number of rhizomes per plant as affected by the different rates as shown in Table 4. At treatment of 4.0 t/ha, the number of rhizomes was higher ($p<0.05$) (5.75), followed by 3.0 t/ha (5.22) and 2.0 t/ha (4.36). The least recorded number of rhizomes was obtained at 1.0 t/ha (3.52). It was further observed that higher yields were obtained with higher quantities of organic fertilizer. Number of tillers per plant as influenced by different rates of cattle dung are presented in Table 4. 4.0 t/ha, produced significantly higher ($p<0.05$) number of tillers per plant (5.92). This was followed by 5.71 and 5.26 recorded at 3.0 t/ha and 2.0 t/ha respectively. The least number of tillers per plant (3.91) was recorded at 1.0t/ha. Length of tillers per plant as influenced by different rates of cattle dung application is shown in Table 4. The result showed significant differences ($p< 0.05$). The significantly longer ($p<0.05$) tillers (25.41 cm) was recorded at 4.0 t/ha. The shortest tiller of 17.20 cm was recorded in the control treatment. Yield of turmeric (t/ha) as influenced by different rates of cattle dung application is shown in Table 4. At 4.0 t/ha, significant higher ($p<0.05$) rhizomes (18.44 t/ha) were recorded. 3.0 t/ha 18.25 t/ha, while the least ($p<0.05$) rhizome yield (6.75 t/ha) was recorded in the control treatment.

DISCUSSION

Increases in the tonnage of cow dung application, with corresponding increase in the plant height agree with the findings of Vanlauwe *et al.* (2001) who opined that soil structures and fertility are maintained or enhanced by the use of animal manure, compost, farm wastes and green manure as valuable sources of crop nutrients and organic matter that can improve soil biophysical conditions, thereby, making soils more productive and sustainable for food production.

The improved number of leaves and leaf area of turmeric of turmeric indicated the influence of cattle dung on them. The result agrees with Ikeh *et al.* (2012a) and Tremblay *et al.* (2011) who reported that livestock manure and droppings supplied some major nutrients (N, P, K, Ca, Mg, S), necessary for plant growth (plant height, number of leaves, leaf area, stem girth) and yield as well as micronutrients. Vanlauwe *et al.* (2001) and Udounang (2015) further reported beneficial effects of organic manure on the growth and yield of plants. Increases in cattle dung, increases yield components of turmeric. This affirms the reports of Udounang and Ndaeyo (2019) and Onunka (2005) that poultry manure is rich in nitrogen and thus plays an important role in the vegetative growth and yield of crops. This was also corroborated with the studies of Ferdous *et al.* (2018) and Effretuei (2020) that increase in number of leaves per plant was higher with attendant increase in yield due to increase in application of cattle dung.

Increasing the rates of application increased the yield per hectare of turmeric, while a decrease led to a subsequent decrease in yield. Olaniyi and Ojetayo (2010) emphasized the need to adopt the use of organic farming to increase farmer's yield and food production. According to Dauda *et al.* (2008), the use of organic manure as a substitute for inorganic fertilizer will help to achieve the global shift towards organic farming. Also, Ahmed *et al.* (2012) opined that organic manure is essential in improving soil productivity and crop production.

The significant response of turmeric to cattle dung rates could be due to low soil fertility status of the experimental site before planting. The result showed increase in cattle dung ratio with increase in growth and yield of the turmeric. The observation agrees with the findings of Nwanyieze *et al.* (2019); Udounang *et al.* (2022a) that high performance of crops under organic fertilizer application may be attributed to the amount of the organic manure that was used leading to the build-up of organic matter that improved the nutrient status of the soil (Ikeh *et al.*, 2012b; Udounang *et al.*, 2022b) with general positive influence on soil nitrogen for crop production. Lal (2016) and Umoh *et al.*, (2022) reported that soil organic matter contents affects crop yield through its role in enhancing and sustaining soil quality and soil health. This affirms the role of the cattle dung application in the soil and hence the attendant effect on turmeric production. According to Ibn (2015) turmeric plants produced more secondary rhizomes when cow dung manure was applied as compared to any other fertilizer. The addition of organic fertilizer improves the soil texture and structure, as well as the binding power and drainage. The use of organic manure lengthens the time that nitrogen is available in the soil aggregate; long-term nutrient availability is important to a long-lived plant such as Java turmeric.

CONCLUSION

Based on the study findings, the application of 4.0 tonnes/ha rate produced significantly higher rhizome yields, followed by 3.0 tonnes/ha. These two rates are therefore, recommended to farmers for higher yield of turmeric in Obio Akpa, Akwa Ibom State.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A feld experiment was conducted during 2016 and 2017 wet seasons at the experimental Farm of National Root Crops Research Institute, Umudike, under the Potato Program at Kuru, and at Teaching and Experimental Farm, Plateau State University, Bokkos ,Jos-Plateau. The experiment studied growth and yield of potato (Solanum tuberosum L.) varieties as influenced by intra–row spacing and potassium application. The experimental design was a Randomized Complete Block Design, laid out as a factorial and replicated three times The treatments consisted of three potato varieties (Zafira, Caruso and Connect), three intra–row spacings (20, 30 and 40 cm) and three potassium (K) fertilizer rates (0, 40 and 60 kg k_2O ha^{-1}). Potassium and intra-row spacing were collectively the main plots, while variety was the sub plots. The results revealed that application of 60 kg K_2O ha^{-1} gave significantly highest ($p<0.05$) higher growth and yield parameters. The result also, indicated that Connect, gave significantly highest ($p<0.05$) higher height and total tuber yield than all the other varieties used, At Bokkos, plant height had highest ($p<0.05$) value at 30 cm intra – row spacing while at Kuru, it was at 20cm intra - row spacing. Plant height and total tuber yield t ha^{-1} gave highest values ($p<0.05$) at 60 kg k_2O ha^{-1}. Variety Connect planted at 40cm intra–row spacing and treated with 60 kg K_2O ha^{-1} produced the tallest ($p<0.05$) plant and highest yield at both locations. Therefore, connect could be adopted for production in the northern Guinea Savana of Nigeria.
Keywords: *Potato, potassium Intra-row Spacing*

INTRODUCTION
Potato (*Solanum tuberosum* L.) belongs to the family *Solanaceae.* The word potato may refer either to the plant itself or the edible tuber (FAO, 2021). Plant nutrition is important especially on the Jos Plateau, where continuous cropping and mining has greatly depleted the soil of the major native nutrients such as N, P and K (Okonkwo *et al.*, 1995). Potato requires a deep well – drained sandy or silt loamy soils with a soil pH between 5.5 to 6.5 with low temperatures (15–20^0). The ideal soil temperature for planting is 13 – 16^0 C and 21^o C for growth. Growth is retarded at temperatures below 7^o C or above 28^o C. Potato requires 400 to 500 mm of rain per annum, spread across five months depending on variety, weather and soil type (AHDB, 2020).

In Nigeria, especially on the Jos plateau, potato is a crop that is harvested early in the wet seasons and tremendously at combating hunger and poverty in homes of resource poor farmers. The problem of spacing is common on farmers field resulting in fewer stands per unit area or overcrowding resulting in competition and subsequently, poor yields. Okonkwo *et al*. (1995), reported that 30 cm intra-row spacing was more appropriate for rain fed ware potato production, whereas, generally, farmers use wider spacings (50–60 cm), and in most cases, grow the crop as an intercrop with maize. Therefore, it has become imperative study more suitable intra-row spacing that will enhance potato growth, development and tuber yield per unit area. Reports have also indicated that low potato yields by on the Jos Plateau attributed to their inability to adequately fertilize, especially potassium, due to scarcity and high cost. It is therefore the objectives of this study to study growth and yield of potato varieties in response to various intra–row spacing and rates of potassium fertilizer.

MATERIALS AND METHODS
A field experiment was conducted during the wet seasons of 2016 and 2017 at Kuru at Plateau State University Teaching and Rsearch, Bokkos, Jos-Plateau, in the Northern Guinea Savanna Zone of Nigeria. Ten soil samples within the experimental sites were randomly collected each year, at a depth of 0–30 cm using soil auger. The soil

samples were bulked into a composite sample air dried, ground into powder and sieved using 2 mm mesh sieve and analyzed for selected physical and chemical properties.

The experiment studied growth and yield of potato (*Solanum tuberosum* L.) varieties as influenced by intra–row spacing and potassium application. The experimental design was a Randomized Complete Block Design, laid out as a in a factorial and replicated three times The treatments consisted of three potato varieties (*Zafira*, *Caruso* and *Connect*), three intra–row spacings (20, 30 and 40 cm) and three potassium (K) fertilizer rates (0, 40 and 60 kg k_2O ha^{-1}). Potassium and intra-row spacing were collectively the main plots, while variety was the sub plots. The results revealed that application of 60 kg K_2O ha^{-1} gave significantly highest ($p<0.05$) higher growth and yield parameters... Weed control was done at planting using pre-emergence herbicide (Alachlor at 1.92 kg a.i ha^{-1} and Atrazine powder at the rate of 4 kg a.i ha^{-1}), using CP-15 Knapsack sprayer at a pressure of 2.1 kg cm^2 and by manual hoe weeding at

4 and 8 weeks after planting (WAP). Earthen up was done at 9 WAP. Pest and disease were controlled by application of Ridomil at the rate of 2.5 g and F–Force (mancozeb 2.0 g a.iha^{-1}), applied bi-weekly from 2 WAP, to prevent fungal diseases attack. Bacterial wilt (*Rhalstonia Solanecearum*) was controlled by rogueing from 3 WAP to harvest. Potato tuber moth and rodents were controlled using Pestox 2.0g a.i $ha^{-1}$and rodenticide (Phostocin) at 1.0g/ per plot respectively at 4 WAP. Harvesting was done at 12 WAP when 95 % of the leaves turned yellow accompanied by senescence,. This was done carefully by lifting the stands with garden fork. Thereafter the tubers were hand-picked and weighed immediately using a portable weighing balance of 120 kg capacityThe data collected were subjected to analysis of variance (ANOVA) using a General Linear Model in statistical Analysis System (SAS) Package. Significant means were sperarted using Duncan's Multiple Range Test, (DMRT) at 5 % level of probability.

RESULTS AND DISCUSSION

Table 1 shows effects of intra-row spacing and potassium fertilizer on plant height of potato varieties at 9 WAP at Bokkos and Kuru during the 2016 and 2017 cropping seasons. At both locations, variety Connect produced significantly ($p<0.05$) taller plants, followed by Caruso, while Zafira produced the shorter plants ($p<0.05$). This could be attributed to varietal response to environmental factors and treatments. Connect was assumed to be more responsive than other varieties. This agrees with the reports of Abong *et al.*, (2013) that potato varieties responded significantly to intra-row spacing and fertilizer application through plant height. The superiority of Connect and Caruso over Zafira in terms showed to morphological superiority hence, faster growth.

At Bokkos, in 2016, 2017 and at Kuru in 2016, height of potato (20 and 30 cm intra–row spacing) were statistically ($p<0.05$) similar, buT taller (40 cm). In 2017, at Kuru, intra - row spacing (30 and 40 cm), were similar ($p<0.05$). A similar trend was observed at Bokkos and Kuru, in 2016, where increased K rates (0 to 40 and 60 kg K ha^{-1} correspondingly increased plant height, This trend was also observed in 2017 at Kuru and Bokkos, for 0 and 40 kg K ha^{-1} at 60 kg K ha^{-1}. but at 40 and 60 kg K ha^{-1}.

Table 2 shows effect of intra-row spacing and potassium fertilizer on total tuber yield potato varieties during the 2016 and 2017 wet seasons and the combined mean of two at Bokkos and Kuru. In 2016, at Bokkos Connect produced the highest ($p<0.05$), total tuber yield followed by Caruso, while Zafira had the least ($p<0.05$), total tuber yield t ha^{-1}. However, in 2017, combined data and at Kuru in the two years of evaluation, Zafira and Caruso were ($p<0.05$), but lower in total tuber yield t ha^{-1} than Connect. Increasing intra-row spacing from 20 to 30 and further to 40 cm at both locations correspondingly increased total tuber yield t ha^{-1}. This trend was still observed at Bokkos except in 2017 at at Kuru, where increasing K rates from 0 to 40 and further to 60kg K_2O ha^{-1} correspondingly increased total tuber yield. Only the interaction of K fertilizer rates and variety on total tuber yield t ha^{-1} in 2016 at Bokkos and Kuru was significant ($p<0.05$). Larger LAI values resulted in greater assimilate production and hence higher DM production and accumulation and subsequently total tuber yield.

CONCLUSION

Base on the findings of this study, variety Connect can be adopted for the study locations in view of its consistencies crop growth and yield. The use of 30 cm intra-raw spacing for potato production for Zafira and Caruso is irecommended for the two locations, while 40 cm intra–raw spacing is recommended for Connect. Application of 60 kg K_2O ha^{-1} is recommended for potato production at Bokkos and Kuru

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An experiment was conducted in the dry season to determine the effect of different mulching materials on weed density, growth and yield of Okra. The study was conducted at the Teaching and Research Farm of Federal College of Agriculture, Ishiagu. The experimental design used was Randomized Complete Block Design (RCBD), consisting of five (5) treatments (rice husk dust, white polythene, saw dust, black polythene mulch and control), and replicated three times. Parameters evaluated were plant height, number of leaves, number of pods, weight of pods at harvest, and density of weeds respectively. The results indicated significant effect (p<0.05) of treatments on plant height at 6 and 9 weeks after planting. Also, on weed density at 4 and 8 weeks of planting. The effect of mulch materials on yield was significant (p<0.05) with rice husk dust treatment, with effect on number and weight of harvested pods. Polythene mulch treatment recorded a significant (p<0.05) reduction on weed infestation. Polythene mulch is therefore, recommended for use in dry season for okra production.
Keywords: *Okra, mulch materials, growth and yield.*

INTRODUCTION
Mulching is an effective method of manipulating a crop's growing environment to increase yield and improve product quality through effective control of weed growth, ameliorating soil temperature, conserving soil moisture, reducing soil erosion, improving soil structure and enhancing organic matter content (Awodoyin and Ogunyemi, 2005). Mulching cropped soils favorably influences the soil moisture regime by reducing evaporation from the soil, reducing erosion and leaching, minimizing weed infestation and increasing the yield of crop by at least 50 % (Awodoyin and Ogunyemi, 2005).
Soil moisture conservation under dry season crop production requires appropriate mulching practices to conserve adequate soil moisture for enhanced plant growth and optimum yield (Cornelis, *et al.*, 2013). Materials that can be used for mulching includes sawdust, polythene, grasses, paper. The use of sawdust, polythene and straw mulches for dry season vegetables production is reported to decrease soil temperature, conserve moisture and with positive roles in water conservation (Dalorima *et al.*, 2014).
Okra (*Abelmoschus esculentus* L. Moench) is a popular vegetable in tropical and sub-tropical countries of the world, generally grown for its pods (Daniel-Kalko, 1982). According to Dalorima *et al.* (2014), okra is grown in both the wet and dry seasons, but attracts higher profit during the dry season when the demand is often higher than supplies. Despite its nutritional and commercial values, this crop is still produced at the subsistence level because of inadequate soil moisture in the dry season (Sanni and Eleduma, 2014). Reports indicate that using the wrong mulch material can lead to crop failure (Dalorima *et al.*, 2014). The objective of this work was therefore, to evaluate the effect of mulch materials on Okra production in the dry season.

MATERIALS AND METHOD
The study was carried out at the Teaching and Research Farm of Federal College of Agriculture, Ishiagu-Ebonyi State, Nigeria, during the 2022 season.
The experimental designed was Randomized Complete Block Design (RCBD) with five (5) treatments replicated three times. Rice husk dust 10 t/ha, saw dust 10 t/ha, black polythene 10,000 m^2/ha, white polythene 10,000 m^2/ha and control (no mulchl). The black and white polythene mulch materials were perforated and placed at recommended field planting distance, and the okra seeds were planted. Saw dust and rice husks dust was evenly spread on the beds according. Weeding was done manually at four (4) weeks intervals after planting. The weeds

were first identified and collected in each plot and weighed to determine treatments with higher density of weeds. Data obtained were plant height, number of leaves, number and weight of pods at harvest. Data obtained were analyzed using analysis of variance (ANOVA)) at 5 % level of probability Obi, (2002).

RESULTS

The result obtained indicated significant ($p<0.05$) changes in plant height at 6 and 9 WAP (Table 1). Black Polythene recorded the highest plant height (22.8 cm and 45.3 cm), while control had the lowest values (4.03 and 10.01 cm). Similarly, the number of leaves (Table 1), were significantly ($p<0.05$), affected at 6 and 9 WAP, with black Polythene bags recording the highest values of (9 and 12 cm), followed by white Polythene (8 and 10 cm), while the least was recorded in control (6 and 7 cm) respectively.

The number of pods differed significantly ($p<0.05$), among treatments ranging from 146 to 238 as obtained in control and rice husk dust (Table 2). Weight of pods, (5.60 t/ha) were significantly higher ($p<0.05$), in plots mulched with rice husk dust though, statistically similar ($p<0.05$), with plots mulched with black polythene (5.06t/ha),

On weed density, result (Table 2) revealed that black Polythene mulch recorded the lowest density of weed (0.2kg and 0.1kg), ($p<0.05$), followed by white Polythene (0.3kg and 0.3kg) while control recorded the highest density of weeds (1.6 kg and 1.8 kg) at 4 and 8 weeks after planting.

Table 1: The effect of different treatments on plant height (cm) and Number of leaves

Treatments	**Plant Height (cm)**			**Number of leaves**		
	3 WAP	**6 WAP**	**9 WAP**	**3 WAP**	**6 WAP**	**9 WAP**
Black Polythene	5.33	22.8	45.3	5	9	12
White Polythene	5.13	20.8	44.7	5	8	10
Rice husk dust	5.04	20.2	44.5	5	8	9
Saw dust	4.43	20.10	42.4	4	6	9
Control	4.03	10.01	20.5	3	6	7
LSD $_{(0.05)}$	NS	2.1	2.8	NS	2.1	2.8

Table 2: The effect of different treatments on yield and weed density (kg)

Treatments	**Yield**		**Weed density (kg)**	
	No of Pods	**Weight of Pods t/ha**	**4 WAP**	**8 WAP**
Black Polythene	212	5.06	0.2	0.1
White Polythene	202	5.04	0.3	0.3
Rice husk dust	238	5.60	1.3	1.1
Saw dust	200	5.10	1.2	1.1
Control	146	2.45	1.6	1.8
LSD $_{(0.05)}$	15.6	0.31	0.02	0.04

DISCUSSION

The higher growth of recorded under mulching may be attributed to enhanced growth of okra plants due to better moisture conservation and suppressed weed infestation. This agrees Hudu *et al.* (2002) who reported superiority of mulched plants over those unmulched. Also, Nwite *et al.* (2008), reported that rice husk dust can be used for the improvement of nutrient status of soils as it contains elements like Ca, Mg, S, Na, Cu, Mn, Fe, K, P, N which are necessary for plant and for soil improvement. The observed reduction in weeds infestation in polythene mulch and higher in pod yield, is in line with Li and Xiao, (1992) using plastic mulch is assumed to be because of better soil moisture retention and reduced soil temperature, and consequently, reduced weed infestation, hence, lesser competition for soil nutrients and water.

CONCLUSION

The use of mulch has been shown to be effective especially in dry season farming. The use of rice husk dust as mulch has proven to be the best of the trial and is recommended to increase okra yield.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A laboratory Patternator was used to determine the discharge rate and the spray volume distribution pattern of fan and cone nozzle. The test was conducted at various nozzle heights above the patternator and various operating pressure. Discharge rate test between fan and cone nozzle was statistically not significant at 5% or 1% level of significance when comparing the difference between the two types of nozzles. The best height of even distribution for fan nozzle was attained at 10cm height above target while for cone nozzle was attained at 40cm. The comparison between the two types of nozzle shows that the difference was not significant statistically at 5% or 1% level of significance.

INTRODUCTION
Crop yield is reduced mainly due to attack of pests, diseases and weeds. Chemicals control is the popular method adopted for controlling most insects, fungi, weeds and diseases. They are applied in varying amounts, depending upon the type and concentration of active ingredients. At present in Nigeria the farmers are mostly using hydraulic energy sprayers in their fields (Bello, 2012). Hydraulic energy sprayers are sprayers that use hydraulic pressure energy to break spray liquid into droplets of a wide range of sizes. In the hydraulic sprayer, a pump supplies energy that carries spray material to the target. Understanding how to use these sprayers is essential for the successful application of agricultural chemicals, especially selective post emergence herbicides. In order to successfully use herbicides, their application must be accurate and uniform.

Nozzles spray tips, multiple nozzle booms, pressure regulation and sprayer calibrations are the essential components of the spray- application technology. Spray tips are the most important nozzles component. It determines the flow and distribution of the spray (Miller and Bellinder, 2001). The proper selection of a nozzle type and size is essential for proper pesticides application. Nozzle breaks the liquid into droplets in the proper direction. This publication covers the comparison of flat-fan and hollow cone nozzles in terms of their discharge rate and spray volume distribution patterns. The finding of the research study presented in this paper could be used in the selection of appropriate nozzle for spraying pesticides in field crops.

MATERIALS AND METHODS
Materials and Equipment: The materials and equipment's listed below were used for the experiments;

v. Stop watch for time recording
vi. Glysophate post emergence herbicides as test fluids for the experiment. It is chosen because of its harmlessness, low cost and readily available.
vii. Measuring Cylinder
viii. A hygrometer consisting of wet and dry bulb thermometers.
ix. A universal laboratory

Methodology: The following outlined procedures were used for carrying out the laboratory test determination of spray volume distribution pattern test and discharge rate test.

Discharge rate test: Each nozzle was mounted on the patternator and discharge at the same time interval was collected in three replicates of operating pressure of 15,30, and 40psi. The discharge rate for each and total discharge rate were determined for the nozzles. Operating pressures and height of nozzle above the target were recorded. The discharge rate was determined using the expression given below (Mathews, 1992);

V = $\underline{Q_{av}}$ ($^{L}/_{min}$)…………………. (1)

T_{av}

Where, V = discharge rate (1/min)

Q_{av} = Average discharge (I)

T_{av} = Average time for discharge (min)

Spray Volume distribution pattern test: The main objective of this test was to determine the degree of uniformity of spray chemical emitting from the sprayer. The test was carried out on a patternator of size 115cm x 115cm. The patternator has 22 continuous triangular grooves at equal spacing of 5mm, a rack carrying spray-collecting calibrated cylinder tubes, which is mounted below the collecting end points of the grooves. Considering the size of the patternator, one nozzle each was mounted and corresponding spray volume distribution patterns were determined. The spray volume distribution test was done for different operating pressures for the two types of nozzles (Flat fan and hollow cone nozzles). The sprayer was operated for 60 seconds (1min) in each situation to be able to obtain a measurable amount of spray from the collecting tube and this was replicated three times. Statistical method of coefficient of variation of the spray collected along the swath was used to analyse the results to compare the variability and the uniformity degree of the spray volume distributed across the swaths of various heights (Buba *et al,* 2013 and Bitrus, 1985). While t-test of significance at 5% and 1% level of significance was used to determine the comparison between the types of nozzles used.

Plate 1: Patternator used in determining the spray volume distribution pattern of the sprayer nozzle at various height and pressure.

RESULTS AND DISCUSSION

Nozzle Discharge Rate (m1/min): The effects of operating pressure and heights of nozzles above the target or patternator on nozzle discharge rate for both fan and cone nozzles are presented in Tables 1 and 2 respectively. It also shows that for a given combination of variables, the discharge rate change appreciably with different operating pressure used.

Table 1: Total Average Discharge for Fan Nozzle Per Unit Time

Nozzle Height (cm)	**Total Discharge Rate (1/min) At Different Operating Pressure (psi)**		
	15	30	45
10	5.14	7.95	9.15
20	5.55	8.8	10.3
30	7.46	10.95	13.22
40	2.86	5.8	10.62

Table 2: Total Average Discharge for Cone Nozzle Per Unit Time

Nozzle Height (cm)	Total Discharge Rate (1/min) At Different Operating Pressure (psi)		
	15	30	45
10	6.42	9.02	10.73
20	8.31	9.98	9.97
30	6.54	8.65	10.7
40	6.88	9.22	9.75

These data were subject to t-test of significance that compared the two types of nozzle if there was any significance difference. From the results of the t-test, the calculated t value (1.12) was lesser than the table t value at degree of freedom equal to 11, at 5% level of significance (2.20) and even at 1% level of significance (3.11). This can be said that the difference between the two types of nozzles that is fan and cone nozzle was statistically not significant, hence that is negligible.

Nozzle spray volume distribution pattern test: The spray volume distribution pattern was carefully studied in the laboratory in order to determine the height of best even distribution of the spray chemical. Uniformity of spray along the swath was determined by coefficient of variation methods. The results are presented in Tables 3 and 4 for both fan and cone nozzles respectively. Tables 3 and 4 show the coefficients of variation results for various nozzles heights (cm) and operating pressure (psi).

Table 3: Coefficient of Variation (%) for fan Nozzles Pattern Obtained from Different Nozzle Heights at Various Operating Pressures.

Nozzle Height (cm)	Total Discharge Rate (1/min) At Different Operating Pressure (psi)		
	15	30	45
10	63.2	24.0	8.6
20	41.8	35.8	47.2
30	66.8	50.4	63.0
40	38.3	49.2	45.6

Table 4: Coefficient of Variation (%) for Cone Nozzles Pattern Obtained from Different Nozzle Heights at Various Operating Pressures.

Nozzle Height (cm)	Total Discharge Rate (1/min) At Different Operating Pressure (psi)		
	15	30	45
10	55.5	58.3	51.6
20	48.9	54.7	54.2
30	55.3	55.2	47.1
40	39.9	38.5	48.9

From Table 3, the height of best even distribution was attained at nozzle height of 10cm while from Table 4, the height of best even distribution was attained at nozzle height of 40cm. Further analysis using t-test of significance that compared the two types of nozzles. The t-test showed that the calculated t value (1.17) was lesser that the table t value at degree of freedom equal to 11, 5% level of significance (2.20) and even at 1% level of significance (3.11). This can be said that the different between the two types of nozzle that is fan nozzle and cone nozzle was statistically not significant that is, it is negligible.

CONCLUSION

The study concluded that both fan and cone nozzle were tested for discharge rate and spray volume distribution pattern test. Discharge rate test between fan and cone nozzle showed that cone nozzle has higher discharge rate than fan nozzle, but further analysis using t-test of significance gave that the different between two types of nozzles was statistically not significant. Spray distribution pattern test was analysed using coefficient of variation method to get the height of best even distribution, which gave the best height for fan nozzle as 10cm and the best height for cone nozzle is 40cm. Further analysis using t-test of significant, compared the coefficient of variation values for both nozzle and obtained that the different between two types of nozzles was statistically not significancee.Showing that any of the nozzles can be recommended depending on the availability.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted in the lowland research farm of the Federal College of Agriculture, Ishiagu, Ebonyi State, during the dry season cropping period (February to April) of 2020 and 2021, to evaluate the effects of different soil amendment sources on selected fertility indices and cocoyam yield. The lowland field is usually used for rain-fed rice production during the rainy season. Randomized complete block design (RCBD) was used to study these soil amendments. The soil amendments include; poultry dropping (PD) at 10t/ha, NPK 15:15:15 fertilizer (NPK) at 300 kg/ha, rice husk dust (RHD) at 10 t/ha, PD at 5t/ha + RHD at 5 t/ha, NPK at 150 kg/ha + RHD at 5t/ha and control, replicated three times. Soil chemical properties evaluated were soil pH, organic carbon, total nitrogen (TN), available phosphorous and cation exchange capacity. The plant parameters studied were cocoyam corms and cormel yield. Results showed that PD + RHD amendment recorded significantly ($p < 0.05$) higher (5.97) pH than other amended plots, whereas soil organic carbon was significantly improved best (13.77 g/kg and 13.80 g/kg) by RHD treated plots in both years. It was obtained that NPK + RHD significantly increased TN in the 1st year as against PD + RHD in the 2nd year. Yield was also improved by the amendment combinations. It is therefore concluded that the complementary use of NPK and PD; and integration of poultry dropping and rice husk dust (PD + RHD) were better soil fertility management strategies for cocoyam production in Southeastern Nigeria.
Keywords: *Cocoyam, corms, cormels, soil amendments, chemical properties, integrated nutrient management*

INTRODUCTION
Cocoyam (*Colocasia esculenta*) is a major source of carbohydrates in Nigeria and a tropical food crop with high potential because of the high yield of the roots (corms) and foliage. The corms and cormels are eaten in the same way as yam (*Dioscorea spp*) and sweet potato (*Ipomoea batatas*), boiled, fried, baked and roasted (Uwah *et al.*, 2011). In spite of the crop's nutritional qualities and industrial uses, its yield in Nigeria (5143kg/ha) is still very low compared with yields in developed countries (Nwite *et al.*, 2016a). The very low yield may be attributed to poor production practices such as inappropriate use of fertilizers and other agrochemicals. In Nigeria, Cocoyam production practices are still carried out by poor rural women farmers who cannot afford the high cost of these fertilizers (Fadina and Ogunyemi, 2002; Apantaku 2000).
The soils on which this cocoyam grows are referred to as an integral component of Agriculture and serve as a medium for numerous ecological, chemical and physical processes. Overburdening of this soil as a natural resource base of agricultural production has always been an issue due to its widely varied applications in the maintenance of human life activities (Omatayo and Chukwuka, 2009). The need thus to effectively manage soil resources in order to achieve optimum productivity of soils is obvious.
In Nigeria and other tropical countries, it is the utmost interest of most farmers to produce sustainable high crop yield. However, according to Ayeni *et al.* (2009), a decrease in soil fertility after a few years of cropping is always a major limitation of these tropical soils. The use of chemical (inorganic) fertilizer in crop production has not been sustainable due to its high cost and scarcity, increased soil acidity and soil bulk density, low water infiltration rate and nutrient imbalance (Nwite *et al.*, 2016b; Nottidge and Ojeniyi, 2005).
However, the complementary use of organic and inorganic fertilizers has been reported to be a good soil fertility management strategy for crop production. Single-use of either organic or inorganic fertilizers in recent years has not really met the expected impact in boosting crop yield to cope with the geometric demand for food in Nigeria (Nwite *et al.*, 2016). The physical, chemical and biological fertility of most Nigerian soils like other tropical soils

have fallen beyond the level considered suitable for efficient and profitable crop production due to loss in nutrients. The soils have to be amended and managed in a special manner to be cultivated profitably (Modal and Sen, 2005; Ogbonna and Nweze, 2012; Udoh *et al*., 2005).

The study therefore aims at investigating the effects of different soil amendment sources on selected soil chemical properties and cocoyam yield improvements in Southeastern Nigeria.

MATERIALS AND METHOD

Description of Experimental Site

The study was carried out in the research farm of the Federal College of Agriculture, Ishiagu, during the 2020 and 2021 cropping seasons. The study area lies within latitude 05^0 56'N and longitude 07^0 41'E in the derived savannah zone of Southeastern Nigeria. The area has a mean annual temperature of about 30^0C and rainfall of 1350mm. Geologically, the area is underlain by sedimentary rock derived from successive deposits of the cretaceous and tertiary period and lies within the Asu River Group (Lekwa *et al*., 1995; Nwite *et al.*, 2008).

Experimental Design/ layout

A randomized complete block design (RCBD) was employed for the study. There were six soil amendment sources used, replicated 3 times. These include;

- Poultry droppings sole at 10t/ha (PD)
- NPK 15:15:15 fertilizer at 300kg/ha
- Rice husk dust sole at 10t/ha (RHD)
- NPK at 150kg + Rice husk dust at 5t/ha
- poultry droppings at 5t/ha + Rice husk dust at 5t/ha
- Control

The land was tilled into suitable seed beds (beds preparation) representing plots with a native hoe, measuring 2 m x 2 m with a plant spacing of 50 cm by 50 cm at a planting rate of one (1) cormel per hole. The poultry dropping and rice husk dust were applied a week before planting while the NPK 15.15.15 was applied at 2 weeks after planting.

Soil Sampling and Laboratory analysis

At the commencement of the experiment, a composite soil sample from random points was collected from the site using a soil auger at 0 - 20cm depth. At the end of each harvest, another set of auger samples was collected from all the identified sampling points on each of the plots from the top (0-20cm) soil depth for laboratory analysis.

The auger topsoil samples were air-dried and sieved through a 2.00mm sieve. Soil fractions less than 2.00mm from individual samples were then analyzed using the following methods.

Particle size analysis: The particle size distribution of the samples was determined by the hydrometer method (Gee and Bauder 1986). Soil pH was measured in a 1:2.5 soil: 0.1 M KCl suspensions (McLean, 1982). The soil organic carbon (OC) was determined by the Walkley and Black method as described by Nelson and Sommers (1996). Total nitrogen was determined by a semi-micro Kjeldahl digestion method using sulphuric acid and $CuSO_4$ and Na_2SO_4 catalyst mixture (Bremner and Mulvancy, 1982). CEC was determined by the method described by Thomas (1982), while the available phosphorous was determined by the Bray 2 method (Bray and Kurtz, 1945).

Data Analysis

Data collected were analyzed using GENSTAT 3 7.2 Edition. Significant treatment means were separated and compared using Fisher's least significant difference (F-LSD) and all inferences were made at 5% levels of probability according to Obi (2002).

RESULTS AND DISCUSSION

Selected initial physical and chemical properties of the soil

The chemical properties of the studied soil before the application of amendments are shown in Table 1. The soil has percent fine sand as 460 g/kg, 290 g/kg silt and 160 g/kg clay, while the coarse sand has 90 g/kg. The soil is acidic with a pH of 4.5. The organic carbon and total nitrogen of the soil were 1.197 g/Kg and 0.140 g/kg, respectively. The analysis indicated that the studied soil was low in cation exchange capacity and available phosphorous.

Table1 Selected initial physical and chemical properties of the studied soil (0-20cm) depth.

Soil properties	Value
Clay (g/kg)	160
Silt (g/kg)	290
Fine sand (g/kg)	460
Coarse sand (g/kg)	90
pH (H_2O)	4.5
Organic carbon (g/kg)	1.197
Total nitrogen (g/kg)	0.140
Exchangeable base (cmol/Kg)	
Sodium (Na^+)	0.08

Potassium (K^+)	0.154
Calcium (Ca_2^+)	3.20
Magnesium (Mg^{2+})	1.60
Cation exchange capacity (cmol/kg)	14.60
Base saturation (%)	36.58
Exchangeable acidity (cmol/kg)	1.40
Available phosphorus (mg/kg)	2.80

Effect of different soil amendment sources on fertility indices (Soil pH, organic carbon, total nitrogen, available phosphorous and cation exchange capacity)

The results (Table 2) showed that there were significant ($p < 0.05$) variations in the soil pH due to the soil amendments used for the two years of study. It was obtained that the highest pH improvement (4.93) was recorded in poultry dropping amended plots within the 1st year, while in 2nd year, plots with integration of poultry dropping (PD) and rice husk dusk (RHD) (PD + RHD) gave the highest significant increase (5.97) on the soil pH. Generally, it was obtained that the mixtures of the amendment sources did improve the soil pH higher in the 2nd year more than their sole sources. These results agree with Nwite *et al.* (2016a) who reported that integration of mineral fertilizer with organic fertilizer or two organic sources reduces the impact of acidity, hence increasing soil pH.

Table 2 reveals that soil organic carbon was significantly ($p < 0.05$) increased in both years of study with the best significant ($p < 0.05$) increase (13.77 g/kg and 13.80 g/kg), respectively from plots amended with sole rice husk dust (RHD). This implies that rice husk dust contains very contents of carbon as an amendment which was transmitted into the soil when applied.

Total nitrogen did not vary significantly ($p < 0.05$) in the 1st year but showed significant ($p < 0.05$) variation in the 2nd year of study. The results (Table 2) indicated that the most significant ($p < 0.05$) improvement of 2.253 g/kg was obtained from PD + RHD treated plots. The study generally indicated that organically amended plots and their integrated forms including the mixture of NPK + RHD increased the soil total nitrogen higher than the sole NPK application. The results showed that all amended plots except the NPK-treated plots significantly ($p < 0.05$) improved the total nitrogen higher than the control.

Available phosphorous varied significantly ($p < 0.05$) within the two years of study due to the amendments employed. It was recorded that plots treated with NPK in the 1st year significantly ($p < 0.05$) improved the available phosphorous higher than treated plots, while in the 2nd year, PD and PD + RHD amended plots which statistically are the same in values (18.26 mg/kg and 15.87 mg/kg), respectively, increased the soil parameter higher than other treated plots including the control.

The results (Table 2) indicated that cation exchange capacity (CEC) varied statistically in both years of study. It was obtained that in the 1st and 2nd year, PD + RHD amended plots improved the soil CEC significantly ($p < 0.05$) higher (27.04 Cmol/kg and 29.18 Cmol/kg), respectively, than other amended plots including the control. Generally, all the treated plots improved the soil CEC statistically more than the control plots. This finding is in conformity with the submissions of Nwite *et al.* (2016b) and Hulugalle and Maurya (1991) who reported a higher increase in soil CEC and other soil nutrients on treated soils compared to the untreated ones.

Table 2 Effect of different soil amendment sources on fertility indices (Soil pH, organic carbon, total nitrogen, available phosphorous and cation exchange capacity)

Soil amendments	Soil pH		Soil organic carbon (g/kg)		Total nitrogen (g/kg)		Available phosphorous (Mg/kg)		Cation exchange capacity (Cmol/kg)	
	Year 1	Year 2	Year 1	Year 2	Year 1	Year 2	Year 1	Year 2	Year 1	Year2
CT	4.30	4.20	9.15	11.06	1.260	1.073	5.44	6.44	16.28	16.59
NPK	4.50	4.23	9.71	8.75	1.220	1.233	17.50	14.13	22.95	19.06
PD	4.93	5.20	11.62	11.92	1.380	2.187	9.43	18.26	20.93	28.52
RHD	4.73	5.07	13.77	13.80	1.073	2.060	8.12	10.09	21.90	27.03
NPK + RHD	4.67	5.27	9.89	10.74	1.440	2.153	8.86	11.12	24.15	20.35
PD + RHD	4.87	5.97	11.21	12.54	1.300	2.253	12.27	15.87	27.04	29.18

Effect of different soil amendment sources on cocoyam tuber weight yield (ton/ha)

The results on tuber yield (Table 3) showed that cocoyam corms were significantly ($p < 0.05$) increased higher (22.17 tons/ha) in the 1st year by plots amended with poultry dropping (PD). The results indicated that all the treated plots increased the cocoyam corms significantly higher than the untreated plots. In the 2nd year of planting, PD + RHD amended areas though statistically the same with PD, NPK and NPK + RHD treated plots significantly ($p < 0.05$) increased the cocoyam corms better than RHD and the control plots.

It was obtained that cocoyam cormels in the 1st year of study varied significantly ($p < 0.05$) with PD + RHD treated plots giving the highest (26.25 t/ha) improvement (Table 3.3). This was followed by plots treated with sole NPK and PD (21.67 t/ha and 21.25 t/ha), respectively. The results revealed that the control plots performed statistically the same as all treated plots except the combined application of poultry dropping (PD) and rice husk dust (RHD) (PD + RHD) amendment. The results also showed significant improvement in the cocoyam cormels in the 2nd year of cropping. The highest significant ($p < 0.05$) yield weight of cormels (37.9 t/ha) was obtained from PD-amended plots. The results generally revealed that except for the NPK amended plots with a value of 28.6 t/ha, all other treated plots increasingly improved the cocoyam cormels higher than the control plots. The implication of this research finding is that sole NPK fertilizer in a short-term performance increases yield with a drastic reduction in yield weight on a long-term basis. This could be attributed to the high rainfall experienced in this zone with the application of sole NPK fertilizers being accompanied by a high rate of leaching losses, increased nutrient imbalance, reduced infiltration, and high bulk density (Nwite *et al.*, 2016a). In view of this, the combined use of chemical fertilizers and organic manures (organo-mineral fertilizer) has been suggested (Egbuchua and Enujeke, 2013). It is also believed that the degradation caused in the soil by the sole application of NPK fertilizer was a true reflection in the yields of cocoyam cormels within the 2nd years of cropping, as NPK fertilizer was higher in yield performance than sole RHD and the control on the 1st year.

Table 3 Effect of different soil amendment sources on cocoyam tuber weight yield (ton/ha)

Soil amendments	Corms (ton/ha)		Cormels (ton/ha)	
	Year 1	Year 2	Year 1	Year 2
CT	8.33	18.33	16.25	19.6
NPK	16.75	30.17	21.67	28.6
PD	22.17	32.92	21.25	37.9
RHD	15.25	20.83	15.00	30.4
NPK + RHD	14.58	27.92	19.17	31.5
PD + RHD	16.67	34.17	26.25	33.0
Mean	**15.62**	**27.39**	**19.93**	**30.2**
LSD (0.05)	**5.086**	**7.697**	**6.454**	**10.28**

CT = Control; NPK = nitrogen, phosphorous, potassium; PD = poultry dropping; RHD = rice husk dust;
LSD = least significant difference.

CONCLUSION

Findings from the study showed that integrated nutrient management practices used, across the studied soil chemical properties performed better than their sole application except in the case of available phosphorous. It is therefore concluded that the complementary use of organic and inorganic fertilizers has been reported to be a better soil fertility management strategy for crop production. It was also noted that the integration of poultry dropping and rice husk dust (PD + RHD) can be a quick restoration of degraded soil and cocoyam crop yield in Southeastern Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A study was conducted to at Makera, Dutsin-Ma Local Government Area, Katsina State, located in the Sudan Savanna Zone to evaluate the effect of cattle dung and different rates of nitrogen fertilizer on growth and yield of vegetable Amaranthus cruentus (Amaranth). The experiment was carried out during the dry season of 2022. The experimental design was a Randomized Complete Block Design (RCBD) laid out in a factorial arrangement (cattle dung and rates of nitrogen), replicated three times The treatment consisted of three cattle-dung levels (0, 5 and 10 t ha^{-1}) and four levels of nitrogen fertilizer (0, 40, 80 and 120 kg N ha^{-1}).. Application of cattle dung significantly ($p<0.05$) increased number of leaves per plant, number of branches per plant, plant height, stem girth and fresh shoot yield of Amaranthus cruentus. Application of 10 t ha^{-1} cattle dung produced significantly higher ($p<0.05$) amaranth fresh shoot yield (1,0891kg ha^{-1}) compared to the other rates used (8340 and 10442 kg ha^{-1}), obtained for application of 0 and 5 t ha^{-1} cattle dung. Nitrogen application also caused significant ($p<0.05$) increases on number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield. Fertilizing the soil with 120 kg N ha^{-1} gave significantly ($p<0.05$) higher amaranth fresh shoot yield (10900kg ha^{-1}) than fresh shoot yields at 0, 40 and 80 kg N ha^{-} (650, 9655 and 1035). Conclusively, application of 10 t ha^{-1} cattle dung and 120 kg N ha^{-1} was found to give better yields on growth and yieldof vegetable amaranth in the study area.it is therefore, recommended.

***Keywords**: Cattle dung, nitrogen fertilizer, , sudan savanna*

INTRODUCTION

Amaranth (*Amaranthus cruentus*) is a very important and common leafy vegetable in Nigeria, generally because it is used in many Nigerian dishes for soup, stew, salad porridge and as garnish (Abdullahi *et al*., 2019). Amaranthus plays a very starring role in human diet as a prominent source of proteins, vitamins, minerals, sugar, fibre and water needed for healthy body growth (Bailey, 1992). Its dietary value and tolerance or plasticity, places it as a suitable vegetable to reduce micronutrient malnutrition, hence enhancing food security (Munene, 2017). Low soil fertility has been one of the major challenges facing increased crop production in Sudan Savanna Zone. It has been reported that the Nigerian savanna soils have low organic carbon, total nitrogen, available phosphorus, effective CEC and exchangeable cations together with clay and silt contents (Singh, 1987). Therefore, it becomes imperative to add soil nutrient sources such as inorganic and organic fertilizers if optimal yield is expected for any crop. Vegetable amaranth, requires a lot of soil nutrients, mainly, nitrogen for better performance and enhanced yiel (Qiang *et al*., 2014). It also reported that leafy vegetables have a great nitrogen need because of its massive vegetative volume (Ayodele, 2002). However, farmers hardly add fertilizers to their leafy vegetables, even when they do, at very low quantities. The quest for safe and healthy soil, plus the growing interest in opting for alternatives to mineral fertilizers has led to increased use of organic fertilizers such as cattle dung. Cattle dung can easily be accessed in the Sudan Savanna. Cattle dung is rich in organic matter or humus with ability to improve the capacity of soils for water and nutrients adsorption (Grubben and Denton, 2004). Also, organic manure is known to give sustenance to cropping systems through better nutrient recycling and increasing physical, chemical and biological soil properties (Ojeniyi, 2000). Therefore, this study was designed to assess the effect of cattle dung and nitrogen fertilizeron growth and yield of vegetable amaranth (*Amaranthus cruentus*).

MATERIALS AND METHODS

The trial was conducted in the dry season of 2022, at Makera in Dutsin-Ma Local Government, Katsina State. The soil of the experimental site was sandy loam with the following properties: pH (0.01M $CaCl_2$), 6.09; organic carbon, 14.65 g kg^{-1}; total nitrogen, 1.7 g kg^{-1}; available phosphorus, 4.51 mg kg^{-1}; and exchangeable cations (cmol kg^{-1}) of $Ca^{2+,}$ 2.65; Mg^{2+}, 0.46; K^+, 0.19; and Na^+, 0.26; and CEC, 4.06 cmol kg^{-1}. The chemical analysis of cattle dung showed the following properties: total nitrogen, 14.01 g kg^{-1}; available phosphorus, 6.55 mg kg^{-1}; and exchangeable K, 4.5806 cmol kg^{-1}. The treatment consisted of three different levels of cattle-dung (0, 5 and 10t ha^{-1}) and four levels of nitrogen (0, 40, 80 and 120 kg N ha^{-1}). The experimental design was A Randomized Complete Block Design (RCBD) laid out in a factorial arrangement of different rates of cattle dung and nitrogen fertilizer, and replicated three times. *Amaranthus curentus* was used.

The nursery beds were prepared manually by tilling the soil repeatedly to give a good seed bed for seed germination. Cattle dung was incorporated on the seed beds, watered and allowed for two days before the amaranth seeds were sown by broadcasting. The experimental field was harrowed and consequently watered to give fine tilths of raised beds of 2 m x 2 m in basin for regular and easy irrigation. The different rates of cow dung (0, 5and 10 t ha^{-1}) were applied at two (2) weeks before transplanting . Seedlings were transplanted at three weeks after planting at a spacing of 40 cm x 20 cm. The field was irrigated every four days. Weeds were controlled using hoe at 2 WAT. Nitrogen was applied at two weeks after transplanting. Samples were taken on number of leaves, number of branches, plant height per plant (cm) and stem girth (mm) of amaranth at 2 and 4 weeks after transplanting (WAT), while fresh shoot yield (kg/ha) of vegetable amaranth was obtained at harvest. Data collected were subjected to analysis of variance (ANOVA) as described by Gomez and Gomez, (1984) using SAS package version 9.0 (SAS institute, 2002). Significant differences among treatments were separated using Duncan's Multiple Range Test at 5 % level of probability.

RESULTS

Application of 5 t cattle dung ha^{-1} significantly ($p<0.05$) increased number of leaves per plant, number of branches per plant and plant height per plant, but statistically similar ($p<0.05$) with application of 10 t ha^{-1} on number of leaves per plant, number of branches per plant and plant height per plant (Table 1). Application of 80 kg N ha^{-1} produced a significantly higher number of leaves per plant than other N rates, but statistically similar with the application of 120 kg N ha^{-1} on number of leaves. The application of 40 kg N ha^{-1} produced a significantly higher number of branches per plant and taller plants than other N rates, but statistically similar with the application of 80 and 120 kg N ha^{-1} (Table 1).

Application of 5 t cattle dung ha^{-1} significantly ($p<0.05$) increased stem girth per plant at both 2 and 4 WAT, but was statistically similar with application of 10 t ha^{-1} (Table 2). However, the application of 120 kg N ha^{-1} produced a significantly higher stem girth than other N rates (Table 2). Application of 10 t cattle dung ha^{-1} produced significantly higher fresh shoot yield than other rates of cattle dung (Table 2). Application of 5 and 10 t cattle dung ha^{-1} produced 25.2 and 30.6% increases in fresh shoot yield of vegetable amaranth when compared with no cattle dung application, respectively. Application of 120 kg N ha^{-1} produced significantly higher fresh shoot yield than application of 40 and 80 kg N ha^{-1}. Application of 40, 80 and 120 kg N ha^{-1} produced 11.6, 19.7 and 26 % increases in fresh shoot yield of vegetable amaranth when compared with no nitrogen application.

Application cow dung 0 t ha^{-1} and of 0 kg N ha^{-1} gave the lowest stem girth per plant at both stages (Table 3).

DISCUSSION

The significant differences observed on number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth after application of cattle dung could be attributed to the decomposition and subsequent mineralization of the incorporated cattle dung to release of nutrients for use by the amaranth for growth and development. This improved performance could also be attributed to the improvement in biological, physical and chemical properties of the soil due to application of cattle dung generally attributed to increased soil organic matter and enhanced the availability of the mineralized elements. and improvements in water retention, soil aeration, soil structure, cation exchange capacity (CEC) and microbial activity (Adesoji, 2015). Eifediyi and Remison, (2010) further reported that manure has the capacity to increase water holding capacity and lessen erosion incidence thereby causing more nutrients to be available to the soil. Okoli and Nweke, (2015) also rep[orted that organic manure has the ability to increase soil organic matter, being a container of soil nutrients, that improve soil organic activities, hence, assist to release nutrients required by the crop.

The marked increases observed on number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth after nitrogen fertilization could be attributed to the important roles of nitrogen as a constituent of protein, nucleic acid and chlorophyll (Dehariya1, *et al*., 2019). These significant increases in growth attributes and fresh shoot yield of vegetable amaranth could also be linked to the vital role nitrogen plays as a component of protein and nucleic acids. (Haque *et al*., 2001) and also, as a basic constituent of many other compounds needed for processes in plant growth such as chlorophyll and many enzymes (Onasanya *et al*., 2009).

CONCLUSION

Based on the results obtained from this trial, it can be concluded that cattle dung (of 10 t ha^{-1}), application increased growth and yield attributes. 10 t ha^{-1} cattle dung ha^{-1} and 120 kg N ha^{-1} are thence, recommended for the production of vegetable amaranth in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study examined the forms and distribution of magnesium in soils of major rice producing areas Afikpo North LGA of Ebonyi state. Soil samples from identified four major rice producing clans (Afipko. Amasiri, Itim and Unwana) in Afikpo North LGA were collected in three replicates for each location at three depths (0 – 15 cm, 15 – 30 cm and 30 – 45 cm), giving a total of 12 observational units. These samples were analyzed in the laboratory using standard methods for physical and chemical properties and forms of magnesium. The experimental design wasa factorial in Randomized Complete Block Design (RCBD).Results of the physical and chemical properties of the soils showed that there was variability of these properties with respect to location and depth. Location, depth, and interaction showed significant variations (P <0.00.05). However, the texture was generally clayey loam and the soils were acidic. Afikpo had the highest amount of the different forms of magnesium, while the least values were obtained in soils of Itim. Apart from non-exchangeable and mineral magnesium forms which increased with depth, all other forms of magnesium studied decreased with depth. Afikpo soil is considered rich in magnesium compared to other rice producing locations studied. The occurrence of the high unavailable forms of magnesium in these soils shows the effect of high magnesium sorption and therefore liming to reduce acidity and cation sorption is recommended.
Keyword: *Magnesium, Status, Assessment, Rice and Afikpo*

INTRODUCTION

Magnesium is widely recognized as the eighth most abundant mineral element on the earth with an estimated crystalabundance of 2.08% (Rosanoff, 2018). It is an essential element that is necessary for most physiological and biochemical processes in plant system (Brady and Weil, 2008). It is important in the formation of chlorophyll for photosynthesis, activation of many plant enzymes needed for growth and in the regulation of opening and closing of stomata (Khalon, 2008). Apart from crop, magnesium is known to affect arrays of soil properties including pH, nutrient availability, help mitigate the effects of aluminum toxicity and increase phosphorus availability in acid soil (Wang, Mulongoy and Tabatabai, 2005) Various factors such as parent material, organic matter content, land use type, minerarological content and physical state of the soil influence the distribution and availability of magnesium to growing plants (Mikkelson, 2010).

The relationship between magnesium in soil and crops is well established and has been widely studied in scientific community (Barber, 2009). According to Chien, (2012),magnesium and other essential nutrients such as calcium are important for optimizing plant growth and yield, thus, understanding the relationship between magnesium in the soil and crops is crucial for managing soil fertility and promoting healthy growth in agriculture and horticulture.

Rice is one of the most staple foods grown largely in Afikpo North LGA of Ebonyi State and yield optimization depends among other soil factors, on the availability of magnesium. Information on the magnesium status of soils ofrice producing areas of Afikpo North LGA is still dearth. This study was therefore to bridge the

MATERIALS AND METHODS

The study was conducted in four different Villages in Afikpo North L.GA namely Afikpo, Amasiri, Uwana and Itim, all of which have 'clay shale' as their parent materials. Afikpo is located between latitude 5.51°N longitude 7.56°E, Amasiri located between latitude 5.54°N, longitude 7.54°E, Unwana located between latitude 5.51°N longitude 7.55°E and Itim located between latitude 5.47°N, longitude 7.55°E. Afikpo North LGA is found within the rainforest zone of Nigeria with avareage annual rainfall of between 2000 -2192mm. The mean temperature is between 25.86°C-35.46°C with a relative humidity of about 74%. Agriculture, especially rice and cassava production, is the main occupation of the people. Sampling sites were selected using free survey sampling techniques and soil samples were collected from each location in three replicates at 0-15 cm, 15-30 cm and 30-45 cm soil depths. These soils were analyzed in the laboratory for physical and chemical properties according to standard methods.

The various forms of magnesium including water soluble, exchangeable, non-exchangeable, fixed and mineral magnesium were determined according to the method of Jackson (1958) as described by Udo et al., 2009).

Statistical Analysis

This study was considered a 4 x 3 factorial in Randomized Complete Block Design (RCBD) in which the location and soil sampling depths were the two factors under consideration. Data obtained were subjected to analysis of variance and means separated, while correlation analysis was used to compare relationships.

RESULTS AND DISCUSSIONS

Physical and Chemical Properties of the soils of the Locations

The textural class of the soils irrespective of location and depth was clayey loam. The soils were generally acidiclow in available P, but high in most basic cations. These soils can support rice production especially when acidity iscontrolled by liming.

Magnesium forms

Solution Mg

Solution Mg concentration varied under the different locations of the studied soils and ranged from 0.14 – 0.55Cmolkg^{-1} with Unwana soils having the highest mean of solution Mg of 0.55 Cmolkg^{-1}, followed by Afikpo with 0.47 Cmolkg^{-1}, and Amasiri with 0.20 Cmolkg^{-1}, while Itim had least with 0.14 Cmolkg^{-1}. The finding is a bit similar with the finding of Obasi *et al.*, (2017), whose solution Mg ranged Means were 1.67, 1.02 and 2.58 mgkg^{-1}for the pedons 1, and 3 for Abakaliki highland, and Abakaliki lowland respectively.

Exchangeable Mg

Exchangeable Mg concentration also varied under the different locations and ranged from 0.49 –1.08 Cmolkg^{-1} with Afikpo soils having the highest exchangeable Mg mean of 1.08 Cmolkg^{-1}, followed by Amasiri with 0.67 Cmolkg^{-1}, and Unwana with 0.55 Cmolkg^{-1} while Itim had the least value of 0.55 Cmolkg^{-1}. A critical Mg value was given as 0.40 Cmolkg^{-1} (Adeoye & Agboola, 1985).

Non - Exchangeable Mg

Non-Exchangeable Mg concentration equally varied under the different locations and ranged from 0.10 – 2.26 Cmolkg^{-1} with Afikpo soils having the highest non-exchangeable Mg mean of 2.26 cmol/kg, followed by Amasiri with 1.52 Cmolkg^{-1}, and Unwana with 1.11 Cmolkg^{-1} while Itim had least, with a value of 0.10 Cmolkg^{-1}. These values are lower than those reported in the findings of Okpamen *et al* (2013), which reported values that ranged from 7.79 to 24.34 Cmolkg^{-1} (between 0 - 15 cm) in the four parent materials studied

Mean	**0.47**	**1.08**	**2.26**	**3.55**	**7.20**

Mineral Mg

Mineral Mg concentration varied under the different locations and ranged from 2.46 – 3.55 Cmolkg^{-1} with Afikpo soils having the highest Mineral Mg mean of 3.55 Cmolkg^{-1}, followed by Amasiri with 3.09 Cmolkg^{-1}, and Unwanawith 2.79 Cmolkg^{-1} while Itim had least with Mineral Mg of 2.46 Cmolkg^{-1}. This validates the findings of Osemwota*et al* (2009) who indicated that the Mg content (Cmolkg^{-1}) of the soils ranged from 2.94 to 5.04 with a mean of 3.86±0.33

Total Mg

The mean values of total magnesium varies under the different locations and ranged from 4.14 – 7.20 Cmolkg^{-1} withAfikpo soils having the highest mean of 7.20 Cmolkg^{-1}, followed by Amasiri with 5.45 Cmolkg^{-1}, and thenUnwana, with 4.51 Cmolkg^{-1} while Itim had the least with a value of 4.14 Cmolkg^{-1}. These values are a bit lower when compared with the findings of Osemwota *et al.* (2009) whose results of total Mg content (Cmolkg^{-1}) of the soils studied ranged from 7.35 to 12.60 with a mean of 9.65±0.79.

Relationship between Some Soil Chemical Properties and Forms of Magnesium

MIN. MG	0.872*	0.775	0.680	0.956*	0.713	0.335	0.919*
TOTAL MG	0.589	0.028	0.999**	0.703	-0.052	-0.492	0.533

*Correlation is significant at the 0.05% level (2-tailed),** Correlation is significant at the 0.01% level (2-tailed)

CONCLUSION

Significant variations in forms of magnesium with location and depth were observed. Soluble magnesium was relatively low in these soils below the critical value for rice production. The study therefore recommended the addition of magnesium fertilizers in addition to other fertilizers to promote profitable and sustainable rice production in these locations.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A trial was carried out to assess the effect of intra row spacing and cattle dung on productivity of vegetable amaranth (Amaranthus cruentus) in a semi-arid environment in the dry season of 2022 at Makera in Dutsin-Ma Local Government, Katsina State. The experimental design was Randomized Complete Block Design (RCBD) in a factorial arrangement of different intra row spacings and rates of cattle dung and replicated three times The treatments consisted of three intra row spacing (10, 20 and 30 cm) and four levels of cattle-dung (0, 5, 10 and 15 t ha^{-1})). Intra row spacing significantly ($p<0.05$) increased number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth. Transplanting vegetable amaranth at 10 cm spacing produced higher ($p<0.05$), fresh shoot yield of amaranth. Transplanting vegetable amaranth at spacing 10 and 20 cm produced 184.2 and 106.7 % increases in fresh shoot yield of vegetable amaranth compared with transplanting vegetable amaranth at 30 cm spacing. Application of cattle dung significantly ($p<0.05$) increased number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth. Incorporation of 10 t/ha cattle dung produced significantly ($p<0.05$) higher amaranth fresh shoot yield than that obtained with application of 0, 5 and 15 t/.ha cattle dung.. Intra row spacing and cattle dung at spacing of 10 cm and 10 t cattle dung ha^{-1} are recommended for the production of vegetable amaranth in the study area.

Keywords: *Intra row spacing, cattle dung, amaranth, semi-arid*

INTRODUCTION
Amaranth (*Amaranthus cruentus*) is a very popular leafy vegetable in Nigeria, with usage in almost every home. Generally, vegetables like amaranth are fast growing and low input requiring crops making it a good and quick source of income for poor resource farmers. However, vegetable amaranth is planted without a proper spacing (inter or intra row), with a belief that leafy vegetables find their space. Plant spacing is a prime factor in growth expression of plant. Inproper spacing limits or narrows available rhizosphere and photoshere needed for the plant to explore and exploit for growth, and invariably lessens full expression of growth characteristics, hence, hinders dry matter accumulation (Adesoji *et al*., 2020). It has been reported that maximum light interception is achievable when optimum plant space is met beginning from early growth (Rajesh *et al*., 2017). For better yield, optimal plant population must be attained for efficient photosynthesis. It has been reported by Lukman and Adesoji, (2021) that using inorganic fertilizers is a common denominator in our farming communities but these fertilizers are seldom applied at the recommended quantities, hence, low crop yields. Therefore, it is very worthwhile to use alternatives like cattle dung which is easily available in the study area. Cattle dung is good generator of organic manure and as a major factor for long term cropping in the tropics because due to slow mineralization of organic manures for enhanced crop yield (Gambo *et al*., 2008). Therefore, this experiment was conducted to evaluate the productivity of vegetable amaranth (*Amaranthus cruentus*) as influenced by intra row spacing and cattle dung in semi-arid environment.

MATERIALS AND METHODS
The experiment was carried out in the dry season of 2021/2022 dry season at Makera in Dutsin-Ma Local Government, Katsina State. The experimental soils were assessed to be sandy loam with the following properties: pH (0.01M $CaCl_2$), 6.09; organic carbon, 14.65 g kg^{-1}; total nitrogen, 1.7 g kg^{-1}; available phosphorus, 4.51 mg kg^{-1}; and exchangeable cations (cmol kg^{-1}) of Ca^{2+}, 2.65; Mg^{2+}, 0.46; K^{+}, 0.19; and Na+ , 0.26; and CEC, 4.06

cmol kg-1. The cattle dung chemical analysis revealed the following properties: total nitrogen, 14.01 g kg^{-1}; available phosphorus, 6.55 mg kg^{-1}; and exchangeable K, 4.5806cmol kg^{-1}. The experimental design was a Randomized Complete Block Design (RCBD), laid out as a factorial (intra row spacing and rates), of cattle dung and replicated three times. The treatments were made up of three intra row spacing (10, 20 and 30cm) and four rates of cattle dung (0, 5, 10 and 15t ha^{-1}). The gross plot size was 2m x 2m ($4m^2$) and net plot was 1.5m x 2m ($3m^2$). *Amaranthus curentus* was used.

Nursery beds were prepared by tilling the soil into suitable orgood seed beds for seed germination. Cattle dung was incorporated on the seed beds, watered and allowed two days before planting of amaranth seeds by broadcasting. The experimental field was harrowed and consequently watered to give fine tilth of raised beds of 2 m x 2 m in basin for irrigation. The different rates of cattle dung (0, 5, 10 and 15t ha^{-1}) were applied two (2) weeks before transplanting by broadcasting in the respective plots and mixing thoroughly into the seed beds using the small African hand-held hoe. Seedlings were transplanted at three weeks after planting at intra row spacings of 10, 20 and 30 cm and 40 cm inter row spacing. Irrigation was done every four days using. Weeds were controlled using the small African hand-held hoe at 2 WAT. Data collection were on number of leaves, number of branches, plant height per plant (cm) and stem girth (mm) of amaranth at 2 and 4 weeks after transplanting (WAT), while fresh shoot yield (kg/ha) of vegetable amaranth was collected at harvest. All data were subjected to analysis of variance (ANOVA) as described by Gomez and Gomez (1984), using SAS package version 9.0 (SAS institute, 2002). Significant differences among treatment were separated using Duncan's Multiple Range Test (Duncan, 1955) at 5 % level of probability.

RESULTS

Intra-row spacing significantly ($p<0.05$) affected number of leaves per plant at 2 WAT only, and number of branches per plant and plant height at both 2 and 4 WAT (Table 1). Transplanting amaranth at spacing the of 20 cm produced significantly ($p<0.05$) higher number of leaves, number of branches per plant and plant height than other plant spacings (10 and 20 cm), but statistically similar ($p<0.05$) with planting at 10 cm on number of leaves at 2 WAT and 30 cm on number of branches at 2 WAT. Application of cow dung was significant ($p<0.05$) on number of leaves per plant, number of branches per plant and plant height at both 2 and 4 WAT (Table 1), where application of 10 t cow dung ha^{-1} produced significantly ($p<0.05$) higher number of leaves per plant, number of branches per plant and taller plants than other rates of cattle dung.

Intra row spacing was only significant ($p<0.05$), on stem girth at 4 WAT. Spacing at 30 cm, eventhough statistically similar ($p<0.05$), transplanting at 20 cm, produced larger stem girth (Table 2). Application of cow dung was significant ($p<0.05$), on stem girth of amaranth at both 2 and 4 WAT (Table 2) where application of 10 t cow dung ha^{-1} produced significantly ($p<0.05$) larger stem girth than other rates of cattle dung. Intra row spacing was significant ($p<0.05$) on fresh shoot yield of amaranth at spacing 10 cm with higher fresh shoot yield at spaces of 20 and 30 cm (Table 2). Transplanting vegetable amaranth at 10 and 20 cm produced 184.2 and 106.7 % increases in fresh shoot yield of vegetable amaranth to 30 cm spacing. Application of 5, 10 and 15 t cow dung ha^{-1} produced 45.3, 60.3 and 57.9 % increases in fresh shoot yield of vegetable amaranth when compared with no cow dung application. Generally, intra row spacing and cattle dung 10 and 10 t cattle dung ha^{-1}, gave significantly better ($p<0.05$), fresh shoot yield of amaranth while lowest fresh shoot yield was obtained at transplanting at spacing of 10 cm plus no cattle dung (Table 3).

DISCUSSION

The significant increases observed on intra spacing for number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth could be attributed to the fact that plant spacing influences due to photosphere and rhizosphere exploitation by the plants (Ibeawuchi *et al*., 2008). Higher results at 10 cm on fresh shoot amaranth could be attributed to maximum light interception, possible when optimum plant space is made through the growth stages (Rajesh *et al*., 2017), especially for leafy vegetables like amaranth. This could also be that spacing at 10 cm enabled large plant populations which aggregately produced higher weight than those amaranth transplanted at 20 and 30 cm spacings.

The significant increases on number of leaves per plant, number of branches per plant, plant height per plant, stem girth and fresh shoot yield of vegetable amaranth after application of cattle dung could be attributed to the organic matter generated as a result of cattle dung decomposition. Adesoji, (2015) reported that this enables slow but a steady release of nutrients, increase soil microbial population and improve soil quality leading to more vigorous root establishment and nutrient absorption of mineralized nutrients for growth and development. Khan *et al*., (2017) reported that application of organic material has the ability to improve plant nutrient availability, bulk density and water holding capacity of the soil and in turn, increases vegetative growth through accelerated division of meristematic tissues and metabolic reactions for increased growth and enhanced yields. Significant increase observed on fresh shoot yield of amaranth after application of cattle dung may be attributed to the increases observed on growth parameters measured.

CONCLUSION

From the results obtained, it can be concluded that intra row spacing and cow dungincreased growth and development of amaranth, especially at 10 cm spacing. The spacing of 10 cm and application of 10 t cattle dung ha^{-1} are therefore, recommended as the most appropriate rates for the production of vegetable amaranth in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study was conducted to determine effect of sowing methods, pre-emergence herbicides and timing on growth and yield of sesame crop. The experiment was conducted at the Teaching and Research Farm, Faculty of Agriculture, Nasarawa State University, Keffi, for two consecutive cropping seasons (2021 and 2022). The experimental design was a Randomized Complete Block Design, laid out as a split plot with three replications. The treatment consisted of two different pre-emergence herbicides (Diuron at 0.8 kg a.i. ha^{-1}*and S-metolachlor at 1.5 kg a.i.* ha^{-1}*), applied at three timings, [3 days before sowing (DBS), immediately after sowing and 3 days after sowing (3 DAS)], hoe-weeding at 21 and 42 DAS and a weedy check (control) and two methods of sowing (drilling and broadcasting). The treatments consisted of a total of 24 treatment combinations. The methods of sowing was the main plots and pre-emergence herbicides, time of application, the sub-plots. The plot size was 3 m x 4 m with alleyways of 1.0 and 0.5 m between replications and plots respectively.The results indicated that sowing methods in 2021 and 2022 indicated that drilling gave the highest (*$p<0.05$*), sesame yields, and plant height, especially when sesame was grown and treated with pre-emergence herbicide application before sowing. The highest (*$p<0.05$*), weed control efficiency was achieved when pre-emergence herbicides were applied before sowing using Metolachlor 3 DBS, with drilling method giving higher (*$p<0.05$*), weed control efficiency than conventional broadcasting. Overall, this study indicated that pre-emergence herbicides applied before sowing and drilled gave higher (*$p<0.05$*), grain yield and weed control efficiency.*

Keywords: *Sowing methods, Pre-emergence herbicides, , Sesame*

INTRODUCTION

Sesame, the "queen of oilseeds", is known as *Sesamum indicum L*. Sesame is a nutrient-dense plant containing oil, protein, lime ash, crude fiber, oxalate, soluble carbohydrates and phytate. Asia is the sixth largest producer, with Africa and Latin America ranking 13th and 3rd, respectively. The largest producers include Myanmar, India and China, while the lowest producers are Mali, Bangladesh, Paraguay and Benin. According to FAO statistics (FAOSTAT, 2022; Dossa, *et al.*, 2023), these major sesame producing countries account for 92.6 % of global sesame production. Africa accounts for 25 % of the global production, with Sudan, Uganda, and Nigeria leading. Nigeria's major sesame producing states are: Benue, Nasarawa, Jigawa, Yobe, Gombe, Kano, Plateau, Katsina, and Kogi States, with Benue and Nasarawa leading (Mohammed, 2021). These states cultivate over 80,000 hectares of sesame with an annual average yield of 40,000 MT. In 2010, Nigeria exported 140,850 MT of sesame, earning a gross income of $139,000,000 (FAO 2021)

The production of sesame is challenged by both natural and man-made problems resulting in a decrease in the productivity of sesame. Key among the problems of production are presence of weeds and a lack of expertise to control (Zakar and Shamsuddeen 2020). The presence of weeds without proper weed management measures, have decreased yields by 50-75 % - especially in the initial stages of growth (Sharma*et al.,* 2021; Lins, *et al.,* 2019). Hence, it is crucial to prevent weed interference to ensure optimal productivity and profitability for sesame (Souza*et al.,* 2020). Selecting appropriate management techniques is a crucial especially at the initial stage of growth.

In the Sudan Savanna Zone of Nigeria, hoe-weeding is the conventional weed control method practiced by farmers. However, this technique is strenuous and can damage growing roots and branches. Accessibility to labor is also unreliable, leading to untimely weeding and greater yield loss. Chemical weed control has emerged as a game-changing method worldwide, as it is better suited to large-scale crop production. Not only is it labor-saving, but it also offers a more cost-effective solution to weed control. Reports have shown that herbicide usage is a more profitable method of crop production than manual hoe-weeding (Ekeleme *et al.*, 2021; Olusegun *et al.*, 2019). However, research on chemical weed control in sesame has primarily been restricted to the Southern Guinea Savanna Zone of Nigeria..

The conventional approach to weed control is no longer feasible in the commercial cultivation of sesame because of its high operational expenses, weak seedling vigour, competitiveness, and inadequacy of labor. As a result, the usage of pre-emergence herbicides has become crucial for large-scale sesame production to ensure timely and effective weed control.

MATERIALS AND METHODS

Experimental Site

Field experiment was conducted during the cropping seasons of 2021 and 2022, at the Teaching And Research Farm of Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University, Keffi. The study area falls within Southern Guinea Savanna Agro ecological zone of Nigeria (NIMET, 2016).

Treatments and Experimental Design

The experiment was conducted at the Teaching and Research Farm, Faculty of Agriculture, Nasarawa State University, Keffi, for two consecutive cropping seasons (2021 and 2022). The experimental design was a Randomized Complete Block Design, laid out as a split plot with three replications. The treatment consisted of two different pre-emergence herbicides (Diuron at 0.8 kg a.i. ha^{-1}and S-metolachlor at 1.5 kg a.i. ha^{-1}), applied at three timings, [3 days before sowing (DBS), immediately after sowing and 3 days after sowing (3 DAS)], hoe-weeding at 21 and 42 DAS and a weedy check (control) and two methods of sowing (drilling and broadcasting). The treatments consisted of a total of 24 treatment combinations. The methods of sowing was the main plots and pre-emergence herbicides, time of application, the sub-plots. The plot size was 3 m x 4 m with alleyways of 1.0 and 0.5 m between replications and plots respectively. Herbicides were applied using CP3 pressurized sprayer.

Land Preparation

The experimental field was sprayed with glyphosate as a pre-tillage herbicides to control the emerged weeds after which the weeds were burnt. The field was then ploughed, harrowed, leveled using an Afrcan hand-held hoe, and marked out 10 m x 70 m. Raised beds of 20 cm height were constructed manually, labeled and placed according to the treatment combinations on each plot.

Fertilizer application

NPK 15:15:15 was applied to each plot to at 75 kg N and 50 kg P, with the full rate of P applied by incporation before sowing. The application of N however, was done in 2 equal splits before planting as starter dose and the second applied at 6 WAS 15 cm away from stands in a continuous band.

Experimental Materials

Sesame seeds (NCRIBEN 01M) were obtained from National Cereal Research Institute, Badeggi-Niger State, Nigeria. Sesame seeds were broadcasted August, 2021 and 2022. Drilled seeds were at the rate of 3 kg/ha, at a spacing of 90 cm between the rows. Fertilizer NPK 15:15:15 and urea and herbicides (Glyphosate - Touchdown®, Diuron and S-Metalachlor – Dual Gold®) was purchased from an Agrochemical shop in Lafia.

Data Collection

Five (5) plants were randomly tagged in each net plot. Data was taken on the following parameters:

Plant height

This was taken at 6 and 9 WAS. Height was measure from the soil level to the tip of the apical bud with a graduated meter ruler (Imoloame, 2009).

Phytotoxicity rating

This was taken at 3, 6 and 9 WAS by visual observation using a scale of 1 to 9, where 1 = no crop injury and 9 = complete crop kill (Imoloame, 2009).

Weed dry matter:

This was done at 3, 6 WAS and at harvest. This was done by harvesting weed biomass by throwing three (3) quadrats (50 cm x 50 cm) in each experimental plot. The weeds were oven-dried and weighed (Imoloame, 2009).

Grain yield/ha:
This was determined after harvest and after threshing. Grain yield/plot was weighed and recorded (Imoloame, 2009

Statistical Analysis
Data were subjected to analysis of variance (ANOVA) using the General Linear Model Procedure using GENSTAT software (2008 Ed.). Significant differences were separated using Fisher's Least Significant Difference at 5 % level of probability.

Results and Discussion
Table 1: Effect of sowing methods and timing herbicide application on Sesame height at 6 and 9 WAS in 2021 and 2022 cropping seasons.
Height of sesame was significantly ($p<0.05$) influenced by method of sowing used. Across both the 6-week and 9-week after sowing (WAS) periods, plants grown through drilling grew taller than those grown through broadcasting. This trend was consistent over the two years of the trial, with the drilling method yielding the highest at 9 WAS in both years. The possible reason for this disparity is that the irregular spacing between plants using the broadcast method may lead to reduced plant population and an increase in competition with weeds for limited nutrients and water, hindering plant growth. These findings contradict those of Katanga and Buba (2014), who reported that most sowing methods had little impact on plant height, except for broadcasting, which resulted in taller plants during all sampling stages.
All of the treatments administered in the experiment resulted in tall plants compared to those hoe weeding. The mean height of the plants at 9 weeks after sowing (9 WAS) in both 2021 and 2022 showed significant differences ($p<0.05$). However, Diuron at 0 DAS and at 2 DAS at 6 WAS in 2021, as well 2 DAS and Metolachlor 2 DAS treatments at 6 WAS in 2022, produced significantly shorter plants. The Metolachlor 3 DBS, Metolachlor 2 DAS, and Metolachlor 0 DAS treatments at 9WAS in both years did not have significant effects on plant height. In 2021, the combined means of Metolachlor 6 WAS and the weedy check resulted in significantly shorter plants.
During the entirety of the sample period, the correlation between the technique of planting and the timing at which herbicides were applied did not produce any significant ($p<0.05$), on the height of the plants.

There were no significant negative effect on the sesame crop due to the sowing methods used in the experiment, even with the pre-emergence herbicides used at 3WAS, 6WAS, and 9WAS, as evidenced by Table 2 in both years of the study. However, in both years of the experiment, the pre-emergence herbicides applied had significant ($p<0.01$) phytotoxic effect on sesame, implying higher absorption herbicides at higher concentrations in sandy loam soils. This result is consistent with Imoloame *et al*., (2010) and Grichar *et al*., (2001) that diuron at 2 WAS and pendimethalin at 1.2 kg a.i./ha reduced sesame plant stands by 8 to 98 %.

The timing of pre-emergence herbicides diuron and metalochlor at 3 days before sowing (DBS) and 0 days after sowing (DAS) in both years did not result in any significant ($p<0.01$) phytotoxicity effect on esame. However, when these herbicides were applied at 2 DAS in both years, they had a highly significant phytotoxic effect on the sesame at all timings (3, 6, and 9 WAS). Among all the treatments applied in the experiment, the timing of 3 WAS in 2022 for both diuron and Metalachlor had the highest mean phytotoxicity on sesame.

The dry matter production of weeds was greatly influenced by the dates on which they were sown. During the two-year trial period, the average mean of the combined means for both drilling and broadcasting at 3 WAS showed that the drilling produced the highest weed dry matter, (8.74). This could be attributed to the high population of dormant seeds in the soil that had escaped the first dose of pre-emergence herbicide applied to both planting methods.

Table 4, results indicated that pre-emergence herbicides had a significant effect on grain yield in both years. Observations of sowing methods in 2021 and 2022 indicated that the drilling method resulted in the highest sesame yield, compared to the broadcasting method. This finding is consistent with Benard and Leap, (2012), which suggested that drilling and cover cropping have greater uniformity and faster emergence, leading to a higher yield and a better ability to suppress weeds. This also agrees with UIES, (2005), that broadcasted seeds generally produce lower yields than drill-seeded crops. A thinner stand can be attributed to poor seed-to-soil contact, deeply covered, and more competitive weeds.

Sesame yield was higher ($p<0.05$), when treated with Metolachlor at 3 DBS, followed by Diuron at 3 DBS. Metolachlor at 3 DBS produced the highest yield ($p<0.05$), and Diuron at 2 DAS respectively produced the highest yield. The low phytotoxicity of Metolachlor at 3 DBS and its efficacy in weed control throughout the season prevented competition for growth resources, leading to better growth and higher yield.

The application of Diuron at 3 DBS has demonstrated the capacity to generate a high yield. This can be attributed to the low phytotoxicity of this herbicide on the crop at 9 weeks after sowing (WAS), in addition to its ability to effectively suppress both weeds hence, dry matter during the entire season. As a result, this prevents weed competition and enables the crop to access more growth resources, leading to a significant increase in yield.

The herbicides previously mentioned exhibited noticeably greater yields at their designated rates. This could be attributed to their minimal or non-existent phytotoxicity to sesame, as well as their efficacy in targeting weeds. This allowed for optimal absorption of nutrients and moisture, resulting in improved growth and a higher yield. These results are consistent with the discoveries made by Grichar et al. (2001), who observed that the use of 3.36 kg a.i./ha metolachlor resulted in an 80% increase in yield compared to the untreated control.

CONCLUSION

From this research, it can be recommended that adopting the drilling method in combination with pre-emergence herbicide application before sowing gave better weed control efficiency using Metolachlor 3 DBS, Overall, this study suggests that pre-emergence herbicides should be applied before sowing when sesame crop is grown using drilling method for higher grain yield and weed control efficiency.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An experiment was carried out to determine the effect of cow manure on growth and yield of sesame varieties (Sesamum indicum L.*) at the Teaching and Research Farm, Faculty of Agriculture, Shabu–Lafia Campus, Nasarawa State University, Keffi-Nasarawa State, during the 2018 and 2019 cropping seasons. The experimental design was a Randomized Complete Block Design, laid out as a factorial consisting of six varieties (NCRIBEN 01M, NCRIBEN02M, NCRIBEN 03M, NCRIBEN 04E, NCRIBEN 05E and E-8) and four level of cow manure (0,5,10 and 15 t/ha). Data was collected on selected growth parameters (plant height, number of branches and number of leaves). The results showed that varieties differed significantly across all parameters. The application of 15 kgha^{-1} of cow manure gave significantly taller ($p<0.05$), plants, higher number of leaves and number of branches. Flowering was significantly ($p<0.05$), delayed in the control study. Also, it was observed that the use of variety E-8 in combination with application of 15 kgha^{-1} of cow manure gave higher growth and yield and is recommended for production of sesame Nasarawa State*.
Keywords: Cow manure; *Sesamum indicum L.*

INTRODUCTION
Sesame *(Sesamum indicum* L.*)* is an oil crop belonging to the family Pedaliaceae. Is an important crop to Nigerian agriculture because of its extensive cultivation. It is grown in tropical and subtropical regions of Africa, Asia, Latin America, India. Sesame oil is reputed to be the king of all vegetable oils, (Shahab-U-Din *et al.*, 2015; Nigerian Export Promotion Council -NEPC, 2010). The major producing States in Nigeria are Nasarawa, Jigawa, Benue, Yobe, Kano, Katsina, Gombe, Taraba and Adamawa. World production in 2020 was 6.01600 MT grown worldwide on 11.743,000 ha with an average yield of 512 kg ha^{-1} , with Asia and Africa producing nearly 97 % of the world supply of sesame, (Food and Agriculture Organization Statistical Database FAOSTAT, 2020).

Naturland, (2002) identified some local varieties cultivated within the tropics and subtropics as the black, white, brown colour and KS-S6.

Organic materials are major sources of organic matter and plant nutrients including cow manure. Their application into soil are reputed to improve soil physical attributes (soil structure, soil aggregate stability, water holding capacity, drainage, aeration, root penetration) and chemical attributes (nutrients content and composition and pH). The application of organic manure would most likely improve growth, yields and seed quality (Craswell *et al., (*2002). Duhoon *et al., (*2015), reports that where chemical fertilizers are available, excessive usage may increase pollution, decrease soil productivity and lead to nutrient imbalance.

The continuous cultivation, coupled up with increased population and industrial development, cultivable lands are becoming small for production leading to losses in fertility. The cost of inorganic fertilizer which many households may not afford. Cow manure is commonly available and affordable. This study therefore seeks to assess the growth and yield of sesame varieties under varying cow manure rates.

MATERIALS AND METHOD
Experimental Site
An experiment was carried out to determine the effect of cow manure on growth and yield of sesame varieties (Sesamum indicum L.) at the Teaching and Research Farm, Faculty of Agriculture, Shabu–Lafia Campus, Nasarawa State University, Keffi-Nasarawa State, during the 2018 and 2019 cropping seasons. The

experimental design was a Randomized Complete Block Design, laid out as a factorial consisting of six varieties (NCRIBEN 01M, NCRIBEN02M, NCRIBEN 03M, NCRIBEN 04E, NCRIBEN 05E and E-8) and four level of cow manure (0,5,10 and 15 t/ha). Data was collected on selected growth parameters (plant height, number of branches and number of leaves). The gross plot size was 3 m x 3 m (9 m^2) and net plot size was 3 m x 1.5 m (4.5 m^2)

Land preparations and manure incorporation.

The field was cleared, and pegged to layout. Ridges were constructed manually at 75 cm between rows. A 1 m gap was left as alleyways between plots, while 1 m was maintained between replicates. The four levels of cow manure were applied by opening the top ridge and covering up and allowed to decomposed two weeks before seed sowing.

Sowing

A pinch of sesame seed was sown at 10 cm spacing on ridges and covered thinly with soil and later thinned to three plants per stand at 3 weeks after sowing (WAS).

Crop protection/weed control

Hoe weeding was carried out at 3, 6 and 9 WAS to reduce competition for nutrients.

Harvesting,

The crop was due for harvest when the leaves and stem turned yellowish. The mature plants were cut at the base using sickles and allowed to dry. The sacks in which harvested plants were put at harvest were gently beaten with sticks to ensure pod breakage and seed removal from capsules. Winnowing was done to separate good seeds from chaff.

Data Collection

The randomly tagged plants in each plot were used for data collection during the growth and assessment at 4, 6, 8, 10 and 12 WAS were assessed at harvest and post-harvest.

Plant Height (cm)

The height of the three tagged plants in each plot were measured from ground level to growing tip of the main stem using meter-rule and means recorded.

Number of Branches

The number of branches were counted from the three tagged plant and means recorded.

Number of Leaves per Plant

The number of leaves per plant were counted from the tagged plants and means recorded.

Statistical Analysis

Data was subjected to ANOVA using F-test to determine significance of treatments (Snedecor and Cochran, 1967). Means were separated using Duncan Multiple Range Test (DMRT) at 0.05 level of significance. SAS was used for analysis.

RESULTS AND DISCUSSION

Effects of Cow Manure and Variety on Plant Height of Sesame Plant

At 4 and 12 WAP in 2018, application of 10 to 15 kg cm/ha $^{-1}$ did not influence growth parameters, ($p<0.05$), but was significantly higher ($p<0.05$), at 5 kg cm/ha $^{-1}$, while in 2019, at 4 WAP there is no significant difference on plant height among the treatments (Table 1). In both years, at 6, 8, 10 and 12 WAP in 2019, each increase in application rate of cow manure significantly increased ($p<0.05$), height of sesame. Similarly, at 4 WAP, in both years NCRIBE04E variety produced significantly higher ($p<0.05$), plant height as compared to other varieties. In both years, at 6 and 8 WAP NCRIBEN 05E produced significantly higher ($p<0.05$), plant than other varieties. At 10 and 12 WAP, in 2018 and 2019 cropping seasons, E-8 recorded significantly higher ($p<0.05$), plant height than other varieties in this study.

Table 1: Effect of Cow Manure and Variety on the Plant Height of Sesame at 4, 6, 8, 10 and 12 WAS in Lafia during the 2018 and 2019 Cropping Seasons.

Means of the same letter(s) within the same treatment group are statistically the same

There were significant ($p<0.05$), interactions were observed between cow manure and variety on plant height at 12 WAS in both years (Table 2). E-8 variety produced the tallest ($p<0.05$), plant height at 15 kg/ha of cow manure.

Effects of Cow Manure and Variety on the Number of Branches of Sesame

The results obtained showed that treatments significantly affected ($p<0.05$), number of branches among (Table 3). In 2018 at 4 WAP, application of cow manure. At 6 WAP in 2018, at 4, 8, 10 and 12 WAP in 2019, each increase in the rate of cow manure applied significantly increased ($p<0.05$), the number of branches, while In 2018, at 8, 10 and 12 WAP, 10 kg /ha and 15 kg /ha of cow manure gave statistically similar ($p<0.05$), number of branches. Similarly, at all sampling periods, in both years, E-8 variety produced significantly higher number of branches than other varieties. There were significant interactions between cow manure and variety on number of branches at 12 WAS in both years (Table 4). The E-8 variety produced the highest number of branches at the application of 15kg/ha of cow manure than other varieties.

The result showed that number of leaves among treatment was significantly different ($p<0.05$), (Table 5). In 2018 and 2019, at 10 and 12 WAP, each increase in the rate of applied cow manure significantly increased number of leaves. Similarly, at 4 WAP in both years, NCRIBEN 04 E variety produced significantly higher ($p<0.05$), number of leaves compared to other varieties, while at 6 WAP in both years variety NCRIBEN 03M produced significantly higher($p<0.05$), number of leaves compared to other varieties. Also, at 8 WAP in both cropping seasons NCRIBEN 04E, NCRIBEN 05 E and E8 recorded significantly higher ($p<0.05$), number of leaves. There were significant interactions ($p<0.05$), between cow manure and variety on number of leaves at 12 WAS in both years (Table 6). The E-8 variety produced the highest number of leaves at 15kg/ha of cow manure.

From the results obtained, the variations in growth and yield of sesame at 15 kg/ha^{-1} of cow manure. This could be attributed to the ability of manure to supply nutrient gradually, but steadily to support crop which growth and hence, high yield (Aliyu, 2003; Annon, 2007). The higher plant high ,number of branches, and number of leaves of sesame than the control supported collaborates Ashri, (2007), Elnaim *et al.*, (2010) and Tefera (2016), especially as observed in E-8 variety. Kolo and Duniya (2006) also reported that E-8 variety significantly outperforms other varieties. Haruna *et al.* (2011) also reported that sesame variety E-8 will produce higher plant height, number of branches and number of leaves.

CONCLUSION

From the results of this study, it can be concluded that both growth and of sesame were better following the application of 15 kg ha^{-1}of cow manure with variety E-8 out-performing all other varieties. Using cow manure at 15 kg/ha^{-1} with E-8 variety of sesame are therefore, recommended for higher yields.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
A field experiment was conducted during 2016 and 2017 wet seasons at the experimental farm of National Root Crops Research Institute, Umudike, under the Potato Program, Kuru and at Teaching and Experimental Farm of Plateau State University, Bokkos-Jos Plateau Stae. The experiment studied growth and yield of potato (Solanum tuberosum L.) varieties as influenced by intra–row spacing and potassium fertilizer in the Northern Guinea Savanna Zone, Nigeria. The experimental design was a Randomized Complete Block Design, laid out as a split plot and replicated three times The treatments consisted of three; potato varieties (Zafira, Caruso and Connect), intra–row spacings (20, 30 and 40 cm) and potassium (K) rates (0, 40 and 60 kg k_2O ha^{-1}). Potassium and intra-row spacing were the main plots, while variety was the sub plots. The result revealed that application of 60 kg K_2O ha^{-1} enhanced ($p<0.05$), crop growth and yield parameters measured. Results also showed that variety Connect, gave better growth ($p<0.05$), in terms of number of branches and total tuber yield. At Bokkos, number of branches had highest ($p<0.05$), value at 40 cm intra–row spacing, while at Kuru, 30 cm intra - row spacing gave higher ($p<0.05$), number of branches and total tuber yield. Number of branches and total tuber yield over all, was highest ha^{-1} ($p<0.05$), at 60 kg k_2O ha^{-1}.with Connects planted at 40cm intra–row spacing at both locations. Therefore, Connect is recommended for the Northern Guinea Savana of Nigeria at 40 cm spacing.
Keywords: *Pottassium Fertilizer, Intra-row Spacing,*

INTRODUCTION
Potato (*Solanum tuberosum* L.) belongs to the family *Solanaceae.* The word potato may refer either to the plant itself or the edible tuber (FAO, 2021). Plant nutrition is important especially on the Jos Plateau, where continuous cropping and mining has greatly depleted the soil of the major nutrients (N, P and K), (Okonkwo *et al.*, 1995). Potato requires a deep well–drained sandy or silt loam soils with a soil pH between 5.5 to 6.5 and low temperatures (15–20^0). The ideal soil temperature for planting is 13–16^0C and 21°C for growth (AHDB, 2015). The problem of spacing is common on farmers field, therefore, resulting in fewer stands per unit area or overcrowding resulting in competition and subsequently, poor yields. Low potato yields from farmers' fields on the Jos Plateau is attrubuted to inability of farmers to adequately provide essential production inputs most especially the inorganic fertilizer, which are scarce, costly and beyond the reach of resource-poor farmer and are sometimes adulterated. It is therefore, the objectives are therefore, to determine growth and yield of potato varieties in response to intra–row spacing and rates of potassium fertilizer on the Jos Plateau. Okonkwo *et al*. (1995), reported that 30 cm intra-row spacing is the recommended intra-row spacing for rain fed potato production. Although generally, farmers use wider spacings of 50–60 cm and in most cases, grow the crop as an intercrop with maize. Therefore, it has become imperative to come up with recommendations for intra-row spacing that will enhance potato growth, development and tuber yield per unit area..

MATERIALS AND METHODS
Field experiment was carried out during the wet seasons of 2016 and repeated in 2017 at Kuru, with an annual rainfall of 1400 mm and at Plateau State University Farm, Bokkos with annual rainfall of 1386 mm in the Northern Guinea Savanna Zone-Nigeria. Ten soil samples within the experimental sites were randomly collected in both years at a depth of 0–30 cm using soil auger. The soil samples were bulked into composite sample, air dried, ground into powder and sieved using 2 mm mesh sieve and analyzed for physical and chemical properties.

The experiment studied growth and yield of potato (Solanum tuberosum L.) varieties as influenced by intra–row spacing and potassium fertilizer in the Northern Guinea Savanna Zone, Nigeria. The experimental design was a Randomized Complete Block Design, laid out as a split plot and replicated three times The treatments consisted of three; potato varieties (Zafira, Caruso and Connect), intra–row spacings (20, 30 and 40 cm) and potassium (K) rates (0, 40 and 60 kg k_2O ha^{-1}). Potassium and intra-row spacing were the main plots, while variety was the sub plots. The result revealed that application of 60 kg K_2O ha^{-1} enhanced ($p<0.05$), crop growth and yield parameters measured. Chemical weed control was done at planting using two pre-emergence herbicides (Alachlor at 1.92 kg a.i ha^{-1} and Atrazine powder), at the rate of 4 kg a.i ha^{-1} using CP-15 Knapsack sprayer at a pressure of 2.1 kg cm^2 and by manual hoe weeding at 4 and 8 weeks after planting (WAP). Earthen–up was done at 9 WAP. Pest and diseases were controlled by application of Ridomil at the rate of 2.5g and F–FORCE (mancozeb 2.0 g a.iha^{-1}), applied bi-weekly beginning at 2 WAP, done to prevent fungal disease attack. Bacterial wilt (*Rhalstonia Solanecearum* L.) was controlled by rogueing from 3 WAP to harvest. Potato tuber moth and rodents were controlled using Pestox 2.0g a.i ha^{-1} and rodenticide (Phostocin) 1.0g/ per plot respectively, at 4 WAP. Harvesting was done at 12 WAP when 95 % of the leaves turned yellow and senescence bagan, indicating maturity. Harvesting was done carefully by lifting out tubers with garden fork. Thereafter the tubers were hand-picked and weighed immediately using a portable weighing balance of 120 kg capacity. The weight in kg was recorded and later on converted to t ha^{-1}. All data were subjected to analysis of variance (ANOVA), using a General Linear Model in statistical Analysis System (SAS), package. significant means were separated using Duncan's Multiple Range Test, (DMRT) (Duncan 1955) at 5 % level of probability.

RESULTS AND DISCUSSION

Table 1 shows effects of intra-row spacing and potassium fertilizer on number of branches of potato varieties at 9 WAP at Bokkos and Kuru during 2016 and 2017 cropping seasons. At both locations, in both years variety Connect produced higher number ($p<0.05$), branches than the other two varieties, while Zafira in 2017 at kuru, produced the lesser ($p<0.05$), robust plants. This could be attributed to varietal response to environmental factors and treatments. Connect variety was most likely more responsive than other varieties. This is line with the report of Abong *et al.* (2010) who reported that, potato varieties responded significantly to intra-row spacing and fertilizer application through number of branches. The superiority of varieties Connects and Caruso over Zafira in terms of plant height implied better morphological differences which resulted in faster growth. At Bokkos, in 2016, 2017 and at Kuru in 2016, height of potato at 20 and 30 cm intra–row spacing were statistically similar ($p<0.05$), and taller than for 40 cm intra–row spacing. In 2017, at Kuru, 30 and 40cm intra-row spacing were also similar ($p<0.05$), and taller than 20 cm intra–row spacing. At Bokkos and Kuru, in 2016, increasing K rates from 0 to 40 and later to 60 kg K ha^{-1}. correspondingly increased plant height ($p<0.05$), while in 2017 at Kuru, height for 0 and 40 kg K ha^{-1}were statistically similar ($p<0.05$), and shorter than 60 kg K ha^{-1}. A similar trend was observed at Bokkos, in 2017, with potato heights in plots with 40 and 60 kg K ha^{-1} were statistically been similar ($p<0.05$), and taller than for 0 kg K ha^{-1}.

Table 2 shows effects of intra-row spacing and potassium fertilizer on total tuber yield of three potato varieties during the 2016 and 2017 wet seasons at Bokkos and Kuru. In 2016, at Bokkos Connect produced the highest ($p<0.05$), total tuber yield followed by Caruso, while Zafira had the least total tuber yield t ha^{-1}. However, in 2017 at Kuru, Zafira and Caruso were statistically similar ($p<0.05$), but lower in total tuber yield t ha^{-1} than Connect. Increasing intra-row spacing from 20 to 30 cm and further to 40 cm at both locations correspondingly increased total tuber yield ha^{-1}. Except in 2017 at Bokkos and Kuru, increasing K rates from 0 to 40 cm to 60 kg K_2O ha^{-1} correspondingly increased total tuber yield, but in 2017, at both locations, 40 and 60 kg K had similar ($p<0.05$), tuber yield ha^{-1} but higher than 0 kg K_2O ha^{-1}. Only the interaction of K fertilizer rates and variety on total tuber yield t ha^{-1} in 2016 at Bokkos and Kuru was significant ($p<0.05$). Larger LAI values were observed to result in greater assimilate production and hence, higher DM production and accumulation and subsequently total tuber yield.

CONCLUSION

Based on the findings of this study, variety Connect is recommended for cultivation in the study locations based on its consistencies in terms of crop growth and yield. The use of 30 cm intra-raw spacing for potato production for Zafira and Caruso recommended as ideal for the two locations while 40 cm intra–raw spacing recommended for Connect. Application of 60 kg K_2O ha^{-1}

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
An assessment of the heavy metal content in scent leaf (O. gratissimum) sold in Warri market, Delta State was evaluated in Abraka, Delta State Nigeria. However, when the scent leaves containing heavy metals were compared with the control (Abraka markets) where there are no oil activities, significant increases were observed in the values obtained for scent leaves in the two markets for all the metals recorded viz: Pb, Cr, Zn, Mn, Cd and Fe. Although, the results fall within allowable values given by FAO/WHO, the metal values could constitute health risks to the people who consume them as they bio accumulate with time. Potential health hazard is eminent to consumers because of their non-biodegradability. It is recommended that a close monitoring of vegetables sold in Warri area should be carried out for heavy metal accumulation to avoid danger posed by them on plants, man and animals. Hence, environmental education at all levels is highly recommended.
Keywords: *Assessment, metal content, Ocimum gratissimum, Warri, Delta State.*

INTRODUCTION
Occimum gratissimum (Scent leaf, Clove basil or African Basil) (Family Lamiaceae, mint family) is one of the most commonly consumed leafy vegetables in Nigeria. This vegetable was said to have originated from India where it was first used as vegetables and medicine. It is a shrub found in the tropical and warm temperate areas. The leaves act as food additives, spice, highly nutritive and medicinal values because of the high aromatic and antioxidant content (Agogidi *et al*., 2014). It is used for the treatment of various diseases including respiratory tract infections, headaches, skin infections, pneumonia, tooth and gum, diarrhoea, fever as repellants for mosquitoes and other insects (Gill, 1992). It is an aromatic perennial herb characterized with much branching, glabrous or pubescent. It can be cultivated or in the wild with many varieties. It is rich in alkaloids, tannins, phytates, oligosaccharides and flavonoids. Other phytochemicals found in scent leaves include phenols, carotenoids, saponnines and minerals including potassium, calcium, iron and magnesium (Gill, 1992). Kurian (2010) noted that the oil from the leaves is antiseptic, antibacterial and antifungal in activity.

Leafy vegetables play important role in animals and human diets but can habour high metal contents based on where they are grown (Agbogidi, 2013; Agbogidi *et al*., 2013). Agbogidi (2013) established that heavy metals at low concentrations play essential roles in the body but at high concentrations, present health risk factors. Man's anthropogenic factors including oil exploration and exploitation activities have resulted in pollution of different types and magnitudes affecting man and his animals (Agbogidi and Eruotor, 2012). It is against this background that a study to assess the heavy metal contents of *O. gratissimum* sold in selected markets in Warri, the hub of oil industrial activities in Delta State in the Niger Delta region of Nigeria. Findings from this study will provide information on the metal status and types in *O. gratissimum* sold in Warri markets, assess the health risks as well as providing baseline information on the populace and compare their levels to Abraka where there are no oil activities to allow for adequate monitoring of metal contents on vegetables in the study area.

MATERIALS
Bitter leaves
Hydrochloric acid
Beakers
Distilled water
Filter paper

Metals e.g. Cd, Cr, Fe, Pb, Mn and Zn
Atomic Absorption Spectrophotometer

METHODS

Study location

The study was carried out in Abraka, Delta State, Nigeria. The study location is located between latitude 5° 45′ and 5° 5 0′ N and longitude 6° and 6° 15′ E. This area is defined by total annual rainfall of about 3.098mm with mean monthly rainfall ranging from 28.8mm. The soil temperature in this area is about 28^0C and soil pH ranging from 4.5-8. (Achuba and Ja-anni, 2018).

Sample collection

The scent leaves were purchased from two markets in Warri (Igbudu Main Market) and Abraka (Big Market).

Sample preparation

10g of the grounded powder samples were weighed and transferred into a labelled beaker and then 30ml of concentrated hydrochloric acid was added and left to stand for 30mins after which it was filtered. The filtrate was diluted with distilled water. The wet digested samples were analysed for heavy metals (Cd, Cr, Fe, Pb, Mn and Zn) using atomic Absorption Spectrophotometer following AOAC (2009).

Statistical analysis

Means and standard deviations of samples were calculated. One way analysis of variance (ANOVA) was conducted to determine the significant difference and the means were separated using Duncan's Multiple Range Test (DMRT) at P <0.05 using SAS (1996).

RESULTS AND DISCUSSIONS

Table 1 presents the results of the heavy metal analysis in *O. gratissimum* from Warri and Abraka markets relative to FAO/WHO allowable levels.

Table 1: Heavy metal content in scent leaf (mg/kg) sold in Abraka and Warri markets, Delta State, Nigeria.

Heavy metal profile (mg/kg)	Abraka market	Igbudu market, Warri	Warri main market	FAO/WHO levels
Lead (Pb)	0.01^b	0.03^a	0.04^a	0.3
Chromium (Cr)	0.07^b	0.10^a	0.15^a	2.3
Zinc (Zn)	0.06^a	0.09^a	0.10^a	99.4
Manganese (Mn)	0.05^c	0.07^b	1.09^a	500
Cadmium (Cd)	0.03^c	0.05^b	0.10^a	0.2
Iron (Fe)	0.06^b	0.10^a	0.13^a	425.5

*Means with same alphabet within same column (metal) are not significantly different using DMRT

From the Table1 above, when the scent leaves containing heavy metals were compared with the control (Abraka markets) where there are no oil activities, significant increases were observed in the values obtained for scent leaves in the two markets for all the metals recorded viz: Pb, Cr, Zn, Mn, Cd and Fe. The observed values obtained for the vegetable sold in Warri markets could be attributed to incidence of exploration and exploitation activities prevalent in Warri communities where the vegetable could have been grown. In same vein, Olusola *et al.* (2021) noted a buildup of heavy metals in the herbal plants sold in major urban markets in southwestern, Nigeria. Although, the results fall within allowable values given by FAO/WHO (2011), the metal values could constitute health risk to the people who consume them as they bio accumulate with time. Potential health hazard is eminent to consumers because of their non-biodegradability (Agbogidi and Enujeke, 2011). Metal toxicity could result in cardiac, neurological, immunological, reproductive and developmental issues among others

It is recommended that a close monitoring of vegetables sold in Warri area for heavy metal accumulation be carried out to avoid danger posed by them on plants, man and his animals. Hence, environmental education at all levels is highly recommended.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Antioxidant activity of Balanites aegyptiaca in wistar rats exposed to chlorpyrifos was investigated in this study. About 1000 g of the powdered leaves of B. aegyptiaca was used for the extraction and methanol was the extraction medium while cold maceration was employed. Thirty wistar rats were randomly divided into six groups of five rats each. Rats in group I were neither treated nor exposed to chlorpyrifos. Rats in groups II to VI were exposed to chlorpyrifos at 2 mg/kg daily for seven days. Rats in groups; II, III and IV were treated with the extract at doses: 100, 300 and 500 mg/kg respectively. Rats in group V were treated with ascorbic acid (150 mg/kg). Rats in group VI were administered normal saline. All treatments were through oral route and were for 7 consecutive days. Seven days after, all rats were humanely euthanized by severing their jugular vein, and 5 ml of blood sample was collected from each rat and transferred into plain container devoid of anticoagulant for serum chemistry and antioxidant assay. There was significant ($p < 0.05$) increase in the mean values of liver enzymes; alanine amino transferase (ALT), aspartate amino transferase (AST) and alkaline phosphatase (ALP) in rats exposed to chlorpyrifos and treated with normal saline vis-à-vis other groups. Similarly, a significant ($p < 0.05$) reduction in the mean values of liver enzymes was recorded in rats treated with ascorbic acid vis-à-vis those treated with 500 mg/kg of crude methanol extract. A significant ($p < 0.05$) increase in the serum level of antioxidants enzymes; superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) were recorded in rats treated with B. aegyptiaca extract and ascorbic acid when compared to group VI. A significant ($p < 0.05$) increase in the mean values of antioxidants enzymes were recorded in group III, IV and V when compared to group II. In this study, methanol leaves extract of B. aegyptiaca largely exhibited ameliorative effect on the impact of chlorpyrifos.

INTRODUCTION
Plants still remains the primary source of supply of many important drugs and minerals in the orthodox medicine today. Plants are being exploited for their active compound which is responsible for their biological function (Clark, 1996). *Balanites aegyptiaca* is commonly known as the Desert date, '*Aduwa*' in Hausa, '*enyi-ndi- mmuo*' in Igbo, and '*Tanni*' in Fulani (Ugwah *et al.*, 2016). It is a desert plant that is widely distributed in the arid zone of Nigeria. It is also found in other African countries like Senegal and Sudan, as well as in India (Chothani and Vaghasiya, 2011; Pandey *et al*., 2012). In Nigeria and Asia, it was reported to be used in a variety of folk medicines (Ugwah *et al.,* 2016).

Chlorpyrifos pesticide was reported in 1070s to have immunotoxic (Beckmen *et al*. 2003). Additionally, Beckmen *et al*. (2003) observed thymic atrophy and reductions in splenic germinal centers in rabbits following exposure to 1.5 mg/kg/day of chlorpyrifos. A number of organophosphate pesticides including chlorpyrifos, malathion, methylparathion and trichlorphon have shown immunotoxic properties (Casale *et al*., 1983) and suppression of primary humoral immune responses in laboratory studies. Noting the toxicity and efficacy of Chlorpyrifos; we embarked on this study to determine how the toxicity can be ameliorated.

MATERIALS AND METHODS
Study Location
The research was conducted in the Department of Animal Health and Production, Binyaminu Usman Polytechnic, Hadejia, Jigawa State, Nigeria.

Plant Collection and Identification

Fresh leaves of *B. egyptiaca* was collected around the main campus of Binyaminu Usman Polytechnic, Hadejia, Jigawa State. The plant was identified at the herbarium of the Department of Plant Biology, Bayero University Kano, Nigeria, with voucher number BUKHAN 359.

Extraction of the Plant Material

About 1000 g of the powdered leaves of *B. egyptiaca* was used for extraction and methanol was employed as the extraction medium and the technique deployed was cold maceration, using a 1-litre capacity separating funnel at room temperature for 48 hours. The initial extraction was done with 1.5 litre of methanol and the process was repeated twice using 750 litres of methanol in each extraction. The extracts obtained during the 3 phases of extraction were pooled together and concentrated under reduced pressure at 55 ºC, and then stored in a vacuum desiccator. Stock solution of the extract at concentration of 1 g/mL was prepared and stored at 4 ºC for pharmacological test.

Experimental Animals

Thirty wistar rats of either sex weighing between 200 and 220 grams were used. They were purchased from the Animal House, Department of Pharmacology and Toxicology, Faculty of Pharmaceutical Sciences, Bayero University Kano. The rats were housed in locally constructed cages at room temperature. Wood shavings were used as beddings in the cages and changed once every day. The rats were allowed free access to feed (commercially prepared) and water *ad-libitum*.

Experimental Treatments

Thirty wistar rats were randomly divided into six groups of five rats each. Rats in groups two to six were exposed to chlorpyrifos (2 mg/kg) daily and then treated as follows:

Group I - The rats in this group were neither exposed nor treated, therefore served as neutral control group.
Group II - Rats in this group received 100 mg/kg of *B. egyptiaca per os* for 7 days.
Group III - Rats in this group received 300 mg/kg of *B. egyptiaca per os* for 7 days.
Group IV - Rats in this group received 500 mg/kg of *B. egyptiaca per os* for 7 days.
Group V - Rats in this group received 150 mg/kg of Ascorbic acid *per os* for 7 days.
Group VI - Rats in this group received 5 mL/kg of normal saline *per os* for 7 days.

Serum Level of Liver Enzymes

Serum level of alanine amino transferase (ALT), aspartate amino trasferase (AST) and alkaline phosphatase (ALP) were determined using chemical auto-analyzer (Bayer® Clinical Chemistry Analyzer, Germany).

Antioxidant Enzymes

Determination of serum glutathione peroxidase (GPx) specific activity

Modified method of Paglia and Valentine (1967) was used to determine glutathione peroxidase (GPx) activity spectrophotometrically.

Determination of serum superoxide dismutase (SOD) specific activity

The specific activity of SOD was measured using the method described by Misra and Fridovich (1972) as modified by Sheridan-Rabideau (2001).

Determination of serum catalase (CAT) activity

The specific activity of catalase in the serum collected from each rat was determined using method described by Beers and Sizer (1952).

Statistical Analysis

The statistical analysis was carried out using SPSS software package, version 20. The results obtained are presented as mean ± standard deviation (M±SEM). A one-way analysis of variance (ANOVA) was used for the data analysis. Means with significant differences among the groups were detected using Bonferroni test at ($p \leq 0.05$).

RESULTS AND DISCUSSION

Liver enzymes (AST, ALT and ALP) reduced significantly ($p < 0.05$) in rats treated with crude methanolic leaf extracts of *B. aegyptiaca* in dose dependent manner. There was significant ($p < 0.05$) increase in the mean values of liver enzymes in rats exposed to chlorpyrifos and treated with normal saline when compared to the other groups. Similarly, a significant ($p < 0.05$) reduction in the mean values of liver enzymes was recorded in rats treated with ascorbic acid when compared to rats treated with 500 mg/kg of the crude methanolic leaf extracts of *B. aegyptiaca*. Awobode (2006), reported that liver enzymes were found in the serum and the level of their activity can be determined, and that depression or elevation of a particular enzyme indicates the presence of damage to specific tissue or organ. The elevated serum levels of AST and ALT may be attributed to hepatocellular damage as reported by Kobo (2012) and Gowda *et al*. (2005).

Table 2: Mean±SEM of serum biomarkers of oxidative stress in wistar rats exposed to chlorpyrifos and treated with crude methanolic leaf extract of *B. aegyptiaca*

	Treatment					
Test	**Neutral control**	***B. aegyptiaca* (100 mg/kg)**	***B. aegyptiaca* (300 mg/kg)**	***B. aegyptiaca* (500 mg/kg)**	**Ascorbic acid (150 mg/kg)**	**Chlorpyrifos (5 ml/kg)**
SOD (μg/ml)	66.67±4.30	48.33±3.44	71.17±4.62	75.83±4.94	75.31±3.99	46.67±3.21
CAT(μg/ml)	72.67±3.47	46.50±3.09	73.50±6.29	75.33±2.36	77.17±3.79	48.33±3.98
GPx(μg/ml)	32.33±1.36	24.15±1.48	30.00±2.99	30.33±1.15	33.50±1.80	24.67±1.54

Superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GPx) are enzymatic antioxidants that mop-up free radicals. A significant ($p < 0.05$) increase in the serum level of specific antioxidant enzymes were recorded in rats treated with *B. aegyptiaca* and ascorbic acid when compared to rats exposed to chlorpyrifos and those treated with normal saline. This could be due to the presence of flavonoids, saponins and alkaloids present in the plant and the finding of this research agrees with the report of Mandal *et al* (2007) in rats subjected to chemically induced hepatocarcinogenesis. The authors there reported the ability of flavonoids, saponins and alkaloids to stimulate the immune systems in an immunosuppressed animals.

CONCLUSION

Treating wistar rats exposed to chlorpyrifos with *B. aegyptiaca* leave extracts for seven consecutive days was noted to be ameliorative.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This research work was conducted at the Teaching and Research Farm of the Faculty of Agriculture (Shabu-Lafia Campus {Latitude 08^{o}*,*33^{I}*N and Longitude* 08^{o}*,*32^{I}*E}), Nasarawa State University Keffi, to study the Effect of Lambda-cyhalothrin Insecticide Spray Regimes on the Growth and Yield of Three Cowpea (Vigna unguiculata(L.) Walp.) Varieties during 2018 and 2019 rainy seasons. There were 12 treatment combination which were replicated three times and laid out in a Randomized Complete Block Design (RCBD). Data were collected on growth parameters such as plant height, number of branches, number of leaves at 4, 6, 8 and 10 WAS; while yield parameters were taken on Total Biological Yield, Grain Yield, Haulms Weight per plot, Seed weight and percentage Harvest index. Analysis was done using GENSTAT software, version 13 and means were separated using Duncan Multiple Range Test on SPSS Version 22. The result of the experiment confirmed that cowpea Fuampea 2 produced significantly(P<0.05) higher growth and yield values than cowpea Fuampea 1 and the local(40 days) variety at all the respective sampling periods of 4, 6, 8 and 10 WAS . The yield parameters consequently showed that cowpea Faumpea 2 is better than other cowpea varieties.*

Keywords: *Contact insecticide, spray regimes, cowpea, Lambda-cyhalothrin, variety, Fuampea.*

INTRODUCTION

Cowpea(*Vigna unguiculata*(L.) Walp) is an annual crop grown for either its seeds or fodder, some varieties may be erect, climbing, prostrate and creeping. Prostrate cultivars can grow to about 80 cm while climbing varieties can grow up to 2 m and root systems of cowpea are well developed (Heuzé *etal*., 2015). A cowpea pod can contain 6-13 seeds that are usually kidney shaped, although the seeds become more spherical and more restricted within the pod(Sheahan, 2012). Cowpea is one of the most ancient human food sources and has probably been used as a crop plant since Neolithic times(Directorate of Plant Production (DPP) and Agricultural Resource Centre (ARC), 2011). Lack of archaeological evidence has resulted in contradicting views supporting Africa, Asia and South America as origin. Cowpea is grown as a main legume crop in Africa mostly in Egypt and Nigeria, South America, Colombia, Brazil, the USA, Mexico, Asia (China, Pakistan and Japan) and in Southeast Europe (Spain, Greece Italy, Portugal and Cyprus) (Antova*et al*., 2014). It has also been reported that out of 7.7 million hectares devoted to cowpea production worldwide, 6.1 million hectares (80%) are in the West African sub-region and Nigeria accounts for 4 million hectarage of cowpea production (Gerei *et al*., 2018). Nigeria is the world's leading cowpea producing country, followed by Brazil, other countries in West Africa, are Senegal, Ghana, Mali, Burkina Faso, Niger, and Cameroon (DPP and ARC, 2011).

Nigeria is regarded as the largest producer and consumer of cowpea in the world with an estimated 45% share of the global cowpea production and over 55% of the production in Africa (Alene *et al*., 2015). There is however, no single variety that has been found to be totally resistant to the numerous insect pests attacking the crop (Dzemo *et al*., 2010). Most varieties described as resistant are only resistant against one or a few insect pests which when used alone cannot provide satisfactory control against insect pests (Pulakkatu-Thodi *et al*., 2014; Abudulai *et al*., 2017). Cowpea varieties have been bred for a wide range of agronomic, grain quality with resistance or tolerance characteristics to abiotic and biotic stresses, but not much attention on developing varieties resistant to weed suppression (Ehlers *et al.*, 2002; Hall *et al*., 2003).

Substantial genetic diversity exists for growth habit characteristics and have excellent opportunity to develop varieties with higher weed suppressive ability as it was done in soybean [*Glycine max* (L.) Merr.] (Ehelers and Hall, 1997). Ewansiha and Tofa (2016) reported that yield potentials of IT98K-573- 2-1 cowpea variety was significantly higher in seed and fodder weights at 1155.3 kgha^{-1} and 6006.4 kgha^{-1} respectively than the other varieties tested (IT97K-499-35,IT98K-205, IT89KD-288 and IT99K-241-2). In another trial by Kirkhouse (2017). The crop has often been referred to as "the poor man's meat" due to the high levels of protein found in the seeds and leaves (Hamid *et al*., 2016). Cowpea seeds provide a rich source of proteins and calories, as well as minerals and vitamins (Gonçalves *et al*., 2016). A seed can consist of 23-25% protein, 50-67% carbohydrates, 8-9% moisture and it has very low fat content (3.99%) (Rangel *et al*., 2003).

Maruca vitrata, is a legume pod borer which has been investigated as a destructive pest of cowpea and other leguminous crops and are widely distributed throughout tropical and subtropical areas of the world where it causes extreme damages (Baoua *etal*., 2011). It is a major concerned cowpea pest in Africa and Southeast Asia whereby the larval stage causes the damage, attacking flower buds, flowers and young pods. Up to 80% cowpea yield losses are recorded (Dannon, 2011). Lambda-cyhalothrin 2.5EC (Kombat 2.5EC) is a non-systemic, contact stomach acting and repellant insecticide is mainly used for the control of wide spectrum of insect pests(Saro, 2018).Spraying contact or systemic insecticides three times on cowpea increases grain yield and economic net returns, (Kotu *et al*., 2017). Contact insecticide application has the ability to improve growth and yield of cowpea whose limiting factor of production has been insect pests destroying seed yield and quality to economic threshold (Tony *et al.,* 2014). Thus, notwithstanding, insecticide application remains the major option for insect pests control practice in cowpea in most African countries. This is so because of the spectacular results obtained in association with their application (Pulakkatu-Thodi *et al*., 2014; Abudulai *et al.*, 2017). However, despite concerted efforts by many institutions over the last two decades to develop varieties with resistance to the cowpea insect pest complex, resistant varieties are still unavailable to farmers. Thus, chemical control using synthetic insecticides therefore remains the most popular control option especially when these pests have exceeded the economic injury level (Jackai *et al*., 2001).

Significant reduction in pod pest infestation levels can be achieved by applying insecticides twice, each at flower budding and early podding respectively. This indicates that two insecticide spray regime at flowering and at podding could produce a good cowpea yield as same as the three to five spray regimes (Ajeigbe and Singh, 2006). Spraying insecticides three times on cowpea increases grain yield and net returns since the technique is attractive to farmers having different attitudes towards risk it can enhance overall cowpea production and, if promoted, its role in reducing food security and poverty among smallholder farmers in the area will be high. However, precautions should be taken during the scaling to reduce the negative externalities which may be associated with the use of the insecticide (Kotu *et al*., 2017).

MATERIALS AND METHODS

This experiment was conducted at the Teaching and Research Farm of Faculty of Agriculture (Shabu-Lafia Campus), Nasarawa State University, Keffi. Lafia is situated at Latitude 08^{o},33^{i}N and Longitude 08^{o},32^{i}E and at altitude of 160m above sea level (Jayeoba, 2013), during the 2018 and 2019 rainy seasons

Soil samples were collected randomly from the experimental site and analyzed. The soil was predominantly loamy at site 1 and loamy clay at site 2 and 3 respectively. Three cowpea varieties were used for the experiment which are Cowpea Faumpea1 and 2 obtained from the Seed Testing Centre, Federal University of Agriculture Makurdi, Benue State Nigeria; while the local variety (40 Days) was obtained from the local market in Shabu, Lafia, Nasarawa State. The contact insecticide used was, Lamda-cyhalothrin 2.5EC, purchased from reputable Agrochemical dealer in Lafia market, Nasarawa State. There were 12 treatment combinations which were replicated three times. The contact insecticide was sprayed at three different spray regimes (once, twice and three times) and the control treatment (no spray).

The experimental site was cleared by applying pre-tillage non-selective herbicide (Paraquat® {Slasher}) to clear the grasses, shrubs were cut down using cutlasses and axes. Further, the site was harrowed, pulverized and ridged

by the use of big and small African hand hoes into net plots.The gross plot size was 3m x 4m ($12m^2$) while the net plot size was at 4m x 1.5m($6m^2$) with an inter and intra row spacing of 40cm x 75cm($3000cm^{2.}$).
The three varieties of cowpea seeds were sown per hole at the depth of 2-3 cm and covered thinly at intra and inter row spacing of 40 x 70cm respectively. Thinning was carried out at 3 weeks after sowing (3 WAS) to 2 plants/stand. Five plants were randomly tagged in each of the net plots for data collection at 4, 6, 8 and 10 WAS. Data collected on plant height, number of branches, number of leaves and total dry matter; while total biological weight, grain yield per plant, haulms weight per plant, 100 seed weight and harvest index were used as yield parameters. All cultural practices were carried out as recommended.
There were two treatment combinations which were replicated three times, these combinations comprises three cowpea varieties; the local variety (V_1), cowpea Faumpea1(V_2), and cowpea Faumpea2 (V_3) and application non-systemic (Contact) insecticides(C) (Combat^R 2.5 EC (market name) known as Lamda-cyhalothrin, containing 2.5 a.i./lit EC, a contact stomach repellant insecticide) in tree spray regimes consisted zero spray (C_0), spraying once (C_1), spraying twice C_2 and spraying thrice (C_3).
The experimental design used was a Randomized Complete Block Design (RCBD) with the varieties forming the main block treatments and the various spray regime treatments allocated within the various blocks. The experiment was analyzed using GENSTAT software, version 13 and means were separated using Duncan Multiple Range Test on SPSS version 22.

RESULTS

The various treatment applied were significantly different (Table 1). In both years, Faumpea 2 variety of cowpea significantly produced the tallest plants height followed by Faumpea1 at all the sampling periods while the local variety produced significantly the shortest plants. The application of Lambda-cyhalothrin contact insecticide in the three spread regimes significantly recorded the highest plant height at both the sampling periods in both years followed by the 2nd spray regime at the respective sampling periods and wet seasons. The least in the plant height was the zero application of Lambda-cyhalothrin contact in both years (Table 1). There was significant interaction between variety and insecticide in both years, at the growth stage of 10 WAS (Table 1). The result however recorded significantly the highest number of branches on cowpea Fuampea 2 followed by Faumpea1 when Lambda-cyhalothrin insecticides was sprayed in 3 regimes while zero application of Lmabda-cyhalothrin contact insecticide produced significantly the lowest number of branches in both years at 4, 6, 8 and 10 WAS (Table 2). There was an interaction between variety and insecticide at 10 WAS in both seasons (Table 2).
The three varieties tested in 2018 and 2019 recorded significantly more number of leaves of cowpea Fuampea 2 followed by Fuampea1at all the sampling periods (Table 3). The application of Lambda-cyhalothrin insecticide in 3spray regimes recorded significantly more number of leaves of cowpea Fuampea 2 than other spray regimes in both years at all the sampling periods (Table 3). Interaction was observed between variety and insecticide at10 WAS in both 2018 and 2019 rainy season (Table 3). The treatments applied on total dry matter of cowpea recorded significant difference at all sampling periods in both 2018 and 2019 wet seasons (Table 4) where the Local cowpea variety produced significantly the least total dry matter of cowpea and Fuampea 2 (V_3) cowpea variety produced the highest total dry matter than Fuampea 1 (V_2) at all the sampling periods of 4, 6, 8 and 10 WAS in both years (Table 4).
When Lambda-cyhalothrin insecticide was applied in three spray regimes (S_3) at all sampling periods, records showed a significantly higher total dry matter of cowpea than other regimes tested in both years (Table 4). The result of this interaction revealed that, interaction between variety and insecticide was not significant at all sampling periods in both 2018 and 2019 rainy season (Table 4). Table 5 recorded significant differences among the various treatments applied where Cowpea Fuampea 2 variety (V_3) recorded significantly the highest 100 seeds weighed, more Grain Yield Per Plant (GYPP), Haulm weight per plant, Total Biological Yield (TBY) and the highest Harvest Index (HI) than the other two cowpea varieties tested in both rainy seasons, respectively. Similarly, all the various yield components tested at the course of this study was confirmed to significantly produce better than others when Lambda-cyhalothrin contact insecticide was applied in three spray regime than the plots with zero insecticide application in both years (Table 5). The application of Lambda-cyhalothrin contact insecticide in three spray regimes produced significantly more total biological yield, higher grain yield, haulms weight, 100 seed weight and the highest percentage harvest index in both 2018 and 2019 cropping seasons followed by the application of insecticide in two spray regimes (Table 5). An interaction occurred between variety and insecticide on grain yield per plants (Table 5).

DISCUSSION

The result of this study showed significant difference in both 2018 and 2019 rainy seasons where cowpea Fuampea 2 variety (V$_3$) consistently performed the best than the other varieties in all the various growth parameters (plants height, number of branches, number of leaves and total dry matter) tested at all the sampling periods of 4, 6, 8 and 10 WAS. The better performance of cowpea Fuampea 2 could be as a result of the genetic makeup imbibed by the variety with high tolerance, resistance and competitive traits to withstand weed suppression and insect pest infestation. This assertion agrees with Ehelers and Hall (1997) who states that substantial genetic diversity exist with growth habit characteristics and represent excellent opportunity to develop varieties with high weed suppressive ability on leguminous plants as was done in soybean, *Gycine max* (L).

Cowpea Fuampea 2 significantly yielded better than the rest of the varieties in terms of its total biological yield, grain yield per plant, haulms weight, 100-seed weight and harvest index. Cowpea Faumpea2 is an improved variety that could have come with some special genotypic traits and abilities to withstand suppression and stress which makes it to yield better than other varieties. This result is in conformity with Ehelers *et al*. (2002) and supported by Hall *et al*, 2003 who states that, cowpea varieties have been bred for a wide range of agronomic, grain quality and resistant or tolerant characteristics to abiotic and biotic stresses.

Cyahalothrin contact insecticide application in three spray regimes (C_3) consecutively showed significantly the highest performance than others in all the growth and yield parameters studied during 2018 and 2019 rainy seasons. This result is in consonance with the finding of Adati *et al.* (2008) who suggested that farmers using improved cowpea varieties would be require to apply 2-3 insecticidal spray regimes in order to increase crop yield due to the different stages of insect pest attack. This also agrees with Saro (2018) who suggested that, the use of Lambda-Cyhalothrin 2.5EC contact stomach acting repellant insecticide is good for the control of wider spectrum of insect pests in crops which in turn gives room for an uninterrupted crop growth and performances. The result of this finding indicates that the more the number of spray regimes (up to 3 spray) the better the significant growth and yield performance of cowpea.

CONCLUSION

The growth and yield parameters of cowpea Fuampea2 variety significantly better than the other cowpea varieties tested in 2018 and 2019 rainy seasons as well as application of cyhalothrin contact insecticide in 3 spray regimes also resulted as the best in the growth and yield performance of cowpea compared to the other spray regimes

RECOMMENDATIONS

The production of cowpea Fuampea2 variety is highly recommended for cultivation according to the findings of this research work due to its significant growth and yielding ability as well as its high resistivity to weeds and insect pests' damage. Application of Lambda-cyhalothrin contact insecticide in 3 spray regimes was found to significantly performed better than 1-2 spray regimes because the fewer the spray regimes the more insects attacks cowpea and low yield return will consequently be resulted.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cocoyam (Colocasia esculenta) of the family Araceae, is an importance staple food in Nigeria because of its nutritional value which makes it a health management crop, weaning food for infants and has a lot of potentials for agro industries. The study was carried out in Umudike (Lat. 5.4801˚N, Long. 7.5437˚E) in the rainforest zone in 2020 cropping season. The treatments include two cocoyam cultivars Nce 001 (Coco Indian), Nce 003 (Ede ofe) and 3 planting dates in April, May and June (10/04/2020, 10/05/2020 and 10/05/2020) laid out in randomized complete block design (RCBD) in factorial arrangement. Data were collected on number leaves, and plant height at 3 months after planting (MAP) and also on number and weight of corms and cormels during harvest. Data collected was subjected to analysis of variances using Genstat Discovery edition 1. Results obtained showed that at 3 MAP number of leaves of Nce 001 and 003 were not influence by planting dates and cultivars but planting dates had a significant influence on plant height. The planting date also had significantly impacted on number of corms, cormels and yield at harvest.
Keywords: *Cocoyam, Colocasia esculenta , Taro, Planting period, Corms, Cormels, yield.*

INTRODUCTION
Cocoyam (*Colocasia esculenta)* belongs to the aroid family Araceae. There are two important species of cocoyam *Xanthosoma sagittifolium* (Tannia) and *Colocasia esculenta* (Taro) which are grown throughout West Africa. The *Xanthosoma sagittifolium* are of two cultivars Nx 01 (white) and Nx 02 (pink) while *Colocasia esculenta* has many cultivars which include NCe 001, NCe 002, NCe 003, NCe 004, Nce 005 and NCe 006. In Nigeria it is cultivated for food security, income and economic in empowerment. It has high nutritional qualities which make it to be used as a health management crop, weaning food for infants, and in agro industries to enhanced livelihoods. It is an important carbohydrate staple food particularly in the southern and middle belt of Nigeria (Amadi *et al*, 2012) where it is consumed in various delicacies boiled, roasted or as a soup thicker depending on the cultivar. Taro corms and leaves have medicinal value which helps to reduce tuberculosis, ulcers, pulmonary congestion and fungal infection (Misra and Sriram, 2002). Among all the root and tuber crops of economic importance cocoyam is the third in position after yam and cassava. Nigeria is the largest producer of cocoyam in the world and Africa (Amadi *et a*l, 2017) with a production estimate of 2.9 million metric tonnes from 994,644 hectares in 2019 (FAOSTAT 2022 downloaded 18th June, 2023). This approximates to about 2.9 tonnes per hectare which is low compared to other competing root and tuber crops like cassava, yam, sweet-potato, and potato. Crop yield can be increased by the use of appropriate good agronomic practices and proper farm management methods which includes period planting (Ebeniro, 2019). Planting periods have been used as escape mechanisms for drought, flooding and disease management in crops production. The objective of this study is to determine the most effective planting period to optimize tuber of cocoyam in the rainforest zone of Nigeria.

MATERIALS AND METHOD
The study was carried out in National Root Crops Research Institute, Umudike experimental field in 2020 cropping season. Umudike is located on longitude 07˚ 33' E and altitude 05˚29' N and at an elevation of 122 above sea level in the rainforest zone of Nigeria. The soil is sandy loam, acidic with low buffering capacity and multiple deficiencies (Ano, 1990). The experiment contained six possible combination of treatments replicated 3 times. The treatments include two cocoyam cultivars NCe 001 (Coco Indian), NCe 003 (Ede ofe) and 3 planting periods April, May and June (10/04/2020, 10/05/2020 and 10/05/2020). The design was randomized complete block design (RCBD) in a factorial arrangement. Good agronomic management practices were carried out including site selection, land preparation, cutting and sorting of corms and cormels, weeding, fertilizer application, weeding and

harvesting. Harvesting was done 7 months after planting. Data collected on growth attributes were on number of leaves per plant, and plant height at 3 months after planting. Yield attributes assessed at harvest were numbers and weights of corms and cormels per plot, Weights were converted to yield/ hectare. Data collected were subjected to analysis of variance using Genstat Discovery Edition 1.

RESULTS

Table 1 indicated the effect of planting period on number of leaves on the two cultivars of cocoyam NCe 001 (Coco Indian), NCe 003 (Ede-ofe) at 3 months after planting. It showed neither planting period nor cultivar had a significant effect on number of cocoyam leaves. Cultivars x planting date interaction effect on number of leaves was also insignificant. The plant height of the cultivars planted in June were significantly (P<0.05) shorter at 3 MAP compared with cultivars planted in April and May. Both April and May plantings had similar plant heights. Planting period x cultivars interaction had no significant effect on plant height at 3 MAP.

Table 1: Effect of Planting period and Cultivar on Number of Leaves and Plant Height at 3 MAP

	Number of leaves				Plant height (cm)			
	Plantings Period (Months)							
Cultivars	April	May	June	Mean	April	May	June	Mean
Nce 001(Coco Indian)	5.00	5.00	5.00	5.00	5.33	47.07	37.33	45.58
Nce 003(Ede-ofe)	5.00	5.00	5.33	5.11	51.67	48;13	37.20	46.67
Mean	5.00	5.00	5.11		52.00	47.60	37.27	
LSD (0.05) for Cultivars = NS LSD (0.05) for planting periods = NS LSD (0.05) for Cultivars x planting periods = NS					LSD (0.05) for Cultivars = NS LSD (0.05) for planting periods = 0.001 LSD (0.05) for Cultivars x planting periods = NS			

On the number of corms and cormels at harvest both cultivars and planting period had a significant effect. The effect of cultivar and planting period on number of corms, cormels and tuber yield of cocoyam is presented in Table 2. Nce 003 had more corms than Nce 001 at all planting periods while early planting (ie planting in April) gave the highest number of corms. Number of cormels followed the same pattern as number of corms. In terms of tuber yield (t/ha), the two cocoyam cultivars evaluated did not differ significantly. However, planting in April gave the highest yield compared to other planting periods. Planting date x cultivar interaction did not significantly affect number of corms and cormels, and tuber yield of cocoyam (Table 2).

Table 2: Effect of Planting periods and Cultivars on number of Corms and Cormels, and yield (t/ha) at harvest.

	Corms				Cormels				Yield (t/ha)			
					Planting periods							
Cultivars	April	May	June	Mean	April	May	June	Mean	April	May	June	Mean
Nce 001	12.67	9.92	6.33	9.64	11.08	8.92	5.33	8.44	11.70	9.44	5.03	8.72
Nce 003	17.50	48.83	10.75	14.36	16.67	13.83	0.92	13.47	10.61	9.05	5.51	8.39
Mean	15.08	12.67	8.54		13.88	11.38	7.62		11.15	9.25	5.27	
LSD (0.05) for Cultivars = 0.032 LSD (0.05) for planting periods = 0.20 LSD (0.05) for Cultivars x planting periods = NS					LSD (0.05) for Cultivars = 0.016 LSD (0.05) for planting periods = 0.02 LSD (0.05) for Cultivars x planting periods = NS				LSD (0.05) for Cultivars = NS LSD (0.05) for planting periods = 0.01 LSD (0.05) for Cultivars x planting periods = NS			

DISCUSSION

Crop yield can be increased by the use of appropriate good agronomic practices/techniques and proper farm management methods include time of planting (Ebeniro, 2019). Early planting is a means reducing the effects of evading drought, flooding, pests and diseases in crops during the cropping season. Results obtained from this study indicate that early planting (ie planting in April) resulted in taller more robust plants which gave highest tuber yield compared to other planting periods especially the late planting in June. Nce 003 produced more number of corms and cormels but did not significantly out-yield Nce 001. The increased yield obtained from April planting could be due to evasion of the peak period of Taro Leaf blight (TLB) which is the most destructive disease of cocoyam. This disease is caused by an oomycetes known as *Phytophthora colocasiae* which thrives under high moisture conditions prevalent at the peak of rainy season (Misra *et al*, 2008; Omane *et al*., 2012). Early planting enables the plants to go far in growth and tuberization before the advent of TLB.

CONCLUSION

Result obtained from this study showed clearly that planting early in the rainy season (April Planting period) resulted in higher yield. Farmers are therefore adviced to plant NCe 001 and NCe 003 early in the season optimum tuber yield.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study was carried out in National Root Crops Research Institute, Umudike experimental field in 2020 cropping season to determine the effect of planting date on some agronomic characteristics and yield of Cocoyam (Colocasia esculenta). The experiment was set up in in randomized complete block design (RCBD) in factorial arrangement. The experiment contained six possible combination replicated 3 times. The treatments were two cocoyam cultivars Nce 001 (coco Indian), Nce 003 (ede ofe) and 3 planting dates April (10/04/2020, May (10/05/2020 and June (10/06/2020). Data were collected on number of leaves, plant height at 3 months after planting, number corms, cormels and yield (t/ha) at harvest. Data collected were subjected to analysis of variances using GENSTAT DISCOVERY edition 1 (Laws Agriculture Trust, 2003). The number of leaves per plant and plant height did not significantly differ amongst the cultivars tested. For planting date, the plants were significantly taller when planted in April compared with the other dates assessed. The corm and cormel were significantly higher (p<0.05) in the cultivar Nce 003 compared with Nce 001. Yield (t/ha) was not significantly different amongst the cultivars. Corm, cornmel and yield (t/ha) were all significantly (p<0.05) higher in cocoyam planted in April compared with the other months

Keywords: *Cocoyam, Taro, planting dated, , growth, yield.*

INTRODUCTION

Cocoyam belonging to family Areaceae is one of the important food crops in some rural communities in Nigeria. Two important varieties of the crop: *Xanthosoma sagittifolium* and *Colocasia esculenta* are grown throughout West Africa. The *Xanthosoma sagittifolium* are of two cultivars white and pink while *Colocasia esculenta* have many cultivars which include NCe 001, NCe 002, NCe 003, NCe 004, Nce 005 and NCe 003. In Nigeria it is cultivated for foodwhile the excess are sold for income to the farm family. It has high nutritional qualities and hence is used in management of some health conditions and weaning food for infants. It is an important carbohydrate staple food particularly in the southern and middle belt of Nigeria (Amadi *et al*, 2012). Taro corms and leaves have medicinal value which helps to reduce tuberculosis, ulcers, pulmonary congestion and fungal infection (Misra and Sriram, 2002). Among all the root and tuber crops of economic importance cocoyam is the third in position after yam and cassava. Nigeria is the largest producer of cocoyam in the world (Amadi *et al*, 2017) with a production estimate of 2.9 million metric tonnes from 994,644 hectares in 2019. s(Ebeniro, 2019). The objective of this study was to determine the effect of planting date on some agronomic characteristics and yield of Cocoyam in Umudike, Nigeria

MATERIAL AND METHODS˚

The study was carried out at the National Root Crops Research Institute, Umudike Experimental Field in 2020 cropping season. Umudike is located on longitude 07˚ 33' E and altitude 05˚29' N and at an elevation of 122 above sea level in the rainforest agro- ecological zone of Nigeria. The soil is sandy loam which is acidic with low buffering capacity and multiple deficiencies (Ano, 1990). The design was randomized complete block design (RCBD) in a factorial arrangement, replicated 3 times. The treatments include two cocoyam cultivars NCe 001 (coco Indian), NCe 003 (ede ofe) and 3 planting periods April (10/04/2020, May (10/05/2020 and June (10/06/2020). Good agronomic management practices were done such as site selection, land preparation, marking of field, cutting and sorting of corms and cormels, weeding, fertilizer application, good field maintenance and harvesting. Harvesting was done 10 months after planting. Data collected on growth attributes were on number of leaves per plant, plant height at 3 months after planting and yield attributes on number of corms, cormels and yield(t/ha) at harvest. Data collected were subjected to analysis of variance using GENSTAT DISCOVERY edition 1 (Laws Agriculture Trust, 2003)

RESULTS

Table 1 show the effect of planting date on number of leaves and plant height of cocoyam at Umudike during the 2020 cropping season. The number of leaves per plant and plant height did not significantly differ amongst the cultivars tested. With respect to planting date, the plants were significantly taller when planted in April compared with the other dates assessed. There were no significant interactions in the treatments tested.

The effect of cultivar and planting dates on the corm, cormel and yield of cocoyam is presented in Table 2.The corm and cormel were significantly higher ($p<0.05$) in the cultivar Nce 003 compared with Nce 001. Yield (t/ha) was not significantly different amongst the cultivars. For planting date, corm, cornmel and yield were all significantly ($p<0.05$) higher in cocoyam planted in April compared with the other months.

DISCUSSION.

Crop yield can be increased by the use of appropriate good agronomic practices/techniques and proper farm management methods include time of planting (Ebeniro, 2019). Early planting is a means of reducing the effects of pests and diseases in crops during the cropping season. . Planting periods have been used to check diseases on potato and sweetpotato (Mishra *et al.* 2008) which can be used as a means of control in other crops of root and tuber. The most effective planting period to grow cocoyam for good yeld in the rain forest zone of Nigeria is 4th month of the year (April), Th NCe 001 and NCe 003 planted in the 4th month of the year (April) had had significantly higher yield than other periods of the year.

CONCLUSION

From the study farmers are advised to plant NCe 001 and NCe 003 in April tfor good yield of the cocoyam.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Late blight disease (LBD) caused by Phytophthora infestans is among the major cause of low yield obtained by potato farmers in Nigeria. This study was undertaken in 2022 in Jos South, Ryiom, Barkin-Ladi, Bokkos, and Mangu LGAs in Jos Plateau of Plateau State to ascertain the level of adoption of the control innovations for LBD disseminated by the National Root Crops Research Institute (NRCRI) Umudike over a decade ago and their impact on the livelihood of adopting farmers. Data were collected from one hundred and twenty (120) potato farmers using a structured and pretested questionnaire. These respondents were among those previously trained in the use of reference technologies. Results obtained indicate a high awareness (65.8 to 77.5%) of late blight management innovations disseminated by NRCRI. There was a high adoption of early planting (73.3%) and the use of fungicides (70.8%) for late blight disease control. There was however low adoption of the use of resistance varieties for controlling the disease (42.5%). The educational status, marital status, and farm size of the respondents had significant positive effects on the level of adoption, while farming experience and membership in cooperative society had significant negative effects on the adoption of the reference technologies. Amongst the constraints to adoption assessed, low knowledge of innovation ranked the highest while cattle menace was the least. The impact of the adoption of reference technologies was low. Despite the high adoption, there was a generally low impact of reference technologies on the livelihood of respondents. We, therefore, recommend the development and deployment of potato varieties resistant to late blight; reassessment of available fungicides for the control of late blight for recommendation to farmers; and re-training of farmers and extension officers on the appropriate application of the technologies

Keywords: *Late blight, Phytophthora infestans Disease control, Innovations, Awareness, Adoption, Impact*

INTRODUCTION
Potato (*Solanum tuberosum* L.) is an important food for many in Nigeria because of its nutritional and organoleptic qualities. Potato tubers contain a higher amount of carbohydrates, and protein per hectare compared to cereals and are a good source of vitamin C, B12, potassium, and fibre (Ghislain *et al*., 2021). In addition, potato is a short-duration crop (90-120 days) and can therefore be grown multiple times within a year. It does well both under rain-fed and irrigated production. The production estimate for potatoes in Nigeria in 2021 is 1.2 million metric tonnes from 319,180 hectares (FAOSTAT, 2021). The average yield is about 3.8 t/ha is very low. Among the major causes of low yield obtained by potato farmers in Nigeria is Late blight disease (LBD)..

Late blight disease of potatoes is caused by *Phytophthora infestans* (Mont.) de Bary. The pathogen belongs to a fungus-like group of ubiquitous organisms known as oomycetes (water moulds). The disease develops and spreads rapidly under high relative humidity, moderate temperature, and substantial rainfall. It infects potato leaves, stems, and tubers at any stage of development and has the potential to destroy the whole potato field within a few days (Tafesse *et al*., 2018). Amadi *et al.* (2021), reported yield reductions between 20-50% due to the disease while Chingle and Kwun-Ndung. (2019), reported that in some severe cases it may lead to total yield loss. It can also lead to serious post-harvest decay of tubers in storage (Johnson, 2008). LBD is of great economic significance. Based on a price of $150 per ton for Potato, the cost of late blight disease is estimated at between $42,000,000 – $105,000,000, per annum. The yield decline and attendant financial loss caused by LBD, reduce food availability, increase food prices, and pose a danger to the income and livelihoods of rural households (Amadi *et al.* 2021, Chuwang, 2014).

Considering the magnitude of yield reduction caused by LBD, the National Root Crops Research Institute (NRCRI) Umudike through her Potato Research Programme, had developed and disseminated to potato farmers on the Jos Plateau over a decade ago, some innovations to control the disease. These innovations include early planting (April-early May) at the onset of rain to escape the peak period for late blight; recommendations on fungicide use and the use of resistant varieties (RC767-2) for the control of late blight. Adoption of these technologies has the potential to reduce disease, increased seed quality, and increase the yield, income, and livelihood of adopting farmers. However, the adoption of improved agricultural innovations has been a long-term concern of agricultural experts, policy makers, agricultural researchers, and many others linked to the sector (Amadi *et al*. 2022). Having disseminated these innovations to potato farmers on the Jos plateau over a decade ago through direct training or indirectly through the training of extension officials who then trained farmers, it is appropriate to assess their level of adoption by farmers and the impact their adoption has had on the income and livelihood of farmers.

The objectives of this study, therefore, were to ascertain the level of awareness and adoption of NRCRI control measures for LBD by potato farmers in Jos Plateau and the impact of their adoption; in order to guide future institutional and policy interventions.

METHODOLOGY

This study was carried out in Jos south, Ryiom, Barkin-ladi, Bokkos and Mangu LGAs of Jos plateau in Plateau State Nigeria in 2022. A purposive and multi-stage sampling technique was used in selecting 120 potato farmers 24 from each LGA as respondents. The instrument for data collection was a set of structured and pre-tested questionnaires. The primary data gathered included the socioeconomic characteristics of respondents, identification of late blight disease symptoms, level of awareness, adoption, impact, and constraints on the adoption of LBD control innovations developed and disseminated by NRCRI Umudike. Descriptive statistics was used to analyse the data generated from the study.

RESULTS AND DISCUSSION

Prevalence and identification of Late blight disease.

The Prevalence of LBD and farmers' ability to identify them are presented in Table 1. A vast majority of the farmers 62% were able to identify symptoms of LBD on their farms while 80% of the farms were attacked by LBD. This indicates a high prevalence of the disease on potato farms in the Jos plateau. The high level of identification and hence awareness reported in this study is in tandem with the report by Farm Radio International (April 9, 2020) "Almost every farmer who has ever grown potatoes has stories of this disease wiping out some or all of their harvest". It is however contrary to Nnadi *et al*., (2019) who reported that farmers' awareness of the disease was very poor and most of the farmers had not heard of *P. infestans*, attributing the disease to supernatural causes, rain, or dew. It is possible that Nnadi *et al*, (2019) tagged their awareness of the disease to the identification of the pathogen. It is possible for farmers to be aware of a disease without knowing what causes it.

Table 1: The distribution of the respondents according to the identification of late blight disease.

Variables	Yes	No
Can you identify LBD?	74(61.7)	46(38.3)
Is your farm attacked by LBD	96 (80.0)	24 (20.0)

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%)

Level of Awareness of Late Blight Control Innovations

The distribution of the respondents according to their level of awareness of LBD control innovations is presented in Table 2. There was a high degree of awareness of LBD control innovations disseminated by NRCRI as a majority of the respondents 77.5%, 73.3%, and 65.8% were aware of early planting, use of fungicides, and use of resistant varieties respectively. This result is in agreement with the interview by Farm Radio International (2020) which showed that most of the farmers interviewed knew about these innovations.

Table 2: The distribution of the respondents according to their level of awareness of LBD control innovations

Variables	Not aware	Aware
Early planting	27(22.5)	93(77.5)
Fungicide	32(26.7)	88 (73.3)
Use of resistant varieties	41(34.2)	79 (65.8)

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%)

Level of Adoption of Late Blight Disease Control Innovations

Rogers (1995) defined adoption as the decision to make full use of an innovation or technology as the best course of action available. The distribution of respondents based on their level of adoption of LBD control innovations in the study area is presented in Table 3. The result revealed a grand mean of 2.29, implying a generally strong adoption of most innovations based on a cut-off point of 2.0. The result specifically revealed high adoption of early planting technology (73.3%) and use of fungicide (70.8%). There was however low adoption of the use of resistant varieties with adoption rates of (42.5%). Tesfaye *et al*., (2018) reported high adoption of the use of fungicides to control late blight in the Jeldu woreda area of Ethiopia. The low-level adoption of the use of resistant or tolerant varieties by potato farmers could be attributed to their unavailability or breakdown.

Table 3: The distribution of the respondents according to their level of adoption of late blight disease control technologies

Variables	Never Adopted	Adopted and Stopped	Adopted and still using	Mean	Decision
Late Blight					
Early planting	26(21.7)	6(5.0)	88(73.3)	2.52	Adopted
Fungicide	25(20.8)	10(8.3)	85(70.8)	2.50	Adopted
Use resistant varieties	61(50.8)	8(6.7)	51 (42.5)	1.92	Not
Grand mean				2.31	

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%), Key: Adopted and still using (3), Adopted and stopped (2) Never adopted (1). Decision: mean > 2.0 high and mean < 2.0 low

Constraints to Adoption of LBD Control Innovations

Table 4 shows the mean of the various constraints faced in the adoption of LBD control innovations by potato farmers in Plateau State. The result indicated a grand mean of 1.45 implying low constraints to the adoption of LBD control innovations. The result specifically revealed low knowledge of innovation (1.78) as the most important constraint. It appears that low constraints resulted in the high adoption recorded in this study.

Table 4: Constraints faced in the adoption of late blight control innovations by potato farmers

Constraints	Mean	Rank	Decision
Low Knowledge of innovation	1.78	1	Low
No access to extension bulletins	1.54	2	Low
Lack of input	1.50	3	Low
Insecurity	1.47	4	Low
Scarcity/high cost of labour	1.30	5	Low
Lack of fund	1.29	6	Low
Cattle menace	1.25	7	Low
Grand mean	1.45		

Source: field survey, 2022, Key: Very serious (3), Serious (2), Not serious (1); Decision: mean > 2.0 high and mean < 2.0 low

Impact of NRCRI Late blight disease innovations on the livelihood of potato farmers

The result in Table 5 showed the mean level of impact of LBD control innovations on the livelihood of potato farmers in the study area. Based on a cut-off point of 3, the grand mean of 2.27 obtained implied a generally low impact on the livelihood of respondents. This result is consistent with the prevailing hardship as a result of losses by farmers due to the recurrent epidemic of late blight in the study area. However, the result was not consistent with the report of Tesfaye *et al.*, (2013), who reported that the adoption of potato production technologies resulted in some impact on the livelihood of adopters in Oromiya and Amhara regions in Ethiopia. These general low-level impacts could be attributed to the poor application of the innovations, the ineffectiveness of available fungicides for late blight, and the unavailability, or the breaking down of resistance in hitherto resistant varieties resulting in farmers not getting the desired result from applied technologies.

Table 5: Impact of adoption of bacteria wilt control innovations on the livelihood of potato farmers

Variables	Mean	Rank	Decision
Purchase of TV/radio	2.70	1	Low impact
Built house	2.42	2	Low impact
Purchase of cycles/car	2.40	3	Low impact
Purchase of cloths	2.36	4	Low impact
Purchase of land	2.35	5	Low impact
Acquired new properties	2.32	6	Low impact
Provision of medical care	2.12	7	Low impact
Children's education	2.01	8	Low impact
Increased production	1.71	9	Low impact
Grand mean	2.27

CONCLUSION

From this study, it is evident that there is a high level of awareness (65.8 to 77.5%) of NRCRI late blight disease control innovations by the respondents. There was also high level of adoption by farmers of early planting (73.3%) and use of fungicides (70.8%) for the control of LBD. There was however low impact of adoption on the livelihood of adopting farmers. This could be a result of poor application of the technologies, ineffectiveness of some recommended fungicides due to acquired resistance by the pathogen, and the unavailability, or the breaking down of resistance in hitherto resistant varieties. It is evident from this study that there is a dire need to develop and deploy to farmers potato varieties resistant to late blight; reassess available fungicides for the control of late blight for recommendation to farmers; and re-train farmers and extension officers on the appropriate application of the technologies.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Bacterial wilt caused by Ralstonia solanocearum is the second most important disease causing low yield obtained by potato farmers in Nigeria. National Root Crops Research Institute (NRCRI) Umudike disseminated over a decade ago four management strategies namely clean seed, rouging, farm sanitation, and use of tolerant varieties for mitigating this disease. This study was conducted in 2022 in five LGAs - Jos South, Ryiom, Barkin-Ladi, Bokkos, and Mangu in Jos Plateau of Plateau State Nigeria. The objectives of the study were to ascertain the level of adoption by farmers of these management technologies and their impact on the livelihood of adopting farmers. Data were collected from one hundred and twenty (120) potato farmers selected from those who were previously trained in the use of the reference technologies. A structured and pretested questionnaire was used to elicit data. Descriptive statistics were used to analyse the data. Results obtained indicate that there was a high awareness (66.7 to 74.2%) of bacterial wilt management technologies disseminated by NRCRI. There was a high adoption of the use of clean seed (74.2%), rouging (71.7%), and farm sanitation (56.7%)for the management of bacterial wilt disease. There was however low adoption of the use of tolerant varieties (45.0%). The impact of the adoption of the use of clean seed, rouging, and farm sanitation on the livelihood of the respondents was low
Keywords: *Awareness, Adoption, Bacterial wilt, Ralstonia solanocearum, Disease control, Technologies*

INTRODUCTION
Potato (*Solanum tuberosum* L.) is an essential food for many in Nigeria because of its nutritional and organoleptic qualities. Potato is a short-duration crop (90-120 days) and can therefore be grown multiple times within a year. It does well both under rain-fed and irrigated production. 1.2 million metric tonnes of potatoes were produced from 319,180 hectares (FAOSTAT, 2021). At about 4.3 t/ha, potato yield in Nigeria is far below the global average of about 21.4 t/ha. Among the major causes of low yield obtained by potato farmers in Nigeria is the prevalence of bacterial wilt disease.
Bacterial wilt is caused by an invasive soil bacterium known as *Ralstonia solanocearum* which has a wide geographical distribution (Yabuuchi *et al*, 1995, Genin, 2010). It is the second most important potato disease in tropical and sub-tropical regions of the world after late blight (Champoiseau *et al*., 2010). Bacterial wilt infects plants through wounds and natural fissures, colonizes the vascular system, and produces large amounts of extracellular polysaccharides, which causes a blockage of the water and nutrient flow within the plant leading to wilting and death of the host plant (Schell, 2000, Sharma *et al*., 2017). After the death of the host, the bacterium returns to the soil and become saprophytic until it finds another host (Genin, 2010). It also infects tubers causing them to rot. A cross-section through such tubers shows brownish discolouration of the vascular system hence the disease is sometimes referred to as brown rot (Fig 1).

Figure 1: Wilted plants; Cross section through the tuber showing a brown discolouration of the vascular system

National Root Crops Research Institute (NRCRI) Umudike through her Potato Research Programme, had over a decade ago, disseminated to potato farmers on the Jos Plateau, some technologies for the management of this disease. These technologies include the use of the clean disease-free seed, farm sanitation, rouging, and use of tolerant varieties for the control of bacterial wilt. These technologies were disseminated through the training of extension agents and farmers. Having disseminated these technologies to potato farmers on the Jos plateau over a decade ago, it is appropriate to assess the level of adoption of these technologies by farmers and the impact their adoption has had on the income and livelihood of adopting farmers.

This study, therefore, was meant to ascertain the level of awareness and adoption of these control measures for bacterial wilt disease by potato farmers in Jos Plateau and the impact their adoption had on the livelihood of farmers.

METHODOLOGY

This study was carried out in 2022. A purposive and multi-stage sampling technique was used in selecting one hundred and twenty (120) potato farmers as respondents. Twenty-four respondents were selected from each of the five major potato-growing local government areas in Plateau State namely Jos South, Ryiom, Barkin-Ladi, Bokkos, and Mangu. The respondents were selected from farmers who were previously trained in the use of the reference technologies. The instrument for data collection was a set of structured and pre-tested questionnaires. The primary data gathered included the socio-economic characteristics of respondents, ability to identify bacterial wilt symptoms (Figure 1) on their farms, level of awareness, adoption, impact, and constraints on the adoption of bacterial wilt disease control innovations disseminated by NRCRI Umudike. Descriptive statistics was used to analyze the data generated from the study.

RESULTS AND DISCUSSION

Socioeconomic characteristic of potato farmers in Plateau State

Table 1 shows the socioeconomic characteristics of respondents. Sixty percent of the respondents were within the young highly productive age range of 31-50 years and 94.2% had some form of formal education and thus are expected to be vibrant enough to be receptive to innovations and possess good knowledge of the phenomenon under study. The result corroborates with the findings of Akinbile *et al* (2013), Efiong *et al* (2014), and Onu *et al.*, (2020). Agwu *et al*., (2008) considered young age an advantage for increased investment and improved technology utilization and hence innovativeness. The Majority of the respondents (51%) had fairly large households (6-10 persons) indicating the abundance of family labour while 63% of them had more than 10 years of experience in potato farming. Seventy-four percent had a farm size of less than 2ha while 50% earned ₦300,000 or less per annum from their potato farm indicating that they were small-scale farmers with low income. A greater majority (59.2%) of the respondents were not members of any cooperative society, which could influence their farming activities negatively.

Table 1: The distribution of the respondents according to their socio-economic characteristics

Variables	Categories	Frequency (n =120)	Percentage	Mean
Age				40.57
	≤30	26	20.6

Prevalence and identification of bacterial wilt disease.

Sixty-one percent of the farmers were able to identify symptoms of bacterial wilt disease (wilting of plants and brown ring inside the tuber) on their farms while 80% of the farms were attacked by the disease. This indicates a high prevalence of the disease on potato farms in the Jos plateau.

Table 2: The distribution of the respondents according to the identification of disease.

Variables	Yes	No
Can you identify the bacterial wilt disease?	73 (60.8)	47 (39.2)
Is your farm attacked by bacterial wilt disease	96 (80.0)	24 (20.0)

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%)

Level of awareness of bacterial wilt control technologies

Table 3 revealed the distribution of the respondents according to their level of awareness of bacterial wilt disease control technologies. There was a high degree of awareness of bacterial wilt management technologies in the study area as 74.2%, 66.7%, 69.2% and 67.5% of the respondents were aware of the use of clean seeds, use of tolerant varieties, farm sanitation, and rouging respectively. Bagamba *et al*., (2006) reported high awareness by Ugandan banana farmers of the control measures for banana bacterial wilt disease. High awareness of technology is an indication of efficient dissemination.

Table 3: The distribution of the respondents according to their level of awareness of bacterial wilt disease management technologies

Variables	Not aware	Aware
Use of clean seed	31(25.8)	89(74.2)
Use of tolerant varieties	40(33.3)	80 (66.7)
Farm sanitation	37(30.8)	83(69.2)
Rouging	39(32.5)	81 (67.5)

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%)

Level of adoption of bacterial wilt control technologies

The distribution of respondents based on their level of adoption of NRCRI bacterial wilt control technologies in the study area is presented in Table 4. The result revealed a grand mean of 2.27, implying a generally strong adoption of most disease control technologies based on a cut-off point of 2.0. The result specifically revealed high adoption of the use of clean seed (2.50), farm sanitation (2.18), and rouging (2.45). There was however low adoption of the use of resistant or tolerant varieties for controlling the disease. Smallholder potato farmers in Kenya, practiced mainly removing and throwing away diseased or infected plants (a form of field sanitation/hygiene) to control of bacterial wilt (Okello *et al*., 2020). Bagamba *et al*., (2006), reported low adoption of control measures for the control of banana wilt disease by farmers in Uganda.

Table 4: The distribution of the respondents according to their level of adoption

Variables	Never Adopted	Adopted and Stopped	Adopted and still using	Mean	Decision
Use of clean seed	29(24.2)	2(1.7)	89(74.2)	2.50	Adopted
Use of tolerant varieties	61(50.8)	5(4.2)	54(45.0)	1.94	Not
Farm sanitation	46(38.3)	6(5.0)	68(56.7)	2.18	Adopted
Rouging	32 (26.7)	2(1.7)	86(71.7)	2.45	Adopted
Grand mean				2.27	

Source: field survey, 2022; Note: figures in parenthesis are the percentages (%), Key: Adopted and still using (3), Adopted and stopped (2) Never adopted (1). Decision: mean > 2.0 high and mean < 2.0 low

Constraints to the adoption of bacterial wilt control technologies

Table 5 presents the mean of the various constraints faced in the adoption of bacterial wilt control technologies by potato farmers in the Jos Plateau. The result revealed a grand mean of 1.45 implying low constraints of adoption of the reference technologies. However, in terms of ranking, low knowledge of innovation was the most important constraint while cattle menace was of least importance. Low constraints may have resulted in the high adoption recorded in this study.

Table 5: Constraints faced in the adoption of bacterial wilt control technologies by potato farmers

Constraints	Mean	Rank	Decision
Lack of fund	1.29	6	Low
Low Knowledge of innovation	1.78	1	Low
Lack of input	1.50	3	Low
No access to extension bulletins	1.54	2	Low
Scarcity/high cost of labour	1.30	5	Low
Insecurity	1.47	4	Low

Cattle menace	1.25	7	Low
Grand mean	1.45		

Source: field survey, 2022, Key: Very serious (3), Serious (2), Not serious (1); Decision: mean > 2.0 high and mean < 2.0 low

Impact of adoption of bacterial wilt technologies on the livelihood of potato farmers

The result in Table 6 showed the mean level of impact of bacterial wilt control technologies on the livelihood of potato farmers in the study area. Based on a cut-off point of 3, the grand mean of 2.27 obtained implied a generally low impact of reference technologies on the livelihood of respondents. The result was not consistent with the report of Tesfaye *et al.*, (2013), who reported that the adoption of potato production technologies resulted in some impact on the livelihood of adopters in Oromiya and Amhara regions in Ethiopia. These general low-level impacts could be attributed to the poor application of the technologies resulting in farmers not getting the desired result from them.

Table 6: Impact of adoption of bacteria wilt control technologies on the livelihood of potato farmers

Variables	Mean	Rank	Decision
Increased production	1.71	9	Low impact
Children's education	2.01	8	Low impact
Purchase of cloths	2.36	4	Low impact
Acquired new properties	2.32	6	Low impact
Provision of medical care	2.12	7	Low impact
Purchase of land	2.35	5	Low impact
Purchase of TV/radio	2.70	1	Low impact
Purchase of cycles/car	2.40	3	Low impact
Built house	2.42	2	Low impact
Grand mean	2.27

CONCLUSION

From this study, it is evident that there is a high level of adoption of the use of clean seed, rouging, and farm sanitation for bacterial wilt disease management by potato farmers in the study area. This however did not translate into a high impact on their livelihood. The re-training of farmers and extension officers on the appropriate application of the technologies for better impact is hereby recommended.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Soil contamination with spent lubricating oil can negatively impact the productivity and safety of crops. The study assessed the bioaccumulation of Lead (Pb) and Cadmium (Cd) levels on Physiology and Agronomic performance of two okra varieties grown on soil contaminated with spent lubricating oil (SLO). The experiment was a 2 x 5 factorial scheme of 2 okra varieties and 5 different rates of SLO arranged in a Completely Randomized Design (CRD) with three replications. 40 plastic containers of 7 litre capacity were perforated at the bottom and filled with top soil. The two okra varieties used for this experiment were (i) Dogo (an indigenous variety) and LD-88 (an improved variety) while the treatments consisted of T0: 0 ml, T1: 5 ml, T2: 10 ml, T3: 15 ml, T4: 20 ml (w/v). The plants were harvested eight weeks after planting while the leaf and pods were analyzed for lead and cadmium bioaccumulation for each of the tested varieties. The result of the study revealed that all the seeds germinated on soil contaminated with spent lubricating oil for both okra varieties at the 5ml treatment. Conversely, there was a progressive decline in the percentage germination and the mean germination time for okra seeds at higher concentration of SLO for both varieties. The result also indicated that growth characters of plant height, number of leaves and branches and leaf area development were significantly higher at 0ml control. Lower values were however recorded for both okra varieties at higher concentrations of SLO. The result on yield and yield characters revealed that days to first flowering were significantly shorter under the 0ml control over other treatments. Conversely, the more the concentration of SLO in the soil, the longer it took both okra varieties to flower. At 10ml concentration, there was only a trace of Cadmium detected while 0.04mg/kg of lead was detected in Dogo variety and 0.03mg/kg for LD-88 variety. The highest leaf relative water content (LRWC) were recorded for Dogo and LD-88 okra varieties (70.4% and 73.5%) respectively while the lowest value was found in the control plants. Hazard quotient increased with increased contamination hence, the need for integrated health risk assessment for inhabitants of areas polluted with such contaminants. Heavy metals of lead and cadmium uptake by okra in this study was not at critical levels, however, their continuous intake may pose danger to human health.
Keywords: *Bioaccumulation, Spent lubrication oil, Heavy metals, Contamination, Okra varieties*

INTRODUCTION
Okra *(Abelmoschus esculentus (L.) Moench*) is an erect, semi-woody herbaceous annual, which is highly variable in growth from less than 1m to over 3m in height. The leaves and fruits of okra plant are mostly eaten fresh in local communities. The fruits are rich in minerals and vitamins while the stem bark yields fibre (Adetuyi *et al* 2011). Among the environmental pollutants, heavy metals represent a significant hazard to the environment, being both an ecological and health risk. The use of fertilizers and pesticides on agricultural farms can be one of the sources for heavy metals contamination in rural areas. These metals are highly persistent and not biodegradable contaminants, therefore, they accumulate in soil, then becoming accessible to plants or leaching to groundwater (Ahmed *et al*, 2019), the presence of these metals in soil raises a concern for crop growth and food security (Khaled, and Muhammad, 2016, Chioma *et al* 2014). Plants grown on soils contaminated with oil usually exhibit with symptoms of metal phytotoxicity resulting in poor growth and yield (Sajjad, *et al*, 2009). In addition, some

plant species are tolerant to heavy metal stress, showing little inhibition or damage and can accumulate high concentrations of the metals in their tissues (Ahmed *et al*, 2019). Some plants tolerate elevated concentration of heavy metals in soil and can easily bioaccumulate these metals hence pose a health risk to animals and humans. This is because the metals can be easily transferred to consumers through food supply and consequently causes health problems (Fernando, 2012, Matthews-amune, 2018). As a result, human health risk from heavy metal bioaccumulation in vegetables has become a subject of growing concern in recent years (Adewuyi, and Opasina, 2010, Deribachew, *et al* 2015). The objectives of this study is therefore to assess the bioaccumulation and translocation factors of lead and cadmium in okra varieties grown on contaminated soil and assess their health implications on consumers at large.

MATERIALS

Okra
Mesh (2mm)
Lubricating oil
Lead (Pb)
Cadmium (Cd)

METHODS

Experimental site and condition

The study was conducted at the Teaching and Research Farm of the Federal Polytechnic, Ado-Ekiti located in the derived savanna zone of Nigeria. The screen house experiment was carried out to assess the bioaccumulation of Lead (Pb) and Cadmium (Cd) levels on Physiological and Agronomic performance of two okra (*Abelmoschus esculentus* L. (Moench) varieties grown on soil contaminated with spent lubricating oil. The experiment was a 2 x 5 factorial scheme of 2 okra varieties and 5 different rates of spent lubricating oil arranged in a Completely Randomized Design (CRD) with three replicates. In this experiment, 40 plastic containers of 7 litre capacity were perforated at the bottom and filled with top soil obtained from the nursery site of the Department. The soil was sieved to remove gravel and debris with a 2mm mesh. 5 seeds each of the two okra varieties were planted per hole and later thinned to two after percentage germination was performed. The two okra varieties used for this experiment were (i) Dogo (an indigenous variety) and LD-88 (an improved variety) while the treatments consisted of T0: 0 ml, T1: 10 ml, T2: 15 ml, T3: 20 ml, T4: 25 ml (w/v).

Source of Experimental Materials and Treatments

The seeds of the two okra varieties used for the study, namely. (i) Dogo (an indigenous variety) and LD-88 (an improved variety) were obtained from the National Institute of Horticulture (NIHORT), Ibadan while the spent lubricating oil was obtained from auto-mechanics workshop in Ado-Ekiti. The soil was treated with the spent lubricating oil to achieve T0: 0 ml, T1: 5ml, T2: 10 ml, T3: 15 ml, T4: 20 ml % v/w (volume of oil, weight of soil) according to the method of Adenipekun and Kassim (2006). The mixing was gradually done to ensure thorough and even mixing while the untreated soil (0% oil) served as control. The soils were watered to 60% field capacity. Two seeds of each okra variety were planted in the 7 litre plastic containers now a mixture of oil and top soil in their different proportions. Watering was done each day in the morning. The plants were harvested eight weeks after planting to allow for bioaccumulation of heavy metals in the root, leaf and fruit of okra while the roots, leaf and fruits were analyzed for lead and cadmium bioaccumulation for each of the tested varieties.

Plant growth measurements

Germination (%) records were taken at commencement of germination for up to15 days after sowing and okra seeds which failed to sprout after that time were regarded as dead. The height of each plant was measured at regular interval of seven days from the soil level to the terminal bud using a meter rule (Odjegba & Sadiq, 2002). The leaf area was determined by measuring the base, the middle and the upper part of leaf with a ruler and calculated using the formula breadth x length x 0.85 and the girth was taken 2cm above the soil level; the same point was maintained till the end of the experiment to ensure accurate reading, using Vernier calipers.

Determination of Total Leaf chlorophyll content:

Total chlorophyll content was estimated according to the spectrometry methods. The 100 mg fresh leaf was crushed in 20 ml of 80% acetone and the extract centrifuged for 10 min at 1000 rpm. Absorbance of the supernatant was recorded at 663nm and 645nm. They were read using a spectrophotometer. Chlorophyll content (expressed as mg/g-1 of each sample) was estimated according to the formula as follows: Chlorophyll a (mg/g-1) = 12.7 (A663) – 2.69 (A645) x VW Chlorophyll b (mg/g-1) = 22.9 (A645) – 4.86 (A663) x VW Total Chlorophyll t (mg/g-1) = [20.2 (A645) – 8.02 (A663) xVW]/1000 Where A = absorbance at the given wavelength, W = weight of fresh leaf sample, V = final volume of chlorophyll solution (Li *et al*., 2018, Oyewusi *et al*,2021).

Determination of Leaf Relative Water Content (LRWC):

Fresh leaf samples were collected from each treatment. A sharp cork borer was used to cut the leaf samples into small discs (5cm diameter). These were weighed and recorded as sample fresh weight (W), after which the samples were hydrated to full turgidity in distilled water for four (4) hours under normal room light and temperature. After 4 h, the samples were taken out of water and quickly dried of any surface moisture using filter paper, and immediately weighed to obtain full turgid weight (TW). Samples were then oven dried at 80^0c for 24 hrs and allowed to cool in desiccators, and weighed to determine the dry weight (DW). Relative water content was calculated using the mathematical expression below:

$$LRWC (\%) = \frac{W - DW}{TW - DW} \times 100$$

Where:
W = sample fresh weight
TW = sample turgid weight
DW = Sample dry weight (Oyewusi *et al;* 2020)

Determination of lead and cadmium concentrations

Lead and Cadmium concentrations were carried out on plant leaves, roots and fruit. 2g of pulverized sample was put into a conical flask. 10ml of HNO3 was added, and then the mixture was boiled with steady heat till it almost dried. This was allowed to cool before 50 ml distilled water was added and boiled for 10 minutes. Mixture was allowed to cool again and then filtered. The mixture was made up to a known volume. Heavy metal analysis was done using Atomic Absorption Spectrophotometer Buck Scientific 210 VGP model. The instrument was first calibrated with already prepared working standard of corresponding elements to be analyzed after which the concentration of the element in each sample was determined.

$$\textbf{Conc. mg/kg} = \frac{\textbf{AAS Reading x Dilution Factor}}{\textbf{Weight of Sample}}$$

Lead and cadmium concentrations were then measured using an Atomic Absorption Spectrophotometer (Bulk Scientific, Model 210 VGP).

Bioaccumulation Factor (BAF): ratio of metal concentration in okra fruit to metal concentration in the soil)
Translocation Factor (TF): ratio of metal concentration in leaf to metal concentration in the root) was calculated to further assess heavy metal accumulation potential of the two okra varieties and the consequent health implication.

$$BAF = \frac{\text{Concentration of metal in fruit}}{\text{Concentration of metal in the soil}}$$

$$TF = \frac{\text{Concentration of metal in plant leaf}}{\text{Concentration of metal in the root}}$$

The germination percentage (PG) was calculated as follows:

$$Germination\ Percent(\%) = \frac{Number\ of\ seed\ that\ germinated}{Number\ of\ seed\ that\ was\ planted} \times 100$$

The rate of flower abortion will also be examined as follows;

$$\text{Rate of flower abortion (\%)} = \frac{\text{Total number of flowers} - \text{Total number of pods}}{\text{Total number of flowers}} \times 100$$

Data Collection and Analysis

Data collection on growth and yield parameters commenced from the first week after planting. Data were collected on days to emergence and % germination percentage**,** leaf relative water content, leaf chlorophyll content**,** leaf area **,** plant height, number of leaves and branches**,** days to first flowering, number of flowers per plant, rate of flower abortion, pod number, pod diameter, pod length, 100 seed weight and Pod weight

Data collected were subjected to One-way analysis of variance (ANOVA) and Duncan Multiple Range (DMR) Test to establish the mean differences at 5% level of probability, using SPSS Version 16.0. Mean, Standard Deviation, and Coefficient of Variability were also used to compare the degree for each variation of each treatment

RESULT AND DISCUSSION

Table 1: Properties of soil before contamination with spent lubricating oil

Properties	Value
Ph (water) %	4.16
Total N (%)	0.10
Available P (mg/kg)	12.76
Ca^{2+} (Cmol/kg)	1.80
Mg^{2+} (Cmol/kg)	0.70
K^{+} (mg/kg)	0.14
Na^{2+} (Cmol/kg)	0.22

Organic carbon (%)	0.78
Organic matter (%)	1.35
Particle size distribution	-
Sand	56.80
Silt	20.00
Clay	23.20
Total porosity (g/g)	35.30
Water holding capacity (g/g)	0.061
Texture	Sandy loam
Bulk density)g/cm^3)	1.32
Property of Spent lubricating oil	
Lead (mg/kg)	39.75
Cadmium (mg/kg)	10.56
Organic carbon (%)	17.30
Zinc (mg/kg)	19.30
Available P (mg/kg)	0.02
Nitrogen (%)	6.80

Table 1 showed the result of soil chemical properties before the experiment. The pH of the soil was 4.16 which is acidic. Organic matter contents analyzed was 1.35%. Nitrogen content was low 0.10 g/kg. The available P content in the soil was low 4.16 mg/kg, K was also low (0.14 cmol/kg), Na (0.22 cmol/kg), Ca (1.80cmol/kg) and Mg (0.70 cmol/kg).The result showed that the soil was sandy loam in texture with high proportion of sand (56.80%). This implies that basic cations such as Ca, K, Na and Mg would be leached more easily as texture determines the degree of retention or ease of leaching of basic cations (Wapa and Oyetayo, 2014). Heavy metals concentration in spent engine oil (Table 1) indicated that the values of Zn, Pb, Cu and Cd were within normal safe range in soils The percentage organic carbon and nitrogen were respectively high Available phosphorus was very low.

Table 2: Assessment of Lead (Pb) and Cadmium (Cd) Bioaccumulation on Germination perrcentage and Mean Germination Time (GMT) of two okra varieties grown on soil contaminated with spent lubricating oil

Treatment	Variety	Number of seeds planted	Number of seeds germinated	Percentage germination (%)	MGT In Days	MGT in hours
0ml	Dogo	5.0	5.0	100	5.0	120
	LD-88	5.0	5.0	100	5.0	120
5ml	Dogo	5.0	5.0	100	6.0	144
	LD-88	5.0	5.0	100	6.0	144
10ml	Dogo	5.0	4.0	80	8.0	192
	LD-88	5.0	4.0	80	8.0	192
15ml	Dogo	5.0	3.0	60	9.0	216
	LD-88	5.0	3.0	60	9.0	216
20ml	Dogo	5.0	1.0	20	13.0	312
	LD-88	5.0	1.0	20	13.0	312

The result in Table 2 shows that all the seeds germinated on soil contaminated with spent lubricating oil for both okra varieties and for the 5ml treatment. Conversely, there was a progressive decline in the percentage germination and the mean germination time for okra seeds treated with 10ml, 15ml and 20mls of spent lubricating oil for both varieties. At 20ml contaminated soil, only 20% of okra seeds germinated with a MGT of 13 days before emergence for both varieties. This shows that the higher the concentration of SLO in the soil, the lower the rate of germination for all the tested okra varieties.

Table 3: Assessment of Lead (Pb) and Cadmium (Cd) Bioaccumulation on growth and growth characters of two okra varieties grown on soil contaminated with spent lubricating oil at harvest

Treatments	Variety	Plant height (cm)	Number of leaves	Number of branches	Stem girth (cm)	Leaf area (m^2)

CV		0.23	2.31	0.17	0.04	0.10

Mean followed by the same superscript significantly different at 0.05% probability on the same row using Duncan's Multiple Test (DMRT)

The result in Table 3 shows that LD-88 performed significantly better for most of the measured growth characters over the Indigenous Dogo variety. The result also indicated that growth characters of plant height, number of leaves and branches and leaf area development were significantly higher at 0ml control, Lower values were however recorded for both okra varieties at higher concentrations of SLO. The result also shows that there was no significant difference in stem girth of okra grown on soil contaminated with SLO while at 20ml contamination, significantly lower values were obtained

CV								

Mean followed by the same superscript significantly different at 0.05% probability on the same row using Duncan's Multiple Test (DMRT)

The result on yield and yield characters shows that days to first flowering were significantly shorter under the 0ml control over other treatments for both okra varieties. Conversely, the more the concentration of SLO in the soil, the longer it took both okra varieties to flower. It took longer days to attain first flowering at 20ml in contaminated soil. For instance, it took Dogo okra variety 58 days while LD-88 days attained first flowering after 51 days. Similarly, number of flower per plant were significantly lower at 20ml concentration while rate of flower abortion was significantly lower at 0ml control and 5ml. Total flower abortion was recorded at 15ml and 20ml for both okra varieties. There was no result recorded for number of pods/plant, pod length, 100 seed weight and fresh pod yield at 15ml and 20ml concentration of SLO for both okra varieties indicating a physiological barrier of okra to production.

ND-Not Detected

Assessment of lead (Pb) and Cadmium (Cd) Bioaccumulation on leaf and pod yield of two okra varieties at harvest is presented in Table 5. The result shows that at 0ml control, there was no detection of any traces of Pb and Cd presence in the leaf and pod of the two okra varieties while at 5ml concentration, there was only a trace of the metals detected in the leaf and pods of okra. At 10ml concentration, there was only a trace of Cadmium detected while 0.04mg/kg of lead was detected in Dogo variety and 0.03 for LD-88 variety. Higher detection at 15ml and 20ml contamination was recorded at for both varieties.

Table 6: Assessment of lead (Pb) and Cadmium (Cd) Bioaccumulation on Leaf Relative Water Content and Chlorophyll concentration of two okra varieties

Treatments	Variety	LRWC	CHL Conc	BAF	TF
0ml	Dogo	(%) 70.4	(Mg/100g 15mg/l	-	-
	LD-88	73.5	16mg/l	-	-
5ml	Dogo	60.9	13.mg/l	-	-
	LD-88	64.6	14.mg/l	-	-
10ml	Dogo	40.7	5.mg/l	-	-
	LD-88	43.9	7.mg/l	-	-
15ml	Dogo	28.9	-	Trace	Trace

	LD-88	33.0	-	Trace	Trace
20ml	Dogo	25.0	-	Trace	Trace
	LD-88	18.9	-	Trace	Trace

LRWC-Leaf Relative Water Content, Chlorophyll Concentration, BAF-Bioaccumulation Factor, TF-Translocation Factor.

The result in Table 6 revealed that LRWC and Chlorophyll concentration was significantly higher at 0ml control for both varieties while at 5ml contamination, LD-88 had higher LRWC and Chlorophyll concentration (64.6%, 14mg/l) over Dogo variety (60.9%, 13mg/l) respectively. Similarly, significantly lower values of LRWC and Chlorophyll concentration was recorded at higher contamination for both varieties. At 15ml and 20ml contamination over the 0ml control. The result revealed that the Chlorophyll concentration was denatured at 15ml and 20ml contamination while the BAF and TF was significantly low and detected as trace. At higher concentrations of oil in soils, most plant species suffers serious depression in growth. This has been attributed to poor soil conditions, dehydration and impaired nutrient uptake by the roots even when they are present, they are not usually in the absorbable form (ions) rather they are present as compounds. In this study, germination of Okra plants was mostly delayed in the soils contaminated with spent lubricating oil, and this effect varied with different oil concentration. About 80% of all the seeds of the two okra varieties failed to germinate at 20ml of contaminated soils and germination only occurred about 13 days after planting. The presence of SLO in the soil-plant microenvironment appears to have affected normal soil chemistry and this inhibited nutrient release and uptake as well as amount of water imbibed **(**Ayub, et al, 2016). The decrease in height of plant with increase in concentration of SLO is probably due to the non-availability of adequate water, as a result of blockage of soil pore spaces thereby affecting infiltration and easy movement of water molecules in and out of the soil pore spaces. This subsequently affected nutrient uptake and mobility. Nevertheless, the growth of the tested okra plants were not significantly affected at lower concentrations as was observed in the 0ml control and at lower 5ml contamination. This implies that okra can tolerate low levels of SLO contaminations. Mohammed and Folorunsho (2015), Matthews-amune et al (2018), Ruqia *et al*., (2015) and Rumteke *et al* (2016**)** discovered that some heavy metals at low concentrations are essential micro-nutrients for plants, but at high concentrations, they may cause metabolic disorders and growth inhibition for most of the plant species. The poor growth performance recorded in soils contaminated with higher amounts of SLO correlated to the level of the leaf relative water contents (LRWC) recorded. The LRWCs of the plants grown in SLO contaminated soils were highly reduced. This translated into low metabolic processes in those plants which affected their growth performance. Mahmood, et al (2019) made similar observations on *Chromolaena odorata* grown in soil treated with crude oil. The SEO treatment had adverse effect on chlorophyll synthesis.

CONCLUSION

SLO affected the growth of the two okra varieties grown on contaminated soil by causing a significant reduction in most of the measured growth and yield parameters as well as contaminating the plants with heavy metals of lead and Cadmium at different concentrations. Hazard quotient increased with increased contamination hence, the need for integrated health risk assessment for inhabitants of areas polluted with such contaminants. This investigation shows that spent lubricating oil pollution has potential adverse effects on Okra plants, though plants can tolerate low levels of contamination at 5ml, hence, appropriate disposal of SLO should be taken seriously by those handling it. Heavy metals of lead and cadmium uptake by okra in this study was not at critical levels, however, their continuous intake may pose danger to human health.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Cocoyam (Colocasia esculenta) corms, purchased from local markets (Amawom and Ndoro) in Abia state, showing spoilage symptoms were examined for rot associated with fungal pathogens. The causatives microorganisms were isolated from the corms by plating the spoilt tissues obtained aseptically onto Potato dextrose agar media supplemented with lactic acid as an antibacterial agent. After four days incubation, the developing mycelia were purified by repeated sub culturing and identified macroscopically and microscopically using the slide culture technique. The organisms recovered from spoilt Cocoyam were Aspergillus niger, Fusarium oxysporium, Botryodiplodia theobromae, Penicillium chrysogenum and Mucur circinelloides. The rot caused due to B. theobromae, M. circinelloides and A. niger were extensive resulting in complete damaging of Cocoyam tissues. A. niger had the highest percentage occurrence ((28.05%) while P. chrysogenum had the least percentage occurrence of (10.00%).The Pathogenicity revealed that all the isolated fungi can elicit infection but at different degree levels. These fungi might have gained entrance into these Corms from the field, wounds during harvest and transportation. It could also be from the store house (Storage). Proper agronomics activities should be carried out on the field to guide against pathogen infestation on the field. Also, proper care should be taken to guide against bruises during harvesting and transportation of these products. All the above precautions should be taken into consideration as some of these spoilage fungi are known to have negative effects on both humans and livestock because they produce mycotoxins.
Keywords: *Pathogenicity, Fungi, mycotoxins, Colocasia esculenta, harvesting.*

INTRODUCTION
Cocoyam is a perennial monocotyledonous herbaceous plant. It consists of a central corm from which cormels, roots and shoots arise (Onwueme, 1978) Each leaf consist of a long erect petiole and large lamina (Williams *et al*., 1982). Edible cocoyam cocoyam (*Colocasia esculenta*) is a major stable carbohydrates food in sub-saharan Africa It is nutritionally superior to other root and tubers in terms of digestible crude protein and minerals like Ca, Mg and P contents (Green, 2003). Cocoyam took the third place out of the most important root and tuber family cultivated in Nigeria after Yam and Cassava (Igbozulike, 2015). It can be used as an anti-poisoning and wound healing agents by applying the fresh mash in the sores opening. Cocoyam is consumed by both humans and animals and equally useful in industries as raw materials. The oxalic acid content in cocoyam made it dangerous to consume raw for animals and humans because of its itching ability. Spoilage of Cocoyam corms through fungi attack leading to loss in quality and quantity of the corms is one of the major problems of Cocoyam production in Nigeria (NRCRI, 2008) Other problems associated include mechanical, physiological, rodents, birds which always resulted into fungal rot (FAOSTAT, 2019). Post-Harvest loss of root and tuber crops has been a very serious problem to farmers as more than 40% of their harvest are lost because of fungal rot. (Olurinola *et al.*, 1992. This study focuses on isolation and identifying Fungi responsible for Cocoyam spoilage.

MATERIALS AND METHODS
Experimental Site
The study was carried out at the Plant Protection Laboratory, National Root Crops Research Institute, Umudike, Abia State, Nigeria.

Collection of Infected Coccoyam Corms
Infected and clean (non infected) corms of cocoyam showing disease symptoms of soft and dry rots were obtained from two local markets (Ndoro and Amawom) in Ikwuano local government in Abia State. The infected corms

were packaged in different sterile polyethylene bags, taken to the laboratory for isolation and identification of pathogens.

Sterilization of Materials

All glassware used in this study were washed with detergent, rinsed, dried and sterilized by autoclaving at a temperature of 121ºC for 15min. The scalpel, cork borer and inoculating needle were sterilized by dipping them in 70% ethanol and passing them over a Bunsen burner flame until red hot.

Isolation of Fungi

The isolation technique used by Ogbo and Agu (2015) was used in this study. A small section of the cocoyam tissue showing advancing margin of rot and adjoining healthy tissue were cut using sterilized scalpel whose surface were sterilized with 70% ethanol and flamed to red hot. The cut pieces were soaked/washed in 70% ethanol for 1min for surface sterilization. The pieces (1mm-2mm) were then rinsed in three successive changes of sterile distilled water (Frank and Kingsley (2014). The cocoyam pieces were placed on sterile paper towels in the laminar Air flow cabinet to dry for 15 minutes.

Inoculation

The dried infected tissues were aseptically plated onto Petri dishes containing acidified sterile solidified potato dextrose agar (PDA) with the aid of sterile forceps and the plates were incubated at room temperature $\pm$27ºC for 5 days. Fungi associated with the cocoyam rot affected tissue were observed and the frequency of isolation determined using method of Okigbo (2003). Sub-culturing was done to obtained pure cultures of the isolates.

Identification of Fungal Isolates

Pure colonies growing on the plates were identified macroscopically and microscopically. Features observed were colony colour, type of hyphae, texture, shape and growth pattern. Direct observation of culture under the light microscope by careful preparation of slides stained with cotton blue-in-lactophenol was done.Sporangiophores, septate or non septate mycelia, special features like rhizoid on the fungi isolated are used for identification Detailed drawings of the diagnostic features and identification were noted and compared to existing manual guides according to Burgess *et al.,* (2008).

Pathogenicity Test

Healthy cocoyam corm were washed with running tap water, rinsed in three successive changes of sterile distilled water, thereafter, the corms were disinfected with 70% ethanol for 1min and again rinsed with sterile distilled water 3 times. The tubers were allowed to air dry (10 min). A flamed 5mm cork borer was used to bore hole into healthy cocoyam corm, a 5mm diameter disc from the purified isolate of 5 day old culture was cut and replaced into the hole created in the healthy corm. The same procedure was used for the control except that sterile agar discs were used instead of the place of the purified cultures (inoculum) in the holes created in the corms. The hole was covered with the small tissue of Cocoyam from the bored hole thereafter, Blue Seal Vaseline was used to completely seal the holes to guide against cross contamination (Ogbo and Agu *et al.,*2015). Two whole corms of cocoyam were inoculated per fungus. The inoculated corms were placed in sterile transparent polythene bags whose inside has been moistened with cotton wool soaked in sterile distilled water to maintain a high humidity. The inoculated corms were kept in the laboratory at room temperature for 14 days and assessed for rot development by cutting through the point of inoculation where rots developed .A transparent ruler was used to measure the rotten parts. The pathogens were re-isolated as previously described and their cultural and morphological characteristics were compared with those of the original isolates.

RESULTS

Table1: Frequency of occurrence of fungi isolated from infected Cocoyam corms

FUNGI	% OCCURRENCE
A. Niger	28.05
R.stolonifer	19.05
B.theobromae	20.05
M.circinelloides	23.01
P.chrysogenum	10.00

The fungi that were isolated through colonial morphology and microscopic characteristics from rotten/spoilt cocoyam corm (*Colocassia esculenta*) resulting from the sampling survey above included *Asergillus niger, Rhizopus stotonifer, botryodiplodia theobromae, Mucur circinelloides* and *Pencillium chrysogenum.* The most frequently occurring was *Aspergillus niger* 28.05% while the least occurring was *Pencillium sp.*10.00% (Table 1) above.

Table 2: Percentage occurrence of isolated pathogenic fungi

Organisms	Percentage Rot (%)
Aspergillus niger	73.00
Rhizopus stolonifer	55.00
Botryodiplodia sp	79.00
Mucur circinelloides	21.00

The fungi tested for Pathogenicity includes A. *niger*, *R. stolonifer*, *B. theobromae and Mucur circinelloides and* were confirmed to cause the similar disease and rot type noticed on the rot infected sample. The result showed that *Mucur circinelloides incited* dry rot at a lower rate (21.00%). The fungus *Botryodiplodia sp* was the predominant, causing 79% soft rot on the *colocassia esculenta.*

Table 3. Frequency of Occurrence of the different Disease Conditions

Disease Conditions	Frequency of Occurrence	% Occurrence
Dry rot	2	22.2
Soft rot	7	77.7
Total	9	100

Table 3 records the frequency of occurrence of the different disease conditions. Dry rot had 22.2% occurrence while soft rot had 77.7 percentage occurrence. The soft rot symptoms showed brownish liquid and soft cocoyam tissues with offensive odour while the dry rot revealed brown dry hard tissue.

DISCUSSION

Fungal pathogens are the major causative agents of rot in root and tuber crops, reducing the yield, and quality per annum (IITA, 1985). The fungal organisms indicated in this study for causing cocoyam rot were *Botryodiplodia theobramae, Aspergillus niger, Rhizopus stolonifer* and *Mucur spp* (Anukworji, *et al*., 2012 and IITA, 1985). These organisms were responsible for cocoyam corm rot in the store and equally in the soil on the field. The pathogenicity test showed that the inoculated fungi causes rot on the cocoyam corm; this was due to the ability of the pathogenic fungi to utilize the tissues of cocoyam corm as nutrients aiding its growth and development. This result is similar to the fungi associated with Nigeria cocoyam (Igbozulike, 2015). Okigbo, (2003) also isolated *Aspergillus niger* and *Fusarium* from spoilt Cocoyam .Onuegbu, (1999) equally isolated *B.theobromae* and *Mucur* species which belong to the group of fast growing fungi that causes rot in Cocoyam. Most recent work of Frank and Kingsley (2014) revealed that *Mucur sp, Aspergillus sp* and *Fusarium sp* out of the five isolated in this study are actual pathogens of root and tuber crops. In this study, most of these fungi tend to cause severe rot in cocoyam production as observed during the pathogenicity test. The infestation of these crops started from the field and later to the storage barn. Healthy planting materials plus clean planting equipment should be used while planting. Injuries should be avoided during harvesting to avoid direct penetration of these pathogenic organisms. Proper temperature and relative humidity should be maintained during storage, because these factors also aid the proliferation of these pathogenic fungi. .All the fungi isolated in this study has also been prove by other research workers (Anukworji *et al.*, 2012,Onuegbu, 1999 and Okigbo, 2003) to be cause of fungal rot in storage of root and tuber crops. *Aspergillus niger* and *Botryodiplodia* are responsible for dry rot while wet rot was caused by *Mucur sp* and *Rhizopus sp.*

CONCLUSION

Cocoyam, a staple crop for human consumption, livestock feeds and industrial uses should be protected against fungal attack due to its importance .Due to being a source of revenue for farmers and the nation Anukworji *et al.*, 2012 ,the crop should be protected against fungal infestation by encouraging farmers to adopt proper agronomics practices to guide against fungi infestation, care should be taken during harvesting and transportation to guide against bruises so as to ensure a healthy nation and in turn have a balanced economy.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
There is need for continuous assessment and development of smut resistant sugarcane varieties as the sugar estates in Nigeria depends more on exotic cultivars that succumb to pests/diseases and suffer quick yield decline due to non-adaptability in their new environment. A study was conducted to assess the performance of thirty five sugarcane accession under smut infestation at NCRI Badeggi. The clones were planted on Randomized Complete Block Design (RCBD) with three replications. Analysis of variance reveals significant differences among the clones for some traits. Highest cane yield (112.80, 111.10 and 104.43 t/ha) were recorded in NCS-009, NCS-003 and NCS-002 for the plant crop. Maximum cane yield for the ratooned crop was observed in NCS-002 (74.43 t/h) which was significantly heavier than the yield documented for many of the studied accessions except for NCS-003, DB75159, NCS-001, B-2, NCS-009 and B 245/B0197. Generally, there was a noticeable yield decline in the ratoon crop of the studied accessions except for B881602 and DB75159 that deviate from the aforementioned trend. The best brix of 23.00% was recorded for Cp72-2086-1 in the plant crop, while BR 971007 and Cp72-2086-1 having the best brix mean value of 23.87 and 23.70 % in the ratooned crop. NCS-002, NCS-007, KNB9218, NCS-003, DB75159, BR971007 and B 245/B0197 proved to be highly resistant to smut infestation during the plant crop in the year 2019 and the ratooned of sugarcanes accessions in year 2020 reveals that NCS-002 was highly resistant to smut and NCS-007, KNB9218, B51410, NCS-003, DB75159, NCS-009 were also resistant to the disease. This evaluation has revealed the potential of some sugarcane accessions and their reaction to smut disease for subsequent utilization in the breeding program.
Keywords: *Smut, accession, resistant, susceptible*

INTRODUCTION
Sugarcane (*Saccharum* spp.) is one of the most important grass species cultivated in the tropics and subtropics (Solomon *et al*., 2019). It belongs to the genus *Saccharum* of the family Poaceae. The crop is recently been used for wide range of value-added products that go beyond food, such as bioethanol, bioelectricity, biohydrocarbons and biochemicals. It contributes about 75% of world sugar production with sugar beet producing the rest (Mani *et al*., 2019). Sugarcane is an important industrial cash crop in Nigeria (Olaoye, 2006) and its cultivation is very useful as it has numerous products and contributes to the national economy greatly.

Sugarcane whip smut (*Sporisorium scitaminea*) is a very destructive disease in all sugarcane growing areas of the world including Nigeria (Sarmad, 2016; Wada *et al*., 2016). It was first reported from Natal, South Africa in 1877 and for many years were mainly restricted to the old World, where it caused repeated outbreaks (Mohammed, 2016). According to Mohammed (2016), the disease was first noted on *Saccharum sinense* and till today it is still the most devastating fungal disease problem in many African sugarcane plantations and is often a serious menace in sugarcane growing areas. It is a serious disease of sugarcane which causes significant quantitative and qualitative loses to cane farmers worldwide. According to Braithwaite *et al.* (2008) yield losses may be 39-56 percent in planted crop and 52-73 percent in ratoon crop. The best eco-friendly and most sustainable means to contain the pathogen are through the use of resistant varieties (Sundravadana *et al.,* 2011; Philip *et al*., 2010).

Evaluation and screening for promising smut resistance clones from diverse sugarcane germplasms to serve as parent in hybridization programmes which shall result in development of smut resistant and high quality varieties is paramount.

Different sugarcane clones exist and are grown by farmers worldwide and efforts have been made by scientists in Nigeria to collect, evaluate and screen these germplasm for yield performance and also for sources of diseases and pest resistance in the existing collections. However due to varietal degeneration and changes in smut races, it has become paramount for continuous hybridization activities to generate smut resistance genotypes that will replace any obsolete clone. Variety resistance is retained for few years, while a known resistant variety may succumb to a new physiological strain (race) of smut with changes in climatic conditions (Mansoor *et al*., 2016). The diseases resistant germplasm of sugarcane plays a leading role for assessment of resistant varieties through breeding program (Begum *et al*., 2007). Resistant genotypes of sugarcane could play a vital role in reducing the yield loss caused by the disease. It has been evidence that selection of resistant parents for hybridization programmes would improve the level of resistance of progenies (Glyn, 2004). Therefore, screening of sugarcane genotypes against smut disease is a pre-requisite in the varietal development activities before hybridization and releasing varieties for commercial purposes.

MATERIALS AND METHODS

The experiment was conducted at the sugarcane research field of National Cereals Research Institute (NCRI) Badeggi (Lat 9° 3' 0"N, Long 6° 9' 0"E and 70.5m above sea level), Niger state. Thirty five sugarcane accessions were sourced from the National Sugarcane Germplasm at NCRI, Badeggi.

The sugarcane accessions were used as the experimental treatments. The experiment was conducted in a randomized complete block design with three replications.

Fresh smut whips were collected from smut affected plants grown at NCRI sugarcane field. The teliospores were gently scraped and thoroughly sieved, using 53 µm mesh. The sieved teliospores were sealed in cellophane bags and stored in the refrigerator at 10°C. Viability of inoculum was confirmed on water agar and those that reveal viability of >70% were taken for preparation of inoculum suspension. Four grams of spores were added in 1 litre of distilled water along with a few drops of Tween 20 for homogenous spore suspension. Finally, the inoculum density was adjusted to 4×10^6 spores/ml with the help of haemocytometer (Nasr, 1977). The planting materials (setts) were completely immersed into the smut inoculum for an hour. The setts were then be removed and put into a sack under shade for 14 hours prior to planting. Ten inoculated setts was planted (lay end to end) per row at a depth of 6-7cm and covered with top soil. The stalks were cut into 3 budded setts and grown on a single row of 5m long with inter row spacing of one meter. The experiment covers a total area of 18m x 34m ($612m^2$). The plant crop was established on 11th February 2019 and the accessions were ratooned on 15th January 2020.

Data was collected on sprout (%) count at 21, tiller count at 3 months after planting, plant height at 3 and 6 months after planting, stalk length, Milleable stalk per plot and cane yield ton/ha at maturity. Brix (sugar content) was measured with the aid of refractometer at 12th months after planting. Smut index was expressed by reaction types evaluated with a numerical rating scale of 1-9 where, 1=highly resistant and 9=highly susceptible as described by Satyavir and Beniwal (1978).

The data collected was use for analysis of variance (ANOVA) using Crop Stat package (version 7.2). Means were separated where significant differences occur among the genotypes.

RESULTS AND DISCUSSIONS

There was significant difference among the studied accessions for sprout percent (table 1). D 8687 gave the best sprout percent (67.80%), while accession B 9054 and B-2 has very low sprout performance (16.23 & 24.47%) in their plant crop. However, with the establishment of ratoon crop NCS-009 and NCS-007 show better performance in sprouting (67.67 & 63.33) than all the screened accessions except NCS-002, B85266, BR00001 and B 245/B0197.

NCS-002 possess more tillers in the plant crop which was significantly superior to the number of tillers recorded for some of the studied accessions except NCS-007, B85266, KNB9218, NCS-003, B-2, BBZ951034, SP81-3250, NCS-009, RB86-7512, BR971007, B47419 and B 245/B0197. The ratoon crop result shows that NCS-002 maintain the best in number of tiller and was significantly similar to the number of tillers recorded for NCS-007, B85266, NCS-003, NCS-009, B47419 and B 245/B0197. The lowest mean number of tillers was observed in BOO 270. According to Sharma and Agarwal (1985) good sprouting and tillering with synchronized millable canes of average thickness are desired selection parameters to evaluate the agronomic performance of sugarcane varieties. Diseased plants produced tillers, which some are of no use as the emerging tillers were very weak and later reveal smut whip there by terminating their growth. Sugarcane smut disease had been noted to cause reduction in sprout percentage of sugarcane setts and increase in number of tillers contrary to healthy plants (Ferreira and Comstock, 2001).

The plant height at six months after planting differs significantly among the accessions and KNB9218 poses the maximum (266.67cm) plant height. During the ratoon crop cycle DB75159 has the tallest plant height at six months after planting which does not significantly differs from the plant height documented for NCS-002, KNB9218, NCS-003, NCS-001, SP81-3250, N27, RB86-3129, NCS-006, NCS-009, RB86-7512, NCS-008, BBZ92653 and B 245/B0197.

Table 1: Mean values of growth performance of sugarcane accessions screened for smut resistant at NCRI Badeggi (2019-2020 and 2020/2021)

Table 2 reveals significant differences among some sugarcane accession under smut infestation for yield parameters. NCS-003 has more average milleable stalks than all the evaluated entries except NCS-002, NCS-007, KNB9218, N27, RB86-3129, NCS -009 and B 245/B0197. The milleable stalks of ratooned crop was higher in NCS 002 which did not significantly differs with number of milleable stalks recorded for NCS-007, NCS-003, B-2 NCS-003 and B 245/B0197. A very high reduction in number of milleable stalks of ratoon crop was noticed in B85266, Boo 270, B881602, B 96399 and B 93220. Also some of the screened accessions (NCS-002, B-2, SP71-618, NCS-006, NCS-009 and NCS-008) reveal more number of milleable stalks in the ratoon crop above the plant crop. The increment in numbers of tillers at the early stage of growth and the reduction of stalk population during the growth of sugarcane is a characteristic of several gramineous. The phenomenon of cane stalk mortality could be related to the factors which induce competition for growth conditions (light, moisture nutrient) and the survival of the tillers after the competition is a character of a variety (Getaneh *et al.*, 2015). However in this study, the survival of the tillers might also depends on the inherent disease resistance of the accessions and the smut strain pathogen present in the environment.

RB86-3129, NCS-006 and NCS-009 shows longer stalks (236.7, 233.3 and 230.30 cm) in the plant crop result which were at par with stalk length of KNB9218, B881602, NCS-001, B96399, SP81-3250, N27, NCS-005, B93220, BBZ 921101, NCS-008, 0535, BBZ92653 and B 245/B0197. B9054 gave the shortest stalk length

(149.23cm) during the plant crop. The ratoon result reveals that NCS-009 and B 245/B0197 perform better in stalk length (186.10 & 186.0cm), while the shortest stalks were observed in B85266, B51410 and Cp72-2086-1 (107.23, 106.90 & 109.0 cm). There was a general reduction in stalk length of the ratooned crop as against what was observed for plant crop.

Maximum brix of 23.00% was recorded for Cp72-2086-1 which was significantly the same with the brix mean values of B51410, NCS-003, BR00001, RB94-2291, SP71-618, B93220 and BR971007. Many of the studied accessions show increase in brix of the ratooned crop. BR 971007 and Cp72-2086-1 has the best brix mean value of 23.87 and 23.70 %. NCS-006 performs poorly in terms of brix (17.13%) in the ratooned crop. Khan et al., (2017) has also reported differences in brix among some evaluated sugarcane varieties in Ethiopia.

The thirty five studied accessions show highly significant disparities in their cane yield per hectare. Three accessions such as NCS-009, NCS-003 and NCS-002 yielded higher (112.80, 111.10 and 104.43 t/ha) and were better in cane yield than some of the evaluated entries. The lowest cane yield of the plant crop was noted in B881602 (22.57t/ha). Maximum cane yield mean value for the ratooned crop was observed in NCS-002 (74.43 t/h) which was significantly heavier than the yield documented for many of the studied accessions except for NCS-003, DB75159, NCS-001, B-2, NCS-009 and B 245/B0197. The variability observed in cane and other studied traits among the accessions confirm that the accession differs in their genetic makeup of diverse parents. EL-Geddway, *et al*. (2002) stated that sugarcane varieties are greatly affected by genetic makeup. Several authors (Bahadar et al., 2000, Getaneh et al., 2015) had reported variation in cane yield among accessions from diverse parents at different ecologies. According to Keerio et al, (2003) unless the genetic potentialities of a variety are high, mere provisions of growing conditions such as manuring, irrigation etc. will not lead to appreciable improvement in cane or sugar yield.

Generally, there was a noticeable yield decline in the ratoon crop of the studied accessions except for B881602 and DB75159 that deviate from the aforementioned trend. This disease reduces the length and weight of canes (Solomon *et al.,* 2000).

Getaneh et al., (2015) said that the inherent genetic makeup of a variety might have contributed towards higher or lower cane yield and sugar content. They suggested that genetically improved varieties may bear ability to produce satisfactory results for per hectare yield and sugar percentage under given set of environmental conditions.

Table 2: Mean values of yield performance of sugarcane accessions screened for smut resistant at NCRI Badeggi (2019-2020 and 2020/2021)

Table 3 exhibits the incidence, rating and reaction types of the studied accessions to smut inoculation. The resistance to smut disease caused by *S. scitamineum* and subsequent whip smut development greatly varied among sugarcane accessions at different region. NCS-002, NCS-007, KNB9218, NCS-003, DB75159, BR971007 and B 245/B0197 proved to be highly resistant to smut infestation during the plant crop and eight accessions (B9054, B51410, B-2, N27, SP71-618, NCS-009, NCS-008 and B 245/B0197) were rated as resistant in their reaction to smut disease.

Smut disease incidence result of the ratooned sugarcanes accessions reveals that only NCS-002 was highly resistant to smut and NCS-007, KNB9218, B51410, NCS-003, DB75159, NCS-009 were also resistant, while all the remaining 28 accessions exhibit different susceptibility reaction type to the smut infestation.

The result of this study confirms the report of Hossain *et al.* (2020) that many genotypes showed different reactions to smut infestation in two consecutive years. They further said that it may be due to environmental variations and change of races/strains/pathotypes in two years. The researchers were of the opinion that sudden breakdown of the previous resistance accessions to smut disease is a pointer to the possibility of the existence of more virulent races of *S. scitaminea* than what was obtained before.

According to Croft and Braithwaite, (2006) ratooning can induce symptom development in latently infected plants. Marchelo *et al.*, (2008) had also reported the building up of smut in successive ratoons of cane especially in susceptible varieties. Sundar *et al.* (2015) stated that the breakdown of disease resistance is attributed to the possible emergence of new virulent pathotypes.

The variation to smut resistance among the studied accession agrees with the report of Agboire *et al*., 2002 and Sabalpara *et al*., 2002 and they demonstrated that source of resistance against smut exist among sugarcane genotypes and can be manipulated through breeding to evolve new promising sugarcane varieties.

CONCLUSION

Based on the result of this evaluation it is concluded that the studied accessions exhibit different reaction to smut infestation depending on the crop cycle. Variations in response to smut infestation revealed by the studied accessions suggested that the accessions differs in their genetic make up, thus providing good chances for sugarcane improvement.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Disease management strategies for sustainable sugar cane production were investigated by using two sugar cane genotypes [Bida local and commercial NCS 001], four rates of sugar cane trash mulch rates (0, 3, 6, 9 t ha^{-1}) and four weed management practices [weedy check, monthly hoe weeding for five months (5 MHW), application of PE diuron + POE 3 – maize force, and application of PE diuron plus POE 3 – maize force + 2 MHW] at Badeggi (Lat. 9° 45′ N, Long. 06° 07′ E). The treatments were arranged in a split-plot design and replicated three times in 2016 and 2017 cropping seasons. Results showed that application of 6 t ha^{-1} mulch produced comparable but lower whip smut incidence to 9 t ha^{-1}. Application of PE diuron plus POE 3 – maize force and 5 MHW, resulted in a comparable whip smut incidence to PE diuron plus POE 3 – maize force plus 2 MHW. Similarly, PE diuron plus POE 3 – maize force, 5 MHW and PE diuron plus POE 3 – maize force plus 2 MHW produced comparable brix content, number of stools and millable stalks. Application of PE diuron plus POE 3 – maize force proved equally effective as 5 MHW in contributing the highest cane yield. Lower whip smut incidence and cane yield were recorded in NCS 001. In all, application of 9 t ha^{-1} trash mulch with 5 MHW or PE diuron plus POE 3 – maize force plus 2 MHW or PE diuron plus POE 3 – maize force strategies effectively managed smut incidence in the present study. The strategies also increased cane girth, brix content, number of stool, millable stalks and cane yield of genotype NCS 001.
Keywords: *Bida local chewing cane, genotype NCS 001, whip smut incidence, trash mulch, cane yield.*

INTRODUCTION
Sugar cane (*Saccharum officinarum*) family Gramineae (Poaceae) is a widely grown crop in Nigeria. It provides employment to over a million people directly or indirectly besides contributing significantly to the national exchequer (FAOSTAT, 2019). Reduction in yield components and cane yield losses due to whip smut disease has been reported by Wada and Anaso (2016). Besides, in this agroecology in Nigeria, the common sugar cane types under production are the chewing cane for human consumption and commercial cane as raw materials for the sugar and sugar-related industries. One potential way to reduce the negative effects of weeds and diseases in the production of these sugar cane genotypes is to use large amount of the trash usually produced by sugar cane as mulch. Sugar cane trash mulches have a direct or an indirect mechanism to lessen disease incidence. This mechanism was also elaborated by Downer *et al.* (2002) who discovered the root rot disease through short- and long-term mulching effects. Other ways to improve the yield of sugar cane, irrespective of the genotypes is by weed management practices. Abiloye *et al*. (2018) and Bassey *et al*. (2021) reported that, PE diuron and POE 3-maize force application significantly reduced weed biomass by a slow rate of decomposition, which is related to its high concentrations of organic carbon, soil moisture content and reduced rate of evapotranspiration resulting from changes in the C/N ratio and allelopathy which translates to reduce the chances of whip smut disease incidence. Research information on disease management for sugar cane when sown under different rates of sugar cane trash mulch, weed management practices and whip smut incidence is scarce in Nigeria. Hence, the objectives of this study were to evaluate the effects of varying sugar cane trash mulch and application of weed management practices on disease management for sustainable sugar cane production.

MATERIALS AND METHODS
A field trial was conducted at the upland sugar cane experimental field of the National Cereals Research Institute, Badeggi (Lat. 9° 45′ N, Long. 06° 07′ E) in the southern Guinea Savanna agroecological zone of Nigeria in 2016 and 2017. Before cultivation, the vegetative cover of the experimental site was manually cleared, ploughed and harrowed with a tractor in the first week of February 2016 and 2017. The land was fully irrigated before planting

by pumping water from a stream using a 3.5 HP water pump with a 12.5 cm diameter hose. Thereafter, the land was marked out into plots with bunds at the edges for water retention. Gross plot size was 5 m x 4 m (20 m^2) consisting of 4 sugar cane rows, and net plot size was 5 m x 2 m (10 m^2) consisting of 2 sugar cane rows. Each row was spaced at 1 m apart. Tender healthy young stalks of seven months old of the two sugar cane genotypes were used as planting material. The stalks were cut into setts each containing three eye buds, planted continuously end-to-end without intra-row spacing in shallow sunken furrows which were later earthened up at 3MAP. The application of pre-emergence (PE) diuron was done immediately after planting at 2.0 kg a.i ha^{-1}. The application of post-emergence (POE) 3 – maize force [metolachlor 375 g L^{-1} plus terbuthylazine 125 g L^{-1} plus mesotrione 37.5 g L^{-1}] at 179.2 g ha^{-1} was applied at 5 weeks after planting (WAP). The NPK fertilizer was applied at 150 kg N, 60 Kg P_2O_5 and 90 Kg K_2O in equal halves at planting and 10 WAP. Irrigation water was applied at 41.3 L per plot once per week from February to April. Rainfall was supplemented with irrigation in May which marked the establishment of the rainy season.

The treatments consisted of a factorial combination of two sugar cane genotypes of chewing cane (Bida local) and commercial cane (NCS 001), and four weed management practices viz [weedy check, monthly hoe weeding for five months (5 MHW), application of PE diuron + POE 3 – maize force, and application of PE diuron plus POE 3 – maize force + 2 MHW] arranged in a split-plot design and replicated three times. Weed management practices were allocated to the main plot, while the two sugar cane genotypes were the subplot. Herbicides were applied with knapsack (CP3) sprayer at a spray volume of 4 L ha^{-1} at 206 KPa. Percent brix at harvest at 12 MAP was taken using Hand refractometer to determine the level of field sucrose. Sugar cane stools per plot were taken by counting the number of stools at 12 MAP with the aid of a tally counter. Millable stalks per stool were taken by counting the number of stalks at 12 MAP also with the aid of a tally counter. Cane yield at harvest was taken from the harvested stalks, weighed and expressed in t ha^{-1}.

Whip smut was not induced artificially in the test cane genotypes as the trial site has been repeatedly cropped to known susceptible canes to *Sporisorium scitamineum*, (Wada *et al*., 2016), so were left to natural infection. Percent smutted stools and stalks were calculated by first counting the total number of stools and stalks in a plot using a tally counter. Then the number of smutted stools and stalks in the same plot was counted and expressed as a percentage of the total to determine the incidence of whip smut at 3, 6, 9 and 12 MAP. All data collected were subjected to analysis of variance (ANOVA). The means were separated using Least Significant Difference (LSD) at 5 % level of probability using SAS version 9.2 statistical package (SAS, 2002).

RESULTS AND DISCUSSION

Smut incidence was significantly higher in Bida local cane than NCS 001 at 3 and 6 MAP in both years (Table 1). However, under trash mulch, smut incidence was highest in plot without mulching. Furthermore, weedy check recorded higher smut incidence compared to other sugar cane plot given the other weed management practices (Table 1). The relatively low smut incidence observed in NCS 001 may be attributed to heavy residue production and better weed competitive ability which stimulate the release of chemicals for the inhibition of pathogens thus, reducing the chances of smut disease spread as reported by Chalker-Scott (2007). On the other hand, the high whip smut incidence recorded in sugar cane plots without mulching agree with reports by other workers that dry environments favour whip smut invasion (Comstock, 2014; Wada *et al*., 2016). The relatively low smut incidence observed under weed management practices can be attributed to decrease in weed dry matter caused by weakening of stems and roots, depletion of weed seed bank and better conditions for crop growth, hence good cane yield. This is consistent with the findings of Singh *et al*. (2011) and Choudhary and Singh (2016).

Higher brix content was obtained in NCS 001 sugar cane compared with that from Bida local sugar cane in both years of study (Table 1). Furthermore, the highest brix content was found in sugar cane plants given 6 t ha^{-1}, but similar to that in 9 t ha^{-1} treated plots in both years. Also, 5 MHW and application of PE diuron + POE 3 – maize force herbicides in the two years of study, and PE diuron + POE 3 – maize force herbicides + 2 MHW in 2016 only recorded similar higher brix content compared to other sugar cane plants given the other weed management practices (Table 1). There was significant interaction between trash mulch and weed management practice on brix content of sugar cane in 2017 where under 5 MHW, brix content was not significantly increased as mulch was increased from 0 to 9 t ha^{-1} (Table 1). Application of 9 t ha^{-1} mulch in combination with 5 MHW, PE diuron + POE 3 – maize force herbicides + 2 MHW or PE diuron + POE 3 – maize force herbicides recorded the highest brix content in this study. Number of stools per plot varied significantly with weed management practices. Genotype NCS 001 produced more stools than Bida local in both years of study (Table 1). The highest number of stools was

LSD - least significant difference, MHW-Monthly hoe weeding, PE- Pre-emergence (Diuron at 2 kg a.i/ha) herbicide, POE-Post-Emergence (3-Maize force at 179.2 g/ha) herbicide, NS-Not significant

Found in sugar cane plots given 9 t ha^{-1} in both years. The 5 MHW and application of PE diuron + POE 3 – maize force herbicides in the two years of study, recorded similar higher number of stools compared to sugar cane plots given the other weed management practices (Table 1). The production of consistently taller sugar cane stalk, higher brix and cane yield in plots with NCS 001 can be attributed to better crop growth in terms of internode length and tillering ability governed by its superior genetic potential and efficient use of applied inputs for improved growth and cane yield. The present result agrees with the findings of Kuri and Chandrashekar (2015).

Genotype NCS 001 significantly produced more number of millable stalks than Bida local (Table 1). Sugar cane applied with 9 t ha^{-1} mulch recorded significantly higher millable stalks than the lower rates in each year of the study (Table 1). Weed management practices significantly affected number of millable stalks per stools Application of 5 MHW produced more millable stalks in 2016 and 2017 seasons, which were similar to those of other weed management treatments. The weedy check consistently produced the lowest millable stalks throughout the study period. The observed increase in the number of stools and millable canes might also be attributed to decrease in weed infestation, increased soil organic matter, improved physical and chemical properties and soil water regimes, which translates into better crop growth. This is in agreement with the work of Cheong and Teeluck (2015)

Cane yield was significantly higher in NCS 001 plots compared with Bida local in the two years of study (Table 1). Furthermore, application of 9 t ha^{-1} mulch recorded significantly higher cane yield compared to plots applied with lower rates in both years. Application of 5 MHW produced higher cane yield in 2016 plant crop while cane yield of PE +POE and PE + POE + 2 MHW were at par. On the other hand, application of PE +POE herbicide recorded the highest cane yield but was at par with PE + POE + 2 MHW treatments in 2017. The result of higher cane yield in this study was similar to the work of Mohammed *et al*. (2019) who recorded the highest cane yield with ILS 708-05 genotype compared to other genotypes tested. These authors also stated that high brix content and cane yield by a sugarcane genotype is a function of the higher genetic potential of the variety.

CONCLUSION

This study has shown that the application of 9 t ha^{-1} trash mulch with 5 MHW or PE diuron plus POE 3 – maize force plus 2 MHW or PE diuron plus POE 3 – maize force effectively managed whip smut incidence, increased growth and cane yield of sugar cane, especially NCS 001 in this agroecology of Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The incidence of a devastating invasive pest of South American origin, the tomato leafminer, Tuta absoluta (Meyrick) (Lepidoptera: Gelechiidae), on tomato (Solanum lycopersicum L.), was reported for the first time in Abeokuta, Ogun State, Nigeria in 2015. The outbreak of this pest in Nigeria and its devastating effects on tomato makes research on its developmental stages as well as search for parasitoids associated with the pest that could be used as potential biological control agent for the management of Tuta absoluta in Nigeria. Samples of T. absoluta used for this study were obtained from infested tomato leaves containing eggs and neonate larvae of the pest at the tomato green houses of Ogun State Agricultural Development Programme (OGADEP), Kotopo, Abeokuta, Ogun State, Nigeria. Eggs and neonate larvae from infested leaves were reared in the Entomology laboratory Horticultural Research Institute, Ibadan Nigerian, at room temperature (25°C - 30°C), relative humidity of 79 – 92% and a 12 hours photoperiod until adult moth and parasitoid emerged. A mean total developmental period of 18.77 days was recorded. A parasitoid species was identified as Apanteles spp and (Hymenoptera: Braconidae) is now reported for the first time on Tuta absoluta in Nigeria. This information is important because the parasitoid being a biocontrol agent, can form an important component in the development of an integrated pest management(IPM) programme for the management of the pest in Nigeria.
Keywords: *Tuta absoluta, Apanteles spp, Lycopersicon esculentum*

INTRODUCTION
The tomato leafminer, *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae), is a key pest of tomato, *Lycopersicon esculentum* L. in Central and South America regions, from where it is allegedly native (Vargas, 1970; Fernandez and Montagne, 1990; Ulle and Nakano, 1994; Uchoa-Fernandes *et al*., 1995; Colomo *et al*., 2002). The larvae of *T. absoluta* attack leaves, stems, and fruits of tomato plants resulting to a yield loss of between 80 - 100% (Lopez, 1991). *Tuta absoluta* (Meyrick) was accidentally introduced to Spain in 2006, from where it spread north to the Netherlands and east to Iran (Desneux *et al*., 2010; 2011; Baniameri and Cheraghian, 2012). In northern Africa, it was reported in Tunisia in 2008 (Abbes *et al*., 2012), Morroco in 2008 (Ouardi *et al*., 2012), north of the Sahel in 2008 (Desneux *et al*., 2011), Sudan and Ethiopia in 2011 (Anon. 2012), Senegal 2013(Pfeiffer *et al*., 2013).
It was detected in Kano State, the largest tomato producing State in Northern Nigeria in early 2015 and by September 2015, unusual larvae feeding symptoms were observed on tomato in the greenhouses of Ogun State Agricultural Development Programme (OGADEP), Kotopo, Abeokuta Ogun State, Nigeria. The invasion of *Tuta absoluta* into Nigeria in 2015 wiped away tomato production in Northern Nigeria and subsequently delayed the take-off of Dangote tomato processing industry which was slated to start production in 2015 . Damage to tomato was caused by the larvae found feeding on leaves, stems and fruits of the plants. On leaves, the larvae fed on the mesophyll tissue within the leaf epidermis, forming irregular leaf mines which later became necrotic, reducing the photosynthetic ability of the plants. On stems, larvae formed extensive galleries which affected the physiological functions of the plants. Fruits were also attacked by the larvae predisposing them to secondary pathogens, leading to fruit rot (Mahlangu *et al*., 2022).
Insecticide application was the main management method adopted by farmers to control *T. absoluta* which was however not quite effective due to the endophytic behaviour of larvae and the development of pesticides resistance by field populations of the pest (Lietti *et al.*, 2005). There are however, potentials for the effective management

of the pest through the use of indigenous parasitoids of the pests (Zappalà *et al*., 2013; Biondi *et al*., 2013; Ferracini *et al*., 2012; Zappalà *et al*., 2012; Urbaneja *et al*., 2012; Abbes *et al*., 2013). Identification of *Apanteles* spp. as a parasitoid of the pest in Nigeria calls for intense study on the biology of the pest and the possibility of rearing the parasitoids for use as biocontrol agents in the management of *T absoluta* in Nigeria.

MATERIALS AND METHODS

Detection of *Tuta absoluta* infestation in the commercial greenhouses (24 × 8 m with 0.3mm size mesh of 45 cm width on the 2 lengths of each greenhouse) of Ogun State Agricultural Development Programme (OGADEP), Kotopo, Abeokuta Ogun State, Nigeria in September 2015. Leaf samples containing 32 eggs and 146 first instar larvae were randomly collected from tomato plants and placed in paper bags. The samples were transferred to the Entomology laboratory of National Horticultural Research Institute, Ibadan Nigerian and reared at room temperature (30°C - 34°C) and relative humidity of 79 – 92% and a 12 hours photoperiod. All the samples collected (leaves with 32 eggs and infested leaves with 146 first instar larvae) were kept in a dual purpose Kilner jar lined with moist filter paper and covered with mesh for aeration and arranged on a work bench. Fresh tomato leaves were introduced into the jars from time to time to ensure the availability of fresh food until pupation.

The above procedure was repeated in the same year with 8 leaves containing 57 eggs and other tomato leaves containing 205 first instar larvae. Emerged moths and their parasitoids were killed with cotton wool soaked in ethyl acetate in a dual purpose Kilner jar. Specimens were mounted and dried in an oven at 35°C for 24 hours and stored in insect boxes and later identified at the insect museums of Department of Crop Protection and Environmental Biology, University of Ibadan, Nigeria.

Parameters Assessed and Statistical Analysis

Parasitoids that emerged were identified and counted while the mean values in days of the developmental stages of *T. absoluta* from egg to adult stage were observed and recorded. Descriptive statistics was used to analyze the data obtained.

RESULTS

Table 1: Developmental period of *Tuta absoluta* and the number of emerged parasitoid at 30°C - 34°C and 79–92% R.H in September

Developmental stage	Mean developmental period (day)	Total number	DevptlRange (day)	Number of emerged parasitoid
Egg to first instar	2.1	32	1-3	0
last instar larvae		146		
Pupae	10.0	57	7-11	0
Pupation to adult emergence	5.7	38	5-7	1 (2.44%)*
Total	17.8			

*Percentage of emerged parasitoid from 41 pupae

Table 2: Developmental period of *Tuta absoluta* and the number of emerged parasitoid at 30°C - 34°C and 79–92% R.H in October, 2015

Developmental stage	Mean developmental period (day)	Total number	Range (day)	Number of emerged parasitoid
Egg to first instar	2.7	59	1-3	0
Last instar larvae to		205		
Pupation	11.6	138	7-12	0
Pupation to adult emergence	6.2	84	4-7	2 (2.33%)*
Total	20.5			

*Percentage of emerged parasitoid from 86 pupae

The mean total developmental period in September 2015 from egg to adult emergence was 17.8 days as shown in Table1. The eggs collected on tomato leaves from the green house fields hatched to first instar larvae within 1 – 3 days (2.1 days mean). Only 57 out of the 146 first instar larvae collected from infested tomato leaves pupated between 7 – 11 days (10.0 days mean). Subsequently, 38 adults of *Tuta absoluta* emerged from the pupae within 5 – 7 days (5.7 days mean). One parasitoid species was identified as *Apanteles* spp. (Hymenoptera:Braconidae) and is now reported for the first time to the best of my knowledge as a parasitoid of T. absoluta in Nigeria.

Similarly, in October 2015, the mean total developmental period from egg to adult emergence was 20.5 days. The 12 eggs collected on tomato leaves from the green house fields hatched to first instar larvae within 1 – 3 days (2.7 days mean). From the 205 first instar larvae collected, only 138 pupated between 7 – 12 days (11.6 days mean). Subsequently, 84 adults *Tuta absoluta* moth emerged from the pupae within 4 – 7 days (6.2 days mean). The same parasitoid (*Apanteles* spp.) was observed on the larvae of *T. absoluta*.

DISCUSSION

The developmental of *Tuta absoluta* from egg to adultgreatly depends on environmental conditions, with average development time of 23.8 days at 27.1ºC (Barrientos *et al*., 1998). The mean developmental period from egg to adult of *T. absoluta* was reported to be 30.18 days at 25 - 26° C and 60 - 70% R.H. (Erdogan and Babaroglu, 2014) while Cuthbertson (2011) reported that the development from egg to adult took 35 days at 25ºC. However, the findings of this research with mean developmental period of between 17.8 – 20.5 days at 30 – 34 ºC would have concurred with the reports of the authors above if the incubation periods of eggs in the green houses were properly recorded in addition to the higher temperature conditions under which the research was conducted.

Classical biological control programmes of several exotic pests species demonstrated the importance of indigenous natural control agents in the regulation of pest populations (Simberloff and Stiling 1996; Pimentel, 2000). In Colombia, Oatman and Platner (1989) reported a broad complex of parasitoids such as *Apanteles* spp. (Hymenoptera: Braconidae) a larval and pupal parasitoid, *Apanteles dingus* (Hymenoptera: Braconidae) a larval parasitoid and *Apanteles gelechiidivoris* (Hymenoptera: Braconidae) had received particular attention in the management of pests species (Vallejo, 1999). The ability of *Apanteles* spp (2.44% and 2.33%) observed parasitizing the larvae of *Tuta absoluta* indicates its potential as an indigenous biological control agent of *Tuta absoluta* in the country. Further studies on rearing, multiplication and used of *Apanteles* spp. is suggested for inclusion in the development of biological control program to manage *T. absoluta.*

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The South America tomato pinworm Tuta absoluta (Meyrick) (Lepidoptera: Gelechiidae) is currently the worst pest of tomato in Nigeria due to its high infestation levels and damage to tomato. Integrated pest management (IPM) strategies are quintessential to control T. absoluta. However, the current IPM strategies for the pest in Nigeria is elementary, and insecticides are the primary control tools, butare however not quite effective in the management of the pest and hence, the unrelenting high yield losses of tomato in the country. The effects of three levels of nitrogen (low, normal and high), three irrigation regimes (once per week, twice per week and once in 10 days) and four management measures (NIHORT-Tuta trap tray, NIHORT-Lyptol, NIHORT-Raktin, and spirotetramat 75g/ L + flubendiamide 100g/ L) are evaluated on the population of T. absoluta and tomato yield. At one application per 10 days (drought) + varying levels of nitrogen with application of managements, there were no record of T. absoluta population and yield loss in the field however, at one application per week +varying levels of nitrogen and management measures, Tuta populations, marketable fruit weight, unmarketable fruit weight, average fruit weight and fruits Yield were recorded and found to be significantly (P<0.05) less than those observed at two applications per week with varying levels of nitrogen and application of control measures. The highest fruit yield was obtained when Tuta populations were low at two applications per week with normal nitrogen and biorational control management compared to synthetic insecticides.
Keywords: *NIHORT-Lyptol, NIHORT-Raktin, Tuta absoluta, Tomato*

INTRODUCTION
The South American tomato pinworm *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae) is an invasive pest of tomatoes in Nigeria (Sanda *et al*., 2018). Following its first detection in Nigeria in 2015, the impacts of *T. absoluta* on tomato production in the country has been serious, causing 100 % yield losses, if left untreated (Oke *et al.*, 2017a, Bala *et al*., 2019). The current economic losses in tomatoes associated with *T. absoluta* in one growing season in Nigeria is estimated at six million US dollars (Bala *et al*. 2019; Sanda *et al*., 2018; Oke *et al*., 2017b). Like most Lepidopteran pests, its four larval instars are the damaging life stage. These caterpillars penetrate, mine, feed, and develop in tomato leaf tissues, consequently limiting and disrupting photosynthesis in tomatoes (Desneux *et al*., 2010; Mansour *et al*., 2018). *Tuta absoluta* is difficult to control and most open-field tomato growers rely on the use of insecticides, which has led to the pest developing resistance to insecticides even in South America and across Europe (Guedes *et al*., 2019). Since the invasion of this pest in Nigeria in 2015, the National Horticultural Research Institute (NIHORT), Nigeria, has developed some Integrated Pest Management (IPM) methods that are environmentally friendly, effective, sustainable, and simple to use. These methods include an insect Trap Tray Technology (TTT), which can be used as attract and kill device. This device attracts and kills *T. absoluta*, and several thousand adults can be killed using a single TTT (Oke *et al*., 2017). Other control strategies such as biopesticides from botanical products (NIHORT-Raktin and NIHORT-Lyptol) have also been developed and patented for the control of *T. absoluta* in Nigeria. However, to develop a complete and an effective IPM strategy, the integration of several control methods is paramount (Desneux *et al*., 2022). This necessitates research into exploring cultural practices by farmers for pest control as well as biotic factors and abiotic factors

such as natural enemies, the role of climatic factors, and fertilization and water inputs, which are important factors that regulate the population of insects.

Bottom-up effects of fertilization and irrigation are crucial for *T. absoluta* population growth (Han *et al*., 2019). The literature on plant–insect interactions has long been central to understanding insect and plant community structure and dynamics (Bruce, 2015). Variability in plant nutritional components is determined by factors such as water, nutrient availability, and others (Gutbrodt *et al.,* 2011; Inbar *et al*., 2001). Such variations in plant quality can lead to trophic cascades such as bottom-up effects on phytophagous arthropods (e.g., on development, fecundity, etc.) (Hunter, 2001). Nitrogen is one of the most applied mineral fertilizers in crop production due to its importance in the composition of plant tissues. The development of Lepidopterans has been positively or negatively correlated to plant nitrogen content, also plant water content is a useful index of its nutritional value for many Lepidopterous larvae (Schoonhoven *et al*., 2005; Inbar *et al.*, 2001). In addition, drought may influence plant chemical defense levels, leading to either enhanced or reduced resistance to herbivores (Inbar *et al*., 2001). Historically, drought periods have been considered a major factor underlying outbreaks of herbivorous insects (White, 1969; Mattson and Haack, 1987). Manipulation of fertilizer levels and irrigating regimes may help to optimize agricultural practices by promoting negative effects on herbivorous insects. However, little damage to plants and negligible crop yield losses may be required (Chau, 2005; Chow, 2012). To minimize *Tuta* damage and increase tomato yield, most smallholder farmers in Nigeria have resorted to increase in fertilizer application with concomitant decrease in irrigation regimes. However, infestation levels and economic damage induced by *T. absoluta* are not abating but rather worsening. Therefore, this paper is focused to investigate the role of fertigation in tomato yield and *T. absoluta* infestation in Nigeria.

MATERIALS AND METHODS

Experimental site and layout

The experiment was carried out in Danja, Katsina State using UC82B Tomato variety.

Experimental design

Tomato seedlings were raised on nursery seed beds and covered with a thin layer of rice straw mulch in January 2022. At two-leaf stage, seedlings were irrigated once with 2.5 g NPK 15-15-15 dissolved in 1 liter of water. At 4 weeks, seedlings were transplanted at planting space of 50 cm and 35 cm intra and inter row respectively. It was a factorial experiment laid in a Randomized Complete Block Design (RCBD) with three replications. A total of 28 plants were planted per replicate per plot. Each experimental plot was 2.1 x 2 m (4.2 m^2). The plants were exposed to the natural field infestation by indigenous population of tomato leaf miner.

Treatment applications

Fertilizer levels

A. Low Nitrogen (LN): NPK 15:15:15 (150 kg/ha) was used as a basal dose in two splits (at two and at five weeks after transplanting (WAT) while Urea fertilizer (50 kg/ ha) was added at seven weeks after transplanting (first fruit-set).

B. Normal Nitrogen (NN): NPK 15:15:15 (300 kg/ha) was used as a basal dose in two splits (at two and at five weeks after transplanting (WAT) while Urea fertilizer (75 kg/ ha) was added at seven weeks after transplanting (first fruit-set).

C. High Nitrogen (HN NPK 15:15:15 (600 kg/ha) was used as a basal dose in two splits (at two and at five weeks after transplanting (WAT) while Urea fertilizer (100 kg/ ha) was added at seven weeks after transplanting (first fruit-set).

Irrigation regimes

i. Drenching of the field once in a week
ii. Drenching of the field twice in a week
iii. Drenching of the field once in 10 days

Management practices

Hand weeding was done three times using hoe at 3, 6 and 9 weeks after transplanting (WAT).

Biorational Tuta management:

1. NIHORT-Tuta trap tray set at 288 m^2, bio-pesticides: NIHORT-Lyptol
2. NIHORT-Raktin sprayed rotationally at 2, 4, 6 and 8 weeks at 1 litre/ 5 litres water.
3. Synthetic insecticide: spirotetramat 75g/ L + flubendiamide 100g/ L sprayed at 15ml/ 15 litres water once in week from week 2 to week 9 (8 times) according to farmers practice.

Data Collection

Data were collected on five randomly selected plants in each plot at one, three, six and nine weeks after transplanting. Upper 3 leaves were selected from each of the five plants and the percentage leaf damage by *T. absoluta* was recorded. Weight of Marketable fruits (kg) (unblemished fruits ≥15g), non-marketable fruits (kg) (blemished fruits and/ or ≤ 15g), and yield per hectare (ton); were measured using digital weighing scale.

Data analysis

Analysis of variance was performed using the general linear model (GLM) procedure in the SAS software and means were compared using Duncan's multiple Range test.

RESULTS

There was no record of *T. absoluta* infestation from untreated plots within the 9 weeks of observations in Fertigation at one application per 10 days + varying levels of nitrogen, however, Tuta infestation gradually increased with increase in applications per week from once per week + varying levels of nitrogen to twice per week + varying levels of nitrogen until complete infestation of the plants was observed at the 9th week with 6 treatments: once / week + low nitrogen, once / week + normal nitrogen, once / week + high nitrogen, twice/ week+ low nitrogen, twice/ week+ normal nitrogen, and twice/ week+ low nitrogen. No Marketable fruit weight was recorded on any of the treatment interactions while unmarketable fruit weight, and fruits yield were significantly affected by fertigation and irrigation interaction. The highest unmarketable fruit weight which translated to fruits yield (0.3kg) and highest average fruit weight (12.16g) were recorded with twice per week + normal nitrogen interaction. Once per 10 days + varying levels of nitrogen interactions did not produce flowers and so no fruits set (Table 1).

Table 1: Effect of Fertilization and Irrigation Regimes on *Tuta Absoluta* Infestation, Marketable Fruit Weight, Unmarketable Fruit Weight, Average Fruit Weight and Fruit Yield/ Hectare (Ton/ Ha) Of Tomato Without Control Between January – May 2022

Means followed by different letter (s) differ significantly at P≤ 0.05 using DMRT WAT= weeks after transplanting, MFW= marketable fruit weight, UmFW= unmarketable fruit weight, AFW= average fruit weight and FY= fruits Yield

In spirotetramat 75g/ L + flubendiamide 100g/ L sprayed field, Tuta populations were not recorded within the 9 weeks of observations however, at one fertigation per 10 days + varying levels of nitrogen Tuta populations showed a gradual increase with increase in number of applications per week from one application with varying levels of nitrogen to two applications per week + varying levels of nitrogen.
However, a complete devastation of the plants were not observed at the 9th week with the 9 treatments. The highest infestations within the 3,6 and 9 weeks were observed on twice per week + normal nitrogen regime (7.2, 47.5 and 51.3) respectively (Table 2). Marketable fruit weight was recorded on all the treatment interactions with twice per week + high nitrogen yielding the highest of 4.45kg although this yield was not significantly different from 4.26kg obtained from twice per week + normal nitrogen. The highest unmarketable fruit weight (2.25kg) was recorded on twice per week + low nitrogen while the highest average fruit weight (47.62g) was obtained from twice per week + high nitrogen regime, however, this value is not significantly different from those obtained on twice per day + normal nitrogen interaction (47.37g). Fruits yield were significantly affected by fertigation and irrigation interaction. Also, the highest fruit yield (6.42kg) was recorded with twice per week + high nitrogen interaction, similarly, this value is not significantly different from those obtained on twice per week + normal nitrogen interaction (6.34kg). Once per 10 days + varying levels of nitrogen interactions did not produce flowers and so no fruits *set al*so (Table 2).

Means followed by different letter (s) differ significantly at P≤ 0.05 using DMRT WAT= weeks after transplanting, MFW= marketable fruit weight, UmFW= unmarketable fruit weight, AFW= average fruit weight and FY= fruits Yield.

Results obtained using biorational treatments of NIHORT-Tuta trap tray, NIHORT-Lyptol and NIHORT-Raktin sprays on tomato fields showed that, Tuta populations were not recorded within the 9 weeks of observations at one application per 10 days + varying levels of nitrogen however, Tuta population records appeared to also gradually increased with increase in number of applications per week. The high number of Tuta populations recorded at two applications per week + low nitrogen, normal nitrogen and high nitrogen levels (32.3, 35.8 and 27.1) respectively were at par and did not differ among themselves. Marketable fruit weight had the highest record (7.04 kg) at two applications per week with normal nitrogen followed by 7.01kg obtained from two applications per week + high nitrogen though there was no significant difference between the two however the least at Two applications per per week + low (1.01kg). The highest average fruit weight (49.21g) and fruits yield were significantly affected by fertigation and irrigation interaction with the highest fruit yield (8.09kg) being recorded on twice per week + high nitrogen interaction, similarly, this value is not significantly different from those obtained on twice per week + normal nitrogen interaction (8.05kg). Once per 10 days + varying levels of nitrogen interactions did not produce flowers and so no fruits s*et al*so (Table 2).

Table 3: Effect of Fertilization and Irrigation Regimes on *T. absoluta* infestation, Marketable fruit weight, Unmarketable fruit weight, Average fruit weight and fruits yield/ hectare (ton/ ha) of tomato with biorational: Nihort-tuta trap tray, Nihort-lyptol and Nihort-raktin for control of *tuta absoluta* between January – May 2022.

Fertigation regime	Nitrogen levels	Tuta populations				MFW (kg)	UmFW (kg)	AFW (g)	FY (t/ha)

DISCUSSION

The varying levels of nitrogen and irrigation regime significantly affected *T. absoluta* infestation on tomato plants consequently affecting plant yield. Drought resulting from minimal application of irrigation, regardless of the level of fertilizer application once per 10 days+ varying levels of nitrogen) resulted in plants with small leaf area and thick cuticle. This made the leaves unattractive and unappealing to *T. absoluta* for feeding and as oviposition site. Tuta populations infestation irrespective of application of pest control, triggers negative bottom-up effects on Tuta which was consistent with the ''Nitrogen limitation hypothesis'' (White, 1993). The level of drought resulted in the plants not reaching its maximum physiological stage of setting flowers and producing fruits. Also, no *T. absoluta* infestation was observed when irrigation was done once in 10 days implying that drought negatively affected *T. absoluta* survival and development. The foliage of the water stressed plant tended to wilt thus probably becoming less edible or nutritious for Lepidoptera larvae (Gutbrodt *et al*., 2011)· This suggests that larvae had difficulty in obtaining enough water for optimal development thus causing a slowdown in their development (Peng *et al*., 2014). In addition, water not only acted as an indispensable ingredient for herbivore metabolism but also mediated nitrogen availability for plants (Huberty and Denno 2004). It is generally known that nitrogen and water contents are positively correlated, to *T. absoluta* larvae development and therefore may suffer a deficit of N-based nutrient in the plants subjected to drought (Cardenas-Navarro *et al*., 1999).

When fields were irrigated once a week with a low Nitrogen level applied, (once per week + low nitrogen) there aws infestation of *Tuta absoluta* on tomato irrespective of the application of control measure and when compared to twice a week irrigation regime. Reduction in the survival rate from egg to pupa or adult stages, pupal weight and consequent slow-down of the development of *T. absoluta* can result from feeding on plants of low quality (Peng *et al*., 2014). These clearly shows that altered nitrogen and water inputs to tomato plants do trigger a bottom-up effect on the biological traits of *T*. absoluta. Peng *et al.* (2014) inferred that *T. absoluta* larvae could be affected by changes in nutritional value and chemical defense in tomato plants. Indeed, nitrogen was considered as a limiting nutrient factor for the growth of many Lepidopteran herbivores because larvae may experience lack of organic nitrogen, i.e. specific protein and/or amino acids, leading to reduced or impaired metabolism during their critical growth period and even to premature death (Hunter and McNeil 1997). Moreover, concentration of non-nitrogeneous compounds in leaves could also be negatively affected by insufficient nitrogen input, such as starch in tomato leaves as well as soluble carbohydrate in young tomato leaves (Royer *et al.*, 2013).

Furthermore, N-limited tomato plants could have higher levels of chemical defense against *T. absoluta*. GDBH (Growth Differentiation Balance Hypothesis) predicts that moderate growth limitations caused by external factors such as low nutrient availability will result in an accumulation of carbohydrates and, subsequently, in increased concentrations of constitutive secondary compounds (Herms and Mattson, 1992). The N-limited tomato plants produced more insect-defensive soluble phenolics (C-based defensive compounds) i.e. chlorogenic acid, rutin, kaempferol-rutinoside since their con- centration is positively correlated with C/N ratio in tomato leaves (Stout *et al.*, 1998). Moreover, the concentration of constitutive tomatine, a key N-based glycoalkaloid defensive compound in tomato, is also positively correlated with leaf C/N ratio (Royer *et al.*, (2013). The application of recommended nitrogen twice a week contributed significantly to increase in leaf area of tomato plant which leads to increase in yield of tomato to certain level. This had the implication on the record of the increased infestation of Tuta and yield of the plants across the control management applied. However, the application of biorational: NIHORT-Tuta trap tray, NIHORT-Lyptol and NIHORT-Raktin enhanced the lowest infestation of Tuta and consequent highest fruit yield reported. Therefore, in developing an integrated pest management for *T. absoluta* involving the use of NIHORT-Tuta trap tray, NIHORT-Lyptol and NIHORT-Raktin, cultural practices such as fertilizer application and level of irrigation regimes are vital as observed in this study.

CONCLUSION

In the field, nitrogen and water inputs to tomato plants affected the *T. absoluta* population on tomatoes and these effects were probably due to a combination of nutritional value and higher chemical defenses, supporting both the ''Plant vigor hypothesis'' and the ''Nitrogen limitation hypothesis'' which are well reported for Lepidoptera pests. Normal fertilization + twice per week irrigation regimes to tomato plants under the applied treatments increased, marketable fruit weight, average fruit weight and fruits yield, however, the highest values were recorded under biorational Tuta management. Irrigation is more critical for tomato growth and production of flowers which provides favourable condition for reproduction of *T. absoluta*. However, the application of biorational control management curb its devastation and consequent production of safe tomato fruits.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The invasion of the South American tomato pinworm, Tuta absoluta (Meyrick) (Lepidoptera: Gelechiidae) to Nigeria in 2016 is one of the most damaging to tomato production. Growers have largely relied on applying synthetic chemical insecticides as the primary management strategy, but excessive use is harmful to the humans and environment. Effect and sustainable control requires the development of IPM with a primary focus on biological control. This study investigated the occurrence, distribution, and abundance of natural enemies of T. absoluta in Nigeria. Sampling was done across four local government areas each from four major tomato-producing states in northern Nigeria. A total of 18 potential natural enemies of T. absoluta including ten predators and eight parasitoids in the Hemipteran and Hymynopteran insect orders were identified. Tapinoma nigerriumu was very abundant across most of the farms sampled in the four States. Similarly, Pheidole spp and N. tenuis were very abundant or moderately abundant, although occurring in few numbers or absent in some farms. Podisus nigrispinus and Zelus spp. were mostly abundant but D. errans, M. pygmaeus, B. pallescens, Xylocoris spp and Debilia spp were rarely or not found in each of the states sampled. This study concluded that the observed biological control agents can be explored for inundative or inoculative releases in the development of biological control programme for this pest.

INTRODUCTION
Nigeria is the largest producer of tomatoes in sub-Saharan Africa (SSA) (FAOSTAT, 2019), and tomato is one of the most important staple foods in the country and across Africa (Aigbedion-Atalor *et al*., 2019; 2020; Borisade *et al*., 2017). Tomato production therefore is a major source of livelihood in Nigeria, providing sustainable job opportunities for over 10 million people along the value chain, especially among smallholder tomato growers cultivating 0.5 to 4 hectares (Oladejo and Oladiran, 2014). However, several factors, including pests and diseases, water availability, and climate variability, constrains production (Borisade *et al*., 2017; Sanda *et al*., 2018). Amongst these factors, invasion of the South American tomato pinworm, *Tuta absoluta* (Meyrick) (Lepidoptera: Gelechiidae) to Nigeria in 2016 is one of the most damaging to tomatoes (Aigbedion-Atalor *et al*., 2019; Borisade *et al*., 2017). Although *T. absoluta* feeds and completes its development on a wide range of host plants, especially Solanaceae, it prefers tomatoes (Desneux *et al*., 2010). It can feed on virtually all parts of the shoot system of tomato, and yield loss is resultant of the disruption of the plant's photosynthetic process by the larvae feeding on leaves, and all four larval instars are destructive (Desneux *et al*., 2010; Biondi *et al*., 2018). Like all ectotherms, environmental conditions such as temperature substantially regulate its development and all aspects of its phenology. However, it is cold and heat tolerant, with thermal thresholds ranging between 14°C and 34.6°C (Krechemer and Foerster, 2015). Thus, when host plant species are available in suitable climatic conditions, *T. absoluta* exhibits high multivoltinism, producing over 12 generations annually without diapause (Biondi *et al*., 2018; Desneux *et al*. 2010). Its long range spread and means of introduction into novel environments have been

attributed almost entirely to anthropogenic-mediated influences, notably global trade and climate change (Desneux *et al*., 2010; Campos *et al*., 2017; Biondi *et al*., 2018). However, aspects of its biology, including its homodynamic and multivoltine behavior, its high reproductive capacity – one female can lay about 260 eggs in her lifetime – as well as its ability to evolve resistance to several insecticides are crucial drivers of its invasive success (Uchoa- Fernandes *et al*., 1995; Zekeya *et al*., 2017). The cumulative impact of these attributes, plus the lack of effective natural occurring enemies of the pest in tomato agroecosystems make management strategies of *T. absoluta* complex. Like all areas in the Afrotropical and Palearctic regions where *T. absoluta* is invasive, the impacts of *T. absoluta* in Nigeria are profound and can result in 100% yield loss, if left untreated (Oke *et al*., 2020a, 2020b; Bala *et al*. 2019). For example, in only one growing season in Kano State (one of the major tomato producing States in Nigeria) in 2016, over 2 billion Nigerian Naria (US $ 5,585,822, US $ 1 equivalent to 357 Naria) was lost due to *T. absoluta* (Bala *et al*. 2019; Sanda *et al*., 2018; Oke *et al*., 2017). The high yield losses countrywide resulted in the shutdown of the largest tomato processing factory in Nigeria, resulting in significant losses of livelihood (Bala *et al*., 2019). *Tuta absoluta* invasion in Nigeria coincided with the outbreak of the Ebola virus in West Africa, in late 2014 and 2015, and earned it the nickname 'Tomato Ebola' due to the similarity in the spread and impact of both organisms in the region (Borisade *et al*., 2017). Since then, tomato growers have relied on applying synthetic chemical insecticides as the primary management strategy for the pest. However, the excessive use of these chemicals is harmful to non-targets/beneficial organisms (Desnuex *et al*., 2022) and human health due to the lack of protective gear during applications and residues in fruit. Also, *T. absoluta* has evolved resistance to almost all insecticides used for control in Nigeria, thus requiring the development of new insecticide active substances (Guedes *et al*., 2019). However, since 2016 the National Horticultural Research Institute (NIHORT) in Ibadan, Oyo State, Nigeria, has heavily invested in developing integrated pest management (IPM) strategies to manage its devastating impacts on smallholder growers and food security in the country. These efforts have resulted in a simple, effective, and sustainable technology called the insect Trap Tray Technology (TTT), which can attract, trap and kill more than five thousand adults per trap. Also, two biopesticides, the NIHORT-Raktin and NIHORT-Lyptol, that can kill all life stages of the pest have been developed. However, there is dearth of information on naturally occurring enemies of *T. absoluta* in Nigeria, yet important for developing biological control programmes that may control the pest. Therefore, this study aimed to investigate the occurrence, distribution, and abundance of natural enemies of *T. absoluta* in Nigeria the rationale of designing biological control strategies to increase the IPM options of *T. absoluta* in Nigeria where its impacts are unrelenting, increasing poverty and food shortage.

MATERIALS AND METHODS

Insect collection and rearing

Surveys were conducted in tomato farms in northern Nigeria in 2019. We selected four local government areas each from four major tomato producing states in northern Nigeria: Jigawa, Kaduna, Kano and Katsina states (Figure 1). Five smallholder tomato grower farms (1 acre – 5 acres) were sampled per local government area. In most (95%) of the farms sampled, tomatoes were grown largely in a monocropping farming system and the age of the tomato plants sampled ranged between 2 weeks after transplant and plants that were being harvested at 14 weeks old fruit harvesting. Whole plants and leaves were sampled for *T. absoluta* infestation in a 5 m sampling area in each farm. Sampling occurred every fortnight from February, March and April 2019. *Tuta absoluta* Infested leaves were collected and placed in sealed airtight plastic paper bags, sealed with parafilm, and taken to the laboratory at NIHORT, Ibadan, while infested whole plants were transplanted into pots (filled with soil) in a cage and then transported to the laboratory. Leaf samples were transferred from the plastic bags to small plastic boxes. Intermittent resupplies of tomato leaves were made to support the development of the larval stage of *T. absoluta.* All samples were labelled individually according to the location/farms where they were collected. The laboratory was maintained at 26±2 °C, 60±10% RH, and L12:D12 photoperiod.

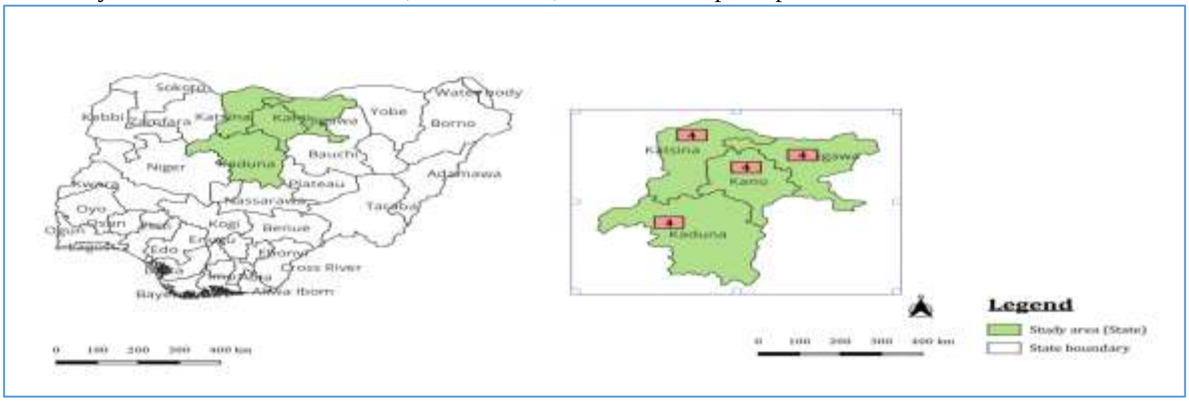

Figure 1: Map showing the study area (States) where sampling was conducted in four States in northern Nigeria. Numbers in pink-shaded boxes indicate the number of local Governments Areas that were sampled in each State.

Abundance of natural enemies

Parasitoids and predators that emerged from field samples collected in each of the four local government areas in the four study states were counted, recorded, and then preserved in 95% ethanol. Identification was done at the insect museum of NIHORT, Ibadan. We grouped the abundance of parasitoids or predator/5m/ acre in each farm/local government area as follows: Very abundant = 20-50, Moderately abundant = 10-20, Abundant = 5 – 10, Few = 1-5, and None = 0

RESULTS

Natural enemies

Based on morphological characteristics, ten predators and eight parasitoids were recorded. The predators included: *Podisus nigrispinus* (Dallas) (Hemiptera: Pentatomidae), *Zelus* spp (Hemiptera: Reduviidae), *Blaptostethus pallescens* (Poppius) (Hemiptera: Anthocoridae), *Xylocoris* spp (Hemiptera: Lyctocoridae), *Debilia* spp. (Hemiptera: Reduviidae), *Dicyphus errans* (Wolff) (Hemiptera: Miridae), *Macrolophus pygmaeus* (Rambur) (Hemiptera: Miridae), and *Nesidiocoris tenuis* (Reuter) (Hemiptera: Miridae) *Tapinoma nigerriumu* (Nylander) (Hymenoptera: Formicidae), *Pheidole* spp (Hymenoptera: Formicidae) (Table 1). .The parasitoids recorded were *Trichogramma* spp (Hymenoptera: Formicidae), Cryptinae spp. (Hymenoptera: Ichneumonidae), *Diadegma* spp. (Förster) (Hymenoptera: Ichneumonidae) *Bracon spp*. (Fabricius) (Hymenoptera: Braconidae), *Apanteles spp.* (Förster) (Hymenoptera: Braconidae)*Cotesia spp.* (Cameron) (Hymenoptera: Braconidae), *Diglyphus spp.* (Förster) (Hymenoptera: Eulophidae) and *Necremnus spp*. (Thomson) (Hymenoptera: Eulophidae) (Table 1).

Table 1: Predators and parasitoids recovered from sampled *Tuta absoluta* infested tomato leaves in major tomatoes producing States of Nigeria in 2019

Species	Family	Order	Target stage	Agent type
Podisus nigrispinus	Pentatomidae	Hemiptera	Adult	Predator
Zelus spp.	Reduviidae	Hemiptera	Adult	Predator
Blaptostethus pallesce	Anthocoridae	Hemiptera	Larvae	Predator
Xylocoris spp.	Lyctocoridae	Hemiptera	Larvae	Predator
Debilia spp.	Reduviidae	Hemiptera	Larvae	Predator
Dicyphus errans	Miridae	Hemiptera	Egg and larvae	Predator
Macrolophus pygmaeus	Miridae	Hemiptera	Egg and larvae	Predator
Nesidiocoris tenuis	Miridae	Hemiptera	Egg and larvae	Predator
Tapinoma nigerriumu	Formicidae	Hymenoptera	Pupae	Predator
Pheidole spp.	Formicidae	Hymenoptera	Pupae	Predator
Trichogramma spp.	Trichogrammatidae	Hymenoptera	Egg	Parasitoid
Cryptinae spp.	Ichneumonidae	Hymenoptera	Larvae	Parasitoid
Diadegma spp.	Ichneumonidae	Hymenoptera	Larvae	Parasitoid
Bracon spp.	Braconidae	Hymenoptera	Larvae	Parasitoid
Apanteles spp. (Förster)	Braconidae	Hymenoptera	Larvae	Parasitoid
Cotesia spp. (Cameron)	Braconidae	Hymenoptera	Larvae	Parasitoid
Diglyphus spp. (Förster)	Eulophidae	Hymenoptera	Larvae	Parasitoid
Necremnus spp.	Eulophidae	Hymenoptera	Larvae	Parasitoid

Abundance

Tapinoma nigerriumu was very abundant across most of the farms sampled in the four States (Table 2). Similarly, *Pheidole* spp and *N. tenuis* were very abundant or moderately abundant, albeit occurring in few numbers or absent in some farms. *Podisus nigrispinus* and *Zelus* spp. were mostly abundant but *D. errans*, M. *pygmaeus*, *B. pallescens*, *Xylocoris* spp and *Debilia spp* were rarely or not found in each of the states sampled (Table 2).
The parasitoid species were generally low or absent across all four sampled States (Table 2).

DISCUSSION

Biological control programmes search, explore, and use predatory insects and mites, parasitoids and nematodes, against target pests. Following *T. absoluta* invasion in Nigeria in 2015, there has been a paucity of the occurrence and abundance of natural enemies of the pest. Conversely, insecticides have been ubiquitously used. Yet, no apparent sign of the pest's pressure has been reported. In fact, it is believed that the founder population had already evolved resistance to synthetic chemical insecticides in South America prior to its invasion across AfroEurasia, including Nigeria. Hence, articulating the unrelenting increase in the population density of the pests despite the increasing frequency of insecticide application. The surveys that we conducted in this study revealed the presence of 18 potential natural enemies of *T. absoluta* in Nigeria. We found 10 predatory species and 8 parasitoids that have been reported elsewhere across South America and the invasion range of the pest. Considering the failure of insecticides, the current high infestation of *T. absoluta*, and the impacts on the socio-economic of the pest's damage in Nigeria, it may be prudent to consider developing biological control programmes with the natural enemies that we found. For example, the potential of *N. tenuis* and parasitoids in controlling populations of *T. absoluta* is well-documented. Aigbedion-Atalor *et al*., 2021, showed that *N. tenuis* can substantially reduce the population of *T. absoluta* either alone or together with a braconid wasp, *Dolichogenidae gelechiidivoris* (Marsh) (Hymenoptera: Braconidae), imported into Kenya for the first classical biological control of *T. absoluta* in Africa. Chailleux *et al*. (2013) underscored the potential of combining *M. pygmaeus* and *Trichogramma* spp for the control of *T. asboluta*. These authors showed that although intraguild predation (IGP) is inflicted on *Trichogramma achaeae* by *M. pygmaeus* when these natural enemies are combined, the risk of IGP depends on the developmental stage of *T. achaeae* inside the egg because the larva is at risk mostly early in its development (when parasitized egg is still yellow). Further, Chailleux *et al*. (2013) highlighted that non-consumptive event, likely probing of the predator on parasitized eggs, may induce mortality in parasitoid offspring without actual feeding on parasitized eggs and that both IGP and non-consumptive events decreased when *M. pygmaeus* was not confined with parasitized eggs in small arenas. The latter authors concluded that despite the negative effects of the *M. pygmaeus* to *T. achaeae*, the addition of *Trichogramma* parasitoids may significantly increase the level of control of *T. absoluta* over what could be attained when only the mirid predator *M. pygmaeus* is present on tomato. Augmentation biological control, using the natural enemies recorded in this study, against *T. absoluta* in Nigeria could be considered. Fundamentally, augmentation refers to all forms of biological control in which natural enemies are periodically introduced, and usually requires the commercial production of the released agents (van Lenteren 2000). Through inundative or inoculative releases, or both, the pest's pressure may be reduced, and tomato yield increased.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Production of cowpea is significantly hampered by insect pest infestations and farmers typically use synthetic insecticides to control them. The effectiveness of Morinda lucida leaf and bark crude extracts against the post-flowering (pod sucking) Riptortus dentipes insect pest of cowpea was tested in a field experiment that was set up in a complete randomized block design and replicated three times. The number of damaged pods, the total weight of harvested pods (g), and the total pod yield (kg/ha) were all summed after the cowpeas were sprayed at 6, 7, 8, and 9 weeks during seed filling to provide information on the insect population. Results indicated that spraying leaf (2.08) and bark (1.75) M. lucida extracts on cowpeas considerably reduced the R. dentipes population compared to untreated plots. Cowpea obtained from untreated plots had the highest pod damage (4.2), while cowpea treated plots with bark extract had the least (1.08) pod damage. Cowpea plots treated with leaf extracts (3.03) considerably outperformed those treated with bark extracts (p > 0.05). A similar trend was observed in terms of overall pod yield. The highest yield (730 kg/ha) was recorded on cowpea plots treated with bark extract, followed by leaf extract (480 kg/ha), while the lowest yield (198.70 kg/ha) was obtained from the control. The findings made it abundantly evident that M. lucida extracts might be potential insecticidal agents to offer beneficial alternatives to chemical management of insect infestations on cowpeas. The active ingredient be isolated and its potency be evaluated on post-flowering sucking bugs.
Keywords: *Bark extracts, insecticidal agents, Morinda lucida, pod damage, post-flowering, Riptortus dentipes*

INTRODUCTION
Cowpea contains equivalent protein quality and quantity to pricey animal protein and may be used as its substitute. It provides elements that are lacking in grains and is a vital component of many households' meals in Africa, Latin America, and Asia. In actuality, all amino acids required for human nutrition—aside from sulphured amino acids—are present in cowpea seeds (Adesina, 2014).
The production and consumption of cowpea is constrained in Nigeria despite its nutritious value because of a variety of insect pest infestations. About 30% of the annual production is thought to be lost to insect pests (Adesina and Enudeme, 2018). According to Rabindra *et al.* (2004), 2.5 to 3.0 million metric tons of pulses are lost annually as a result of pest issues. Complete crop failure is possible, particularly when management methods are not used. However, when insects are managed using pesticides, cowpea output in Nigeria can be increased and increased tenfold (Ajeigbe and Singh, 2006).
The major insect pests known to attack cowpea at pre-flowering, flowering, and post-flowering stages are; *Seriesthrips occipitalis, Taeniothrips sjostdti, Maruca testulalis, Acythomyia horida, Riptortus dentipes,*

Anoplocnemis curoipes and *Cydia ptychora* causing damage from 50%, 20% and 35% (IITA, 1973) i.e., over 90% potential stage (Raheja, 1976).

The most popular control method has been the use of synthetic insecticides, which have caused a number of issues that were not anticipated at the time of their introduction. These issues include the acute and chronic poisoning of applicators, farmworkers, and even consumers; the extinction of fish, birds, and other wildlife; the disruption of natural biological control agents and pollinators; extensive groundwater contamination that may endanger human and environmental health and the evolution of resistant insects. (Md. Wasim *et al.,* 2009; Maurya et al., 2019; Pathak et al., 2022). Researchers from all over the world are looking for alternatives to chemical pesticides as a result of the numerous concerns connected to their use. pesticides made from plants have long been promoted as appealing substitutes for manmade chemical pesticides (Echereobia *et al.,* 2010). The use of plant extracts in the control of insect pests is advantageous for management of the pest population and the preservation of a healthy ecological balance. Therefore, the goal of this study is to assess *Morinda lucida* bioefficacy in combating the cowpea pest *Riptortus dentipes*, which is a post-flowering (pod-sucking) bug.

MATERIALS AND METHODS

Study Area and Land Preparation: During the 2022 growing season, the experiment was carried out in the Rufus Giwa Polytechnic Teaching, Research, and Commercial Farm in Owo, Ondo State, Nigeria (7° 11' 43" N, 5° 33' 57" E). Prior to the trial, maize was grown on the test plot. To achieve an idyllic location tilth, the plot was disc ploughed, harrowed and ridged.

Plant extracts Preparation: Fresh *Morinda lucida* stem bark and leaves were obtained from the Polytechnic neighbourhood, cleaned with clean water to remove any dirt, and then left to drain. 1 kg of each plant material was weighed using an electronic balance, thoroughly crushed with a mortar and pestle to produce finely grounded materials, and then soaked in 1.5 litres of water in a plastic bucket, left overnight with occasional stirring to form a thorough mixture. The mixture was then filtered the next day with 1.5 litres of water using a muslin cloth. After that, the aqueous extracts were set for use (Oparaeke, 2005).

Crop establishment and Field Layout: Three treatments; 10% v/v crude aqueous extracts of *M. lucida* leaf, back, and control (without insecticide)—were used in the field experiment, which was set up using a Randomized Complete Block Design (RCBD) and replicated three times for each treatment. Each treatment was assigned to a 5-by-5-meter plot, with three main rows and two discard rows (one on either side of the main rows) in each plot size. To check for spray drift, a 1.0-meter-wide border margin was placed between each plot. A week after planting, supply was carried out by sowing two seeds of the indigenous cowpea variety Kano white in each hole with a 60cm x 60cm spacing. Between 3 and 6 weeks following planting, weeding was done. Following bug sampling with a knapsack sprayer once a week for four weeks, starting from flower bud initiation or onset, the leaf extracts were administered between 8 and 10 am (that was the time when the insects were less active). of flowering.

Data Collection and Analysis: Insect pests were visually counted from the middle row of each plot at the time of 60% formation of buds and flowers in the early morning hours of 6–7 a.m. to determine the effectiveness of aqueous plant extracts in reducing insect infestation and damage to cowpeas. Additionally, the insect count was done 3 and 7 days (DAS) following each spraying. Data on the number of infested (damaged) pods, the number of harvested pods, and the weight of the grain were collected at 5-day intervals when the pods displayed indicators of maturity. ANOVA was used to analyze the acquired data, and a Duncan's Multiple Range Test (DMRT) with a 5% significance level was used to distinguish the significant treatment means.

RESULTS

At the conclusion of the experiment, the cumulative pod-sucking insect population on cowpeas treated with *M. lucida* extracts showed that the insect population on cowpeas in the control and leaf extract-treated plots did not differ significantly Figure 1). On the other hand, cowpea plots treated with bark extract, had the least population of bugs (1.75). The outcome in Figure 2 demonstrates that the aqueous extract significantly ($p > 0.05$) reduced pod damage by pest insect species that feed on pods compared to the untreated check. Cowpeas in the control plot had the considerably highest ($p > 0.05$) pod damage (4.2), whereas cowpeas treated with bark extract had the least pod damage.

Table 1 shows how insecticidal plant extracts affect pod weight (kg) and overall pod production. According to the results, cowpeas treated with bark extract had the highest pod weight (677g), while those without insecticidal control had the lowest pod weight. However, the pod weight of cowpeas treated with leaf and bark extracts differs noticeably from one another. Regarding the overall pod yield, a similar pattern was seen. The highest yield (730 kg/ha) was recorded by cowpeas treated with bark extract, followed by leaf extract (480 kg/ha), while the lowest yield (198.70 kg/ha) was obtained from the control.

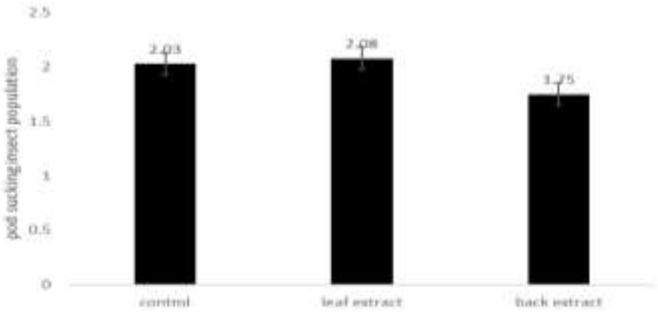

Figure 1: Effect of leaf and bark extracts of *Morina lucida* on pod sucking insect population

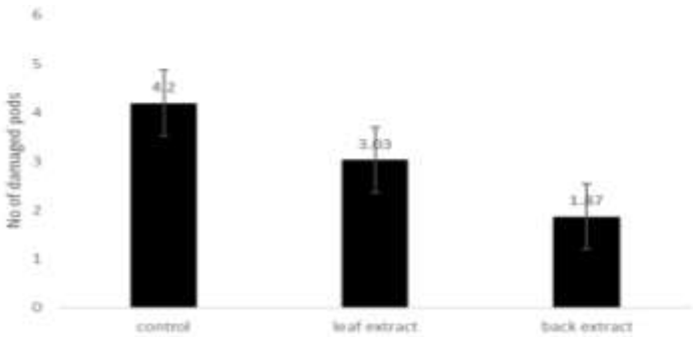

Figure 2: Effect of leaf and bark extracts of *Morina lucida* on pod damaged

Table 1: Effect of leaf and bark extracts of *Morina lucida* on cowpea yield

Treatments	Pod weight (g)	Total pod yield (g/ha)
Control	261.0a	198.7a
Leaf extract	600b	480.0b
Bark extract	677a	730a

Treatments with a different alphabet in the same column are significantly different using DMRT at a 5% probability

DISCUSSION

For many centuries, farmers with few resources in low-income countries have utilized plant-based pesticides to manage insect pests of both field crops and conserved products. Nevertheless, many scholars have documented the effectiveness of various plant components as biopesticides for the management of various insect species (Oparaeke 2004).

The findings of the current study showed that cowpea pod-sucking bugs' population and damages was decreased by using aqueous bark extracts of the tested plants. According to Owolade *et al.* (2004), Adesina and Afolabi (2014), Adesina and Ileke (2014), Adesina *et al*. (2016a), Adesina *et al*. (2016b), and Adesina and Enudeme (2018), who reported the effectiveness of many botanical extracts in the management of various insect pests of crops and the population suppression ability of the plant extracts, suggested that the plant materials possess insecticidal properties. It is unclear exactly how the aqueous leaf extracts work to reduce the bug population in cowpeas. It might, however, be the outcome of contact activity or perhaps it was due to an antifeedant or repellent effect. Insects did not perch on the leaf surfaces following treatment applications, according to visual inspection of the treated plots. This corroborates the report of Stoll's (2000) that one of the main mechanisms by which aqueous plant extracts reduce insect damage to crops is by repellency.

Comparison among all treatments, revealed that the yields from sprayed plots and plant extracts were better. This finding is consistent with earlier research report by Nderitu *et al.* (2008), who found that aphid infestations can cause significant yield losses in the absence of insecticides. The outcome supported earlier studies' results that plant extracts boost vegetable and pea plant yields by shielding them from insect pests (Stoll 2000).

CONCLUSION

Due to the phytochemicals perceived in the extracts, the study demonstrated that *M. lucida* plant extracts had strong insecticidal properties in controlling cowpea post-flowering insect pests and boosted cowpea productivity. As a result, it is hereby recommended that cowpea farmers in the research area adopt *M. lucida* bark aqueous extracts as a potential substitute for synthetic insecticides.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The aim of the research was to investigate the efficacy of 4-chlorophenoxy acetic acid at varying plants density. Field trials were therefore conducted during the rainy season of 2020 at Bayero University Teaching and Research Farm and Audu Bako College of Agriculture Demonstration Farm Dambatta. The treatments consisted of three population density (22,222, 26,666 and 33,333 plants ha^{-1}) and four concentrations of 4-CPA (0, 50, 75 and 100 mgL^{-1} of distilled water). The experiment was laid out in a Split Plot Design and replicated three times. The data collected on yield and yield components were subjected to analysis of variance. The result showed that 4-CPA had significant effect on fruit length, fruit diameter, marketable fruit yield and total fruit yield. Plant population density was observed also to significantly influence total fruit yield and marketable fruit yield. Based on the findings of the study, it was suggested that farmers in the areas of study can be advised to grow UC82B tomato and apply 4-CPA at a density of 22,222 plants ha^{-1} for higher yield of the crop during rainy season.
Keywords: *Tomato, Plant density, 4-Chlorophenoxy acetic acid, Fruit yield*.

INTRODUCTION
Tomato requires a relatively cool and dry climate for high yield and premium quality. Tomato production is mainly under field condition, where changes in climatic conditions especially high temperature, high humidity, rainfall, pests and diseases does not allow the realization of full economic yield of the crop. However, it is adapted to wide range of climatic conditions from temperate to hot and humid tropical environment, with optimum temperature for growth in the range of 20 – 27 °C (Grubben and Denton, 2004). Moreover, marked prohibition of photosynthesis happens at temperatures above average, causing remarkable decrease in yield. Therefore, improved agronomic practices with potential for reducing the effect of high temperature and humidity for high yield of tomato especially during the wet and dry seasons should be investigated in order to meet up with the all year round demand of the crop. Several reports indicated increased fruit size and fruit setting in tomato due to manipulation of plant population density and application of plant growth regulators such as 4-chlorophenoxy acetic acid (Tomatotone) and 2, 4-dichlorophenoxy acetic acid (2, 4-D) (Ozguven, 2000). It is with all that in mind that the research was conceived with the aim of determining the effect of 4-Chlorophenoxy acetic acid (4-CPA) and population density on yield of tomato under rain-fed condition.

MATERIALS AND METHODS
The research was conducted during the 2020 rainy seasons at two locations, Research and Teaching Farm of Faculty of Agriculture, Bayero University Kano (BUK) which lies on latitude 11^{0} 97' 98.6'' N and longitude 8^{0} 42' 03.7'' E and 475 m above the sea level and demonstration Farm of Audu Bako College of Agriculture, Dambatta (DBT) which lies on latitude 11^{o} 83' 40.3'' N and longitude 08^{o} 10' 33.9'' E and 418 m above the sea level all within the Sudan Savanna Zone of Northern Nigeria. The treatments were on RomaVF variety which consists of three different spacing of 75 x 60 cm, 75 x 50 cm and 75 x 40 cm inter and intra row spacing to obtain the plant population densities of 22, 222, 26, 666 and 33, 333 plants ha^{-1} respectively as dictated by the treatment combination and four concentrations of 4-Chlorophenoxy acetic acid, (0, 50, 75 and 100 mgL^{-1} of distilled water). The experiment was replicated three times and laid out in a Split Plot Design with population density assigned to the main plots, while 4-CPA was assigned to the sub plots. Seedlings of UC82B variety were raised using seed beds until they were ready for transplanting at 6 weeks old. The 4-CPA treatment was applied after it was prepared by mixing 0, 50, 75 and 100 mg of 4-CPA powder L^{-1} of distilled water and two drops of baby shampoo were

added to enhance stickiness of the 4-CPA on the flowers as recommended by (Baliyan *et al*., 2013). The mixtures were later applied to the flowers after few flowers had opened, about 1 ml per flower cluster was applied using hand held sprayer in the morning as from 8 am as recommended by Asian Vegetable Research and Development Center (AVRDC), (2001). Harvesting was done by hand picking at the time the fruits attained physiological maturity spanning four pickings. The data collected were subjected to analysis of variance using Genstat (17th Edition) and the means were separated using Fisher's Protected Least Significant Difference Test at 5% level of probability.

RESULTS

Table 1 shows the effect of 4 – CPA and population density on number of flower clusters plant^{-1} during 2019 rainy season at BUK and Dambatta. At both location population density effect on the number of flower clusters plant^{-1} was significant where the result recorded indicated population densities of 22,222 and 26,666 plants ha^{-1} were at par and produced significantly higher number of flower clusters plant^{-1} than population density of 33,333 plants ha^{-1}. However, the result showed no significant difference among the 4-CPA concentrations on number of flower clusters plant^{-1}.

Fruit length of tomato as affected by population density and 4-CPA concentrations during the 2019 rainy season at BUK and Dambatta is also shown in Table 1; the result obtained shows that difference in plant population densities was recorded to be significant on fruit length at both location the result obtained showed that 22,222 plant^{-1} had significantly longer fruits than 26,666 and 33,333 plants ha^{-1} which were statistically similar. Also the result revealed that application of 4-CPA significantly affected fruit length of tomato at BUK, 75 and 100 mgL^{-1} were at par in fruit length but 100mgL^{-1} was significantly higher in fruit length than 0, and 50 mgL^{-1} 4-CPA concentrations statistically similar also, while at Dambatta the result showed no significant difference among the 4-CPA concentrations on fruit length of the tomato. Also, Table 1 shows the fruit diameter of tomato as affected by population density and 4-CPA concentrations during 2019 rainy season at BUK and Dambatta. Population density significantly affected the fruit diameter in both locations, the result indicated that 22,222 plants ha^{-1} was significantly higher in fruit diameter than 26,666 and 33, 333 plants ha^{-1} which were at par with one another at BUK, while at Dambatta 26,666 and 22,222 plants ha^{-1} were at par but 22,222 plants ha^{-1} was significantly higher in fruit diameter than 33,333 plants ha^{-1}. However, at BUK the result revealed significant effect of 4-CPA concentrations on the fruit diameter, the result showed that 4-CPA concentrations of 50, 75 and 100 mgL^{-1} were statistically at par with another but recorded significantly higher fruits diameter than the control, but at Dambatta the result shows no significant effect of 4-CPAconcentrations on fruit diameter of the tomato.

Table 2 showed the interaction between population densities and 4-CPA concentrations on fruit diameter of tomato in 2019 at Dambatta. Considering the population densities under 0 mgL^{-1} 4-CPA concentration there was no significant effects among the population densities, also under concentration of 50 mgL^{-1} 4-CPA the trend was the same, but under 75 mgL^{-1} 4-CPA, population densities of 33,333 and 26,666 plants ha^{-1} were statistically similar but significantly higher in fruit diameter (39.54 and 42.29 mm) than population density of 22,222 plants ha^{-1} (35.36 mm), while under 100 mgL^{-1} 4-CPA , there was no significant effect among the population densities. Looking at 4-CPA concentration under population density of 33,333 plants ha^{-1}, there was no significant effects among the 4-CPA, while under population density of 26,666 ha^{-1}, 50 , 75 and 100 mgL^{-1} 4-CPA were all at par but 75 mgL^{-1} was significantly higher in average fruit diameter (42.29 cm) than 0 mgL^{-1} 4-CPA, average fruit diameter of 35.96 cm, but under population density of 22,222 plants ha^{-1} 0, 50 and 75 mgL^{-1} 4-CPA were at par with each other but 50 mgL^{-1} was significantly higher in fruit diameter (39.58 cm) than 75 mgL^{-1} 4-CPA fruit diameter of 35.36 cm.

The interaction between population densities and 4-CPA concentrations on average fruit length of tomato in 2019 at Dambatta was also presented on Table 2. Studying the population densities under 0 mgL^{-1} 4-CPA, population density of 22,222 plants ha^{-1} was significantly higher in fruit length (8.26 cm) than 33,333 plants ha^{-1} which was also higher (7.60 cm) than 26,666 plants ha^{-1} (6.85 cm), while under 50 mgL^{-1} 4-CPA, population densities of 22,222 and 33,333 plants ha^{-1} were at par with one another but 22,222 plants ha^{-1} was significantly higher in fruit length (8.57 cm) than population density of 26,666 plants ha^{-1}, but under 75 mgL^{-1} 4-CPA all the population densities were at par in average fruit length, while under 100 mgL^{-1} 4-CPA the trend was also similar to that of 75 mgL^{-1}. Looking at the 4-CPA under population density of 33,333 plants ha^{-1}, 50 and 75 mgL^{-1} were statistically similar but 75 mgL^{-1} was significantly higher in fruit length (8.38 cm) than100 mgL^{-1} which was also higher (7.77 cm) than 0 mgL^{-1} 4-CPA, while under population density of 26,666 plants ha^{-1}, 100, 75 and 50 mgL^{-1} 4-CPA were at par but significantly higher (7.79, 7.93 and 7.59 cm) than the control (6.85 cm) fruit length, but under population density of 22,222 plants ha^{-1} the result showed that all the 4-CPA concentrations were statistically at par in fruit length.

Table 2: Interaction between Population Densities (ha^{-1}) and 4-CPA (mgL^{-1}) on Average Fruit Diameter (mm) and Fruit Length (cm) of Tomato during 2019 Rainy Season at Dambatta.

SE±			1.163			0.330

Means followed by the same letter(s) are not significantly different at 5% level of significance using Fisher's protected least significant difference test.

Table 3 revealed the Marketable fruit yield t ha^{-1} of tomato as affected by population density and 4-CPA concentrations during the 2019 rainy season at the two locations of the trial. Marketable fruit yield was significantly affected by population density at both locations of the trials, the result indicated that at BUK, 22,222 plants ha^{-1} was significantly higher in marketable fruit yield than 26,666 and 33,333 plants ha^{-1} which were at par with one another, while at Dambatta, 22,222 plants ha^{-1} was significantly higher than 26,666 plants ha^{-1} which in turn was significantly higher than 33,333 plants ha^{-1}. Furthermore, Marketable fruit yield t ha^{-1} was significantly affected by application of 4-CPA, the result indicated that at both locations, 100 and 75 mg L^{-1} 4-CPA concentrations were at par with one another but significantly higher in marketable fruit yield than 50 mg L^{-1} 4-CPA which was in turn higher than 0 mgL^{-1} which was the control.

Non Marketable fruit yield t ha^{-1} of tomato as affected by population density and 4-CPA concentrations during the 2019 rainy season at the two locations of the trial is shown on Table 3 also, the result revealed that Non Marketable fruit yield t ha^{-1} was not significantly affected by population density at both BUK and Dambatta, but was significantly affected by 4-CPA concentrations; at BUK, 4-CPA concentration of 75 mgL^{-1} was significantly higher in non-marketable fruit yield than 4-CPA concentrations of 100, 50 and 0 mgL^{-1} which were at par with one another, while at Dambatta there was no significant difference among the 4-CPA concentrations. Table 3 also showed the total fruit yield (t ha^{-1}) of tomato as affected by population density and 4-CPA concentration during the 2019 rainy season at the two sites of the trial. Total fruit yield in tons ha^{-1} was significantly affected by population density. The result recorded indicated that at the two sites; 22,222 plants ha^{-1} was obtained to be significantly higher in total fruit yield than 26,666 and 33, 333 plants ha^{-1} statistically at par with one another. Total fruit yield in tons ha^{-1} was also significantly affected by 4-CPA application; the result indicated that 4-CPA at 100 mgL^{-1} concentration was significantly higher than 4-CPA concentrations of 75 and 50 mg L^{-1} which were statistically at par with one another but significantly higher than 0 mg L^{-1} concentration.

DISCUSSION

Effect of Population Density on Growth and Yield of Rain Fed Tomato.

The Fresh yield per plant was found to be higher on the low population density of plant ha^{-1} during the trials and this could be attributed to the availability of more space for nutrients and sunshine exploitation by the tomato which was in line with the findings of Papadopoulos and Pararajasingham (1997) who in their studies reported that high plant densities have been shown to have detrimental effect on assimilate partitioning, because of an inadequate supply of photosynthates due to increase in shading. Also Baloch *et al.* (2002) observed that lowering plant densities increased the nutrient area per plant and this led to an increase in agronomic characters such as fruits diameter and yield. Schomaker and Been, (2006), observed that plant population density plays an important role in increasing or decreasing the yield of crop per unit land area, the result of the study indicates that plant population density of 22,222 plants ha^{-1} had significantly higher marketable and total fruit yield in the two successive years of the trials at both locations. The result obtained is in harmony with what was reported by Uko *et al*, (2013) and Baloch *et al.* (2002) that low plant density recorded more fruit number and highest fruit diameter and weight than high plant population density.

Effect of 4-CPA on Yield of Rain Fed Tomato

The result of the study showed that application of 4-CPA significantly increases the total fruit yield of tomato at both locations, higher fruit yield was obtained with application of 100 mgL^{-1} 4-CPA. This could be attributed to the ability of the 4-CPA to enhance flower retention by the plant resulting to more fertilized flowers without much abscission and high fruit retention. This result was supported by the findings of Asian, Vegetable Research and Development Center (AVRDC, 2012), Nandwani *et al.* (2014), Ozguven (2000), Baliyan *et al.* (2013) and Lathiya and Sanjeev (2017) who reported that application of plant growth regulators has been shown to improve fruit setting in tomato, they further reported that sprays of hormone especially 4-chlorophenoxy acetic acid on flower cluster effectively increase the fruit set as well as fruit production. Also Karim *et al.* (2015) had shown that application of 4-CPA induced higher number of fruit set to some extent. It was further reported that application of plant growth regulators increased fruit set of summer tomato (Rahman *et al.*, 2015). 4-CPA is also used in reducing pre-harvest fruit drop and resulting in increased number of fruits and yield in tomato crop. Meliha *et al.*, (2006), further revealed that the growth regulating substances used increased the number and size of fruits of tomato and their fresh and dry weights with 4-CPA being most effective.

CONCLUSION

From the result of this study, it can be concluded that; Tomato responded positively to 4-CPA application and population density where the highest yield was recorded with plant population density of 22,222 plants ha^{-1} due to application of 100 mgL^{-1} 4-CPA concentration. Therefore, based on the findings of this study, it can be suggested that farmers in the areas of study can be recommended to grow tomato and apply 4-CPA at 100 mgL^{-1} of distilled water in order to increase fruit yield of the crop during rainy season.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The three edible essential oils (EEO), clove, Syzgium aromatic (L.) Meril and Percy; West African Black pepper (WABP), Piper guineense Schum and Thonn. and ginger, Zingiber officinale Rosc. were evaluated to determine their repellency and toxicity effect to adult Sitophilus oryzae on ten paddy rice varieties using the Petri dish chamber test on each of the paddy. Four concentrations of the different edible essential oils (EEO) were prepared by dissolving 0.25, 0.5, 0.75 and 1.0 mg each in 2 ml analytical grade acetone while the control was treated with 2 ml pure analytical grade acetone. Before the introduction of test insects into the Petri dishes, the acetone used as the carrier was allowed to evaporate completely. Thereafter, 30 unsexed adult S. oryzae that were 2 - 3 days old was released at the center of the Petri dish and then covered with the lid. The number of insects present in treated and untreated discs was recorded after 30 minutes and 24 hours respectively. The experiment was laid down in a complete randomized designed (CRD) and replicated three times. Data analyses was carried out in a one-way and two-way analysis. Probit analysis was carried out to determine the LC_{50} effect of the EEOs on S. oryzae. Edible essential oil extracted from clove, WABP and ginger were used to repel adult S. oryzae on paddy rice variety which showed varying degrees of repellency by these oils as observed in this study, repellency classes of III – V was achieved at concentrations of 0.25 – 1.00 mg/30 cm^2 using the different oils. The repellency effect of ginger oil was more effective in repelling the rice weevil than clove and WABP. The result of the LC_{50} showed that clove oil (LC_{50}= 0.358 mg/5 g) caused high mortality of adult weevil of compared to 0.531 and 0.658 mg/5 g for WABP and ginger oils, respectively.

INTRODUCTION

Rice (*Oryzae sativa* (L.) constitutes the world most used cereal and highly important staple for more than half of the people of the world's population (Fukagawa and Ziska, 2019). Nigeria production has risen from 4.78 million metric tons to 8.34 million tons in 2021 (KNOEMA, 2021). The two most commercially used cultivars are *Oryzae sativa* (L.) known as the Asian rice and *O. glaberrima* (Steaud) called the African rice (Tajuddin, 2014; Wambugu *et al*., 2021). As a nutritionally staple food recognized globally, rice plays an important role in the culture, diet and economies of millions of people around the world (Fukagawa and Ziska, 2019). The consumption of rice per capital in Nigeria was 32 kg, indicating 4.7% increase in the past decades (Okrent and Kumcu, 2016).

In an attempt to increase production in order to meet the food need of the growing population, farmers encountered a lot of challenges ranging from decrease in rainfall, reduction in yield due to abiotic stress, vulnerability of local rice varieties to pre and post- harvest diseases and insect pests from the field to store among others (Sinding, 2009; Norton *et al*., 2010). About 37% of rice grain yield is lost annually, resulting in 20-40% weight loss to insect pests and diseases (Mondal *et al*; 2017). In developing countries pest account for 15%-100% and 10-60% pre and post-harvest loses of grain respectively (Mihale *et al.*, 2009; Kumar and Kalita, 2017). The rice weevil, *S. oryzae* is the major insect pest of both paddy and milled rice in storage (Akhtar *et al*., 2015). It can damage the whole grain by feeding on the endosperm causing lost f weight, nutrient, quality, and reduces germinability of the seedling leading to loss of market value (Costa *et al*., 2016; Zakladnoy, 2018).

The losses incurred by farmer from insect pests' and diseases damage on rice, compel them to look out for effective control measure that will curtail the obnoxious pests, hence the use of synthetic pesticide with quick and broad spectrum in controlling insect pests (Tudi *et al*., 2021). The indiscriminate use of these synthetic pesticides have posed great concern about environmental hazard and economic sustainability due to paucity of fund as well as many species of insect pests developing resistance to the pesticide used over time (Zhu *et al*., 2016; Mahmood *et al*., 2016). Therefore, this research evaluated the repellent and toxicity efficacies of *Syzgium aromatic*, *Piper guineense* and *Z. officinale* against rice weevil, *S. oryzae* infesting paddy.

MATERIALS AND METHODS

Collection of Paddy Rice Varieties

Fifteen paddy rice varieties (FARO 17, FARO 20, FARO 22, FARO 27, FARO 30, FARO 31, FARO 32, FARO 37, FARO 30, FARO 44, FARO 50, FARO 57, FARO 60 and FARO 61) used for the experiment were obtained from the National Cereals Research Institute, Badeggi (NCRI), Niger State; and three local varieties Jamila, Lafia Sippi and Water proof were purchased from farmers in Lafia, Nasarawa State at the end of the 2020 harvest season. All paddy rice collected were stored in the freezer at -0ºC for 2 weeks in order to kill any insect eggs and adults that may have harbored inside the kernel (Ileke *et al.*, 2020). After 2 weeks, the rice paddy was put in the desiccator in order to dissipate any moisture that would have been absorbed by the kernel and kept in the laboratory cupboard in tightly sealed polypropylene sheet until needed for the experiment.

Sourcing and insect culturing of the rice weevil, *Sitophilus oryzae* L.

The initial parent stock of the rice weevil, *S. oryzae* used for the experiment were sourced from an already infested polished rice obtained from a Rice Merchants at Lafia market. This batch of insect was re-infested on 750 g of polished rice (Jamila variety) put in five different jars and kept in the Agronomy laboratory Faculty of Agriculture, Shabu-Lafia Campus Nasarawa State University, on 08. 33ºN and 0.8 32ºE, north central Nigeria (Lyam, 2000) under ambient temperature and relative humidity of 27ºC±2 and RH 65±3, respectively. Emerging adults from the culture was re-infested following the method described above for upwards of three generations in order to acclimatize the insects to laboratory conditions. Adult that emerged from the third generations were used for the study.

Procurement of edible spice plant materials

Dry 5 kg each of the seeds of clove, *Syzygium aromaticum*, West African Black Pepper, *P. guineense* and ginger rhizome, *Z. officinale* were purchased from Lafia market in Nasarawa State. Each of these spices were cleaned, and sorted in order to obtain dirt free materials. The edible spices were macerated in a mortar with a pestle and thereafter milled into a semi fine powder using a kitchen Kenwood® blender. Essential oils from the spices were extracted from the pulverized seeds of clove, West African black pepper and rhizome of ginger at the Science and Technology Complex Laboratory (SHETSCO) Sheda, Abuja FCT.

Processing of the edible essential oil

The edible essential oil was extracted from the semi-fine powders of clove, *Syzygium aromaticum*, West African Black Pepper, *Piper guineense* and ginger rhizome, *Zingiber officinale*, using a Glass Steam Essential Oil Distiller (Hydro distiller) model EME31000/CEB with a round bottom flask. The powder stock of clove, West African Black Pepper, and ginger were soaked with distilled water in a round bottom flask for 4 - 6 hours and heated for 1 hour at 100ºC. The extracted oil and water were removed from the receiving flask and the essential oil was transferred via a separating funnel. Each extracted edible spice oil (ESO) was stored in a sample bottle, labelled and kept in the laboratory cupboard until when needed for the experiment.

Insect Bioassay

Determination of repellency effect of the edible essential oil treatment on paddy rice

Repellency of the edible essential oils to adult *S. oryzae* was determined using the Petri dish chamber test as described by Sighamony *et al*. (1984) on each of the paddy rice. The test arena consists of a 9 cm diameter Whatman No.1 filter paper cut into two halves. One half of the filter paper was held in place with the other half with a cello tape, thus forming a whole unit. Four concentrations of the different edible essential oils (EEO) were prepared by dissolving 0.25, 0.5, 0.75 and 1.0 mg each in 2 ml analytical grade acetone. Each concentration was applied to one half of the filter paper disc as uniformly as possible by means of the pipette. The other half of the filter paper was left untreated. In the control chambers, half of the paper was treated with 2 ml pure analytical grade acetone and the other half left untreated. Before the introduction of test insects into the Petri dishes, the acetone used as the carrier was allowed to evaporate completely. Thereafter, 30 unsexed adult *S. oryzae* (2 - 3 days old) were released at the center of the Petri dish and then covered with the lid. The number of insects present in treated and untreated discs was recorded after 30 minutes. The experiment was laid down in a complete randomized designed (CRD) and replicated three times.

Determination of toxicity effect of edible essential oil on *S. oryzae*

Toxicity of edible essential oils against adult S. *oryzae* was carried out using 0.25, 0.5, 0.75 and 1.0 mg of the oils dissolved separately in 2 ml of analytical grade acetone and treated on 20 g of one variety of paddy rice in a 50 ml glass jar with a lid. A glass rod was used to stir the oil on the paddy rice in order to ensure adequate coating of seeds with the oil; stirring was stopped when the acetone used as the carrier have completely evaporated. The control was treated with the same amount and weight of seeds treated with 2 ml analytical grade acetone alone. This was stirred until complete evaporation of the acetone. Thereafter, 30 adults (2 - 3 days old) *S. oryzae* were introduced into the paddy rice by means of a pooter. Adult mortality was taken 24 h after treatment. The adults were counted as dead if it did not respond to probing with a fine brush bristle (Su, 1976). The experiment was laid down in a complete randomized designed (CRD) and replicated three times.

Determination of toxicity effect of edible essential oil on *S. oryzae*

Toxicity of edible essential oils against adult S. *oryzae* was carried out using 0.25, 0.5, 0.75 and 1.0 mg of the oils dissolved separately in 2 ml of analytical grade acetone and treated on 20 g of one variety of paddy rice in a 50 ml glass jar with a lid. A glass rod was used to stir the oil on the paddy rice in order to ensure adequate coating of seeds with the oil; stirring was stopped when the acetone used as the carrier have completely evaporated. The experiment was laid down in a complete randomized designed (CRD) and replicated three times.

Data Collection and Analysis

Repellency effect of edible essential oil

The number of adults repelled from the treated half disc of Whatman No. 1 filter paper 9 cm in the Petri dish was recorded and calculated according to McDonald *et al.* (1970) as follows:

$$\text{Percent Repellency (PR)} = \frac{Nc - Nt}{Nc + Nt} \times 100$$

Where:

Nt = number of insects present on the treated half disc

Nc = Number of insects present on the untreated half disc

The percentage class of repulsion (CR) was classified according to McDonald *et al.* (1970) as follows:

0 > 0.01 = 0

0.1 to 20 = I

20.1 to 40 = II

40.1 to 60 = III

60.1 to 80 = IV

80.1 to 100 = V

Toxicity effect of edible essential oil

Probit analysis was used to calculate the lethal concentration (LC_{50}) of the toxicity effects of the edible essential oil on treated adult *S. oryzae*; while fiducial limit was used to determine the significant differences between the oil treatments.

Statistical Analysis

All data collected were analyzed in one-way and two-way ANOVA. Differences between mean responses were compared using the Least Significant Difference (LSD) statistic ($P \leq 0.05$). All data with zeros were transformed to square root method using $\sqrt{x} + 0.5$. All percentage data were transformed before analysis. Data analysis was carried out with STAR® (2013) analytical package.

RESULTS

Effect of concentration rates on the mean percentage number of adult *S. oryzae* repelled by the three edible essential oils infesting paddy rice.

The edible essential oils extracted from clove, *S. aromaticum*, *P. guineense* and *Z. officinale* were used to determine the repellent effect of the oils on the rice weevil, *S. oryzae* as shown on Table 1.a below. The results of the observation showed that the three edible essential oils significantly ($P \leq 0.05$) repelled the rice weevil at higher dosage rates when compared to lower dosage rates.

Extracts from clove oil at the dosage rate of 1.00 mg repelled higher number of adult *S. oryzae* (77.80) significantly ($P \leq 0.05$) more than all the dosage rates, 0.75 (71.11), 0.50 (63.33) and 0.25 (63.33) mg and the control (53.33) while 0.25 mg and the control were not significantly different from each other ($P \geq 0.05$). Higher number of adult *S. oryzae* was repelled more in treatment with 1.00 mg (85.56) of WABP but this was not significantly different ($P \geq 0.05$) from treatment with 0.75 mg (84.44); and were significantly different ($P \leq 0.05$) from treatments with 0.50 (61.11) and 0.25 mg (41.11) which were all significantly different ($P \leq 0.05$) from the control (33.33). The repellency effect of treatment with ginger oil showed that, all the oil treatments were significantly different ($P \leq 0.05$) from each other with treatment with 1.00 mg (92.22), 0.75 mg (84.44), 0.50 mg (74.45), 0.25 mg (61.11) and the control (33.33), respectively (Table 1.3a).

Table 1; a Effect of concentration rates on the mean percentage number of adult *S. oryzae* repelled by three edible essential oils infesting paddy rice

Dosage (mg/30 cm^2)	Edible Essential Oil Type			
	Clove	WABP*	Ginger	Mean
0.25	53.33^{+b}	41.11^{b}	61.11^{b}	51.85
0.50	63.33^{b}	61.11^{c}	74.45^{c}	66.30
0.75	71.11^{b}	84.44^{d}	84.44^{d}	80.00
1.00	77.78^{c}	85.56^{d}	92.22^{e}	85.19
0.00 (Control)	32.29^{a}	33.33^{a}	33.33^{a}	32.98
Mean	59.57	61.11	69.11	

Means with the same letter in the column are not significantly different at 5% level of probability using Least Significant Difference (LSD) Test ($P \leq 0.05$).
\+ = Repellence percentages of three replicates
*WABP = West African black pepper

Interaction effect of three edible essential oils on mean percentage numbers of adult *S. oryzae* repelled on paddy rice varieties

Repellency effect of all the three edible essential oils (EEO) were statistically and significantly effective ($P \leq 0.05$) from each other (Table 1b). The highest repellency effect was recorded with the use of ginger oil with 92.22% repellency which was significantly different from oil treatment with WABP (85.56%) and that of clove (77.78%). The effect of treatment with WABP oil was also significantly different ($P \leq 0.05$) when compared with the effect of clove oil.

Table 1;b Interaction effect of three edible essential oils on mean percentage numbers of adult *S. oryzae* (L.) repelled on paddy rice varieties

Edible Essential Oil Type	Treatment Means (mg/30 cm^2)
Clove	77.78^{c}
WABP	85.56^{b}
Ginger	92.22a

Means with the same letter in the column are not significantly different at 5% level of probability using Least Significant Difference (LSD) Test ($P \leq 0.05$).

Classification of Repellency of the Three Edible Essential Oils against *S. oryzae* Infesting Paddy Rice

Table 1.c showed the repellency classification of the three edible essential oils on adult *S. oryzae*. The results showed that clove oil at the dosage rate of 1.00, 0.75 and 0.50 mg elicited Class IV (77.78, 71.11, 63.33) repellency, respectively; while WABP and ginger oil at the dosage rate of 1.0 mg were classified as Class V (85.56 and 92.22), respectively. All the three oils clove (53.33), WABP (61.11) and ginger (41.11) recorded Class III when used at the dosage rate of 0.25 mg. However, ginger at the rate of 0.50 mg was Class III (61.11). WABP (74.45) on the other hand was classified as Class IV at the dosage rate of 0.50 mg. All the control treatments were classified as Class II.

Table 1;c Classification of Repellent Action of the Three Edible Essential Oils against *S. oryzae* infesting Paddy Rice

Dosage (mg/30 cm^2)	Edible Essential Oil Type					
	Clove		**WABP***		**Ginger**	
	Mean % Repellency	[a] Repellency Class	Mean % Repellency	Repellency Class	Mean % Repellency	Repellency Class
0 (Control)	32.29	II	33.33	II	33.33	II
0.25	53.33	III	61.11	III	41.11	III
0.50	63.33	IV	74.45	IV	61.11	III
0.75	71.11	IV	84.44	V	84.44	V
1.00	77.78	IV	85.56	V	92.22	V

*WABP = West African black pepper

[a] Repellency Class: Class II = 20.1 – 40%; Class III = 40.1 – 60%; Class IV = 60.1 – 80%; Class V = 80.1 – 100%.

Contact Toxicity Effect of Three Edible Essential Oils on the Adult *S. oryzae* Infesting Paddy Rice

The contact effect of clove, WABP, and ginger edible essential oils against the adult rice weevil, *S. oryzae* is presented on Table 2.a. The results showed that essential oil from clove was the most toxic at a concentration ratio of LC_{50} of 0.385 followed by WABP oil at LC_{50} 0.581. Lowest mortality of the adult *S. oryzae* was recorded in ginger at LC_{50} 0.658 signifying less contact toxicity. The Fiducial confidence level limit between the three edible essential oils were 0.118 - 0.564, 0.381 - 0 703, and 0.491 - 0.992, respectively for clove, WABP and ginger. The regression analysis in Figures 1, 2, and 3 inveterate that there is an increase in toxicity effect with an increase in concentration among the three oils of clove, WABP and ginger and the r^2 regression analysis showed that the interaction between the concentrations and the use of the EEOs as contact toxicity on adult *S. oryzae* were significant for clove, 0.873; WABP, 0.991 and ginger, 0.993, respectively.

Table 2.a Toxicity effects of Three Edible Essential Oils on *S. oryzae* infesting Rice Paddy in Storage

Edible Essential Oil Plant	Plant Part	LC_{50} (mg/5 g seed)	95% Fiducial Limit	Slope values	R^2 values
Clove	Seed	0.385	0.118 – 0.564	1.114	0.873
WABP*	Seed	0.531	0.381 – 0.703	1.693	0.991
Ginger	Rhizome	0.658	0.491 – 0.992	1.619	0.993

*WABP = West African black pepper

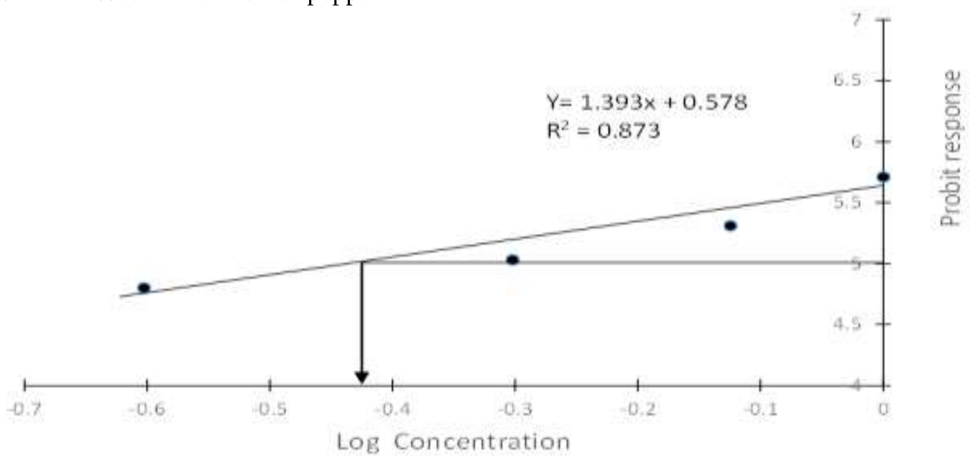

Figure 1: Toxicity Effect of Clove Edible Essential Oil (Log. Conc. -0.415, LC_{50} = 0.385 mg); Fiducial Limits (Confidence Interval): 0.118 - 0.564 mg/5 g seed.

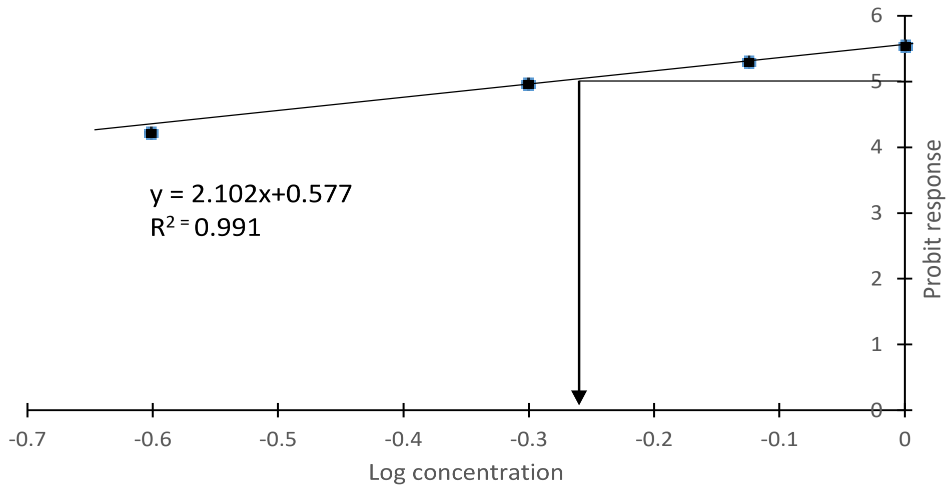

Figure 2: Toxicity Effect of WABP Edible Essential Oil (Log. Conc. -0.275, LC_{50} = 0.581 mg); Fiducial Limits (Confidence Interval): 0.381 - 0.703 mg/5 g seed.

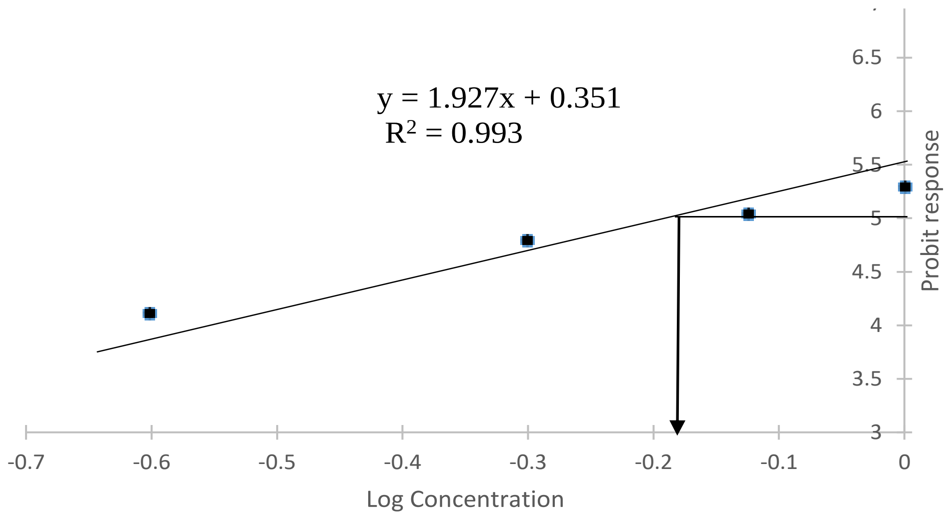

Figure 3: Toxicity Effect of Ginger Edible Essential Oil (Log. Conc. -0.182, LC_{50} = 0.658 mg); Fiducial Limits (Confidence Interval): 0.491 - 0.992 mg/5 g seed.

DISCUSSION

Repellency effect of three edible essential oil extracted from clove, WABP and ginger on adult *S. oryzae* infesting paddy rice varieties

Edible essential oil extracted from clove, WABP and ginger were used to repel adult *S. oryzae* on paddy rice variety (Tables 1.3a, 1.3b and 1.3c) showed varying degrees of repellency by these oils. In an earlier report, Ajayi and Lale (2000-2001) reported that oils extracted from clove, WABP and ginger caused repellency classes of II – V on adult *Callosobruchus maculatus* at concentrations of 50 – 250 mg/30 cm^2. As observed in this study, repellency classes of III – V was achieved at concentrations of 0.25 – 1.00 mg/30 cm^2 however at lower dosage rates and on different stored produce and stored pests.

The results are also in agreement with the report of Asawalam (2006) who reported that *P. guineense* oil evoked repellency class V on maize weevil; Bandara and Senevirathne (2022) who reported that clove oil evoked class V on the rice weevil, *S. oryzae* and Suthisut *et al*. (2011) had also showed that ginger oil evoked class V on the maize weevil, *S. zeamais* at higher dosage rates.As found out in this study for repellency, ginger oil seems to have contained higher repulsion ability than clove and WABP, Table 4,3b; this however, depends on the chemical constituents inherent in the oil which might contain irritant and foul-smelling chemicals that have the ability to strongly repel stored product insect pests (Al-Harbi *et al*., 2021; Patiño-Bayona *et al*., 2021).

Toxicity effect of three edible essential oil extracted from clove, WABP and ginger on adult *S. oryzae* infesting paddy rice varieties

The results in Table 2.a, Figures 1, 2 and 3, showed increase in weevil mortality after 24 hours with increase in lethal concentrations of the treatment applied. Clove EEO caused high mortality of adult weevil (LC_{50} = 0.358 mg/5 g seed), followed by WABP (LC_{50} =0.531 mg/5 g seed), while the lowest mortality was recorded in ginger oil (LC_{50} = 0.685 mg/5 g seed). In toxicity studies involving products obtained from other plant species, it was reported that insect mortality was due to the biologically active components of the plant products. The edible essential oils from clove, WABP and ginger were able to cause mortality of adult *S. oryzae* at very low lethal concentrations (LC_{50}). The results obtained from this study is in agreement with results of Ajayi and Lale (2000-2001) who reported the toxicity of clove, WABP and ginger oils on *C. maculatus* at very low LC_{50}.

The propensity of the edible essential oils to cause mortality to the adult *S. oryzae* could be due to the constituents in the plant product oils. The oil obtained from clove oil has been reported to contain eugenol, a sesquiterpene and β-caryophyllene, and α-humulene (Haro-González *et al*., 2021); *Piper* species have been reported to contain pipercide, dihydropipercide and guineensine (Gutiérrez *et al*., 2013) and ginger contains a mixture of chemical substatnces which include zingiberene, methylheptone, nonylaldehyde and linalool (Rahmani *et al*., 2014). Although, this aspect was not investigated in the present study, it is probable that the insecticidal properties of these spice oils may be attributable to these biologically active components. Clove oil has however been reported to be more toxic to adults of *C. maculatus* than oils extracted from WABP and ginger oil (Ajayi and Lale, 2000-2001). This is in consonance with the results obtained from the present study. The eugenol contained in clove appears to contain higher insecticidal potency than the active components of WABP or ginger oil since the former was more toxic than the latter.

This study provided evidence that the essential oils made from *S. aromatic*, *P. guineense* and *Z. officinale* were toxic to rice weevil. As a result, they might be employed as botanical entomocides in place of synthetic chemical insecticides to lessen the risky side effects associated with the use of chemical insecticides that can caused environmental health hazards.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A study was carried out on 40 sweet potato genotypes plus two Check local varieties to select sweet potato genotypes with high storage root yield, high dry matter content and high total carotene using a randomized complete block design with three replications at the Western experimental field of NRCRI, Umudike .The planting materials were healthy four (4) node seed vine from the terminal portion of healthy sweet potato mother plants. Each genotype was planted on a 9m^2 plot at a spacing of 100cm between ridges and 30cm between plants on the crest of the ridge. Data collected were on: total number of storage roots, number of large roots, total fresh root weight, weight of large roots. These Data were analyzed with ANOVA and means were separated using Standard error of different means. Storage root dry matter content was determined by oven drying of 100g of fresh sample at 80^{0}C for 48 hours. Results indicated that the dry matter content of the storage roots of the sweet potato genotypes evaluated ranged from 27.7% to as high as 41.2% with mean of 35.2%. However, the Orange fleshed genotypes PG17362-N1 with 38.3%, PGA16021-39 with 36.7%, NAN with 36.3%, NRSP/2019/490 (Smiles) with 34.2%, and NRSP/2019/580 with 32.2%. had dry matter content higher than the reference variety UMUSPO/3 and UMUSPO/4 with both dry matter content of 29.9%, respectively: There may be a challenge combining high dry matter and high beta-carotene. However, with recurrent selection, it is possible to accumulate favourable genes together, so that progress can be made over time.

Keywords: *High dry matter, orange fleshed and carotene*

INTRODUCTION

Sweet potato is an important carbohydrate food, feed and vegetable crop for people in Nigeria. The storage roots of sweet potato which are rich in carbohydrate can be pounded as fufu and its leaves which is rich in minerals and proteins could be used as vegetable for human consumption. Orange fleshed sweet potato varieties are rich in Beta-carotene, a precursor of vitamin A, while Purple-fleshed sweet potato varieties contain anthocyanin, which contain anti-oxidant properties that reduces the aging of cells (Lebot, 2009). Vitamin A deficiency is a serious health problem that results in blindness, weakness and death especially in children below 5 years. Vitamin A boost immunity and is good for pregnant women and lactating mothers. Gurmu et al., (2014) reported that orange fleshed Sweet potato is widely adaptable from the rainforest to the savanna region and generates large amounts of carbohydrate food per unit area within short period of 3.5 to 4 months after planting, giving it an advantage over major root and tuber crop as observed by Mwanga et al (2011). The Storage roots of orange fleshed sweet potato could be boiled, baked, roasted, fried and included in a variety of dishes. The storage roots can also be dried and pulverized to make flour for formulation of bakery products.

Farmers, Marketers and Food processors depend on consumers' preferred traits. Consumer are more attracted to white/cream colour due to the beauty and consistence when frying or boiling. This is related to high dry matter which constitute high carbohydrate. Most sweet potato landraces use as staple food have white/cream flesh colour with dry matter contents which range from 30-to 37% (Rukundo et al., (2013), while dessert types of orange flesh sweet potato have dry matter ranging from 17.7 to 26.3 % (Mcharo & La-Bonte, 2007). Carbohydrate is the most important constituent of dry matter in sweetpotato which make up to 80-90% of the storage root weight. This explain the less choice of orange fleshed which constitute high beta-carotene, but with less dry matter (Picha, 1987). Kambale et al., (2019) reported negative correlation between dry matter content and beta-carotene, but significant and positive correlation between beta-carotene and colour chart comparison. The selection of orange fleshed sweet potato cultivars by urban consumers depends on sensory profiles, knowledge, level of promotion of the crop, and previous experiences of consumers on the crop. Cooking method and utilization have critical influence on taste and consumptive quality of the storage roots (Sugri et al., 2012). Fontes et al., (2011) observed that cooking of the sweet potato orange fleshed storage roots leads to changes in physical, sensory and chemical characteristics of the final product. However, low dry matter content of orange flesh types lose their quality (mealiness) because cooking affect the textural characteristics of the storage root. Frying according to Sugri et al., (2012) enhances sensorial characteristics such as texture, flavour, smell, colour, as well as overall palatability of the product.

The average yield of storage roots of the sweet potato crop in farmers field is only 6t/ha. This low yield is attributed to low yielding of varieties and late maturing of local landraces that farmers are cultivating. This low weight can also be attributed to low dry matter content of the storage root. Woolfe (1992) reported that starch constitutes on average 60 to 70% of dry matter content of storage roots of sweet potato. Dry matter content (DMC) has been used extensively as a selection index for traits such as starch content, flour yield, carbohydrate measure, cooking qualities and taste of the genotypes (Woolfe, 1992). Genotypes with high DMC can be good for storage, and could be candidate for industrial utilization and for international trade. Woolfe (1992) in his work on dry matter content reported highly significant positive correlation between dry matter content and starch content while Lebot (2009) indicated that starch is mainly determined by the additive effect of polygenes. As a results of the food and nutritive benefits of orange fleshed sweet potato, various breeding approaches are being used to develop and improve the orange fleshed sweet potato. The objective of this study was to select sweet potato genotypes with high storage root yield, high dry matter content and high total carotene.

MATERIALS AND METHODS

A total of 40 genotypes plus two Check varieties were evaluated in a randomized complete block design with three replications at the Western experimental field of NRCRI, Umudike. Each genotype was planted on a 9m^2 plot at a spacing of 100cm between ridges and 30cm between plants on the crest of the ridge. The planting materials from all the clones are healthy with four (4) nodes seed vine cut from the terminal portion of healthy sweet potato mother plants and were planted on the ridges with at least two nodes of the seed vine stick inside the soil.

The sweet potato crop were kept weed-free until harvest. At harvest the following data were collected: total number of storage roots, number of large roots, total fresh root weight, weight of large roots. Data collected were analyzed with ANOVA and means were separated using Standard error of different means. Storage root dry matter content was determined by oven drying of 100g of fresh sample at 80^{0}C for 48 hours.

RESULTS AND DISCUSSION

Number of storage roots: The result of 42 sweet potato genotypes on: total number of storage roots, number of large roots, total weight of fresh storage roots, fresh weight of large roots and storage root dry matter content are presented in Table 1.

Table 1: Number, weight, flesh colour and dry matter content of the storage roots of orange fleshed genotypes evaluated

Genotypes	Total number of storage roots	Number of large roots	Total fresh weight of storage roots	Fresh weight of large storage roots	Flesh colour of storage roots	% Dry matter of storage roots

Note: DO = Deep Orange, Y= yellow, LY = light yellow, O = orange, LO = light orange, YO = yellow intermediate orange.

The number of storage roots produced by each of the genotypes varied significantly ($p<0.01$) and ranged from 15 number of roots per plot as produced by UMUSPO/4 to 117 number of storage roots per plot as produced by NRSP/PO3/16. This was followed by TIO-JOE/OP/322 with 101 number of roots per plot with a general mean of 52.4 number of roots per $9m^2$ plot. Total number of storage roots is not a good index for measuring Storage roots for commercial yield. Total number of storage roots indicated the potential yield with which the farmer visually estimate the yield of the sweet potato crop.

The large root is for the commercial roots with marketable attributes. The large roots varied significantly ($p<0.01$) within the sweet potato genotypes and ranged from 7.0 number of storage as produced by UMUSPO/4 to as high as 89 number of storage roots as produced by NRSP/PO3/116, followed by TIO-JOE /OP/322 with 83 number of storage roots per plot with general mean of 35.9 number of storage roots per $9m^2$.

Weight of Storage roots: This is the fresh matter weight of the storage root of the sweet potato genotypes. The fresh storage root yield is weight of fresh matter and water in the storage roots. The total fresh storage root weight varied significantly ($p<0.01$) among the sweet potato genotypes. The least total fresh root weight was 3.2t/ha as was produced by UMUSPO/4 to as heavy as 23.5t/ha as was produced by NRSP/2012/066. This was followed by 23.3t/ha produced by NRSP/2012/187 with general mean of 14.2t/ha. The total fresh root weight was made up of the weight of small roots and weight of large roots. However, the weight of large fresh roots varied significantly ($p<0.01$) among the genotypes and range from 2.2t/ha (UMUSPO/4) to as heavy as 20.6t/ha (NRSP/2012/066) followed by 18.1 as produced by NRSP/2012/187 with general mean of 10.4t/ha. Large storage root are roots for commerce. The orange and Yellow fleshed genotypes that produced large roots with weight heavier than the two Check varieties: UMUSPO/3 and UMUSPO/4 were selected for further advancement. Fifteen sweet potato genotypes out of 42 which represent 37.5% were outstanding in yield performance more than the two check varieties.

Storage root dry Matter Content: Storage root dry matter is the remaining part of the edible root after its water has been completely drained away by heat or dry air. The dry matter content of the storage roots of the sweet potato genotypes evaluated ranged from 27.7% to as high as 41.2% with mean of 35.2%. However, the Orange fleshed genotypes with dry matter content higher than the reference variety; UMUSPO/3 which had dry matter content of 29.9% were: PG17362-N1 with 38.3%, PGA16021-39 with 36.7%, NAN with 36.3%, NRSP/2019/490 (Smiles) with 34.2%, and NRSP/2019/580 with 32.2%. The following white/cream and yellow sweet mpotato genotypes exceeded the dry matter bench mark of 29.9% set by the national check variety UMUSPO/3 and UMUSPO/4. Cemsa 74-228 with 41.2% followed by PGA14351-4 with 38.4%, PGA14398-4 with 36.7%, PGA14442-1 intermediate yellow orange with 36.3%, PGA14008-9 with 34.5% and PGA17362 –N1 with 38.4% (Table 1).

Carbohydrate is the most constituent of dry matter in sweet potato. Mcharo and La Bonte (2007) reported that 80 - 90% exists in form of starch and sugars. According to Woolfe (1992) starch is quantitatively the most important component of sweet potato storage root dry matter content and that it is found in two general forms such as amylose and amylopectin. The ratio of amylose and amylopectin is genetically controlled and differs between genotypes. Woolfe reported that starch constitutes on average 60 to 70% of dry matter content of storage roots of sweetpotato. Dry matter content (DMC) has been used extensively as a selection index for traits such as starch content, flour yield, carbohydrate measure, cooking qualities and taste of the genotypes (Woolfe, 1992). Genotypes with high DMC can be good for storage, and could be candidate for industrial utilization and for international trade. Woolfe (1992) in his work on dry matter content reported highly significant positive correlation between dry matter content and starch content while Lebot (2009) indicated that starch is mainly determined by the additive effect of polygenes. These genotypes could be proposed according to a specific condition under particular location for high dry matter content, and they can be good candidates for industrial purposes. Genotypes with high dry matter content are good sources of starch, so it can contribute for industrial utilization (Scott et al., 2000). Lu and Sheng (1990) observed that raw dry matter content of above 35% is an ideal material that refers to the processing industry. Therefore, breeding for high DMC, should be a focus of plant breeding objectives. Comparing, with other studied traits such as storage root yield and harvest index. Diaz et al (2021) reported of dry matter content of 37.2% and 33% for two South American orange fleshed clones. In this study, the dry matter content of the sweet potato genotypes ranged from 27.7 to 41.2% (Table 1). Various researchers have reported high heritability estimates of 75 - 88% of dry matter content of 64% (Jones *et al* 1986) which indicated high genetic gain for improvement. Nevertheless, there is negative correlation between beta-carotene and dry matter content (and with sugar and starch (Lebot, 2009). There may be a challenge combining these traits in one cultivar. However, with recurrent selection, it is possible to accumulate favourable genes so that progress could be made over time.

Genotypes containing higher levels of β-carotene are more likely to have lower levels of starch and, therefore, lower levels of dry matter (Cervantes-Flores et al 2008). However, with the use of recurrent mass selection, successes have been attained in breeding varieties that combine both traits in that several high dry matter cultivars have been developed that have high levels of beta-carotene (Gruneberg *et al*., 2009). High dry matter of OFSP storage roots have taken on greater importance for export for baby food manufacturing industries. Higher dry matter OFSP are to develop export opportunities.

The dry matter content of 31.0% the genotypes were above 30.0%, which indicated that these genotypes would possess acceptable taste. This is because good sweet potato taste is associated with high dry matter content. Also sweet potato genotypes with high dry matter content would yield high starch and flour for industrial uses such as making of baby foods (Caetano *et al*. 2017).

CONCLUSION

Breeding for high dry matter content in Orange fleshed sweet potato has been one of the breeding objectives and challenge of the breeding programme. Genotypes containing higher levels of β-carotene are more likely to have lower levels of starch and, therefore, lower levels of dry matter. With recurrent selection methods, it is possible to accumulate favourable genes so that progress could be made over time. However, with the use of recurrent mass selection, successes have been attained in breeding varieties that combine both traits in that several high dry matter cultivars have been developed that have high levels of beta-carotene. High dry matter of OFSP storage roots have taken on greater importance for export for baby food manufacturing industries. Higher dry matter OFSP are to develop export opportunities. The dry matter content that ranged from 28 to 30.0% is acceptable to sweetpotato consumers as high dry matter content gives good taste and this has been extended up to 38% to include industrial uses and for export. The genotypes with high dry matter content should be tested in different locations for yield stability for selection of superior genotypes with high dry matter that will be acceptable to the end-users.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The competition for conventional feedstuff between livestock and humans has led to an increase in the cost of livestock and poultry feeds. Therefore, this review has necessitated the search for alternative non-competitive feedstuffs in order to partially replace maize and soybean in animal feeds. Cassava is a tropical crop, and its fodder is rich in crude protein (CP), minerals and vitamins with about 85% of the CP fraction existing as true protein. The cassava root is very high in energy capable of completely or partially replacing maize. Cassava by-products are also high in nutrients and could contribute significantly to the nutritional needs of animals. Specifically, cassava leaves are high in CP (25.10%) with an amino acid composition similar to soybean. However, the use of cassava in animal production is limited by the presence of cyanogenic glucosides (linamarin and lotaustralin) that releases hydrogen cyanide (HCN) known to cause pathophysiological changes in the liver of the animals. Importantly, several processing techniques (peeling, grating, drying, ensiling, boiling, soaking/retting, fermentation and combination of processing methods) are well known to reduce or eliminate the concentrates of cyanogenic glucosides in cassava with great success. It is concluded that processing reduces HCN contents of cassava to a tolerable level for animals. However, combination of different processing methods showed to have reduced HCN better than the use of a single processing method.
Keywords: *Processing techniques, cassava, animal feed, cassava by-products, livestock and poultry*

INTRODUCTION
Cassava production is vital as it is seen as the future of food security in Nigeria (Jiwuba *et al*., 2018); with approximately one billion people currently depending on it as a major carbohydrate source (Ezenwaka *et al*., 2018). Recently cassava annual production has increased by approximately 100 million tonnes since 2000 (Morgan and Choct, 2016), this may be partly due to the high demand for cassava food products and for use in livestock and poultry feeds. FAO (2014) reported a 4.6% cassava output growth in 2013 and 2014, with Nigeria being the world's largest producer. Under tropical conditions, it is the most productive crop in terms of energy yield per unit land area, with a yield of between 25 and 60 tonnes/ha (1 ha ¼ 10,000 m^2) (Garcia and Dale, 1999). These have enhanced the availability of the by-products for animal feeds.
The use of cassava by-products in animal feed is an age-old practice. Traditionally, farmers would sundry the peels in small quantities as a feed resource. Transforming cassava by-products into nutritious animal feed has the potential to partially replace maize in animal feed while reducing environmental pollution and minimising post-harvest losses. This crop-waste by-product could be a valuable feed alternative. This review therefore examines different processing methods used in producing different types of cassava by-products for animal feeding.
Peeling: Almost every technique of cassava processing starts with peeling. Cassava peel contains cyanoglycosides, linamarin and lotausralin, which yield HCN during hydrolysis and have been reported to be toxic to livestock and humans. The parenchyma (pulp) can remove 50 per cent of cyanogenic glycosides by peeling. Bitter varieties of cassava contain about 650 ppm of HCN in the peel and about 310 ppm in the parenchyma (Panghal *et al*., 2019). Varieties of sweet cassava can contain about 200 ppm of HCN in the peel and 38 ppm in the roots (Bayitse *et al*., 2015). Nonetheless, sweet cassava varieties when peeled, may be eaten raw or after boiling, while the bitter varieties need more detoxification for goats and other livestock to consume.
Grating: Grating is size reduction of the roots and therefore increases the surface area for better contact with linamarin and linamarase for easy detoxification. The reduction of the size allows the intracellular linamarin to be

released out of the cell and to react with extracellular linamarase enzyme to yield HCN that can be easily volatilized. The concentration of cyanide in the grated product depends largely on the period during which glucoside and glucosidase interact in an aqueous medium (Tewe, 1992). However, grating provides a larger surface area for fermentation but not sufficient for detoxification; therefore, it is necessary to combine it with other methods to improve the evaporation of HCN.

Drying: Drying is one of the methods used in processing and enhancing the nutritional value of cassava products by reducing cyanide and moisture. Drying is generally accepted as an effective method of processing cassava root, because it results in products that are shelf-stable with moderately low content of cyanide and moisture. Cassava drying or roasting generally comes after peeling, chipping and grating before spreading them thinly out to dry in the sun or in oven. Given advanced drying systems, sun drying is the most commonly used method in Africa's cassava processing and as such, the sun-dried cassava products are the most popular. Sun drying appears to be more effective at reducing cyanide than oven, drying method, because cyanide has contact with linamarase for a longer period when using sun drying (Ngiki *et al*., 2014). Ravindran (1991) claimed that sun drying alone in a cassava sample could eliminate around 90 per cent of the initial cyanide value. Olafadehan (2011) reported a reduction of HCN from 710.98 mg/kg from unprocessed cassava peel meal to 165.36 mg/kg in a sundried cassava peel meal; this explicitly demonstrated the efficacy of sun drying processing method in cassava peels detoxification. Vantsawa and Okenarhe (2014) in a study reported a reduction of HCN from 3.16 mg/100g on freshly harvested cassava leaves to 1.46 mg/100g in a sundried cassava leaves; hence demonstrated the role of sun drying as one of efficient processing methods of detoxifying cassava leaves.

Ensiling: The ensiling process causes the intact glucoside to disintegrate through marked disruption of the cell, decrease in pH of the ensiled medium and intense heat generation. Ensiled cassava by-products are commonly used for feeding ruminants and non-ruminants. Olafadehan (2011) reported a reduction of HCN from 710.98 mg/kg from unprocessed cassava peel meal to 299.21 mg/kg in an ensiled cassava peel meal in 14 days ensiling period. In another study, Loc *et al*. (1997) found that the HCN content of ground whole cassava root was reduced from 109 ppm to 64 ppm after 60 days of ensiling, whereas ensiling the chipped root reduced HCN from 111 ppm to 71 ppm. Similarly, Okah *et al.* (2017) reported that ensiling cassava peel meal reduced the cyanide content to 6.25 ppm of the initial value of 27.30 ppm after an ensiling period of 21 days.

Boiling: Boiling is a high-temperature processing technique that results in the inactivation of heat-sensitive β-glucosidase linamarase and therefore linamarine is not hydrolyzed into cyanohydrin, resulting in a reduction of only up to 50% in cyanide content (Panghal *et al*., 2019). Boiling (heat) enhances immediate evaporation of HCN in cassava by-products. The reduction in cyanogenic glycosides content was related to the boiling time. Jansz and Uluwaduge (1997) reported that boiling cassava reduced about 50-70 per cent of the cyanogens. Boiling cassava leaves was reported to reduce HCN by 75 per cent (Hidayat *et al*., 2002). Vantsawa and Okenarhe (2014) recorded reductions in HCN from 3.16 mg/100 g on freshly harvested cassava leaves to 0.62 mg/100g in dried cassava leaves per boiled and shaded leaves.

Soaking/Retting: Soaking the roots of cassava is usually preceded by fermentation, boiling or drying. Retting, accompanied by sun drying, is used in some parts of Africa as a way of processing cassava roots. This technique of soaking cassava roots in stagnant or slow running water induces tissue splitting and starchy mass extraction. The water softens the cassava root cells, offers a more fermenting medium, and promotes the leaching of cyanogenic glycosides. The approach extracts a large amount of free HCN but has little effect on bound cyanide. Soaking peeled or unpeeled cassava roots is practiced in Nigeria and some other parts of West African countries (Jiwuba *et al*., 2018) to produce *fufu*, *waluwa* and *kanyakaska*. This method reduces HCN for unpeeled cassava roots by about 31.0 percent and cassava roots by 49.9 percent, peeled roots. Olafadehan (2011) reported reduction of HCN from 710.98 mg/kg from unfermented cassava peel meal to 98.10 mg/kg in a retted cassava peel meal.

Fermentation: Traditionally, fermentation has played a dynamic role in the processing of cassava for years. Fermentation increases the abundance and digestibility of nutrients, sensory qualities, shelf life and increases the tolerable amount of anti-nutrients (Panghal *et al*. 2019). Fermentation as a processing technique mainly enhances cassava nutritional values by biosynthesizing vitamins, essential amino acids and proteins, through enhancing protein content and fibre digestibility, as well as enhancing bioavailability of micronutrients and reducing anti-nutritional factors. The importance of fermentation in cassava processing is based on its ability to reduce to relatively insignificant levels the cyanogenic glucosides. Aerobic and anaerobic fermentation of cassava favours linamarin hydrolysis into HCN. Iyayi and Dosel (2000) and Enidiok *et al*. (2008) have reported reduction in cyanide levels by up to 80 percent and 41 percent during fermentation processes respectively. Many lactic acid bacteria and yeast have linamarase activity and are known to contribute significantly to the breakdown of cyanogenic glycoside during cassava fermentation (Kimaryo *et al*., 2000). The concentration of cyanide between 2–3 ppm completely inhibits the growth of other microorganisms like *Escherchia coli*, and this resistance property favours the growth of lactic acid bacteria for fermented cassava (Kobawila *et al*., 2005). During lactic acid fermentation of cassava roots, a drop in pH is observed and this is the result of the production of organic acids by lactic acid bacteria (Kobawila *et al*., 2005). Such microorganisms are able to use the cyanogens and their degradation products, thereby removing their substrate from these harmful substances and making the substrate safe. Linamarase enzymes work on cyanogenic glycosides during the fermentation process and are accountable for cassava products being detoxified. Fresh cassava root contains approximately 400 to 440 mg / kg HCN that could be reduced to 84 mg / kg by wet fermentation and 14 mg / kg by solid-state fermentation (Muzanila *et al*., 2000) and 15 or 8 g / kg by fermentation (Udedibie *et al*., 2004).

Lambri *et al*. (2013) documented the effect on toxin reduction by the type of microorganisms used in fermentation. The selected micro-organisms with grated cassava roots were inoculated for 48hrs. *S. Cerevisiae* was found to be more effective in reducing HCN by 65.9 per cent compared to *L. plantarumm* V22 (50.9 per cent), *O. Oeni* (55.1%) and mixed cultivation (34.2%). The use of nutrients by microorganisms or leaching out is responsible for increasing nutrient content. The type and state of the fermentation depends on the vitamin, protein, amino acid, and mineral levels after fermentation. The other result of fermentation is the removal of anti-nutrients that are found in cassava, i.e. phytates and tannins. Gidamis *et al*. (1993) reported that fermentation in the solid state reduces 89.6 per cent of the total cassava roots cyanogens. Ernesto *et al.* (2002) recorded that retention of cyanide in heap fermentation was found to be 12.5–16.5 per cent.

Combination of processing methods: From the above discussion, it is quite clear that a single method is not self-sufficient to reduce the cassava toxicity up to safe limits, so different methods can be used in conjugation to have cumulative impact. Oke (1994) confirmed that soaking cassava roots prior to sun drying increases the efficiency of detoxification (97.8–98.7%). Retting fresh cassava roots for 3 days then drying for 3 days give the result of 85.9% cyanide reduction. On the other side, crushing roots before sun-drying allow 96–99% of total cyanogens to be removed. This is explained by the fact that crushing damages the plant cells and thus linamarase enzyme comes in direct contact with linamarin. Therefore, sun-drying decreases cyanohydrin and free cyanide (Heuberger, 2005). Soaking and fermenting cassava roots for 3 days allow a decrease of 5.7% of total cyanide content (Westby and Choo 1994). Oke (1994) stated that grating and peeling cassava prior to fermentation, then sun-drying or oven drying with slight heat can result in a product free from cyanogens for any cassava variety. Amoa-Awua *et al.* (1996) reported that sun drying for 6hrs followed by fermentation for 2 days results in 22% less cyanogens. Drying of superficially peeled cassava roots, heap fermentation, and incubating for 3 days, then grinding, sun-drying, and powdering to produce flour after removing of fungal mycelium give a high loss of cyanogens. Grating, fermentation, wetting, drying, and steaming may allow only 2% of cyanogens retained.

CONCLUSION

This review found that cassava roots could be processed to animal feed by different processing methods. This review also showed that cassava roots contain HCN that limits their use in animal feed. It is strongly suggested that HCN content of cassava roots be reduced to a tolerable threshold before use as animal feed. Evidences exist that processing cassava roots reduces the HCN contents. However, combination of different processing methods showed to reduce HCN better than the use of a singular processing method.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The world today is face with high demand of food due to increase in population and risk from climatic change. There is therefore need to develop plant varieties with high yield advantage that can withstand the advert environmental condition. The aim of this study is to select genotypes with good proximate nutrient qualities among the elite cassava genotypes. Twenty four cassava clones were selected from biotic/abiotic stress tolerance breeding population of the cassava programme of National Root Crops Research Institute (NRCRI), Umudike. The clones were obtained through hybridization and then raised from true seeds in 2015. Four check varieties namely; NR 03/0155, NR03/0211, NR 01/0004 and CR 36-5 were also added to the planting materials. The trial was set up as a Randomized Complete Block Design (RCBD) with three replications in each location. Yield and associated traits were evaluated at harvest. Fresh root weight in kg/plot and its related components were determined at harvest (12 MAP) from the ten inner plants of each plot using quantitative methods.. The data analysis was done using GENSTAT 11 program and Analysis of Variance (ANOVA) for all the traits evaluated. Correlation was done to estimate relationships existing among the traits measured. The result showed that there is significant (P<0.05) difference among the genotypes for all the traits. The findings of the study showed that there were variations in the performances of the genotypes across all the traits evaluated with the best ranking (45.36% of dry matter contents, 27.70% of starch content and ranking index of 9.60) genotype as CR14B-180 and the worst ranking (30.53% of dry matter content, 16.41% of starch content, and ranking index of 4.31) genotype as COB 159-5-4. The best genotype showed good attribute and acceptable range for the traits evaluated.
Keywords: *Proximate, elite cassava, hybridization, genotypes.*

INTRODUCTION
Cassava is described as very important staple crop and the bread of the tropics (Abah, *et al.*, 2022) and an important food security crop in the developing world and a major source of food calories. Starchy tuberous roots of cassava provide food for people in sub-Saharan Africa and Latin America. Cassava is grown mostly by small-holder farmers as an important food and as a cash crop with the average fresh tuber yield under traditional farming practices in sub-Saharan Africa ranges between 8 and10 tons per hectare while the potential yield capacity could be as high as 40 to 60 tons per hectare. The production increases in cassava results not only from surface area expansion of cassava production, but also from productivity increases from genetic research and better agronomic practices which have boosted yields over the years (Nweke *et al.*, 2001).
Economic value for cassava products is largely dependent on the dry matter content (DMC). This is the potential of the crop that reflects the true biological and economic yield. High dry matter content and starch is the main characteristic trait preferred by consumers and processors of cassava. For instance, in sub-Sahara Africa, small-scale farmers preferred cassava varieties that have high dry matter content and starch. The dry matter content in cassava is however influenced by factors such as the age of the plant, crop season, location and light use efficiency. Storage root (DMC**)**) trait in cassava is a component of storage root yield, a complex quantitative inherited trait and it reflects the proportion of useable fresh root yield (Kawano *et al*., 1987). Dry matter content (DMC) is commonly measured using either specific gravity through suspension of a root sample in water and air, or the oven-drying method, which has been the most widely used method. This is where a representative root sample is weighed and then oven dried to constant weight (Fukuda *et al.*, 2010). The oven-drying method is tedious when working with a large number of samples. Likewise, it is difficult to implement this approach where the source of

electricity is unreliable. Both oven-drying and specific gravity method could be substituted by NIRS, which has been shown to predict dry matter content with a high degree of accuracy (Belalcazar *et al*., 2016).

Cassava starch has a high potential used both in industry and for human consumption. The unique properties of cassava starch suggest its use even for specialty markets such as adhesives, baby foods, non-allergenic products and food for hospitalized persons (Moorthy, 1994; Masumbu, 2002). Starch is a valuable ingredient for the food industry, being widely used as a thickener, gelling, bulking and water retention agents. Cassava starch is used directly in different ways or as a raw material for further processing in the production of paper, textiles, as monosodium glutamate (MSG), and as an important flavoring agent in Asian cooking (FAO, 2011; IITA, 2001). Apart from culinary requirements, cassava starch can find application in various industries such as pharmaceuticals, cosmetics, biopolymers, textile, and biofuels (Nassar, 2000). Native and modified starches can be used to influence physical properties of many foods like gelling, thickening, adhesion, moisture retention, stabilizing, texturizing, and anti-stalling applications. Starch and its derived products are important in the paper, pharmaceutical, wood, packaging and textile industries, as well as in ethanol and alcohol production, battery making, and in the production of explosives like matches (Moorthy, 1994**).**

In respect of the importance of cassava to the world, it is face with many challenges demand due to the increase in the population and climatic threat from the environment, there is therefore the need to develop varieties that have high yield performance and high nutrient qualities. This study is therefore carried out to select genotypes with good proximate nutrient qualities among the elite cassava genotypes.

MATERIALS AND METHODS

Source of planting materials

Twenty four cassava clones were selected from biotic/abiotic stress tolerance breeding population of the cassava programme of NRCRI, Umudike. The clones were obtained through hybridization and then raised from true seeds in 2015 and the clonal trial was established in 2016/2017 planting season. Four check varieties namely; NR 03/0155, NR03/0211, NR 01/0004 and CR 36-5 were also added to the planting materials.

Site/location of the experiment

The trial was conducted in National Root Crop Research Institute (NRCRI) Headquarters at Umudike Abia State Nigeria. Umudike lies between latitude 05^{0} 29'N, longitude 07^{0} 33'E and altitude 122m above sea level. It is in the rain forest zone characterized by acidic ultisol soils with annual rainfall range of about 1800m-2500mm and temperature range of 22^{o} C-33^{o} C.

Experimental design

The trial was set up as a Randomized Complete Block Design (RCBD) with three replications in each location. Plot size of 20m^2(4m x 5m dimension i.e. 4 rows by 5 plants) was used with planting distance of 1m x 1m inter and intra row spacing giving a total plant population of 10,000 plants/ha.

Agronomic practices

The trial was carried out in two planting seasons, that is, 2016/2017 and 2017/2018 seasons. Field establishment for the first season was done in the month of July 2016 for all the four locations while the second year planting across the locations was carried out in August 2017. The land was cleared, ploughed, harrowed and ridged using a tractor. Weeding was done at 5 weeks after planting (5WAP), 3 months after planting (3MAP) and 9 months after planting (9MAP). Fertilizer NPK 15:15:15 was applied at 6 weeks after planting (6WAP) at the rate of 400kg/ha.

Data collection

Yield and associated traits were evaluated at harvest. Fresh root weight in kg/plot and its related components were determined at harvest (12 MAP) from the ten inner plants of each plot using quantitative methods. Other field data collected includes; net stand count or number of plants harvested/plot, number of roots per plot, root weight in air, root weight in water and specific gravity.

Determination of Weight in air (Wa), Weight in water (Ww) and Specific gravity

Methodology for specific gravity

The specific gravity was carried out following the standard method of Jaramillo *et al.*, 2005.

- Root sample weighing about 3kg was collected from each genotype and bagged in net sample bags.
- Weighing of sample in air (Wa) was done using a suitable balance
- Weight of the same sample of 3kg was weighed in water (Ww) using sensitive scale.
- Ensuring to use the same container to weigh both in air and in water and that the roots are generally free from soil and other debris.

%Starch and Dry matter content

The starch and dry matter contents were carried out following the standard method of Jaramillo *et al.*, 2005:

Starch and Dry matter content are measured in percentage and calculated by both specific gravity method and oven drying method in laboratory.

Gravimetric method

Determined of **specific gravity:** was done following the methods of Jaramillo *et al.*, 2005. Estimation of dry matter content and starch content in cassava is based on the principle of a linear relationship between specific gravity with dmc and/or starch.

$$Specific\ gravity = \frac{W_a}{W_a - W_w}$$

Where, Wa represents root weight in air and Ww is the root weight in water.

% dmc = 158.3 x specific gravity – 142

% starch = 210.8 x specific gravity – 213.4

Data analysis

Data collected from the field trial were subjected to analysis. The data analysis was done using GENSTAT 11 program and Analysis of Variance (ANOVA) for all the traits evaluated. Correlation was done to estimate relationships existing among the traits measured. Proximate analysis was done in the laboratory to determine starch yield, dry matter content, ash content, crude fibre and cyanide potential.

RESULTS AND DISCUSSION

Figure 1 showed the correlation analysis between the different traits evaluated. The result showed that there is no significant ($p>0.05$) correlations among the traits except between the dry matter content and the starch content with a significant positive correlation coefficient of 0.86. The result of the anova on Table 1 showed the variance component of the different traits measured. The result showed that there is significant ($P<0.05$) difference among the genotypes for cyanide content, crude protein, dry matter content and starch contents of the roots analyzed, but there was no significant difference ($P>0.05$) in the ash content. Table 2 result showed the mean values of the cassava genotypes evaluated which showed that there is significant ($P<0.05$) difference across the genotypes for all the traits. Root weight ranged from 11.03 to 66.33kg with the mean of 33.21kg, cyanide content ranged from 18.52 to 108.10Mg/HCN with the mean of 49.56 Mg/HCN, crude fibre ranged from 0.19 – 2.22% with the mean value of 1.11%, ash value ranged from 0.27 to 1.96 % with the mean value of 1.35%, dry matter content ranged from 23.19 to 45.83% with the mean value of 34.83% and the starch content ranged from 13.23 to 27.80% with the mean value of 21.67%. These results were agreed with the findings of according Nambisan, (2011), that cyanide toxicity of freshly harvested cassava root to humans and animals are classified as follows: non-toxic (less than 50 mg HCN kg^{-1}), moderately toxic (50–100 mg HCN kg^{-1}) and highly toxic (above 100 mg HCN kg^{-1}). Therefore, the result obtained shows that aside CW450-75 and NR030155 which has the values of 105.00 mg HCN kg^{-1} and 108.10 mg HCN kg^{-1} respectively, the genotypes fall within the category of low to moderately toxic type of cassava root genotypes.

Crude fibre is the part of food made up of cellulose and lignin. Food materials with high crude fibre content are low in nutritional value. The result showed low value (0.19 and 0.79) for crude fibre content, with the lowest genotypes as NR 010004 and NR 050046 respectively. These values are also in agreement with the finding of Nambisan (2011). The ash content is an indicative of inorganic constituents (such as minerals). It helps to determine the amount and type of minerals in food; important because the amount of minerals can determine physiochemical properties of foods, as well as retard the growth of microorganisms. (Nambisan (2011). For cassava, the standard generally ranges from 1 to 2% Nambisan (2011). The ash content varied significantly also among the genotypes with the range from 0.27 – 1.96, which fell within the acceptable range.

The ranking index showed that genotypes CR14B-180 ranked as the best genotype across all the traits evaluated, followed by COB 154-5-4 while genotype COB 159-5-4 ranked as the worst genotype.

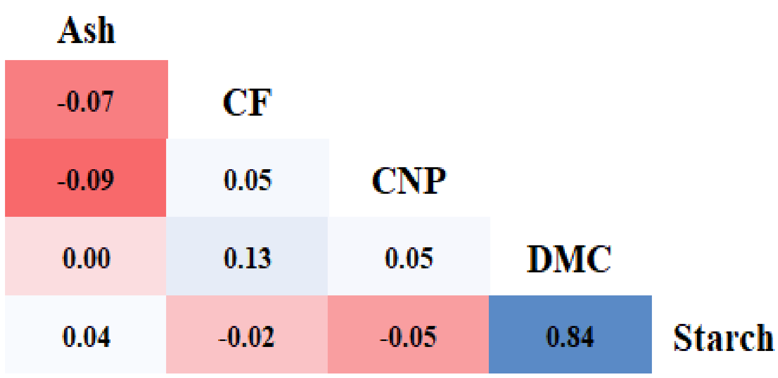

Figure 1: Correlation among the 24 cassava genotypes for the traits evaluated

Table 1: Variance component of the traits

Traits	Genotypic variance	Error variance	F-value
Ash content	111.30	114.90	0.530

CONCLUSION

The findings of the study showed that there were variations in the performances of the genotypes across all the traits evaluated with the best ranking genotype as CR14B-180 and the lowest ranking genotype as COB 159-5-4. The best genotype showed good attribute and acceptable range for the traits evaluated.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study was conducted on Nutrient Composition and Organoleptic Quality of "Fish Kilishi" made from Clarias gariepinus and Mormyrus rume. 10kg live fish was procured from fish sellers in Lafia. The fish sample was divided into 5 Kg each giving the total of 2 samples comprising of T1 (C. gariepinus), T2 (M. rume). The experiment was conducted in a completely randomized design. Organoleptic parameters which included texture, aroma, appearance, taste and general acceptability were assessed. 40 judges were used for the organoleptic assessment. Results of organoleptic assessment of C.gariepinus had the average means of 9.50±0.9, 9.10±.71, 9.50±0.89, 9.90±1.71 and 10.0±0.00 for texture, aroma, appearance, taste and general acceptability respectively. M. rume had the average mean value of 8.00±1.45, 7.80±1.44, 9.00±1.03 and 9.40±0.94 for texture, aroma, appearance, taste and general acceptability respectively. The result by panelist showed that fish kilishi made with C. gariepinus had the highest mean value in texture, aroma, taste and general acceptability. The result of proximate composition of C. gariepinus kilishi had the mean value of 34.13±0.01, 2.29±0.23, 29.45±1.01 and 10.92±0.29 for crude protein, crude fibre, ash, ether extract, moisture content and nitrogen free extract, respectively while M. rume had the mean value of 27.13±1.01, 1.77±0.06, 6.09±0.01, 19.45±0.58, 8.45± 0.52 and 37.11±0.64 for crude protein, crude fibre, ash, ether extract, moisture content and nitrogen free extract respectively. The most preferred product is the fish kilishi made with C. gariepinus and M. rume. This study therefore recommends C. gariepinus for production of fish kilishi. Adequately, filleting the bones, fins and head of the fish should be considered during the preparation of kilishi.
Keywords: *Fish Kilishi, Clarias gariepinus, Mormyrus rume*

INTRODUCTION
Fish is an extremely perishable food with deterioration commencing immediately after harvest (Agbo *et al*., 2002). Prior to death, the enzymes normally get involved in the digestion of ingested food and all microbial activities are controlled. As soon as fish dies, enzymatic action begins on the flesh and alimentary system leading to soft destructive changes. The process is referred to as autolysis. Fish is liable to accelerated physiological, chemical and microbial processes after harvests that invariably lead to deterioration and loss of wholesomeness. It is therefore necessary to come up with some measure of processing such as reduction in moisture content, denaturation of endogenous enzymes and microorganisms or packaging in order to curtail perishability (Vadivel, 2008). Fish consumption provides health benefits to the human population. There is strong evidence that fish, in particular oily fish, lowers the risk of coronary heart disease (CHD) mortality by up to 36 percent due to a combination of EPA and DHA (FAO/WHO 2011). In many low-income countries with water and fisheries resources, fish is important for livelihoods, income and as food for the rural poor people who suffer disproportionately from undernutrition, including micronutrient deficiencies (Thompson and Subasinghe, 2011). Fish is by far the most frequently consumed animal-source and thereby makes a valuable contribution to the diversity of everyday diets, dominated by carbohydrate-rich staples. Fish can therefore be considered an irreplaceable animal-source, providing essential nutrients of high bioavailability which are found in limiting amounts in the diet. These nutrients include animal protein, essential fats, minerals, and vitamins. Small fish, eaten whole or as fish products, e.g. dried fish are particularly rich in calcium and other micronutrients (FAO, 2014).

Kilishi is an Hausa word which refers to slicing, dressing, sun-drying, application of slurry of spices and roasting. Kilishi is a sliced heat-dried seasoned roasted ready-to-eat meat product known to have originated from the Hausa/Fulani speaking people of Northern Nigeria (Odusole and Akinyanju, 2003; Olusola, 2006; Okonko *et al*., 2013). Kilishi has been a convenience travel food across the Sahelian countries and as an export commodity from Nigeria to Saudi Arabia particularly during Hajj. The major problem in the kilishi production has been poor processing and low product technology. This has been tackled with the new improvement done at the University of Benin kilishi research centre. The improvements recorded have enhanced its processing, preservation efficiency, packaging for easy handling, marketing and distribution that will enable kilishi product to be exported to Europe and United States of America through the University of Benin kilishi factory. It is a ready-to-eat convenience meat product (Igene, 2012; Okonko *et al*., 2013). *Clarias gariepinus* was chosen for kilishi preparation because of its availability locally and higher flesh to bone ratio (Achionye-Nzeh and Omoniyi, 2002). It is commonly known as catfish and a valuable fish in Nigeria, which belongs to the family Clariidae. The present study is aimed at utilization and value addition of *Mormyrus spp* and *Clarias gariepinus.*

MATERIALS AND METHODS

Ingredients and Spices for Processing

The defatted groundnut used for slurry formulation were purchased from Lafia Central Market. The principal ingredient were the defatted groundnut dough which were bought from groundnut millers at Lafia, Nasarawa State. Other ingredients used included table salt (sodium chloride), Maggi seasoning and curry powder while spices included dried hot (chilli) pepper (*Capsicum frutescens*), cloves (*Eugenia caryophyllata*), candle wood (*Fagara zanthoxyloides*), ginger (*Zingiber offinale*) and onion (*Allium cepa*).

Preparation of slurry

Slurry was prepared using salt (1.88%), maggi seasoning (0.14%), pepper (4.85%), clove (0.40%), candle wood (0.23%), ginger (2.35%) and onion (11.73%) respectively. The formulations was thick due to high proportion of the principal ingredients (defatted groundnut) used. There was no variation in the spices used.

Fish dressing

The fish samples were washed thoroughly with saline solution and the scales, bones, fins, heads and tail were removed using dissecting set. This enhanced easy filleting of the fish.

Filleting of fish

The samples were exposed to air for 10 minutes so as to reduce the moisture content. With the use of a sharp knife, the samples were cut ventrally from the tail to the head region in fillet form.

First sun drying

The freshly prepared fillets were sun dried to reduce its moisture content.

Infusion of partially dried fillets into slurry

The dried fillets were infused in the prepared formulated slurry containing salt (1.88%), maggi seasoning (0.14%), pepper (4.85%), clove (0.40%), candle wood (0.23%), ginger (2.35%) and onion (11.73%) thoroughly for 10 minutes to ensure absorption of the slurry.

Second sun drying

The infused fillets samples were mounted again in a sun drying raft for 21 hours to undergo second drying. This was to ensure a permanent absorption of the slurry on the fillet.

Roasting

After drying, the dried fillets were roasted at average temperature of 232℃ for seven minutes in the departmental smoking kiln (to ensure blending of ingredients into the dried fish fillets and to enhance taste of the finished products).

Storage of the Products

The fish products were packaged in separate clean air tight containers and were labeled according to their respective samples and it was as such that the plates in which the fish was served for organoleptic assessment. The fish kilishi was stored at room temperature of 28±2℃ for the experimental period.

Sensory (Organoleptic) Evaluation

Samples from the prepared kilishi products were subjected to sensory evaluation immediately to obtain data for the selection of the best out of the two fish species used. The test utilizes the sense of texture, aroma, appearance, taste and general acceptability for quality assessment of dried fish kilishi. The sense of touch was used to assess the texture of the fish, and appearance was used to detect changes in colour and general appearance of the sample. The sense of aroma helped in determining the flavour of good and bad quality of sample. The sense of taste was helpful in determining the palatability and general acceptability of the dried kilishi samples. A 40 membered panel was constituted which consisted of staff and students of the faculty. A 10-point hedonic scale ranging from A (Excellent) = 10; B (Good) = 8; C (Fair) = 6; D (Unsatisfactory) = 4 and E (Unacceptable) = 2 was adopted for each quality parameter. Pencils, tissue paper and water was provided to the judges.

Data Analysis

Data obtained was subjected to One-way Analysis of Variance (ANOVA) in a completely randomized design using SPSS statistical package. Significant mean differences were separated at 5% significance level.

RESULTS AND DISCUSSION

Table 1: Organoleptic assessment of Kilishi made from *Clarias gariepinus* and *Mormyrus rume*

	Organoleptic parameters				
Species	**Texture**	**Aroma**	**Appearance**	**Taste**	**General acceptability**
Clarias gariepinus	9.50± 0.89^{a}	9.10± 1.71^{a}	9.50± 0.89^{a}	9.90± 1.71^{a}	10.00± 0.00^{a}
Mormyrus rume	8.00±1.45^{b}	7.80±1.44^{b}	9.50±0.89^{a}	9.00±1.03^{b}	9.40±0.94^{a}

Means with different superscript along the column differed significantly at P≤ 0.05

Table 2: Nutrient composition of kilishi made from *Clarias gariepinus* and *Mormyrus rume*

	Nutrient composition (%)					
Species	**Crude protein**	**Crude fibre**	**Ash**	**Ether extract**	**Moisture content**	**Nitrogen free extract**
C. gariepinus	34.13± 0.01^{a}	2.29± 0.23^{a}	5.76±0.69^{b}	29.45±1.01^{a}	10.09± 0.29^{a}	17.45±0.35^{b}
Mormyrus rume	27.13±1.01^{b}	1.77±0.06^{b}	6.09±0.01^{a}	19.45±0.58^{b}	8.45± 0.52^{b}	37.11±0.64^{a}

Means with different superscript along the column differ significantly at P≤ 0.05

The result of the sensory scores of kilishi prepared from *Clarias gariepinus* and *Mormyrus rume* was presented in Table 1 above, which revealed that kilishi made from *Clarias gariepinus* was most preferred in terms of texture, aroma, taste and general acceptability of the product with average mean scores of 9.50±0.89, 9.10±1.71, 9.90±1.71 and 10.00± 0.00, respectively. The preferredness of catfish could be due to its flavour, juiciness and tenderness as reported by Safari *et al.* (2001). The species of the fish had influenced on the panelist decision. According to Moloney (1999), meat texture is an important component of meat tenderness and palatability and it has two major components – the first is the impression of wetness produced by the release of fluids from the meat during the first few chews, while the second is the more sustained juiciness that apparently results from the stimulating effect of fat on the production of saliva and the coating of fat that builds up on the tongue, teeth and other parts of the mouth. Meat juices play a vital role in conveying the overall impression of palatability to the consumer. Principally sources of juiciness as detected by the consumer are the intramuscular lipids and water content. When these two combined, the melted lipid constitutes a broth which when retained in the meat is released upon chewing. Such broth may also stimulate the flow of saliva, and thus improve the meat's apparent juiciness (Hedrick *et al.*, 1994). In kilishi inherent muscle water is of less importance in texture because of its low water activity. However the apparent texture observed would be due to the ability of the kilishi to elicit copious flow of salivary juice to moisten the kilishi.

The proximate composition of *Clarias gariepinus* and *Mormyrus rume* kilishi was presented in Table 2. Catfish kilishi had the highest crude protein mean of 34.13±0.01 %; this differed significantly from the mean protein percent of the *Mormyrus rume* 27.13±1.01 (Table 2). This showed that processing fish as in kilishi production improves the percent protein of the product thus making it nutrient dense. Igene *et al*. (1990) reported a value of 50.02% crude protein for traditional kilishi after roasting. Bello and Tekwata (2015) also reported crude protein between 50.76 to 63.3 for solar tent and sun dried kilishi from bony-tongue (*Heterotis niloticus*). The major part of the protein comes from the groundnut cake which has 55.85% (Badau *et al*., 1997). All other ingredients contributed their quota of protein too. The highest crude fibre content obtained in kilishi from *C .gariepinus* (2.29±0.23) was significantly different from that of *M. rume* kilishi (1.77±0.06). Badau *et al*. (1997) reported crude fibre range of 6.1-25.0% for ingredients used in kilishi production. Though the recipes were constituted from virtually the same ingredients, differences were obtained in the crude fibre values of kilishi products. It can therefore be deduced that the varied rate of absorption and adsorption of the dried raw meat slices in the different spice mixture is responsible for the significant differences observed in the crude fibre content of kilishi produced. The ash content of the kilishi samples ranged from 6.09% in *M. rume* to 5.76% in *C. gariepinus*. The result of ash content is in line with the findings of Bello and Tekwata who reported ash content values of 5.00 to 5.33 for fish kilishi made from *Heterotis niloticus.* The pattern of ash content observed in this study revealed that the ash content is influenced by the fish species. Also, another reason could be because most of the ingredients in the slurry might have lost their mineral contents into the slurry hence, into the fish product and this agrees with the report of Elizabeth (1995) who observed that the ash content of any processed meat would be the content of the muscle tissue in addition to that of ingredients used. The ether extract content obtained in this study was highest 29.45±0.01 in kilishi made from *C. gariepinus* and lowest 19.45±0.58 in kilishi made from *Mormyrus rume.* Similar higher values between 17.34 to 19.20 were reported by Iheagwara and Okonkwo (2016). Generally, the fat content of the kilishi samples were high and this can be attributed from the groundnut cake powder which represent a considerable proportion of the product (Igene *et al*., 1990). The moisture content of the kilishi samples ranged from 8.45% - 10.09% with *C. gariepinus* having the highest moisture content of 10.09%. The reduction in moisture content of *M. rume* is desirable as this can affect the quality of the sample positively in relation to other kilishi sample (Apata *et al*., 2013). Generally, the moisture content of the kilishi samples indicates that the kilishi samples were sufficiently dried to minimize microbial growth though moisture values of 6.92%, 9.87% and 10.00% as observed by Jones *et al*. (2001), Apata *et al*. (2013) and Olusola *et al*. (2012), respectively.

CONCLUSION AND RECOMMENDATIONS

It can be concluded that fish kilishi was highly interested and highly accepted by consumer immediately after roasting. Through, the two samples of fish were accepted by the consumers, but the Clarias kilishi was preferred most.

It is recommended that clarias should be used for kilishi due to their strong and hardy nature. Also, the bones, fins and head of the fish should be removed during the preparation of kilishi.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted in Enugu State to assess the level of women involvement in yam processing/value addition in the area. The study was to identify improved yam technologies used by respondents, assess the level of participation of women in yam processing and determine the effect of socio economic factors on yam processing among women.. The study population constituted all women yam producers and processors in Enugu State, Nigeria and the sampling size of the study was Sixty (60) respondents. Primary data were collected using questionnaire. The most common improved technology used by the respondents was organic manure. The most involved processing activities were yam chips, yam flour and yam flakes. Marital status, household size and education had significant effects on yam processing. It was recommended that women should receive more training so that they can participate effectively in yam management technologies and processing activities.
Keywords: *Women, involvement, yam, processing, value addition*

INTRODUCTION
Yam originated in South East Asia and was brought to West Africa in the 16th century. It is one of the principal tuber crops in the Nigerian economy. Nigeria is the leading world producer accounting for over 65% of world yam annually; producing an average of 38 million metric tons (Odinwa*etal* 2016). Yam is an important source of carbohydrate for many people of the Sub Saharan region especially in the yam zones of West Africa. It is the second most important tuber crop in Africa, after cassava, with production reaching above one third of the level of cassava (FAO, 2002). Yam tuber is essentially a starchy food; its principal nutritional functions being the supply of calories to the body. Even though National Root Crop Research Institute, Umudike (NRCRI) had trained rural women in South East Nigeria on value addition of root and tuber crops, including yam, yet not many women are into yam processing/ value addition. Yam can be processed into starch, yam flour, yam ball, yam chips (Salawu, *etal* 2014). Aerial yam can be processed into high quality bulbifera flour, whole meal bulbifera flour and fufu flour. Industrial processing and utilization of yam includes starch, livestock feed, flour and pounded yam flour, yam balls and yam chips, Traditionally, the processing of yam to pounded yam using pestle and mortar is highly valued but is gradually being replaced in the market with instant-pounded yam flour. Processed yam can be easily stored for a long period of 12 - 18 months (Salawu, *etal* 2014) .Women farmers face more constraints than men even though they are more involved in processing of yam. They have less farm size, poor access to most yam production resources, little access to decision making and poor education. Also cultural barriers affect women in yam production and processing activities in parts of South East Nigeria. (Nahanga 2015). This research was carried out to show case women contribution to processing of yam with the following objectives; identification of yam processing technologies used by the women, assessment of level of participation of women in yam processing and examination of the effect of socioeconomic factors on yam processing in the area.

MATERIALS AND METHODS
The study was conducted in Enugu State, Nigeria. The population of the study constitutes all yam producers. Multi-stage sampling technique was used to select the respondents. Local Government Areas purposely selected for the study for reason of large concentration of yam producers were Animi, Agwu and Nkanu West. Two communities were randomly selected from each of the LGAs. A list of all women yam producers in the selected communities were obtained from the extension agents and community leaders in the area, which formed the sampling frame of the study. From the frame, ten (10) women yam farmers were randomly selected for the study which gave a total of sixty (60) respondents for the study. Data were collected using structured questionnaire

administered to these farmers. Data collected were analyzed with descriptive statistics such as frequency tables, means and percentages and multiple regression analysis.

RESULTS AND DISCUSSION

Table 1; Distribution of the respondents according to the yam technologies used

Types of technologies	Frequency	Percentage	Rank
Inorganic fertilizer	35	58.33	6th
Improved variety	52	86.67	2nd
Pesticide	20	33.33	9th
Herbicide	31	51.67	7th
Organic manure	58	96.67	1st
Minisett	39	65.00	4th
Seed yam	40	66.67	3rd
Ware yam	37	61.67	5th
Value addition	21	35..00	8th

Source: Field Survey, 2021 (Multiple response 333)

Results in table 1 presents the improved yam technologies used by the respondents in the study area. The improved yam technologies used by the respondents in Enugu State in their order of popularity, include: organic manure (96.67%), improved variety (86.67%), yam seed (66.67%), minisett (65.00%), ware yam (61.67%), inorganic fertilizer (58.33%), herbicide (51.67%) value addition (35..00%) and pesticide (33.33%). These results show that the most common improved yam technology used in Enugu State, Nigeria was organic manure . Increased utilization of organic fertilizer could be attributed to the fact that it was cost effective and safe.

Table 2. : Mean rating of the level of involvement of women in yam processing/value addition in Enugu State

Indicators	SA	A	D	SD	Total	Mean	Decision
Yam starch	0 (0)	0(0)	0(0)	60(60)	60	1.00	
Yam flour	41(164)	15(45)	4(8)	0(0)	183	3.05	
Chips	29(116)	21(63)	6(12)	4(4)	195	3.25	
Flakes	24(96)	20(60)	10(20)	6(6)	182	3.03	
Amala	10(40)	18(54)	23(46)	9(9)	149	2.48	
Strips	8(32)	17(51)	28(56)	7(7)	146	2.43	
Bread	5(20)	10(30)	26(52)	19(19)	121	2.02	
Ball (Akara)	8(32)	14(42)	20(40)	18(18)	132	2.20

Biscuits	0(0)	0(0)	10(20)	50(50)	70	1.17	
Croquette	0(0)	1(3)	24(48)	35(35)	86	1.43	
Confectionaries	1(4)	1(3)	30(28)	28(32)	67	1.12	
Grand Mean						**2.04**	**Rejected**

Source: Field Survey, 2021. Critical mean score = 2.5.

Table 2 presents the level of involvement of women in yam processing/value addition in the study area. The grand mean of the level of participation of women in yam processing in Enugu State was 2.04 and was rejected because the value was less than the critical mean value of 2.5. Out of thirteen value addition activities considered in the study, only four (yam flour (3.05) yam chips, (3.25) yam flakes (3.03)) had very high participation by the respondents. .Apart from Amala and strips, all other value addition activities received low level of participation among the respondents.

Source: Field Survey, 2020, Note: +Lead equation, ***1% level of significance, ** 5% level of significance, *10% level of significance, Values in parenthesis are the t-value

The Ordinary Least Square result of the effect of socio economic factors on yam processing in Enugu State is presented in Table 3. The linear functional form was chosen as the lead equation.. The coefficient of multiple determination (R^2) was 0.645which implies that 64% of the variations in yam processing was explained by the independent variables included in the model. However, the significant variables were marital status, ,household size, education and membership of cooperative .

The coefficient of marital status and household size were statistically significant and positively related to the yam processing at 1%. This result implied that a unit increase in the household size and marital status of the respondents result to an increase in the yam processing. This is expected because large household size may serve as a means of cheap labour for yam processing activities in the study area. This result is in consonance with Nwaobiala(2018) who reported that relative large household size enhanced availability of labour for increased efficiency among farmers. The coefficient of education was statistically significant and positively related to the yam processing at 1%. This result implied that a unit increase in the educational level of the respondents resulted in increase in the yam production among the respondents. More educated women are likely to adopt new technologies.. The result corroborates with that of Abudu *et al*(2014) who reported that education positively influenced farmers' productivity.

CONCLUSION

The most common improved yam technology used by the respondents was organic manure. The level of participation of women in yam processing in the study area was low. Only yam flour, yam chips and yam flakes recorded high level of participation among the respondents. Marital status, household size and Education exerted significant effects on yam processing in Enugu State.

RECOMMENDATIONS

There is need to guide, educate and encourage women to embark on yam processing to enhance their welfare status

Women should be taught to be more involved in improved yam management technologies than is currently in place in the area

Training on yam value addition is needed among women in the study area for increased participation.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study analysed factors influencing farmers' knowledge on post-harvest management of maize in Niger State, Nigeria. A multi-stage sampling technique was used to select one hundred and eighty (180) maize farmers in the study area. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected was analysed using knowledge test and Poisson Regression Model. Finding showed that 57.8% had knowledge score of between 16-20 while 72.7% of the respondents had high knowledge on post-harvest management in maize. The coefficient of age (-.0046825), education (.0095443), farming experience (-.0043662) and storage facilities (0.0391843) influenced farmers' knowledge on post-harvest management in maize. It is recommended that older farmers should be enlightened by extension agents and stakeholders involved in agro-processing on the benefits embedded in post-harvests technologies in order to improve their income and livelihood. Also, the cost of post-harvest materials and tools should be subsidized by government and stakeholders for farmers to access at affordable price as this which will go a long way to enhance farmers' knowledge and probably improved on the level of adoption of post-harvest management.

Keywords: *Factors Influencing Farmers knowledge, Post-harvest Management, Maize*

INTRODUCTION

Maize (*Zea may*) is one of the most widely consumed stable crop in Nigeria. Maize crop thrive in almost all the ecological zones of the country. Larger proportion of the maize produced in Nigeria is carried out by smallholder farmers with inadequate access to incentives that enhance their productivity (Akanbi, Alarape & Olatunji., 2019). Notwithstanding, Nigeria just like other Sub-Saharan African countries produced low output in maize compared to developed countries due to many constraints such as biotic factors or abiotic factors like low soil fertility, pests and diseases, drought, unavailability of improved seed, weeds, less remunerative prices, lack of market opportunities and lack of knowledge on post-harvest management practice in maize (Issa, Kagbu & Abdulkadir, 2016). Maize as a cereal crop requires a lots of post-management practices in other to reduce post-harvest farm losses and also meet up the growing needs of world population. The population of the world is growing rapidly which has resulted to crave increase in consumption. The objectives of the study are to: determine the farmers' knowledge of post-harvest management in maize; and determine the factors influencing knowledge level of maize in the study area.

MATERIALS AND METHODS

The research was carried out in Niger State of Nigeria. The State can be found in the Guinea Savannah ecological zone of Nigeria. The State is located within longitude 3^{o} 30' and 7^{o} 20' East and latitude 8^{o} 20' and 11^{o} 30' North. The State has a population of about 6,220.617 (National Bureau of Statistics (NBS) (2019). However, with a growth rate of 3.2%, the State has estimated population of 6,625,106.376 in 2021 (NBS, 2019). Some of the crops grown in the area are yam, cotton, Shea-butter, maize, sorghum millet, cowpea, soybean, beans, rice and groundnut. Some of the tree crops are Mango, citrus, coconut, cashew, banana, pawpaw. The inhabitants of the State also rear some livestock like goats, sheep, cattle and chicken among others. The other non-agricultural activities engaged in by men include blacksmithing, leatherwork, mat and basket making, trading while women also engage in technical handicraft and trading (Niger State Geographical Information 2015). Multi-stage sampling technique was employed for this study. The first stage involved random selection of three (3) Agricultural zones in the State. The second stage involved random selection of one (1) Local Government Areas from each of the zones making a total number of three (3) LGAs. The third stage involved random selection of four (4) communities each from the selected LGAs making a total of twelve (12) villages. The fourth stage involved the use of proportional sampling to select 10% of the farmers from the sampling frame to give a total of one hundred and eighty (180) respondents. Primary data was used for this study area. Data was collected by the researcher assisted by trained enumerators using structure questionnaire complimented with interview schedules. Objective i was achieved by carrying out knowledge test for the farmers. Knowledge test was based on the post-harvest management used for maize by the farmers. A total number thirty-three (33) knowledge questions in maize were subjected to knowledge test. Knowledge scores were recorded for each farmer. Each of the statements carried a full weight one (1). Farmers were asked to choose one response against alternative responses as right, wrong or I don't know. For each right response, a farmer received a full weight of 1, for each wrong or I don't know, a farmer receives 0. Thus, the knowledge score ranged from 0 to 100, where $\leq$ 25=Very Low Knowledge, 26-50=Low Knowledge, 51-75=High knowledge, >75=Very High Knowledge.

Factors influencing the knowledge level of respondents on post-harvest management was achieved using poisson regression model, both the implicit and the explicit models are specified below:

Knowledge level of farmers' (Y) is a function of =f $(X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8X_9......X_n)$

$Y= b_o +b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 +b_5X_5+b_6X_6+b_7X_7+b_8X_8+b_9X_9 + b_{10}X_{10}+b_{11}X_{11+}b_{12}X_{12+}b_n X_n+ U$

Y =Farmers' knowledge on post-harvest management (test scores of post-harvest management by the farmers)

X_1= Age (years), X_2= Sex (Male= 1, Female= 0), X_3= Level of education (years), X_4= Household size (number), X_5= Farm size (hectares), X_6= Farming experience (years), X_7 = Affordability of post-harvest management (affordable =1, not affordable= 0), X_8=Access to storage facilities (number), X_9 = Access to extension (number), X_{10} = Access to credit (yes =1, no= 0), X_{11} =Annual farm income (naira), X_{12} = Cost of acquiring storage facilities (naira), B_1-B_2=coefficient

U = Error term

RESULTS AND DISCUSSION

Total Knowledge Scores of Maize Farmers

Results in Table 1 indicated that 57.8% of the farmers in had knowledge score of between 16-20 in maize while 27.8% had of maize farmers had knowledge score >20. The mean knowledge score of the maize was 18.6. This implies that maize farmers had adequate knowledge on post-harvest management in maize. High knowledge might likely equip farmers with skills and techniques needed to curb post-harvest losses that negatively affect farmers' income and livelihood status.

Table 1: Distribution of the farmers according to total knowledge scores in maize (n=180)

Knowledge Scores	Frequency	Percentage	Mean
1-5	0	0	18.6
6-10	1	0.6	
11-15	25	13.9	
16-20	104	57.8	
>20	50	27.8	

Sources: Field survey, 2018

Farmers Knowledge on Post-Harvest Management in Maize

Table 2 revealed that 72.7% of maize farmers had high knowledge on post-harvest management practices in maize while 26.1% had low knowledge. This implies that greater proportion of farmers had high knowledge. High knowledge is expected to reduce the effect of post-harvest losses thereby increasing the food security and livelihood status of maize farmers.

Table 2: Knowledge of farmers on post-harvest management in maize (n=180)

	Frequency	Percentage
Very high knowledge	2	1.1
High knowledge	131	72.7
Low knowledge	47	26.1
Very low knowledge	0	0

Sources: Field survey, 2018

Factors Influencing Farmers Knowledge on Post-harvest Management of Maize

Poisson regression was used to determine factors influencing farmers' knowledge on post-harvest management. The result in Table 3 indicated Pseudo R^2 of 0.815, implying that about 81.5% of variation in the knowledge on post-harvest management was explained by the independent variables included in the model, while the remaining

19.5% were due to external factor not capture by the researcher. The chi-square statistics 106.98 was significant at 1% level of probability indicating fitness of the model. The coefficient of age (-.0046825) was negative and significant at 1% level of probability, implying that as farmers get older, their knowledge on post-harvest management tend to decrease. The findings agreed with Wango (2016), who stated that majority of farmers with knowledge on Agro-Ecological Intensification The coefficient of education (.0095443) and positively significant at 1% level of probability, this implies that increase in education will lead to increase in knowledge of farmers on post-harvest management. This agreed with Oyewole and Ojeleye (2015) who posited that knowledge of farmers on improved farming practices increased with attainment of higher level of education among farmers in Kano State, Nigeria. The coefficient of education was also positive and statistically significant at 5% level of probability. The coefficient of farming experience (-.0043662) positive and significant at 1% level of probability, this implies that increase in numbers of years in farming will reduce farmers' knowledge on post-harvest management. The coefficient of access to storage facilities (0.0391843) was positive and significant at 1% level of probability, implying that adequate access to storage facilities will increase farmers' knowledge on post-harvest management.

Table 3: Factors influencing farmers knowledge on post-harvest management (n=180)

CONCLUSION AND RECOMMENDATIONS

Based on this finding it can be concluded that majority of maize farmers had high knowledge on the post-harvest management of maize. Also, the coefficient of age, education, household size, farming experience, affordability of post-harvest management, access to storage facilities, and access to credit had influenced on farmers' knowledge on post-harvest management. It is recommended that older farmers should be enlightened by extension agents and stakeholders involved in agro-processing on the benefits embedded in post-harvests technologies in order to improve their income and livelihood. Also, the cost of post-harvest materials and tools should be subsidized by government and stakeholders for farmers to access at affordable price as this which will go a long way to enhance farmers' knowledge and probably improved on the level of adoption of post-harvest management.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The purpose of this study was to see how different drying procedures affected the concentration of three essential bioactive chemicals, namely Quercetin, Rutin, and Tannin acid, in ginger extract. The drying methods investigated were shade drying, freeze drying, vacuum oven drying, and fresh without any drying treatment. The concentrations of the compounds were measured in milligrams per gram (mg/g) in triplicate using high performance liquid chromatography. The results demonstrated substantial changes in compound concentration across drying processes, with Freeze drying and Vacuum Oven drying showing higher amounts than Shade drying and Fresh sample. For Quercetin, Vacuum oven drying showed the greatest concentration (1.352 ± 0.062), followed by vacuum oven drying (1.253± 0.057) and shade drying (0.964± 0.045). Fresh samples, on the other hand, had the lowest Quercetin content of 0.499± 0.023.Rutin concentrations followed a similar pattern, with vacuum oven drying producing the greatest concentration (0.541± 0.027), freeze drying (0.468 ±0.023), shade drying (0.425± 0.021), and fresh samples (0.211± 0.012).Furthermore, freeze-dried samples showed the greatest tannic acid contents (0.351± 0.018), followed by vacuum oven drying (0.326± 0.016), shade drying (0.278± 0.014), and fresh samples (0.153 0.009). This research provides important insights into optimizing the drying process to preserve and enhance the bioactive chemical content of ginger.

INTRODUCTION
Citronbergetal; *(*2013) opined that plant-derived compounds, particularly Quercetin, Rutin, and Tannin acid, have received significant attention as a result of their potential health benefits which include, antioxidant, anti-inflammatory, and anticancer properties. However, the choice of drying method applied can have significantly impact on the concentration of these bioactive compounds.
Zhang *et al*; (2016) and Nile and Park, (2015) reported that ginger (*Zingiber officinale*) apart from being a popular spice; also have health and medicinal advantages. Its bioactive components, include quercetin, rutin, and tannic acid which are believe to be responsible for its wide range of pharmacological activities, including antioxidant anti-inflammatory anti cancer, anti-fungi and antibacterial effects.
The usefulness of ginger in relieving nausea has been observed in certain research investigations (Grante*etal;* 2000). A common preservation technique that can change the composition of these chemicals is drying. The influence of various drying methods on the retention of ginger's bioactive components may differ. In this study, four distinct drying techniques—shade drying, vacuum oven drying, freeze drying, and fresh ginger were used to evaluate and compare the quercetin, rutin, and tannic acid content of the ginger.

METHODOLOGY
Sample Collection and Preparation
The sample for this investigation was chosen with care.For each drying technique, the sample was cleaned, weighed, and divided into four equal pieces.

Drying procedures
Four distinct drying procedures were used: shade drying, freeze drying, vacuum oven drying, and a fresh ginger (*Zingiber officinale*) that will serve as control.

Extraction and Analysis of Compounds
Methanol was used as the extracting solvent for the dried and fresh ginger samples. 5g of the weighed samples were refluxed with methanol (100ml) for 15 minutes in a water bath and filtered through Whatman filter paper (No.41). The residue was refluxed three times with 70ml of methanol for 15 minutes and filtered. The solvent was

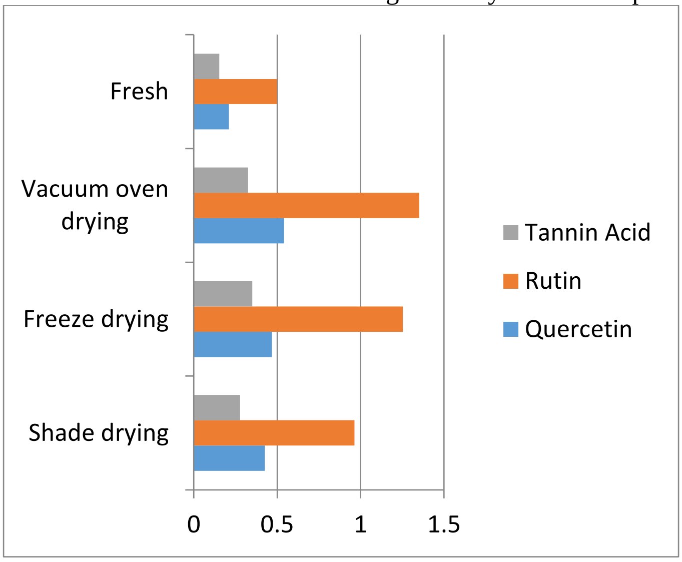
then evaporated using a rotary vacuum evaporator. This procedure was performed for all the samples. The extract was analyzed using High performance liquid chromatography. Statistical Analysis: ANOVA was used to examine the significance of differences between the means of the different drying processes.

RESULTS AND DISCUSSIONS:

The analysis's findings revealed considerable differences in the amounts of quercetin, rutin, and tannic acid among the various drying techniques. In milligrams per gram (mg/g) **of** dried ginger, the mean values and standard deviations for each constituent are shown in Table below.

Drying Method	Quercetin (mg/g)	Rutin (mg/g)	Tannin acid (mg/g)
Shade drying	0.425 ± 0.021 c	0.964 ± 0.045 c	0.278 ± 0.014c
Freeze drying	0.468 ± 0.023 b	1.253 ± 0.057b	0.351 ± 0.018a
Vacuum Oven drying	0.541 ± 0.027 a	1.352 ± 0.062a	0.326 ± 0.016b
Fresh	0.211 ± 0.012 d	0.499 ± 0.023d	0.153 ± 0.009d

The Data represents means of triplicate measurements. The means that are not sharing a common letter in each column for each measurement are significantly different at $p<0.05$



Quercetin content : Freeze drying and vacuum oven drying significantly enhanced the Quercetin content (1.253± 0.057 mg/g and 1.352 ±0.062 mg/g, respectively) as compared to shade drying (0.964± 0.045 mg/g) and fresh sample (0.499± 0.023 mg/g). This implies that both freeze drying and vacuum oven drying are more effective at preserving Quercetin content.
Rutin content : Freeze drying (0.468 ±0.023 mg/g) and vacuum oven drying (0.541± 0.027 mg/g) both exhibited significantly higher Rutin content than shade drying (0.425 ±0.021 mg/g) and fresh sample (0.211± 0.012 mg/g). These findings demonstrate the ability of freeze drying and vacuum oven drying to retain rutin content.
Tannin acid Content: Tannin Acid levels were greater after freeze drying (0.351± 0.018 mg/g) and vacuum oven drying (0.326 ±0.016 mg/g) than after shade drying (0.278 ±0.014 mg/g). Tannin Acid content did not differ

significantly between freeze drying and vacuum oven drying. Tannin Acid concentration was lowest in the Fresh sample (0.153± 0.009 mg/g).

CONCLUSION

This study clearly shows that the drying method used has a substantial impact on the concentration of bioactive compounds in the sample. Freeze drying and vacuum oven drying were discovered to be preferable strategies for conserving and improving the Quercetin, Rutin, and Tannin Acid levels. These discoveries are critical for enterprises producing herbal medicines and plant-based foods, as they can adjust their drying methods to maximize the retention of key bioactive components. Further research should be conducted to investigate the possible influence of these drying processes on other bioactive compounds, as well as to assess the effects on product quality and shelf life.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Adoption of cassava flour processing technologies in Enugu State, Nigeria was studied. Data were obtained from 120 respondents using questionnaire and oral interview schedule. Percentage response and probit model analysis were used to address the objectives of the study. The farmers' educational level and extension services were the socioeconomic determinants to the adoption of improved starch processing technologies in the study area. Enhancing processors' access to educational level and extension services were recommended.
Keywords: *Adoption, Cassava Flour, processing technologies, Enugu State, Nigeria*

INTRODUCTION
Cassava starch is a whitish, powdery material, which is used is used to produce such diverse products as food, paper, textiles, adhesives, beverages, confectionery, pharmaceuticals and building materials (Alinnor, 2002). Starch is derivatives from grain or root crops, however, the latter is more preferred. According to IITA, (2014) cassava starch has intrinsic characteristics, including high paste viscosity, high paste clarity, and high freeze-thaw stability, which are advantageous to many industries.
Starch as asserted by Food Agriculture and Organization, (FAO), (2017) can be produced through the following processing steps: sorting of cassava, peeling and washing of the root, grating, soaking the root for fermentation, milling, drying and storage.
The improved processing technologies were disseminated for onward adoption by the processors courtesy of extension services arm of Agricultural Development programme (ADP) (Ume, Onwujiariri and Nwaneri, 2020). However, information on the rate or extent of adoption of the technologies is not yet known. Therefore, the need to abridge this research gap, especially as it is influenced by the processors' socioeconomics characteristics. Specifically, the objectives of the study were to: describe the socioeconomic characteristics of the farmers and determine the extent of the adoption of the technologies.

MATERIALS AND METHODS
Enugu State lies between latitudes 6°30'N and 7°10'N of Equator and longitudes 6°35' E and 7°30' E of Greenwich Meridian. The state has an estimated population of about 4, 1671 million people (NPC, 2006) and land area of 16,727 square km^2.The inhabitants were mainly agrarians and still engage in non-agricultural activities. A well-structured questionnaire was used to collect data for the study. Multi-stage random sampling technique was used to select one hundred and twenty farmers for the study. Percentage response and probit model analysis were used to address the objectives of the study.

Probit model
It is represented as: $Y_i = B^1 X_1 . Xn + e$ ……………..(1)
$Y_i = 0$ if $Y_i < 0$; $Y_i = 1$ if $Y_i > 0$
Where Y_1 = an underlying latent variable that indexes use of the technology, Y_1 = observable dummy variable that indexes use of the technology (used = 1, not used = 0, b_1 = a vector of estimated parameter,X_1 = individual

characteristics of the respondents, e = error term .The model is specified in an implicit form as follows: Y= F (X_1, X_2, X_3, X_4, X_5, X_6, X_7, X_8 + ei)………..(2)
Where :Y = Adoption rates (%), X_1 = Age in years, X_2 = Educational level in years, X_3 = Household size in persons, X_4 = Years of farming experience in years, X_5 = Extension contact.(Dummy), ei = Error term.

RESULTS AND DISCUSSIONS

Table1: Socioeconomic Characteristics of the Respondents

Variable	Frequency	Percentage
Age		
24 – 40	48	40
Above 40	72	60

Access to Extension services		
Access	30	25
No Access	90	75

Sources: Field survey, 2022

Table 1 shows that 60% of the respondents were above 40 years that dominated adoption of starch processing technologies in the study area. Aged processors not only have the agility to surmount the stress and strains associated with starch processing, but as well efficient in resource use (Ume, *et al*; 2020). Most (83.3%) of the sampled processors had formal education. Educated people are often prudent in resource management and as well not technology adoption friendly (Nweke, *et al* 2001). Most (66.7%) of the respondents had large household sizes ranging from 7 years and above. This connotes availability of cheap labour for processing, especially if the members are of labour age and still living with the household head (Adeoye-Agomoh, Ume, and Chukwu, 2022). Further, 68.3% of the respondents had processing experience of 11-40 years, while the least (31.7%) had an experience of 1 -10 years. Experienced processors could be able to distinguish among technologies for better options to be taking as reported by Ume, *et al* (2020). Besides, 75% of the respondents had no access to extension services, hence delimiting their exposures to extension services such as having technical assists in implementing certain intricate technologies, hence leading to non-adoption no matter how economical feasible and technically efficient the technology could be (FAO, 2017).

*, ** and *** implies significant at 10%, 5% and 1% respectively, Figures in parentheses are the t-ratio
Source; Field Survey, 2021

The result in Table 2 shows that there was an inverse relationship between processors' age and technology adoption. The decrease in the adoptability of individuals with advancement in age could be cited to explain the correlation (IITA, 2014). Also, the positive sign of the coefficient of education with technology adoption, implying that high educational status of the processor could expedites adoption of technologies. This could be because educational attainment enhances individual access to information in order to be more objective in evaluating innovations, which would directly influence his/her processing enterprise (Alinnor, 2002). Additionally, coefficient of extension services was positively related to the rate of adoption and significant at 1% probability level. Extension services aid in educating processors on importance of technology adoption in enhancing their productivity. The finding of Adeoye-Agomoh, *et al.*(2022), agreed with the above statement. They reported on the import of extension agents in giving processors information on input sources in order to ease technologies adoption.

CONCLUSION AND RECOMMENDATION

The farmers' educational level and access to extension services were the socioeconomic determinants to the adoption of improved starch processing technologies in study area. There is need to enhance farmers' level of education through workshops, seminars and adult education. Furthermore, extension agents should be adequately motivated through prompt payment of their salaries and other out of pocket expenses incurred during the discharge of their functions

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study determines the perception of maize farmers' on the benefits of post-harvest management and constraints in Niger State, Nigeria. A multi-stage sampling technique was used to select one hundred and eighty (180) maize farmers in the study area. Structured questionnaire complimented with interview scheduled were used for data collection. Data collected were analysed using frequency, percentage and mean. Finding showed that the mean age of maize farmers was 42years while 80% of maize farmers were males. Also, maize farmers agreed that post-harvest management is good at meeting farmers need in time of food scarcity ($\bar{X}$ =4.16), post-harvest management improved farmers income($\bar{X}$ =4.12) and post-harvest management are not too difficult to finance with mean value of ($\bar{X}$ =4.01). the most constraints associated with post-harvest management were inadequate training (97.2%), shortage of fund (95.0%) and iinadequate credit facilities (91.7%). It is recommended that that credit and fund should be made available by governments and non-governmental organization so that farmers' could purchase post-harvest tools that are needed to enhance the longevity of agricultural produce. Post-harvest materials and tools should be subsidized by government and stakeholders for farmers' to access at affordable price.
***Keywords**: Benefits, Constraints, Maize farmers, Post-harvest management.*

INTRODUCTION
Maize is one of the most widely consumed cereal crop in Nigeria. Maize is grown in almost all the ecological zones of the country, although with different in yield and productivity. Maize is mostly produced by smallholders with inadequate access to incentives that enhance their productivity (Akanbi *et al.*, 2019). Maize is rich in carbohydrate, protein, iron, vitamin B and minerals (Oyelami *et al.* 2018). It is also used as food mostly especially in infants and feeding of farm animals. Maize crop cannot withstand too much of stress and despite been grain in nature, it is highly susceptible to post-harvest losses due to activities of weevil and other insect (Oyelami *et al.* 2018). According to Saran *et al.* (2012), majority of the agricultural produce maize inclusive in developing countries experience lost due to inadequate post-harvest management. The losses often encountered by farmers most times forced them to sell produce at the point of production only to buy back at highly exorbitant prices few months after harvesting. It is expected that post-harvest management practices such as preservation, conservation, quality control/enhancement, processing, packaging, storage, distribution, marketing will reduce the post-harvest losses encounter by maize farmers (Pelemo *et al.*, 2018). The study determine perceived benefits of post-harvest management of maize in Niger State of Nigeria. The specific objectives are to: describe the socio-economic characteristics of respondents in the study area, determine the perceived benefits of post-harvest management of maize and identify the constraints to post-harvest management.

METHODOLOGY
The research was conducted in Niger State of Nigeria. The State can be found in the Guinea Savannah ecological zone of Nigeria. In terms of land mass, it is the largest State in Nigeria. It covers a total land area of 74,224km^2 thus accounting for about eight percent of Nigeria's land area (Niger State Geographical information system, 2015). It is located within longitude 3° 30' and 7° 20' East & latitude 8° 20' and 11° 30' North, with a population of about 3,950,249 (NPC, 2006) and with a growth rate of 3.2%, the State has estimated population of 5,586,000 in 2017 (Niger State Geographical Information System, 2015). The most predominant soil type is the ferruginous tropical soils. The soils are fertile, its hydrology permit the cultivation of most of Nigeria staple crops and still allows sufficient opportunities for grazing, fresh water fishing and forestry development. Some of the crops grown in the area are yam, cotton, Shea-butter, maize, sorghum millet, cowpea, soybean, beans, rice and groundnut.

Some of the tree crops are Mango, citrus, coconut, cashew, banana, pawpaw. The inhabitants of the State also rear some livestock like goats, sheep, cattle and chicken among others. Multi-stage sampling technique was used for this study. The first stage involved random selection of three (3) Agricultural zones in the State. The second stage involved random selection of one (1) Local Government Areas from each from the selected zones making a total number of three (3) LGAs. The third stage involved random selection of four (4) communities each from the selected LGAs making a total of twelve (12) villages. The fourth stage involved the use of proportional sampling to select 10% of the farmers from the sampling frame to give a total of one hundred and eighty (180) respondents. Primary data was used for this study area. Data was collected by the researcher assisted by trained enumerators using structure questionnaire complimented with interview schedules. Objectives of the study were achieved using descriptive statistics such frequency distribution, percentages and mean

RESULTS AND DISCUSSION

Socio-economic Characteristics of Maize Farmers

Results in Table 1 revealed that the mean age of the farmers was 42 years. This indicates that maize farmers were still in theire active and productive age. This finding is in line with Rashid *et al.* (2015) reported that post-harvest practices were mostly dominated by young farmers in Ekiti. Results in Table 1 indicated that majority (80.0%) of maize farmers were males. This finding showed that majority of the farmers in both States were males. Male dominance might be attributed to women involvement in domestic and other farm activities. Results in Table 1 showed 48.3% of maize farmers had no access to extension. This finding indicated that more than half of the farmers did not access extension. Access to extension to some extent is expected to improve skills, knowledge and perception of farmers' on post-harvest management, this is because access to extension grant farmers opportunity to access new innovation that will improve their income and livelihood. This finding agreed with Barnabas *et al.* (2019*)*, who reported that majority of farmers in Kogi State, Nigeria had access to extension services. Results in Table 1 indicated that 63.3% of maize farmers in belong to cooperative. This result showed that more than half of the farmers belong to cooperatives. Entries in Table 1 further indicated that 22.8% of the farmers had access to credit This results showed that majority of maize farmers did not have access to credit. This scenario could negatively affect farmers with low income status who cannot afford to acquire post-harvest materials.

Perception of Farmers on the Benefits of Post-Harvest Management in Maize

The results in Table 2 showed that maize farmers agreed that post-harvest management is good at meeting farmers need in time of food scarcity ($\bar{X}$ =4.16), post-harvest management improved farmers income ($\bar{X}$ =4.12). This finding was in agreement with Anyawun and Mendie (2017), who stated that utilization post-harvest management have ability of increasing income and livelihood of farming populace in rural areas. Also, farmers agreed that post-harvest management are not too difficult to finance with mean value of ($\bar{X}$ =4.01), implying that adoption of post-harvest management do not requirement huge amount of capital. Maize farmers further agreed that post-harvest management improved farmers produce shelf life ($\bar{X}$ =3.86), post-harvest management increase farmers standard ofliving ($\bar{X}$ =3.82), post-harvest management grants farmers more market opportunities with mean value of ($\bar{X}$ =3.82), post-harvest management meet farmers daily food needs ($\bar{X}$ =3.80), post-harvest management are compatible with farmer indigenous food preservation ($\bar{X}$ =3.79) and post-harvest management enhance quality of farmers produce with mean value of ($\bar{X}$ =3.79). However, maize farmers disagreed with the following statements; post-harvest management expose farmers to extension ($\bar{X}$ =2.98), post-harvest management keep farmers produce cool all through the year with mean value of ($\bar{X}$ =2.95), post-harvest management do not increase farmers' standard of living with mean value of($\bar{X}$ =2.82), and post-harvest management give lower returns with mean value of ($\bar{X}$=2.16).

Table 2: Perception farmers' on the benefits of post-harvest management in maize (n=180)

Perception Statements	SA	A	UN	DA	SD	Sum	Mean ($\bar{x}$)	R	D
ost-harvest management is good at meeting farmers need in time of food scarcity	76 (42.2)	80 (44.4)	8 (4.4)	8 (4.4)	8 (4.4)	748	4.16	1st	A

Note: SA= Strongly agreed, A=Agreed, UN=Undecided, DA=Disagreed, SD=Strongly disagreed R=Ranking, D=Decision

Constraints associated with post-harvest management

Table 2 showed that inadequate training (97.2%) was the most constraints associated with post-harvest management in the study area. This implies that farmers did not have access to enough training on post-harvest management in maize. This finding concurs with that of Johnson *et al.* (2016), who stated that inadequate training was the major constraints faced by smallholder farmers in Sub-Saharan Africa. Shortage of fund (95.0%) was ranked 2nd, implying that maize farmers lack access to adequate fund. The finding is in consonance with that of Mohammed *et a*l. (2018) who indicated that shortage of fund and inadequate access to credit were the major constraints affecting soya bean production in Northern Region of Ghana. Inadequate credit facilities (91.7%), signifying low access to credit whether from formal or and non-formal sectors. Other constraints associated with post-harvest manage were high cost of post-harvest materials (85.6%), lack of farmers' participations (81.1%) and transportation challenge (80.0%) ranked 3rd, 4th, 5th and 6th respectively.

Table 2: Constraints associated with post-harvest management (n=180)

Variables	Frequency	Percentage	Ranking
Inadequate trainings on post-harvest	175	97.2	1st
Shortage of funds	171	95.0	2nd
Inadequate credit facilities	165	91.7	3rd
High cost of post-harvest materials	154	85.6	4th
Lack of farmers participations	146	81.1	5th
Transportation challenge	144	80.0	6th
Loss in market value	121	67.2	7th
Insect attacks	120	66.7	8th
Inadequate market information	116	64.4	9th
Disease attack	98	54.4	10th

Sources: Field survey, 2018

CONCLUSION AND RECOMMENDATIONS

Based on this finding it can be concluded that majority of maize farmers were male in their active age. Also, maize farmers agreed that post-harvest management is good at meeting farmers need in time of food scarcity, post-harvest management improved farmers' income and post-harvest management are not too difficult to finance. The most constraints associated with post-harvest management were inadequate training, shortage of funds and high cost of post-harvest materials. It is recommended that credit and fund should be made available by governments and non-governmental organization so that farmers' could purchase post-harvest tools that are needed to enhance the longevity of agricultural produce. Post-harvest materials and tools should be subsidized by government and stakeholders for farmers' to access at affordable price.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was on impact of postharvest management practices on food security among female headed households and intended to describe the socio-economic characteristics, examine the impact of post-harvest management practices on food security, and assess the factors influencing food security among female headed households. The study area was Ivo LGA of Ebonyi state. The study was based on responses from 95 respondents collected with the aid of a well-structured questionnaire. Descriptive statistics such as frequencies, percentages, ranking and, mean scores were used in this study while the inference was made with the aid of Pearson Correlation analysis. Results show that the average age and household size was 32 years and 6 persons respectively, occupation type showed that 42.1% of the respondents are sole farmers while 48.4% of the respondents have secondary school certificate. Outcome of the Pearson Correlation (r) shows that postharvest management practices have a very weak but positive relationship on the food security of female headed households. Ethnic conflicts, income size and number of dependents were ranked respectively as 1st, 2nd and 3rd major factors influencing food security among female headed households. The study concludes that there is no meaningful relationship between postharvest management practice and food security status among female headed households based on the lack of statistical significance. It recommends that efforts should be made by government to instil peace between communities. Also, there is need for government intervention on the female headed households to assist in providing solace to the household. Finally, policies that will be favourable to female headed households such as ease of access to farmland should be implemented.

***Keywords**: Female headed household, Food security, Postharvest management practices.*

INTRODUCTION

There is no doubt that food is one of the basic needs of every human being and this has made it compulsory to boost food production with the development, introduction, and adoption of improved technologies. Agriculture remains central to most African countries economies and its 169 growth has major implications for the region's food security and poverty reduction (Onyeneke *et al.*, 2019). Food value chain systems should take into consideration the need for proper post-harvest management. This can be achieved by early harvesting and storing techniques with controlled on farm drying practices (Osuji *et al.*, 2021). Post-harvest practices have been there for decades ranging from traditional storage systems to modern ones (Adikwu *et al.*, 2023). Post harvest management practices are the methods engaged in the handling of agricultural produces from farm to table (harvesting, transporting, and handling, storing, processing) (Bekele, 2021).

Food security indices have been measured globally using various indicators such as per capita expenditure on food, food insecurity access scale, food consumption score, per capita food consumption (FAO, 2022). Food security is achieved when all four pillars – availability, access, utilization, and stability- are met (FAO, 2022). Availability ensures there is a trustworthy and consistent source of food; access concerns the capability of individuals in having sufficient resources to produce and/or purchase adequate food; utilization deals with people having adequate knowledge and fundamental sanitary conditions to select, prepare and distribute food capable of providing good nutrition; while stability sees to the sustenance of the availability, access and utilization over time (Swiss Agency for Development and Cooperation (SDC, 2017). The target of food security is to make sure the health of individuals and households are secured. According to Elemasho *et al.*, (2022) post-harvest loss is a serious threat to food security and inefficiency in the global food system. Postharvest loss is the degradation in both quality and quantity of a food production from harvest to consumption. Continuous high loss of staple crops has a significant negative impact on food security (Morris *et al.*, 2019). The long-term effect of post-harvest loss is the loss of interest in farming.

Female headed households is one which has the head of the household as a female because of the male head been absent dead or unavailable for about a year or more), with major decisions as well as economic provision of the household resting on the female (Milazzo and Van de Walle, 2022). The rate of female headed households is different in various countries but has increased in developing countries over the half century because of divorce, spouse death, addiction or disability of husband, increased life expectancy among women migration or being abandoned by husband (Horrel and Krishnan, 2007). Food security at female headed household is worse in developing countries (Lutomia *et al.*, 2019). To better understand the challenges and problems of female headed households, there is need for qualitative research that covers all aspects of their lives and shows their living conditions from the perspective of their own experiences and views. Therefore, this study intends to describe the socio-economic characteristics, examine the impact of post-harvest management practices on food security, and factors influencing food security among female headed households.

METHODOLOGY

The study area for this study was Ivo LGA of Ebonyi state. It is geographically situated between latitude 5° 36^1 and 6° 59^1 N and longitude 7° 35^1 and 7° 4^l E. It covers an Area of 3506 Sqkm^2 with population of about 220,919 people (NPC, 2006). The rainfall ranges from 1500-2500mm, temperature ranges from 28-45° and moderate relative humidity of 65%. A Purposive and multistage random sampling technique was employed in selecting respondents for this study. Five (5) villages were randomly selected from two (2) autonomous communities in the study area (=10 villages), ten (10) households headed by females were purposively selected from the selected villages. This will give a sample size of hundred (100) female house heads. Analysis was subject to only ninety-five (95) returned questionnaires by the respondents. Descriptive statistics such as frequencies, percentages, ranking and, mean scores was used in this study while the inference was made with the aid of Pearson Correlation analysis.

RESULTS AND DISCUSSION

Socio-economic characteristics of the respondents.

The socio-economic characteristics discussed in this study includes age, level of education, employment status, and household size.

The results showed that most of the respondents (34.7%) belong to the age bracket of 30-34 years, the respondents within the ages 25-29 years represent 18.9 % of the respondents, 17.9% of the respondents belonged to age group of 20-24 years while 14.7% of the respondents belong to the age group of 35-39 years and 13.7% belonged to age group of 40-44 years. The average age of the respondents was at 32 years. This result implies that most of the respondents are youths and fall within the active age group. This is in line with a study by Omotesho and Muhammad-Lawal (2013) which states that most respondents are early youths who are active and possess the strength to go about their daily economic activities. Also, table 1 revealed that most respondents (52.6%) have a household size of between 7-9 people, while 29.5% of the respondents had household of 4-6 people and 17.9% of the respondents had a household of 1-3 people. The average household size of the respondents is 6 people. This shows that the respondents have a moderate household size. This is in a disagreement with a study by Onweremadu and Asiabaka (2013) which states that most female headed households have a high family size.

The table also shows that 48.4% of the respondents used for this study had secondary school certificate as their highest form of education, the respondents with primary school certificate was represented by 26.3% of the respondents while 16.8% of the respondents had tertiary education certificate and 8.4% of the respondents had no formal education. This implies that the females heading their households in the study area are formally educated. This disagrees with a study by Ugo (2020) that most rural female headed household are headed by females who have no school certificate.

Table 1; Socio-economic characteristics of respondents for this study

Variables	Frequency	Percentage	Mean score
Age (years)			**32 years**
20-24	17	17.9	
25-29	18	18.9	
30-34	33	34.7	
35-39	14	14.7	
40-44	13	13.7	
Household size (persons)			**6 persons**
1-3	17	17.9	
4-6	28	29.5	
7-9	50	52.6	
Occupation type			
Civil/public servant	31	32.6	

Sole farmer	40	42.1
Business owner	24	25.3
Educational qualification		
No formal schooling	8	8.4
Primary school certificate	25	26.3
Secondary school certificate	46	48.4
Tertiary level certificate	16	16.8

Impact of post-harvest management practices on food security among female headed household.

A Pearson correlation coefficient was computed to find the linear relationship between postharvest management practises and food security status among the female headed household in the study area. The correlation coefficient between postharvest management practices and food security status of female headed households was calculated to be 0.054. This value suggests a weak positive correlation between both variables, indicating a minimal linear relationship between them. The result however is against a study by Ogundele (2022) which state that a reduction in food losses through appropriate post-harvest management practices will improve food security.

Table 2; Correlation between food security status and post-harvest management practices

	FSS	*PHMP*
Pearson Correlation	*1*	*.054*
Sig. (2-tailed)		*.606*
N	*95*	*95*
Pearson Correlation	*.054*	*1*
Sig. (2-tailed)	*.606*	
N	*95*	*95*

- *PMHP (Post harvest management practises), FSS (Food security status)*
- *r(93)=.054,p>.05 (positive but very weak relationship/ not significant)*

Factors influencing food security among female headed households.

The results in table 3 showed that 96.8% of the respondents affirm that ethnic conflicts within the area is ranked as the 1st influence of food security among female headed household followed by income size of female head ranked 2nd with 91.6%, number of dependents, farm size and insecurity on the road is ranked as 3rd, 4th, and 5th respectively with 89.5%, 84.2% and 64.2%. Climate change is ranked 6th with 53.7%, access to credit ranked as 7th while poor post-harvest processing and storage is ranked at 8th with 45.2%. The least factor ranked 9th was the level of education at 41.1%. This result agrees with a study by Henri-Ukoha *et al.* (2013) which showed that female headed households are highly vulnerable and income, farm size and so on have implication for food security and are determinants to food security among female headed households.

Table 3; Ranking of factors influencing food security among female headed households.

Influencing factors	**Frequency***	**Percentage (%)**	**Ranking**
Climate change	51	53.7	6th
Ethnic conflicts	92	96.8	1st
Insecurity on the road	61	64.2	5th
Income size	87	91.6	2nd
Access to credit	50	52.6	7th
Level of education	39	41.1	9th
Farm size	80	84.2	4th
Number of dependents	85	89.5	3rd
Poor post-harvest processing and storage techniques	43	45.2	8th

*Multiple responses recorded

CONCLUSION AND RECOMMENDATIONS.

The study concludes that there is no meaningful relationship between postharvest management practice and food security status among female headed households based on the lack of statistical significance. It recommends that efforts should be made by government to instil peace between communities. Also, there is need for government intervention on the female headed households to assist in providing solace to the household. Finally, policies that will be favourable to female headed households such as ease of access to farmland and so on should be implemented.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Analysis was carried out on some selected cassava flour to determine heavy metals content in some cassava flour sold in Igboora, Oyo state. At 3 selected sites and markets, three samples were collected, digested and analyzed. Copper, Nickel, Lead, Manganese, Arsenic, Chromium and Zinc were determined using atomic absorption spectrophotometer (AAS BULK 220). The concentration of lead in the samples from Towobowo, Oja onilado and Oja oba were 0.14 mg/kg, 0.424 mg/kg, and 0.28 mg/kg respectively. Concentration of manganese from three samples varies from 0.013 mg/kg to 0.031 mg/kg. The highest value for chromium from all the samples was 0.001 mg/kg. Zinc gave the highest concentration of 4.55 mg/kg in Oja oba samples. While the concentration of ranges from 0.06 mg/kg to 0.34mg/kg. The highest concentration of Nickel from all samples was 0.361 mg/kg. However, all the samples showed Cadmium and Arsenic content to be below detection limit. Results showed that the heavy metals content copper, nickel, lead, manganese, arsenic, chromium and zinc (except for lead in samples from Oja Oba and Oja Onilado which was slightly higher) in these food samples falls within permissible limits when compared with FAO/WHO recommended values.
Keywords: *Cassava flour, Concentration rates, Atomic absorption spectrophotometer, Heavy metals*

INTRODUCTION
Cassava (Manihot spp) is the most staple food crop in tropical Africa. It has high adaptivity to a variety of ecological conditions which makes it the most important famine reserve crop (Onwueme, 1978). Current trend in cassava production indicated that the production is increasing globally and the growing of cassava is expanding to semi arid areas (WHO, 2001). Cassava can be consumed either raw (i.e. boiled) or in a variety of processed forms known by different names depending on local customs and preferences. Despite the high level of cassava production, Nigeria consumes virtually all that are produced. The household's consumption can be transformed into a number of products both for domestic and industrial uses (Abdullahi, 2003). Cassava can be classified into two broad forms; fermented and unfermented cassava, based on the processing technology. There are four major forms of cassava products; meal, chips, flour and starch (Wheatley, 1993). Cassava flour is gaining fast recognition as a good substitute for wheat flour in the bakery, biscuit and fast food industries (Nweke, 1996).
The quality to be considered in the production of flour for human consumption are nutritional factors, mineral composition, chemical composition, absence of mycotoxins, heavy metals, and residual cyanogens (Asiru, 2004). Cassava flour has major potential as an additive to or substitute for other types of flours in private households and food industry. Although cassava has low nutritional value, yet remains an important stable food in tropical regions of Africa. Cassava can be used in private household to create a range of dishes, including pastries such as cookies, biscuits and rolls, doughnut, cakes, bread, flakes etc. Cassava flour is less expensive than imported wheat flour, enabling household users to occasionally surprise the family with some cookies or a cake at no extra cost (Asiru, 2004). However, cassava flour contains a list of mineral elements in trace amount and are essential to the body but may also contain a number of heavy metals that are absorbed from the soil. Heavy metals are not good for the body; they could be very toxic when consumed in large quantity (Motto, 1990).
Heavy metals, when present even at low concentrations in foods, have the capability to cause human health problems. Information about the dietary intake of such metals is important to assess risks to consumers. Dietary intake could account for some fractions of the toxic metals found in the blood and urine of many Nigerians (Babalola *et al*., 2007)

Food safety is an important aspect of a nation's economic stability and due to previous reports on the degree of pollution of some other food items (Adekunle *et al.*, 2004 and Adekunle *et al.*, 2009).
This study, therefore aimed at assessing some heavy metals concentration in cassava flour sold in three major markets in Igboora, Oyo State South-West Nigeria as a case study.

MATERIALS

Cassava
Metals e.g. Cu, Cd, As, Ni, Pb, Cr and Zn
HNO3
HClO3
Distilled water
Atomic Absorption Spectrophotometer

METHODS

Sample Collection

Cassava flour samples were obtained from three major markets (Towobowo, Oja-Oba and Onilado) in Igboora, Oyo State and grouped into three. Samples were stored in transparent polythene bags and transported to the laboratory for analysis.

Sample preparation

Quartering was carried out on the samples after proper mixing to obtain composite samples. Sub-samples (1 kg, each) were taken at random from the composite sample (15 kg) and were processed for analysis by wet-ashing method. The samples were oven dried at 60 °C for 24 h.

Heavy metals determination

The dried samples were powdered in a mixer grinder without overheating the sample. 0.5 g each of dried samples was digested with HNO_3 and $HClO_4$ in a 5:1 ratio until a transparent solution was obtained. The digests were filtered and diluted to 25 ml with distilled water using analytical reagent grade chemicals. Atomic Absorption Spectrophotometer was used to determine mineral elements (Cu, Cd, As, Ni, Pb, Mn, Cr and Zn) concentration.

RESULTS AND DISCUSSION

The result of the analysis of the levels of the heavy metals and their levels found in the samples of Cassava flour from three markets in Igboora, Oyo State are presented in Table 1. From the results obtained for Ni in this study, the cassava samples from the three major markets (Towobowo, Oja Onilado and Oja Oba) had concentration rates of (0.36 mg/kg, 0.071 mg/kg and 0.052 mg/kg) respectively, while samples from Towobowo gave higher concentrations as shown in Table 1. Ni activates some enzymes function in the body but its toxicity at higher level has its effect in the blood and kidney. All the samples that were analyzed for Zn were below the acceptable limit of 50.0 mg/kg. Zn levels were from 2.75 mg/kg to 4.55 mg/kg. Zn is an essential trace element for humans; it is vital for many biological functions and plays a crucial role in more than 300 enzymes in the human body. Zn is needed for growth and plays a vital role in fertility. In males, Zn protects the prostate gland from infection (prostates) and ultimate enlargement (prostatic hypertrophy). Zn deficiency in the body is worse than its toxicity. Concentration levels of Cu in the samples are (0.26 mg/kg, 0.06 mg/kg and 0.34 mg/kg) Copper is essential in the body for good health. It helps prevent inflammation in arthritis and similar diseases, but in high doses, it can cause anemia, liver disease and kidney damage. The results show that Pb concentrations for cassava flour samples are 0.14 mg/kg, 0.28 mg/kg and 0.424 mg/kg. These samples except for those samples from Towobowo slightly exceeded WHO maximum acceptable limit of 0.2 mg/kg. Therefore, there could be risk of Pb poisoning from cassava flour samples from Onilado and Oja Oba markets, and it is well established that exposure to high levels of Pb may cause kidney damage leading to renal failure (Laura *et al*., 2009 and Colgan, 2003). Such concentration of Pb in cassava flour samples and other trace heavy metals will affect huge populations especially children (Wang *et al*., 2006 and Canfield *et al*., 2003) and all exposed adults (Saraiva *et al*., 2007). Pb is considered a potential carcinogen and is associated with etiology of a number of diseases especially cardiovascular diseases. All the samples analyzed for Cadmium and Arsenic fell detection limit. Cr concentration was detected at 0.001 mg/kg. Cadmium has no known biological functions. It interferes with some essential function of Zn, thereby inhibiting enzyme reactions and nutrient utilization. It catalyzes oxidation reactions, generating free-radical tissue damage (WHO, 1992)

Table 1: Concentration of heavy metals in Cassava flour from 3 different markets in Igboora

Elements	Site A	Site B	Site C
Cu mg/kg	0.26 $\pm$ 0.03	0.06 $\pm$ 0.03	0.34 $\pm$ 0.02
Ni mg/kg	0.36 $\pm$ 0.01	0.071 $\pm$ 0.01	0.052 $\pm$ 0.01
Pb mg/kg	0.14 $\pm$ 0.02	0.28 $\pm$ 0.01	0.424 $\pm$ 0.02
Cd mg/kg	BDL	BDL	BDL
Mn mg/kg	0.031 $\pm$ 0.03	0.021 $\pm$ 0.03	0.013 $\pm$ 0.02
As mg/kg	BDL	BDL	BDL
Cr mg/kg	0.001 $\pm$ 0.01	0.001 $\pm$ 0.01	BDL

Zn mg/kg	2.75 ± 0.02	4.55 ± 0.03	3.84 ± 0.01

Mean ± standard deviation, BDL = Below Detection Limit

Table 2: WHO Permissible limits of selected heavy metals

Elements	Quantity
Cu	10 mg/kg
Ni	0.5 mg/kg
Pb	0.2 mg/kg
Cd	0.05mg/kg
Mn	0.02 mg/kg
As	0.01 mg/kg
Cr	0.05 mg/kg
Zn	50 mg/kg

Trace metal level for metal concentration established by WHO (1982)

CONCLUSION AND RECOMMENDATION

The study revealed the presence of heavy metals in samples from the area of study and indicated slight pollution activities. The concentration of heavy metals in the cassava flour were within the WHO maximum acceptable limit for food except for lead whose values were slightly higher than the permissible limits in samples collected from Oja oba and Onilado markets. The observed findings calls for serious health concern as heavy metals are bio accumulative in human organs and tissues and can result in various diseases and disorders, when not properly controlled.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Vegetables are valuable sources of affordable nutrients, especially in developing countries; processing before consumption (heat treatment or boiling) may have effect on these nutrients. This project determined the effect of heats on minerals composition of Talinum triangulare (water leaf). The research was carried out by treating Talinum triangulare, with heat at temperature of 70^{0}C and 80^{0}C and without heat (ambient) for control. Three samples were air dried and extracted with ethanol. Mineral, phytochemicals, vitamins and antioxidant properties analyzed were carried out with standard procedures. The result showed that as the heat increase the mineral, phytochemicals, vitamins and antioxidant properties decreases. Overall, this study demonstrated that heat has a marked effect on the mineral, phytochemical, vitamin and antioxidant content of Talinium trangulare. It was found that the sample's nutritional value was significantly reduced after being heated to 80 ºC for 5minutes, with large decreases seen in both vitamin and antioxidant content. Thus, this study suggests that caution should be exercised during food preparation to ensure that the sample's nutritive value is maximized.
Keywords: *Mineral, phytochemicals, vitamins, antioxidant heat, Talinum triangulare*

INTRODUCTION
The term vegetable is generally described as the edible plant part which may be regularly or culturally consumed raw or cooked as unsweetened spiced or salted. In African countries, various species of vegetables are widely eaten boiled. Some others (mainly fruit vegetables) are eaten raw. Different types of leafy vegetables have been part of human diets since pre-historic times. These vegetables are typically low in calories, low in fat, high in protein per calories, high in dietary fibre, high in some mineral substances such as K, Ca, Mg, Na while others may be present in trace amounts. They are very high in phytochemicals such as vitamin C, carotenoids, flavonoids and saponin (Ghias and Abdur, 2012).
Waterleaf is characterized as growth tolerant in various soil types, temperature and moisture levels, and grows well under shade. In some places in Nigeria, it is often considered to be a very common plant but only a few people in Sub-Saharan Africa recognize it as a potential vegetable (Schippers, 2000). The Yoruba call it "Gbure" whereas the Igbos call it "Magborodi" in Sierraleone, it is referred to as "Bologi" while in Cameroon it is called "Clok-Sup" (Schippers, 2000).
Talinum triangulare is an important low cost food containing low levels of fat and high levels of vitamin, mineral, fibre and some calories and protein (Oguntona, 2011; Bolaji *et al.*, 2008; Mepha *et al.*, 2007). Waterleaf has the cheapest and most abundant sources of protein (Fasuyi, 2006) and enhances flavor, taste, colour and aesthetic appeal to the diet (Mepha *et al.*, 2007). Consumption of this vegetable ensures the intake of various essential vitamins thus avoiding the problem of malnutrition. However, they contain anti-nutritional which reduce the bioavailability of some nutrients (Akindahunsi and Salawu, 2005).
Effect of heat has been identified as the one factor which has the greatest adverse effect on vegetable (*Talinum triangulare*) High temperature and prolonged heating time associated with conventional heaters often causes heat damage and adversely affect the texture, colour, flavor and nutritive value of waterleaf.
This study aims to investigate on the effects of heat on mineral composition, phytochemicals, vitamins, and anti-oxidant properties of water leaf (*talinum triangulare).*

MATERIALS AND METHODS

Study Area

This study was carried out in the research laboratory of Science Laboratory Technology, Oyo State, college of Agriculture and Technology (OYSCATECH), Igboora.

Sample Preparation

The fresh leaves of harvested water leaf were removed from the main stalk and were sorted to remove the bruised ones. The good shape leaves were thoroughly washed in water and drained using plastic sieves. The drained leaves were divided into three (3) equal portions of 260g each.

Drying of the Sample

The first portion was spread on a stainless stray and air dried at ambient temperature in a well ventilated room. The weight was measure at 24h intervals until a constant weight was reached.

Heat Treatment of the Sample

The second and third portions of the sample were boiled using 1,200mL of water at 70°C and 80°C respectively for 5minutes. This was thereafter spread on a foil paper followed by air drying at ambient temperature.

Determination of Mineral composition, phytochemicals, vitamins and anti-oxidant properties

The three portions of samples (untreated, heat threated (70^{0}C and 80^{0}C)) were used for determination of mineral composition, phytochemicals, vitamins (A, B_1, B_2, B_6, C and E), and anti-oxidant properties using the methods described by Maciej *et al.*, (2007)

The method of Artington (2005) was used to determine sodium and potassium contents of the dried waterleaf samples using flame photometry. The calcium, magnesium and iron contents were determined after wet digestion with a mixture of nitric, sulphuric and hydrochloric acids using Atomic Absorption Spectrophotometer (AAS ZA3000).

Tannin content was determined as described by Mensah, *et al.* (2008) and flavoniods, Phenols, alkaloids, steroids, terpeniods, saponnins contents were also determined with the methods of Oguntona (2001).

The methods described by Maciej*et al.*, (2007) was used for vitamin A, Nethaji *et al.* (2010) for Vitamin B1(Thiamine) and vitamin B_2 (Riboflavin), Ahmad (2012) for Vitamin B_6 (Pyridoxine), Bekele and Geleta, (2015) for Vitamin C and Sami *et al., (*2014) for Vitamin E.

DPPH radical scavenging activity

The scavenging effect on DPPH free radical was measured following the method described by (Shimada *et al.*, 2003) with some modifications. Sample solution (5ml and α-tocopherol methanolic solutions (positive control group) were added to 1ml of 1mm DPPH in methanolic solution. The mixture was shaken and left to stand for 30 minutes at room temperature. The absorbance rates of the resulting solution and the positive control group was measured at 517mm. The lower absorbance (ASN) represents a higher DDPH scavenging activity, which is expressed as (1-test sample absorbance 1 blank sample absorbance) *100%.

Ferrous ion chelating ability

This was carried out according to the method described by Decker and Welch (1990)

Trolox equivalent antioxidant capacity

The ABTS scavenging activity was determined using the trolox equivalent antioxidant capacity (TEAC) method described by Yeh and Yen (2003).

Measurement of No productions in mnc-cms

The measurement was done as described by Yang and Park, (2006).

RESULTS AND DISCUSSION

Table 1: Mineral element concentrations of *Talinum triangulare* ethanol extract

S/N	Mineral elements	Concentrations Room Temperature (Control)	Following Extractions at 70^{0}C	80^{0}C
1	Iron	30.90	30.20	28.60
2	Manganese	0.50	0.04	0.09
3	Zinc	10.60	10.10	9.60
4	Copper	16.40	16.00	16.00
5	Phosphorus	65.50	59.80	59.00
6	Calcium	65.50	59.80	59.00
7	Sodium	260.80	256.10	254.30
8	Lead	0.08	0.08	0.001
9	Potassium	186.50	130.20	126.30

Table 2: Phytochemicals composition of *Talinum triangulare* (Waterleaf) Extract.

S/N	Phytochemicals	Room Temperature (control) (Mg)	Heat treatment at 70^0C (Mg)	Heat treatment at 80^0C (Mg)
1	Tannins	1.14	1.11	1.01
2	Flavonoids	23.5	20.7	18.6
3	Terpenoids	1.60	1.41	1.22
4	Steroids	0.14	0.12	0.12
5	Phenols	30.60	28.10	28.20
6	Alkaloids	29.40	28.70	26.42
7	Saponnis	1.00	0.80	0.17

Table 3: Vitamin composition of *Talinum triangulare* (Waterleaf) Extract.

S/N	Vitamins	Room Temperature (control) (Mg)	Heat treatment at 70^0C (Mg)	Heat treatment at 80^0C (Mg)

ABTS - 1.1 Azino ethyl benzothiazoline sulfonic acid
NO - Nitric acid
FRAP- Ferric ion reducing antioxidant power
OH- Hydroxyl ion

The results of the mineral contents of ethanol extract of *Talinum triangulare* are presented in Table1. It can be observed that heat treatment significantly affected the mineral element content of the *Talinum triangulare* ethanol extract. The mineral elements examined were iron, manganese, zinc, copper, phosphorus, calcium, sodium, lead and potassium.
The mineral elements compositions in the extracts were appreciably high in mineral content with the extract without heat having the highest values. The sodium content in the extract ranged from (260.80mg/L – 254.30mg/L), potassium (186.50mg/L – 126.30mg/L), calcium (65.50 – 59.0mg/L), phosphorus (65.50mg/L – 59.0mg/L), iron (30.90 – 28.60mg/L), copper (16.40 – 16.00mg/L), zinc (10.60mg/L – 9.60mg/L), manganese (0.5 – 0.09mg/L) and lead (0.08mg/L – 0.001mg/L). These ranges were from the extracts with and without heat treatments. This result is in accordance with the findings of Aletor and Adeogun (2004) who reported that mineral element could be made available in considerable amount by destroying the anti-nutritional factors which inhibit the mineral elements product in the food during drying, soaking and cooking processes.

The findings of this research are also in close agreement with many findings such as Asaolu *et al.,* (2012) and Oladele and Aborisade (2009).
The *Talium triangulare* extract was highly rich in the mineral element content, which indicates that the *Talinum triangulare* is a good source of mineral element need for the growth of plant and animals. The extract without heat treatment had the highest value compared to the heat treated extract (70^0C and 80^0C). The heat treatments significantly affected the mineral composition of *Talinum triangulare* and increase in the temperature caused a decrease in the mineral composition.

There were decreases in the concentration of phytochemicals as the temperature of the treatment increases as showed in table 2.

The highest values was observed with the phenols (28.20 - 30.6%) followed by alkaloid (26.42-29.40%), flavonoids (18.60-23.50%), terpenoids (1.22-1.60%), tannins (1.01-1.14%), saponnins (0.17-1.00%) and steroids (0.12-0.14%) being the least.

There was a decrease in the concentration of vitamins as the temperature of the treatment increased for vitamins B_1, B_2, B_6, C and E in the extract, except for vitamin A. VitaminB_1 ranged from (9.61 – 8.26mg/100g), Vitamin B_2 ranged from (2.98 – 1.26mg/100g), vitamin B_6 ranged from (14.57 – 10.01mg/100g), Vitamin C ranged from (29 – 50 – 26.70mg/100g) and Vitamin E ranged from (10.21mg/100g – 8.2mg/100g). The sample without application of heat had the highest value, while the temperature at 80^0C treatment had the lowest concentration of vitamins. The reduction in the vitamin concentration is as a result of sample been exposed to heat treatment. This is agreement with study of Negi and Roy (2000) who also demonstrated a loss of vitamins in green leafy vegetables which is a function of processing method such as temperature. The decrease is attributed to the thermo sensitive, labile and hydro soluble nature of vitamins which easily leached into heating medium.

The Vitamin C is a water soluble vitamin that easily dissolves in water. This simply implies that water can be used to dissolute the water soluble vitamins. The heat applied aided the dissolution of the vitamins due to the ability of temperature as factor affecting rate of chemical reactions.

DPPH activity ranged from (36.00-14.63) ug/ml with the highest value observed in *Talinum triangulare* extracts treated at 80°C. This indicated that scavenging of radicals was reduced at 70°C and 80^0C which is in agreement with the work reported by (Gruptal and Prakash, 2009). Also, the result is similar to the values obtained from (Kuyanya, *et al.*, 2011).

ABTS antioxidant activity obtained for the water leaf of the sample ranged (78.5-130.9) ug/ml with the catchin had most potency than treated sample. The next potent sample is the control sample in the antioxidative potential to scavenging the free radicals. The value for the treated sample was much higher than the one obtained for the effect of the beat on the Talinum. The values are also lower than the values obtained for two varieties of Talinum (Ezckwe, *et al*, 2002) (16.90 mmol TE/100g) and Fontem, (2001) (67.00 mmol TE/100g).

Nitric oxide radical (25.4-50.3) ug/ml indicating that the most potent antioxidant was Catechin Next to the Catechin was control sample and 70°C and 80°C respectively. This values are the pointer that the control sample are potent than the other treated samples in having the ability to scavenge the free radicals produced by Nitric oxide. This implies that the control sample have the bioactive compounds that are responsible for antioxidant product.

The value of FRAP in this study ranged from (47.3-69.1ug/ml). This is also showed that the control sample is having the ability to possess antioxidant properties than the heat treatment samples which are next to the Catechin (Standard antioxidant).

Hydroxyl free redicals ranged from (50.6-100.3ug/ml) shows similar trend exhibited by free radicals. Variation in the antioxidant activities are to be expected due to the heat treatment (Tenny, *et al.*, 2005).

The reduction level of vitamin C also shows that the antioxidant activities of the vegetable decreases as the temperature increases because vitamin C is a strong antioxidant agents (Button, 2004). Vitamin E is an antioxidant that protects body tissue from damage caused by free radicals. The vitamin E is a fat soluble vitamin. The result from this study indicates that as the temperature increase, the vitamin E level in the sample decreases from temperature at 70^0C and 80^0C. There was high level of vitamin E in the sample without heat (control) than the heat treated samples. (Guyton and Hall, 2006).

CONCLUSION AND RECOMMENDATION

The traditional preparation of *Talinium trangulare* involves the application of heat. The effects of preparation using heat on the nutritional composition and antioxidant properties of *Talinium trangulare* studied showed that the application of heat decreased the content of minerals, phytochemicals, vitamins, and antioxidant properties of *Talinium trangulare*. The antioxidant properties of the plant were shown to also decrease significantly at high heat temperatures. This study found that the application of heat to *Talinium trangulare* decreased its nutritional composition and antioxidant properties, suggesting that the traditional preparation method of the plant at high temperature could hinder its overall nutritional quality.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Analysis of profitability of gari processing in Anambra State, Nigeria was studied. Primary data were obtained from 120 respondents using questionnaire and oral interview. Percentages responses and gross margin analysis were used to analyze the data. Gari processing was profitable in the study area with net farm income of N39,300. Also, the major constraints to gari processing were poor access to credit, high labour cost and high cost of cassava roots. The need to enhance the processors' access to credit facility, labour saving devices and availability of cassava roots at subsidized costs were recommended.
Keywords: *Analysis, profitability, Gari processing Anambra State, Nigeria.*

INTRODUCTION
Cassava is the most widely available source of carbohydrates and dietary energy in Africa (Food Agriculture Organization Statistics (FAOTSAT, 2018). Gari, a derivative of cassava as asserted by Ibekwe, Chikezie, Obasi, Eze and Henri- Ukoha, (2012) has features, included creamy-white or yellow (if fortified with red palm oil) granular flour with a slightly fermented flavour and a slightly sour taste made from fermented gelatinized fresh cassava tubers. FAOSAT (2018) reported that gari constitutes more than 75% of cassava derivatives produced in Africa inform of most consumed and trade off. As a result, according to Oladipe (2011) the price of gari is often a reliable indication of the demand and supply of cassava.
The wide acceptability of the cassava derivative in cassava producing area by both rural and urban dwellers according to FAOSAT, (2018) could be ascribed to its relatively long shelf life, ease of preparation for consumption and cheaper than other carbohydrate sources, especially rice and maize. Nevertheless, gari can be consumed with a variety of additives such as sugar, groundnut, fish, meat and stew (Oladipe, 2011).
In the last decades, the prices of gari has been on decline in Nigeria, South East, Nigeria in particular and many processors are opting out of the business, for more lucrative enterprises. The low production and productivity of gari processing can be related to high cost of labour, high transaction cost, poor transportation, irregular and seasonal supply of cassava roots, high cost of energy sources, scanty of cassava processing machines and among others (Ewebiyi,Ikotun and Olayemi, 2020). Therefore, it becomes paramount to determine the factors that affect processors' performance in processing and their productivity in terms of profit accruing from the gari processing in the study area
The specific objectives of the study are to describe the socioeconomic characteristics of the processors, estimate the profitability of gari processing and identify constraints to gari processing in the study area.

MATERIAL AND METHODS
Anambra State lies between latitudes $06^0 45'$and $05^o 42'$ North of Equator and longitudes $7^0 5'$ and $06^0 05'$ East of Greenwich Meridian. It occupies a total land area of 7,340square kilometer with a population of approximately 3,756.104 million people (NPC, 2006).A total of 120 processors were interviewed and used for the study. Structured questionnaire and oral interview were used to collect the data. Percentage responses and Gross margin analysis were used to capture the objectives of the study.

Model Specification

Gross margin (GM) analysis,

It is the difference between the total revenue (TR) and the total variable cost (TVC)

$G.M. = TR - TVC$ ………………………………(1)

NFI = TR – TFC………………………………..(2)
GM = Gross margin (₦), NFI = Net farm income (₦), P1 = Market (unit) price of gari (₦), Q = Quantity of gari (kg), ri = Unit price of the variable input (kg), xi = quantity of the variable input (kg), K = Annual fixed cost (depreciation) (₦), i = 1
2 3 …….. n , j = 1 2 3 …….. m

RESULTS AND DISCUSSION.

Table 1; -Mean Socioeconomic Statistics of Gari Processors in Anambra State, Nigeria.

Variable	Mean	Std Deviation
Age (Year)	36	2.112
Educational Level(Years)	4.6	0.225
Household Size(No)	4.2	0.015
Processing Experience (Years)	10.4	0.007
Membership of Organization(No)	2.4	0.019

Source; Field Survey, 2021

The mean socioeconomic statistics of gari processors in Anambra State, Nigeria is shown in table 1.On the average, a typical gari processor was 36 years This could infer most of the processors of gari are innovative, motivational and adoptive individuals, hence could improve their welfare (Ibekwe; *et al;*2012). Similarly, an average gari processor had educational level of 4.6 years. People with high formal education tends to have more access to information on given technology in order to boost their adoptability of such innovation than those that are less or not educated (Adeoye-Agomoh, Ume and Chukwu; 2022). As well, the average household size of the sampled processors was 4.2 persons. Literatures show that the impact of household size to gari processing depends on the magnitude, age structure and available farm labour among members (Onadipe,2011). Furthermore, an average gari processor had processing experience of 10.4years. Processors with long years of processing experiences have more propensity of setting realistic goal (Ume; *et al;*-2020). Additionally, an average processors belonged to 2.4 organizations such as cooperatives, farmer club, social club etc. Organization such as cooperative enables members to have access to information on improved innovations, credit and material inputs of the technology, in order to boost the adoption of such technology(Ewebiyi,*et al;* 2020)

Table 2 Costs and return of processing 1000kg of cassava roots to gari

Item	Unit	Price/ unit	Quantity	Value
Revenue				
Gari	Kg	140	600	84,000
Total Revenue				84,000
Variable Cost				
Inputs				
Cassava tuber	Kg	30	1000	30,000.
Firewood				4000
Palm oil				300
Sub Total				34,300
Labour for gari processing				5000
Transportation				400
Total Variable Cost				39,700
Fixed Cost				
Depreciation				5,000
Total Fixed Cost				5,000
Total Cost				44,700
Net return				39300

Source; Field Survey, 2022
.
To estimate the net revenue for the production of gari using 1000kg of cassava tubers, net margin analysis was used. The result showed that after processing 1000kg of cassava tubers, 600kg of gari was produced. A kilogram was sold at N140 for 600 kg and this gave an estimated total revenue of N84, 200. The total cost is made of total variable cost and total fixed cost. The total cost of processing 1000kg of cassava roots to produce 600kg of gari was N46, 800. The cost of inputs was N34, 300 which accounted about73.29% of the total cost, .Labour cost was N5000:00, which is equal to 10.68%· of the total cost; transportation .cost was N400 which· is about 0.856.% of the ·total cost while the total fixed cost was about N5000 and about 10.68% of the total cost. The high contribution of cassava input in gari processing could be related to recent economic recession in the country as farmers sell this resource (cassava roots) at exorbitant prices to keep afloat (Samuel, 2017). Net returns per 1000kg of cassava

tubers processed to gari ,defined as the difference between total revenue and total cost· per 1000kg roots was estimated at N39,300 in the survey year.

Table 3Constraints to gari processing

Variable	Frequency	Percentage
Poor access to credit	100	83.33
High labour cost	92	76.67
Scarcity of milling machines,	78	65
High cost of cassava roots	110	91.67
Bad road	54	45

*Multiple Responses
Source; Field Survey, 2022

Most (91.67%) of the respondents reported high cost of cassava roots. The reason for high cost of cassava inputs could be related to different uses of the cassava roots and during the period of the year (Cassava tuber is expensive during dry season; December – March , owning to the fact that cassava roots are difficult to harvest due to hard soil) (Ume, *et al;* 2020). The least (45%), was bad road. This could be associated with many both feeder and major roads connecting urban markets are high deplorable with few vehicles plying there, at very exorbitant prices (FAOSAT, 2018, Adeoye-Agomoh, *et al;* 2022).

CONCLUSION AND RECOMMENDATION

Gari processing is profitable in the study area. The constraints to gari processing were poor access to credit, high labour cost, scarcity of milling machines, high cost of cassava roots and bad road. Based on the results, the following recommendations were made. The need to enhance processors' access to credit facility at reduced interest rate, ensure availability of roots all year round by mechanizing roots harvesting and need to renovate bad roads in the study area for to and fro of gari processing inputs and output to markets in urban areas

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
One of the major problem of agricultural products is the post-harvest losses at various stages resulting to economic and quality deterioration and losses. The study assessed the economic losses of stored paddy rice in Benue State, Nigeria. Data for the study were collected from 246 rice farmers selected from 12 communities and 6 Local Government Areas (LGAs) using multistage sampling technique. The collected data were analyzed using descriptive statistics and multiple regression model. The result showed that on average, rice farmers in the study area lost ₦2090 per 100kg of stored paddy rice. The multiple regression analysis revealed that age level of education (β=0.63), farming experience (β=0.44), annual income (β=0.60), household size (β=0.26), and involvement in off-farm business (β= -0.25) influenced economic losses of stored paddy rice in the study area. The study recommended that the design and implementation of policies and programmes targeted at minimizing storage losses of paddy rice should take into consideration the characteristics of the rice farmers. In addition, Government and Non-governmental organizations should aid farmers through their cooperatives to acquire improved and cost effective drying equipment; and farmers' cooperatives in the study area should come together and build a standard storage facility.
Keywords: *Economic losses, storage, paddy rice, magnitude, determinants*

INTRODUCTION
In spite of the numerous policies and programmes put forward by various administrations in Nigeria over the years to make the country self-sufficient in rice production, postharvest storage losses have continued to erode the gains from such efforts. In a report by Danbaba *et al*. (2019), 10-30% of paddy rice produced in Nigeria does not reach the final consumers due to inefficient postharvest management practices. This has resulted in deficit between the domestic demand for rice and domestic production which as at 2022 was 2.00 million metric tonnes (Ibirogba, 2022) and projected to increase to 4.5million metric tonnes by 2029 (Olowa, 2020).
In order to find a lasting solution to the incidence of post-harvest losses, many empirical researches have surfaced. While these studies have contributed to our understanding of the post-harvest losses menace, information on the economic losses of stored grains especially in rice production is still scanty. Thus, the main objective of this study was to assess the magnitude and determinants of economic losses of stored paddy rice in Benue State, Nigeria. Specifically, the study aimed to: estimate the magnitude of economic losses of stored paddy rice; and identify and analyse the determinants of the economic losses. The null hypothesis tested was that the socioeconomic characteristics of rice farmers do not significantly influence the magnitude of economic losses of stored paddy rice in the study area.

METHODOLOGY
The Study Area
The study was conducted in Benue State, which lies within the lower river Benue trough in the middle belt region of Nigeria. It geographical coordinates are Longitude 7°47′ and 10°0′ East. Latitude 6°25′ and 8°8′ North and occupies a land mass of 34,059 km^2. The State is one of the North Central States in Nigeria with a population of about 6,141,300 (Brinkhoff, 2022). Farmers who engaged in arable crop production like rice, yam, cassava, sweet potato, maize, vegetables, soybeans as well as livestock like poultry, goat, sheep, piggery, cattle and fish abound in the State.

Population of the Study

The population of the study consisted of the 210,839 registered rice farmers in Logo, Kwande, Guma, Makurdi, Agatu, and Apa Local Government Areas of Benue State obtained from Benue State Agricultural and Rural Development (BNARDA) in 2021. These LGAs were chosen because of their vast production of rice.

Sampling Technique and Data Collection

Multi-stage sampling technique was employed to select a sample of 246 rice farmers. The data for the study were collected using structured questionnaire.

Analytical Techniques

The data collected were subjected to descriptive and econometric analyses. Descriptive statistics such as mean, percentage, and frequency table were used to describe the economic losses of stored paddy rice while multiple regression model was used to identify and analyse the determinants of economic losses.

The four functional forms: linear, exponential, semi-log, and double-log were tried. The double-log was selected as the lead equation based on the magnitude of R^2, the *a priori* expectation, and number of significant coefficients of the independent variables.

The four functional forms were specified as follows:

Linear:

$$Y= a_0+b_1X_1+b_2X_2+b_3X_3+b_4X_4+b_5X_5+b_6X_6+b_7X_7+b_8X_8+b_9X_9+b_{10}X_{10}+b_{11}X_{11}+ \varepsilon_i \quad (1)$$

Exponential:

$$\ln Y = a_0+b_1X_1+b_2X_2+b_3X_3+b_4X_4+b_5X_5+b_6X_6+b_7X_7+b_8X_8+b_9X_9+b_{10}X_{10}+ b_{11}X_{11}+\varepsilon_i \quad (2)$$

Semi-log:

$$Y= a_0+b_1X_1+\ln b_2X_2+b_3X_3+\ln b_4X_4+\ln b_5X_5+\ln b_6X_6+b_7X_7+\ln b_8X_8+b_9X_9+\ln b_{10}X_{10}+b_{11}X_{11}+\varepsilon_i \quad (3)$$

Double-log:

$$\ln Y= a_0+b_1X_1+\ln b_2X_2+b_3X_3+\ln b_4X_4+\ln b_5X_5+\ln b_6X_6+b_7X_7+\ln b_8X_8+b_9X_9+\ln b_{10}X_{10}+b_{11}X_{11}+\varepsilon_i \quad (4)$$

Where: Y = Economic losses of stored paddy rice (Naira); a_0 = Constant; b_1-b_{11} = Regression coefficients; $\ln$ = Natural logarithm; X_1 = Sex (male=1, female=0); X_2 = Age (years); X_3 = Marital Status (single=1, married=0); X_4 = Farm size (Ha); X_5 = Level of education (years); X_6 = Household size (number of persons); X_7= Cooperative Membership (member=1, Non-member=0); X_8 = Farming Experience (years); X_9 = Extension Contact (had contact=1, had no contact=0); X_{10} = Annual Income (Naira); X_{11} = Off-farm business (involved =1, not involve = 0); and ε_i= Error term

The *a priori* expectation was that the coefficient of sex, farm size, marital status, household size, and off-farm business involvement would be positive while those of age, level of education, farming experience, membership of cooperative, extension contact, and annual income would be negative.

RESULTS AND DISCUSSION

Economic Losses of Stored Paddy Rice

The distribution of rice farmers by economic losses of stored paddy rice is presented in Table 1.

The result shows that majority (66.7%) of the rice farmers in the study area recorded between ₦2000 and ₦12,000 economic losses per 100kg of stored paddy rice. On average, the rice farmers recorded ₦2090 economic losses per 100kg of stored paddy rice.

Table1: Distribution of rice farmers by economic losses of stored paddy rice (n=246)

Variable	Frequency	Percentage	Mean
Economic losses (₦'000/100kg)			₦2090/100kg
≤1	80	32.5	
2-12	164	66.7	
13-23	1	0.4	
≥24	1	0.4	

Source: Field survey data, 2022

Socio-economic Determinants of Post-Harvest Storage Losses Intensity

The socio-economic determinants of economic losses of stored paddy rice are presented in Table 2. The result in Table 2 shows that 58.95% of the variation in the level of economic losses of stored paddy rice was explained by the independent variable included in the model as shown by the R^2. The F-value (24.15) as shown in Table 2 was significant at 1% level. Thus, the null hypothesis that socio-economic factors do not significantly influence economic losses of stored paddy rice in the study area was rejected.

Source: Field Survey data, 2022. Values in bracket are standard error, ***= sig @ 1%, ** =sig @ 5%, * = sig @ 10%, NS = not significant; †= lead equation.

Analysis of the result in Table 2 shows that the coefficient of level of education, farming experience, and annual income were significant at 1% level positively related to economic losses of stored paddy rice. Farmers who are well-educated and experienced including those with higher annual income are expected to experience minimal post-harvest storage losses as their attributes favour adoption of modern post-harvest technologies that prevent losses of rice along the post-harvest chain. However, farmers with these favourable adoption attributes that their economic losses increase are those without access to the necessary equipment and infrastructures that minimizes post-harvest storage losses. According to Okadonye *et al*. (2021), if farmers are provided with adequate equipment and necessary infrastructures, they tend to experience minimal post-harvest losses.

The coefficient of household size was significant at 10% and positively related to economic losses of stored paddy rice. Farmers with more household members would most likely employ family labour to save cost. However, often time, family labour are less skilled in good storage practices thus resulting in high post-harvest losses. This finding corroborates Babatunde *et al*. (2019) who observed a positive relationship between household size and post-harvest losses among rice farmers in Kwara State, Nigeria.

The coefficient of off-farm business involvement was significant at 10% and negatively related to economic losses of stored paddy rice. This is expected owing to the increase in income that comes with such involvement and thus, enhancing the farmers capacity to adopt technologies that minimizes storage losses. This finding agrees with Mutungi *et al*. (2003) who observed off-farm income as one of the determinants of adoption of improved post-harvest technologies among maize farming households in Tanzania.

CONCLUSION AND RECOMMENDATIONS

On average, rice farmers in the study area recorded ₦2,090 economic losses per 100kg of stored paddy rice. Evidence from the study also shows that the socio-economic characteristics of rice farmers in the study area influence the economic losses of stored paddy rice. The variable off-farm business involvement decreases economic losses stored paddy rice by 0.25%, while educational level, farming experience, annual income, and household size increases it by 0.63%, 0.44%, 0.60%, and 0.26% respectively.

Based on the findings of the study, the following were recommended:

- The design and implementation of policies and programmes targeted at minimizing storage losses of paddy rice should take into consideration the characteristics of the rice farmers especially their educational level, farming experience, annual income, household size, and off-farm activities involvement.

- Government and Non-governmental organizations should aid farmers through their cooperatives to acquire improved drying equipment, from simple tarpaulins and covers, to grain drying equipment and shelters that protect from the rain.
- Farmers' cooperatives in the study area should come together and build a standard storage facility with modern facilities as this will aid famers who lack the means to acquire farm storage technologies and thus enabling them to safely store their grains.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Decision making on the adoption of new technologies towards promoting advancement of development is key to sustainable development. The study assessed cassava processors decision on the adoption of environmental free technologies in Otukpo Local Government Area of Benue State, Nigeria. Multi-stage sampling technique was adopted for the study. Primary data were collected and used for the study. The data were collected through administering questionnaires directly to the respondents. Data for the study were analyzed using both descriptive and inferential statistics. The study found that majority (95.8%) of the cassava processors used mechanical energy for processing cassava, it was further revealed that majority (85.0%) of the cassava processors practiced land filling technology in processing cassava. The logistic regression results on the factors affecting processors decision on adoption of environmental free technologies revealed that the coefficient of gender (-1.242) and processing experience (0.208) were the socioeconomic factors affecting Cassava mash soft dough (akpu/fufu) processors. It was also revealed that age of the processors (0.077), household size (-0.243) and off-farm income (0.000) were the socioeconomic factors affecting garri processors decision on adoption of environmental free technologies, while household size (0.347) and off-farm income (0.000) were the factors affecting starch processors decision on adoption of environmental free technologies. The study therefore recommended that cassava processing facilities should be located very far from residential areas, important streams, rivers or municipal drinking water sources to avoid possible pollution of the environment and water bodies, loans and grants should be made available to cassava processors in order to be invested in other income generating activities since off-farm income of processors is positively related with adoption of innovation. In addition, processors should be educated on the best technology to adopt in the processing of cassava to eliminate environmental pollution.

Keywords: *Environmental Free Technologies, Adoption, Cassava, Processor*

INTRODUCTION
Cassava (*Manihot esculenta* Crantz) is a very important food crop that is capable of providing food security. Cassava roots can be converted through processing into enough food. Machine application for cassava roots processing has helped greatly to add value, leading to profit making and provision of food (Ezike, Sennuga and Afolayan, 2022). However, the growing use of these cassava processing technologies and the clusters of the numerous of small scale cassava processing units is causing environmental and human health concern, including other urban and rural areas of the developing countries (Nnadozie, 2015). For instance, the water discharged from a cassava processing factory is acidic with a high organic matter content (soluble carbohydrates and proteins) and suspended solids (lipids and non-soluble carbohydrates - starch or cellulose fibers) is capable of emanating foul odour and unappealing sight and breeding ground for mosquitoes and houseflies especially if the wastes are untreated before discharging them into stagnant ditches and gutters (Ehiagbonare, *et al*., 2009). Land fill technology is a system of trash and garbage disposal in which the waste is buried between layers of earth to build up low-lying land.

METHODOLOGY

Study Area

The study was carried out in Otukpo Local Government Area of Benue State, Nigeria. It is located in the North-central geopolitical zone of Nigeria and has its headquarters in the town of Otukpo. The study area is bordered by Gwer-West, Gwer-East, Apa, Ohimini, Ado of Benue State, Ankpa and Olamaboro LGAs of Kogi State. The Local Government has a population of 266, 411 people according to the National Population Commission (NPC 2006). The area is mostly inhabited by the Idoma people. Otukpo LGA is regarded as the capital of the Idoma Nation. It has an average temperature of 29^oC and is mostly characterized by grassy and flat topography, and with two distinct seasons, which are the dry, and rainy seasons with the total precipitation estimated at 1550mm of rainfall per annum. The area is widely renowned for its rich agricultural heritage with crops such as yam, maize, cassava, beniseed, soybeans, and millet grown in large quantities. A number of minerals such as kaolin are found in the LGA as well. Other important economic enterprises undertaken by the people include animal rearing, trade, and lumbering (Benue State Agricultural and Rural Development Authority, 2005).

Sample size and Sample Techniques

The study adopted a multi-stage sampling technique. First, a purposive sampling technique was used to select two (2) districts based on their high participation in cassava processing. The second stage involved a simple random selection of two communities from each selected districts. Finally, a proportion of 5% (0.05) was used to get the sample size from the sample frame of all the cassava processors; this gives every member of the population a fair chance of being selected. Thus, a total of 120 respondents were selected.

Data Collection and Data Analysis Techniques

Primary data were collected and used for the study. The data were collected through administering questionnaires directly to the respondents. Data for the study were analyzed using both descriptive and inferential statistics. Descriptive statistics such as frequencies, percentages and mean were used to identify environmental free technologies adopted by cassava processors, while logit regression was used to examine the factors affecting the processors' decision in adopting environmental free technologies.

Model Specification

Logit regression was employed to estimate the factors affecting adoption of improved technology by cassava processors in the study area. The logit function can be defined in its inverse logistic form as:

$$\text{Prob}(Y_i=1)=\text{Ln}\left(\frac{P_i}{1-P_i}\right)= \beta_0+ \beta_1X_{1i}+ \beta_2X_{2i}+ \beta_3X_{3i}+ \beta_4X_{4i}+ \beta_5X_{5i}+ \ldots\ldots \beta_{10}X_{10i} \ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

Where, Y= technology adoption (1 adoption and 0 non adoption)

X_1=gender (male = 1 and female =0)

X_2=level of education of farmers (years)

X_3=age of the farmers (years)

X_4= processing experience (years)

X_5=size of household (number)

X_6=access to credit (1= access and 0=no access)

X_7=membership of cooperative (Yes = 1, No = 2)

X_8=off farm income (Naira)

X_9=extension contact (number of times)

X_{10}=marital status (1=married and 0=single)

β=estimated parameters, including the constant term (β_0).

RESULTS AND DISCUSSION

Technologies Adopted by Cassava Processors

Table 1 revealed the technologies adopted by cassava processor. The result revealed that majority (85.0%) of the cassava processors practiced land filling technology in processing cassava and it ranked 1st. It also revealed that 69.1% of the respondents (ranked 2nd) used open pit in processing cassava. Closely and ranking 3rd is heap method used by 68.3% of the respondents, while 67.5% of the respondents used modern fuel source and are ranked 4th. It is also revealed that 46.7% of the respondents used lagoon in cassava processing and this ranked 5th while few of the respondents (30.0%) wear protective clothing when processing cassava in the study area. The high percentage of the respondent using land filling and open pit methods are due to the fact that the products like chips, flour, garri amongst others are mostly displayed for sun drying during or after processing and the fermentation processes involved.

Table 1: Technologies Adopted by Cassava Processors

Variables	Frequency	Percentage	Rank
Heap	83	68.3	3rd
Open Pit	83	69.1	2nd
Wearing of Protective Clothing	36	30.0	6th

Modern Fuel Source	81	67.5	4th
Lagoon	56	46.7	5th
Land filling	10	85.0	1st

Source: Field Survey, 2022

Factors Affecting Processors Decision on the Adoption of Environmental Free Technologies

Table 2 shows the logistic regression results on the factors affecting processors decision on adoption of environmental free technologies. The result revealed that the coefficient of gender of the processors of the akpu/fufu was negative and significant at 5%. The negative sign could be related to decrease in an attitude of different gender in adoption of environmental free technologies. Furthermore, the coefficient of age of processors of garri and flour were positively significant at 10%. The positive sign of the age is stem from information and skilled acquired from years of observations and experimentations with various cassava-processing technologies aimed at curtailing significantly pollution of the environment. This study agrees with Nnadozie (2015) who posited that regular and long experimentation helps in adopting pollution free technologies.

Also, educational level of the chips processors was positive and significant at 5%. Educational attainment of individual enhances their receptiveness of processing innovation and efficient use of resources to avoid pollution of the environment. This finding is in line with Ume *et al.* (2020). The marital status of chips processors was positive and significant at 10% level of significance. Married couple may through sharing experience adopt a better way of processing cassava that will protect the environment from pollution. This study gives credence to Kolawole (2014) who posited that married respondents adopt more environmental friendly technologies.

Furthermore, the coefficient of household size of garri processors was negative and significant at 5%, this implies that increase in household size reduce adoption of environmental free technology. This may be due to the fact that large family often leads over exploitation of natural resource when the family members try to carter for their different needs. The household size of starch processors was positive and significant at 1%. This indicates that more household size in starch processing encourages adoption of environmental free technologies. This may be due to the fact that few households are involved in starch processing in the study area. This study gives credence to Ani *et al* (2019).

On the coefficient of processing experience, the fufu/akpu and chips processors have positive coefficient that is significant at 1% and 10% respectively. Processing experience enhance the cassava processors' ability of maximizing their outputs at a minimum cost, with high prudence of conserving the ecosystem, from possible environmental pollution as a result of their action. This is in line with the findings of Ume *et al.* (2020) who posited processors' years of experience correlates with efficiency and effectiveness in accomplishment of processing activities with minimal detriment to the environment.

The off-farm income of garri, starch and flour processors were positive and significant at 10%, 1% and 10% respectively. Off-farm income could be used by processors in acquiring material inputs, equipment and hiring labour in adopting environmental free technology thus minimizing toxicity of the ecosystem. This is in line Ume *et al.* (2020); Nnadozie (2015). Therefore, the null hypothesis that states, the socioeconomic characteristics of cassava processors have no influence on their adoption of environmental free technologies is hereby rejected.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Solanum melogena possess nutritive and medicinal values that makes it a valuable addition to diets. This is basically because they contain reserve load of nutrients and phytochemical compositions such as saponin, phenol, flavonoids, tannins, carbohydrates and proteins among others. In this study, phytochemical composition of methanol extract of solanum melogena fruits were analysed quantitatively and qualitatively using standard analytical methods. The results showed the presence of alkaloids, flavonoids, tannin, terpenes, phenol, carbohydrate,protein, cardiac glycosides, coumarine and quinone but emodin and anthocyanin were absent. Quantitative analysis of the fruit were expressed in (mg/100g); total phenol (0.62), tannin (0.587), alkaloids (2.88), falvonoids (0.132) , saponin (6.60). The findings therefore suggest that the fruit is a good source of nutrient and phytochemical components required for medicine and food supplements.

Keywords**:** *Solanum melogena*, phytochemicals. Food supplements, analytical, compounds

INTRODUCTION
Natural products like leaves, stem, fruits and seeds are used traditionally as a source of medicine since time immemorial. More than 80% of the world's population in poor and less developed countries depends on the traditional phyto-constituents based medicines for the fulfillment of their primary health care needs along with some other uses (Rizvi and Mishra, 2013,). *Solanum melongena*, known as eggplant in English, Igba in Yoruba is a fruit that belongs to the nightshade family (Solanaceae) and is widely consumed worldwide. *Solanum meogena* is a good source of dietary fiber, vitamins, and minerals, including potassium, magnesium, and calcium. It is also rich in phytochemicals, such as phenolic compounds, flavonoids, and alkaloids. The fruits of *S. melogena* have a great dietetic value resulting from variable chemical composition. These fruits have low energy value (100 KJ per 100 g). These nutrients or bioactive compounds play important roles in satisfying human needs for energy, body building and other life processes; a deficiency may results in abnormalities (Adam *et al*., 2012). Previous studies have shown that the consumption of eggplant fruits help reduce the risk of chronic diseases such as cancer, cardiovascular disease, and diabetes (Kaplan and Ng, 2017). The presence of phenolic compounds such as flavonoids in the fruits of *S. melogena* makes them a good antioxidant for scavenging free radicals and inhibit lipid peroxidation (Gürbüz *et al*., 2018). There has been an increasing interest in therapeutic potentials of medicinal plants such as antioxidant in reducing free radical-induced tissue injury. Many vegetables, fruits, and other plant species are commercially exploited as antioxidants because of their phytochemical compositions (Koleva *et al*.,2002). Report have shown a lot of work on Phytochemical composition on the fruits of *S. melogena* extracted using methanol. The objective of this work is therefore to determine the phytochemical composition of the fruit of *S. melogena* using methanol to support the established literature facts or determine the deviation.

MATERIALS AND METHODS
Sample collection and preparation
Solanum melogena fruits were obtained from Towobowo market in Igboora. Plant identification and authentication was done at Department of Botany, University of Ibadan, Ibadan. The fruits were washed, sliced and air dried at the chemistry laboratory in the Department of Chemistry for two weeks. The dried fruits were later ground to powder with a grinder and packed into a 200 ml brown bottle and labeled with cello-tape

Preparation of the Methanol extracts

The dried powdered fruits were weighed (200 g) into white musilin cloth. The muslin cloth was tight firmly and then immersed into 500 ml methanol with frequent agitation (Ndukwe *et al*., 2015; Handa *et al*., 2008) for the extraction of phytochemicals present in tested fruits.The set up was left for twenty-four hours after which different chemical test was carried out on the extract.

Phytochemical Screening

The phytochemical analysis of the fruit was conducted according to the methods described by Yadav and Agrawala (2011). Quantitative phytochemical determination were carried out using Mythili *et al.* (2014) method.

RESULTS AND DISCUSSION

Table 1: Qualitative analysis of the phytochemical composition of methanol extract of *Solanum melogena* fruits

S/N	Phytochemicals	Relative Presence
1	Saponins	+ve
2	Tannins	+ve
3	Flavonoids	+ve
4	Steroids	+ve
5	Terpenoids	+ve
6	Coumarins	+ve
7	Emodins	-ve
8	Quinones	+ve
9	Anthocyanins	-ve
10	Alkaloids	+ve
11	Cardiac glycosides	+ve
12	Phenols	+ve
13	Chalcones	+ve
14	Di-terpenes	+ve
15	Proteins	+ve
16	Carbohydrates	+ve

Table 2: Quantitative analysis of the phytochemical composition of methanol extract of *Solanum melogena* fruit

Phytochemical	Concentration (mg/100g)
Total Phenolics	0.628±0.004
Tannins	0.587±0.004
Alkaloids	2.88±0.02
Flavonoids	0.132±0.003
Saponins	6.60±0.04

Table 1 showed the results of the preliminary phytochemical constituents of the methanol extract of the fruit of *Solanum melogena*. The results revealed the presence of phytochemicals (saponin, tannin, flavonoids, steroids terpenoids, coumarin, cardiac glycoside and chalcone) and nutritive nutrients (protein and Carbohydrates). Emodin and Anthocynin was however absent in the preliminary test. This result was in agreements with the work of Ossamulu *et al*. (2014), Agoreyo *et* al. (2012) and Tiwari and Mehta, (2009). The presence of these chemicals support the ethno medicinal uses of this plant.

Table 2 showed the percentage phytochemical composition of *Solanum melogena* fruit (mg/100 g). High saponin (6.6 mg/100 g) and alkaloids (2.88 mg/100 g) content with tannin support the wider uses of the plant for medicinal uses.The present of phenolic content make the plant to be useful as anti clotting agent, immune enhancer and hormone booster (Amakoha *et al*., 2002).

CONCLUSION

The results of the study revealed that methanol extract of *Solanum melogena* fruits contained phytochemicals such as alkaloids, flavonoids, tannins, phenol, terpenes and cardiac glycosides. The presence of these potential bioactive substances make the fruits to be a useful raw materials in the medical sector while its protein and carbohydrate composition make it useful as food supplements for growth of animals and humans.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The β-carotene-rich sweet potatoes (orange-fleshed sweet potatoes [OFSP]) are one of the bio-fortified novel staple crops and excellent source of energy and vitamins that has been contributing to the advancement of nutritional status. Consumption of OFSP is one of the dietary strategies adopted to attack the deficiency of Vitamin A in sub-Sahara Africa. This study investigated the chemical composition and organoleptic properties of breads produced from composite flours of wheat and OFSP. The OFSP tubers were processed into flour, which was used to substitute 25, 50 and 75% of wheat flour in breads. The breads were compared with 100% wheat flour bread (control) for the nutrients composition and sensory properties. The results showed that addition of OFSP flour to wheat flour reduced the protein, carbohydrate and fat contents from 11.92% in the control to 8.75% in the blend containing 75% OFSP flour, 75.54 to 74.40% and 1.74 to 1.22%, respectively, while total ash, fiber and β-carotene contents increased from 0.93 to 2.22%; 0.24 to 4.55% and 0.211 to 7.89 mg/100g, respectively. The texture, taste and colour of all the breads were acceptable to the panellists, with the bread produced from 75% and 25% OFSP having the highest rating after control in texture (4.5), taste (4.7), flavour (4.8) and appearance (4.7) using a 6-point scale with 6 as extremely liked and 1 as extremely disliked. Breads with improved nutrients composition and acceptable sensory qualities can be produced from wheat flour and OFSP flour blends. Thus, wheat and OFSP composite flour is recommended for use in the production of acceptable breads of high nutritional quality.

INTRODUCTION
Bread is made from dough made of flour and water and is typically baked. It is one of the most popular foods throughout the world (Onoja *et al*., 2011). The consumption of bread in Nigeria is on a steady increase because it is a convenient and ready to eat food normally consumed at breakfast, lunch, and sometimes dinner. Despite the outstanding qualities of wheat flour for bread making, wheat flour is low in health-promoting bioactive compounds like vitamins (A, D,E, B_1, B_2 and B_{12}), beta-carotene, polyphenols and flavonoids as well as dietary fibre (Liu, *et al*., 2020).

According to the World Health organization (WHO), a large number of people in sub-Saharan Africa whom starchy foods dominate their food intake and are resource poor to purchase processed food that are fortified with micronutrients (WHO, 2011). Therefore, these individuals suffer from micronutrient malnutrition (hidden hunger) which mostly affects the infants, children, women of reproductive age and the aged; a population generally referred to as vulnerable groups. Many of the vulnerable groups suffer deficiencies of essential micronutrients such as vitamin A, zinc, iodine, and iron (Akombi, *et al*., 2019). Micronutrient malnutrition is a major risk factor for the increased incidence of under-nutrition leading to inhibited cognitive abilities, Vitamin A deficiency, weak immune system, anemia, night blindness in pregnant women and children, retarded growth, impeded reproductive potentials, increase the risk of diseases, and ultimately death (Kamanga and Mndala, 2019). Promoting the consumption of micronutrient-rich food can contribute to the reduction of micronutrient deficiencies with minimal resource investments (Mwanga, *et al*., 2017). Consequently, Low, *et al*. (2017), Shasha, (2011), Ukpabi, *et al*.

(2012), and Nwankwo and Bassey, (2013) opined that one of the most effective ways of liberating at-risk people is through development of selective breeding of sweet potato with high-carotene germplasm.
Orange-fleshed sweet potato (OFSP) is one of the sweet potato varieties being promoted in sub-Saharan Africa as a food-based measure to complement other efforts in reducing the occurrence of Vitamin A Deficiency (VAD) in this region (Kapinga, 2007; Low, *et al*., 2009; Tumwegamire, *et al*., 2004). It is a vital crop that contributes to the advancement of nutritional status and its consumption is one of the dietary strategies adopted to attack the deficiency of Vitamin A in sub-Sahara Africa (Okello, *et al*., 2018). Studies have indicated that consumption of boiled roots improved the vitamin A markers in adults and children (Hotz *et al*., 2012; Low *et al*., 2017). In spite of its nutritional value, OFSP is underutilized in Nigeria compared with other root and tuber crops consumed. OFSP has been found to be a good composite to wheat flour. This study therefore, aimed at assessing the nutrients values and sensory attributes of bread made from composite flours of wheat and OFSP.

MATERIALS AND METHODS

Materials

OFSP roots were obtained from a farm at Vandikyar, in Benue state, Nigeria. Other ingredients such as wheat flour, butter, salt, milk, yeast and sugar for baking were purchased from Lafia modern market in Nasarawa state.

Methods

Preparation of Orange-fleshed sweet potato into flour and formulation of composite flour blends

The OFSP roots were sorted to remove weevil infested ones, washed with clean water, peeled, sliced and soaked for 24 hours, then dried in an oven at 65°C for 8 hours until it becomes brittle. The brittle shredded OFSP was grounded through a corn meal grinder and passed through a mesh sieve. The flour was then packed in plastic container. The ratios of wheat flour and OFSP composite flour blends was 100:0, 75:25, 50:50, 25:75 and 0:100. Other ingredients used in bread production were added.

Preparation of Dough and Baking

The flour dough was prepared according to the method used by Akubundu, (2005). The composite flours dough were prepared and baked according to the method specified by the National Root Crop Research Institute, Umudike, (IITA, 2002; Eddy, 2007). Baking was carried out in food laboratory in College of Agriculture, Sciences and Technology Lafia.

Chemical Composition of flour

Moisture, fat, ash, crude fibre, protein contents of the flour blends were determined using the AOAC (2010) methods and total carbohydrate was calculated by difference while energy was calculated using the Atwater Conversion factors in Kcal. β-carotene was determined spectrophotometrically as described by AOAC (2010) method.

Sensory Evaluation

Bread samples were allowed to cool and organoleptically examined for the attributes by selected semi-trained panellist (N=15) consisting of staff and students of the Department of Nutrition and Dietetics and Home & Rural Economics, College of Agriculture, Sciences and Technology Lafia, Nasarawa state. The bread samples were 3-digit coded and presented to the panelists in white plastic plates. Each sample was rated on perceived intensities of standard sensory attributes (Taste, Colour, Texture, Appearance and General Acceptability) using a 6-point scale with 6 as extremely liked and 1 as extremely disliked. Drinking sachet water was served in glass to the panelists, and they were told to rinse their mouths after tasting each bread sample. Most panelists were between the ages of 18–35 years and were regular consumers of breads.

Statistical analysis

Experiments were conducted in triplicate. The means and standard deviations (SD) were calculated taking all the readings into consideration. Statistical analysis was performed using SPSS (Statistical Package for Social Sciences, version 21.0). One-way ANOVA (Analysis of variance at the level of significance ($p \leq 0.05$) was performed to ascertain the significance of the means.

RESULTS AND DISCUSSION

Proximate composition and β-carotene contents of composite flours

Total carbohydrate, moisture, crude proteins, crude fats and caloric values of wheat and OFSP composite flour were presented in Table 1. The proximate composition of the composites flours were not significantly different ($p \leq 0.05$). The crude protein content of 100% wheat flour was the highest (11.92%), while that of 100% OFSP flour was the lowest (4.90%). Carbohydrate contents of the flour blends were 75.54, 71.10, 74.13, 74.58 and 74.40% respectively, for 100% wheat flour; 75% wheat and 25% OFSP flour; 50% wheat and 50% OFSP flour; 25% wheat and 75% OFSP flour and 100% OFSP flour. The highest carbohydrate contain in 100% wheat flour is as a result of it lowest fiber contain because it's a refined flour. Crude protein content of the composite flours ranged from 11.91% in 100% wheat flour to 8.75% in sample substituted with 75% OFSP flour. The highest value was observed in 100% wheat flour and that is because wheat is a rich source of protein compared to OFSP. The protein content of wheat flour in this study is slightly higher than that of Calderon *et al*. (2022), which reported that protein content in their study had a protein level of 11.6. Crude fat ranged between 1.74% in 100% wheat flour to 1.18% in flour substituted with 75% OFSP flour. Addition of OFSP flour to wheat flour reduced the protein and fat contents of the flour blends, while ash, carbohydrate and β-carotene contents increased by the increase of OFSP flour to the blends. This could be attributed to the reduction in the amount of wheat flour in the composite flour blends. Wheat flour is a rich source of protein and fat compared to OFSP flour, which has the bulk of nutrient as carbohydrate and Crude fiber. The caloric values ranged from 328.18 to 365.46 kcal/100g (table 1). The higher calorie value observed in 100% wheat flour may be because of it higher fat, protein, and carbohydrate and lower fiber contents. The ash (2.44%) contents of 100% OFSP flour sample is slightly higher than those in sample substituted with 75% (1.60%), 50% (1.65%), and 25% (2.22%) wheat flour, respectively. Ash content increases with increasing amount of OFSP flour. The ash content was similar to the one reported by Nurminah, and Nainggolan, (2019). An increase in ash and β-carotene contents with an increase in the amount of OFSP flour in the blends indicates that bread made from OFSP contain minerals and vitamins that are high enough and good for people who want to get more valuable food products, not just eating, but getting more nutritional benefits. The β-carotene contents of the composite flour blends increased with increasing proportion of OFSP flour in the blends, values ranged from 0.211 mg/100g in 100% wheat flour to 7.89 mg/100g in 100% OFSP flour. The β-carotene level in 100% OFSP is lower than that (8.64 mg/100g) reported by Kolawole *et al*. (2021). Vitamin A is a fat-soluble vitamin that is naturally present in many foods as β-carotene. It is important for normal vision, immune system, and reproduction. Deficiency of this nutrient is one of the major challenges facing developing nations. Vitamin A deficiency can lead to night blindness and other acute diseases.

Table 1: Proximate and β-carotene Composition of Wheat-Orange-Fleshed Sweet Potato Composite Flour

Sample	Moisture (%)	Crude Protein (%)	Crude Fat (%)	Total Ash (%)	Crude Fiber (%)	Carbohydrate (%)	Caloric Value (Kcal/100g)	β-carotene (mg /100g)
W_{100}	9.64^a±0.01	11.91^a±0.07	1.74^a±0.02	0.93^a±0.02	0.24^a±0.01	75.54^a±0.05	365.46±0.08	0.211^a±0.03
$W_{75}OFSP_{25}$	10.86^a±0.02	11.90^a±0.20	1.62^a±0.02	1.60^a±0.02	2.90^a±0.006	71.10^a±0.22	346.58±1.85	3.94^a±0.03
$W_{50}OFSP_{50}$	9.10^a±0.46	10.20^a±0.08	1.52^a±0.02	1.65^a±0.03	3.40^a±0.07	74.13^a±0.53	351.00±1.68	5.27^a±0.03
$W_{25}OFSP_{75}$	8.72^a±0.02	8.75^a±0.02	1.18^a±0.02	2.22^a±0.02	4.55^a±0.02	74.58^a±0.03	343.94±1.78	6.58^a±0.36
$OFSP_{100}$	9.92^a±0.02	4.90^a±0.12	1.22^a±0.01	2.44^a±0.02	7.17^a±0.01	74.40^a±0.10	328.18±0.96	7.89^a±0.02

Values are means ± standard deviations of 3 replicates. Means with same the superscripts in the same column are not significantly (p>0.05) different. OFSP = Orange-Fleshed Sweet Potato; W = wheat.

Sensory properties of Breads

The sensory attributes scored were texture, taste, flavour, appearance and general acceptability and the result of the mean scores is presented in Table 2. The result obtained showed that 100% wheat bread (control) had the highest mean scores of 5.2, 4.8, 5.3, 5.3 and 5.2 in texture, taste, flavour, appearance and general acceptability respectively; followed by bread produced from wheat substituted with 75% OFSP wheat flour with the mean scores 4.5, 4.7, 4.8, 4.7, and 4.6, respectively in texture, taste, flavour, appearance and general acceptability, while bread produced from 100% OFSP flour had the lowest mean scores in texture, taste, flavour, appearance and general acceptability (3.9, 4.3, 4.6, 4.2 and 4.2, respectively). There was decrease in the mean scores as OFSP flours were added however the decrease was not significant (P>0.05). The study revealed that the more OFSP flour is added, the lower the sensory values. The higher rating for the control sample may be due to the fact that the panelists are familiar with wheat bread, while the low ratings for other breads produced from composite flours substituted at various ratios and 100% OFSP flour may be due to the panelists not being familiar with the breads. In general, all the bread samples compared well with the control sample, and were well accepted. Consequently, the study has shown that OFSP flour could be used with wheat as composite flours to produce acceptable bread.

Table 2: Mean Sensory Scores of breads produced from Wheat and OFSP Composite Flour

Samples	Texture	Taste	Flavour	Appearance	General acceptability
A	5.2^a	4.8^a	5.3^a	5.3^a	5.2^a
B	4.5^a	4.7^a	4.8^a	4.7^a	4.6^a
C	4.3^a	4.7^a	4.7^a	4.4^a	4.7^a
D	4.1^a	4.4^a	4.6^a	4.4^a	4.3^a
E	3.9^a	4.3^a	4.6^a	4.2^a	4.2^a

Values within a column with the same superscripts are not significantly>0.05 different. A=Bread produced from 100% Wheat flour, B=Bread produced from 75% Wheat and 25% OFSP flour, C=Bread produced from 50% Wheat and 50% OFSP flour, D=Bread produced from 25% Wheat and 75% OFSP flour, E=Bread produced from 100% OFSP flour.

CONCLUSIONS AND RECOMMENDATION

Orange-Fleshed Sweet Potato, β-carotene staple crop, can be used as a substitute and or alternatives to wheat flour for the preparation of a number of food products such as breads, cakes, biscuits and other bake products. It is generally used in foods to improve the sensory properties and enhance the nutritional values as well as reducing the over relying on high cost wheat for baking and confectionaries. The use of OFSP flour, however, is recommended to produce acceptable breads of good sensory and nutritional quality.

ACKNOWLEDGEMENT

The authors are gratitude to Mal. Muhammad Nura Yakubu and Fortune Oil Mills Limited, Quality Control Laboratory Kano who carried out the nutritional analysis of the samples. The authors are grateful to all the respondents who participated in the study. Efforts of Hajiya Halima Y. Shittu, Nasarawa State Nutrition Officer and Mrs. Clementina Okoro of Federal Capital Territory Primary Health Care Board, Nigeria is also acknowledged for sourcing the OFSP tubers used in the research.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The cassava value chain presents a critical avenue for economic growth, and analyzing its profitability offers insights into optimization opportunities, with particular emphasis on exploring the feasibility of youth involvement to ensure long-term sustainability and innovation. This study analysed the profitability of cassava value chain among Agro-processing Productivity Enhancement and Livelihood Improvement Supports (APPEALS) beneficiaries in Kogi State, Nigeria. Primary data obtained through questionnaire administration to 210 APPEALS beneficiaries were analysed using descriptive statistics and gross margin analysis. Findings from the study showed that 80% of the farmers were males and 20% were females; 75% and 78% of the female respondents were processors and marketers, respectively. Gross margin of ₦241, 937.70 and net margin of ₦237,986.85 were obtained, among cassava farming beneficiaries. The return on investment among the farmers was 4.50. The cassava processors recorded a positive gross margin with a mark-up of about 28% and 98% among the garri and fufu processors, respectively. The marketers recorded a gross margin of ₦109, 598.65, a net return of ₦ 105,708.10, and an RoI of 1.27. In conclusion, the profitability analysis showcased the viability of cassava value chain for beneficiaries through substantial gross and net margins, along with a strong return on investment (ROI). The study's findings underscore the economic viability of the cassava value chain, providing a compelling rationale for youth engagement.
Keywords: *APPEALS, beneficiaries, cassava, value chain, profitability, youth.*

INTRODUCTION
A value chain is the set of activities that producers engaged to produce agricultural commodities (De Marchi *et al.*, 2018). Along the chain, value is added which give such product a competitive advantage in terms of quality and attracting a higher price at the market (Gereffi, 2018). Value chain encompasses series of activities or processes that aims at creating and adding value to an article (product) within it, analyzing the opportunity cost of the new sequence along the product worth (Lee *et al*., 2018). According to Mbanjo *et al* (2020), more than 291 million tons of cassava were produced worldwide in 2017, of which Africa accounted for over 60%. In 2017, Nigeria produced 59 million tons making it the world's largest producer (approximately 20% of global production) with a 37% increase in the last decade. Nigeria exports about 3.2 million tons annually and earned a record $136 million in 2013. The crop can serve as; food, flour, animal feed, alcohol, starches for sizing paper and textiles, sweeteners, prepared foods and bio-degradable products. These products are derived from several forms, ranging from fresh leaves and roots to modified cassava starch (Agricultural Research Council, ARC 2019).
Agro-Processing Productivity Enhancement and Livelihood Improvement Supports (APPEALS) is a Federal Government of Nigeria FGN-World Bank Assisted project. The aim of this intervention is to enhance the productivity of small and medium scale farmers and improve value addition along priority value chains (Rice, Wheat, Cassava, Cocoa, Cashew, Aquaculture, Poultry, Maize, Dairy, Ginger, and Tomato) in the participating States of Kogi, Cross River, Kaduna, Kano, and Lagos States. According to the Federal Ministry of Agriculture and Rural Development (FMARD), the project has five (5) components, including production and productivity enhancement; primary processing, value addition, post-harvest management and women and youth empowerment;

infrastructure support to agribusiness clusters; technical assistance, knowledge management and communication; project management and coordination.

The Kogi State APPEALS is aimed at boosting agricultural productivity, value addition, and livelihoods in Kogi State, Nigeria. This project focuses on empowering smallholder farmers and agribusinesses by providing targeted support, including improved agricultural techniques, access to modern technologies, and enhanced market linkages. APPEALS in Kogi State emphasizes key agricultural value chains such as rice, cassava, and cashew, aiming to enhance their competitiveness and sustainability. The cassava value chain plays a significant role in driving agricultural transformation and rural development. This initiative focuses on enhancing various aspects of the cassava value chain to improve productivity, increase income for smallholder farmers, and promote agribusiness growth. APPEALS project employs a multi-faceted approach that includes improved farming techniques, assess to quality inputs, value addition and processing, market linkages, entrepreneurship and agribusiness development, and capacity building.

The present study with focus on profitability analysis along the cassava value chain with prospects for youth involvement is crucial to address several pertinent challenges. Firstly, understanding the economic viability of each link in the cassava value chain is essential to identify potential bottlenecks and areas for optimization. This analysis can provide valuable insights into where value addition and efficiency improvements are most needed. From this foundation, understanding the potential for youth engagement becomes pivotal, as it will be driven by the economic viability uncovered in the analysis. Linking profitability outcomes with youth prospects ensures a strategic alignment between economic viability and youth inclusion. By substantiating youth involvement opportunities with profitability data, the study can guide targeted policies and interventions that not only optimize economic gains but also channel the energies of the youth towards sustainable agricultural entrepreneurship, thereby fostering both economic growth and meaningful youth engagement within the cassava sector.

METHODOLOGY

The area of study is Kogi State, Nigeria. The State is located between latitudes 7°30’N and 7.500^{0}N longitudes 6^{0}42’E and 6.700^{0}E with an area of 29,833km2 and a population of 4,473,490 in 2016 estimated from 2006 census (NPC 2016). The study adopted quantitative research approach. As provided by the Agro-processing Productivity Enhancement and Livelihood Improvement Support, (APPEALS), Kogi State has ten (10) cassava clusters with a total of four hundred and fifty-nine (459) beneficiaries. The respondents were drawn using a multistage random sampling technique to obtain a total sample size of 210 respondents (70 farmers, 70 processors, and 70 marketers). The primary data obtained through questionnaire administration were analysed using descriptive statistics and the Gross Margin Analysis.

The Gross Margin analysis used in this study is as follows:

$GM = TR – TVC$ Profit = $TR – TC$…… eqn1

Where:

TR = Total Revenue, TVC = Total Variable Cost, TC = Total Cost, GM = Gross margin,

$NI = GM – TFC$ ………………eqn2

Where:

NI = Farm Net income (N/ha), TFC = Total fixed cost (N/ha).

The fixed cost includes depreciation of fixed assets computed using the straight-line method of depreciation (3 years).

RESULTS AND DISCUSSION

Socioeconomic Characteristics of Actors along the Cassava Value Chain

Table 1 presents selected socioeconomic characteristics of APPEALS beneficiaries along the cassava value chain. Males are more actively involved in cassava farming which could be associated with the nature of activities expected to be performed in production/farming activities. The mean age (32, 30, 33 years) across these value chain actors could be regarded as active and productive age. In Nigeria’s age categorization, the actors are basically youth in their productive age. This age category is necessary for high productivity in the cassava value chain. The marital status distribution of the respondents as shown in Table 1 indicates that more married actors are found across the cassava value chain. The result is expected because married people are societally assumed to be more responsibly and ready to provide daily meals for their households. Hence, their involvement in income generating activities such as cassava production, processing, and marketing. The finding on education is expected to positively influence beneficiaries’ adoption of innovation for improved productivity. The mean production, processing and marketing experience in this study shows that farmers, processors, and marketers had considerable years of experience which is an advantage towards production and adoption of technologies in the cassava value chain. Membership of an association is expected to enhance information dissemination and efficient production, processing, and marketing of cassava. The findings of this study on socioeconomic characteristics agree with previous empirical studies; see for example: Ekwe *et al*. (2017), Sirela (2018) and Osuji *et al*. (2017).

Table 1: Socioeconomic Characteristics of Actors in the Cassava Value Chain

Profitability among Enterprise within the Cassava Value Chain

The gross margin and profitability analysis of cassava farming enterprise is presented in Table 2. The result showed a gross margin of ₦241, 937.70 while net margin was ₦237,986.85, providing evidence of profitability of cassava farming among the beneficiaries. The return on investment was 4.50 indicating that for every ₦1 invested, ₦4.50k is earned. This result agrees with the findings of Njukwe *et al.* (2014); Olukunle (2013); Emerole *et al* (2014); and Odemero (2015) who found that for every ₦1 invested in cassava production, more than ₦1 is returned as an added value to initial money invested.

The Gross margin of garri per basket of tuber and fufu/flour are presented in Table 3. The analysis was carried out based on weekly production activities of the processors (using one basket of tubers). This approach was adopted because processing and sales among small scale processors were done on weekly basis. Table 3 shows a generally low gross margin and profit for *garri* enterprise and the *fufu* or flour processing industry. *Fufu* had both a higher profit and mark-up, and a better monetary prospect as compared to the *garri*. Narsey (2013) has stated that items with low turnover rates (field observation shows that garri had a higher demand rate and turnover) have higher carrying costs and require higher mark ups for a reasonable profit to be made. Items with higher turnover have lower mark ups. This may have accounted for the higher mark up in *fufu* sales as observed among APPEALS beneficiaries.

The average costs and return analysis in the cassava marketing enterprise is presented in Table 4. The gross margin was ₦109, 598.65 while the net return was about ₦ 105,708.10. The implication is that the cassava marketing is a profitable venture among the APPEALS beneficiaries. This result was further corroborated by the return on investment (RoI).

Table 2: Average costs and return among cassava farmers

Variables	Unit	Price	Quantity	Value (₦)
Total Revenue	Tonnes	450,000.50	0.68	306,000.34
Variable Costs

CONCLUSION AND RECOMMENDATIONS

The profitability analysis demonstrated substantial gross and net margins, underscoring the viability of cassava farming for beneficiaries, as evidenced by a robust return on investment (ROI) of 4.50. Moreover, cassava processing indicated favorable outcomes, with significant positive gross margins and mark-ups observed, while cassava marketing emerged as a profitable endeavour among APPEALS beneficiaries, yielding substantial gross margins, net returns, and an ROI of 1.27. The demonstrated profitability, coupled with the potential for innovation and sustainable entrepreneurship, presents a compelling case for involving youth in the cassava sector. This engagement not only ensures the sector's long-term vibrancy but also contributes to addressing youth unemployment and fostering inclusive agricultural development. Based on findings from this study, the following recommendations are made:

1. Building upon the observed gender distribution and roles, APPEALS, Kogi State government and other relevant stakeholders should establish tailored training programs that equip both male and female youth with the necessary skills for different stages of the cassava value chain. By providing comprehensive training in farming, processing, and marketing, youth can contribute effectively to various segments, fostering inclusivity and ensuring a skilled workforce.
2. Capitalizing on the profitability demonstrated by cassava farming, processing, and marketing. The government should develop youth-focused entrepreneurship support programmes that offer accessible funding, mentorship, and guidance for starting and sustaining ventures along the value chain. Encourage youth to leverage the positive gross margins and mark-ups identified, nurturing a new generation of agripreneurs.
3. Given the substantial role of technology in the cassava value chain's profitability, APPEALS and State government should establish youth-oriented technology hubs. These hubs should provide resources for youth to learn, adopt, and innovate with modern technologies in farming, processing, and marketing. Such an approach taps into the tech-savvy nature of youth, aligning their interests with the sector's growth and sustainability.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study analyzed determinants of value addition among rice processors in Benue state, Nigeria. A multistage sampling technique was used to sample 252 rice processors in six local government areas of Benue State namely: Agatu, Gwer-East, Makurdi, Otukpo, Kwande and Gboko based in the intensity of rice processing activities. A structured questionnaire was used for data collection. Descriptive statistics was used to analyze objective one and double log regression analysis was used to achieve objective two. The result shows that the major challenges confronting rice processors in the study area low quality of paddy rice, high transportation cost, and limited access to post-harvest and market facilities. Other challenges that also ranked are high capital requirement, lack of improved storage facilities, lack of improved rice threshing machines, limited access to working capital, and insufficient modern mechanical drying facilities. The result of the regression analysis shows that majority of the independent variables have positive elasticities as expected which implies that these variables have positive influence on value addition among rice processors in the study area. The coefficients of level of education, income, access credit, access market, processing experience and price of rice product are positive and statistically significant at 5 % level of probability indicating that 5 % increase level of education, income, access credit, access market, processing experience and price of rice product will increase rice value addition by 1.27 %, 4.37 %, 6.36 %, 4.04 %, 4.00 % and 9.35 % respectively. The coefficients for household size and processing cost are negative and statistically significant at 5 % level of probability. This implies that a 5 % increase household size and processing cost would lead to 1.96 % and 4.23 % decrease in rice value addition when other variables are constant. Therefore, policy measures aimed at increasing the level of education, income, access credit, access market and processing experience of rice processors are recommended to burst rice value addition in the study area.

Keywords: *Determinants, Value addition, Rice, Processors*

INTRODUCTION
Rice is the most economically important food crop in many developing countries and has also become a major crop in many developed countries where its consumption has increased considerably (Ajala & Gana, 2015). Over the past few decades, rice has become of the leading food staples in Nigeria, surpassing cassava in food expenditure. Rice consumption is estimated to be rising at 5.1% annually and is expected to reach 36 million metric tons (MT) by 2050 (Federal Ministry of Agriculture and Rural Development (FMARD), 2011. The demand for rice in Nigeria is estimated to be 5 million metric tons (MT) yearly (Johnson & Masias, 2017). It has been reported that rice consumption has increased fast than production, resulting in a growing dependency on import (International Food Policy Research Institute, IFPRI, 2016). The demand for rice has grown significantly over the last 40 years is attributable changing consumer dietary patterns and population growth. Nigeria spends about N356 billion annually for about 2 million MT of milled rice (FMARD, 2011). It has become necessary to meet the demand of the world's current population growth rate through value addition. Value addition in the processing and marketing of rice including all the activities, processes or strategies and distribution of rice which in one way or the other contribute to benefit/utility maximization (Ugwu, Mgbakor, & Chitor 2014).
The benefits of value addition are many. Some scholars for example: Jessie, Kumar, Chaitanya & Reddy (2022); Suneetha, Kumar, Rao & Prasad (2020) stated that creation of employment opportunities, increasing business's profit and profit margin, mitigation of imbalance of trade, improvement in the host country's gross domestic product (GDP) are benefits derivable from value addition in paddy rice. In spite of the perceived benefits of rice

value addition to the Nigerian economy and Benue State in particular being the "Food Basket of the Nation", there are no sufficient empirical evidence to show that actors in the rice value chain have been studied. This situation calls for concern. It has become necessary to study the determinants of value addition of a major staple grown, eaten and traded in different parts of Benue State. It is therefore imperative to undertake a study of this nature because of the significance of rice in the socioeconomic lives of Benue people.

METHODOLOGY

This study was conducted in Benue State of Nigeria. The state was chosen based on the intensity of rice production in the region. A multistage sampling procedure was employed in selecting the respondents for the study. The first stage involved the purposive selection of six local government areas (LGAs) namely: Agatu, Gwer-East, Makurdi, Otukpo, Kwande and Gboko LGAs based on the intensity of rice value addition activities as captured by Benue Value Chain Development Programme (VCDP) office (BN/FGN/IFAD-VCDP, 2021). In the second stage, to ensure even distribution of the sample for the study, a judgmental sampling method was used to select twelve (12) milling communities in the selected six LGAs namely: Agatu and Obagaji in Agatu LGA; Aliade and Taraku in Gwer East LGA; Wadata and Wururkum in Makurdi LGA; Otukpo and Mile 4 in Otukpo LGA; Adikpo and Jato Aka in Kwande LGA; and Gboko-west and Tse-Kucha in Gboko LGA based on the predominance of the rice value chain actors. In the third stage, two hundred and fifty two (252) rice processors were selected from the list of rice processors registered with Benue Value Chain Development Programme (VCDP) BN/FGN/IFAD-VCDP, 2021) for the analysis of value addition among rice processors.

Data were collected with aid of a structured questionnaire. Descriptive statistics was used to realize objective one and multiple regression model was used to achieve objective two. Following Nyor & Mbanasor (2018), regression model was adopted for the analysis and specified as follows:

$$\ln Y_i = b_0 + b_1 \ln X_1 + b_2 \ln X_2 + b_3 \ln X_3 + b_4 \ln X_4 + b_5 \ln X_5 + b_6 \ln X_6 + b_7 \ln X_7 + b_8 \ln X_8 + b_9 \ln X_9 + b_{10} \ln X_{10} + b_{11} \ln X_{11} + + e_i \quad (1)$$

Where: Y_i = value addition proxies by quantity of rice processed (Kg), X_1 = age (Years), X_2 =Sex (Male=1, otherwise =0) , X_3 = level of education(years), X_4 = Household size (number), X_5 = Income (₦), X_6 = access to credit (1 = yes, 0 = otherwise), X_7 = access to market(1 = yes, 0 = otherwise), X_8 = processing experience (years), X_9 = Processing cost (₦), X_{10} = price of rice product (₦), ln = natural logarithm, b_0 = intercept on dependent variable, $b_1 – b_{10}$ = parameters to be estimated, and e_i = error terms.

Equation (1) predicted that value addition will be positively affected by level of education, income, access to credit, access to market, processing experience and price of rice product and will be negatively affected by age, household size and processing cost. The model linearized so as to standardize the variables.

RESULTS AND DISCUSSION

The result in Table 1 shows the challenges to rice processing among processors in the study area. The result indicated that the most serious challenge to rice processing in the study area is low quality of paddy rice followed by high transportation cost, and limited access to post-harvest and market facilities. Other challenges that also ranked are high capital requirement, lack of improved storage facilities, lack of improved rice threshing machines, limited access to working capital, and insufficient modern mechanical drying facilities.

Table 1: Challenges faced by ice processors in the study area (n=252)

Challenges	Mean score	Rank
Low quality of rice	3.90	1st
High transportation cost	3.80	2nd
Lack access to post-harvest and market facilities	3.80	2nd
High capital requirement	3.79	4th
Lack of improved storage facilities	3.58	5th
Lack of improved rice threshing machines	3.51	6th
Limited access to working capital	3.50	7th
Insufficient modern mechanical drying facilities	3.49	8th
Insufficient modern milling facilities	3.40	9th
High cost of electricity and diesel	3.39	10th
Insufficient modern weighing facilities	3.30	11th
Lack of appropriate market facilities	3.29	12th
Insufficient modern storage facilities	3.10	13th
Lack of improved rice huller or polisher	2.99	14th
Limited credit	2.89	15th

Source: Computed from field survey data (2023)

Challenges with mean score ≥3.0 (median of the 5-point likert scale) are considered serious.
The result suggests that for a rice processor to achieve good quality output in processing rice the quality of paddy rice should be a matter of priority. In conformity, Okunola, Adekanye, Adewumi, & Ashamu (2019) who identified contamination of rice with stones and other impurities as one of the major constraints to rice processing operations in Ekiti State, Nigeria. The result of the ordinary least squares (OLS) estimates of determinants of value addition among rice processors is presented in Table 2. The double log regression model was accepted as lead equation based on its high value of R^2 adjusted, least standard error and more compliance with the a priori expectations. Majority of the variables have positive elasticities as expected which implies that these variables have positive influence on value addition among rice processors in the study area.

Source: Computed from field survey data (2023)
***Significance at p≤0.01; **Significance at p≤0.05; *Significance at p≤0.10. Figures in parentheses are t-test statistics.

Dependent variable: Value addition proxies as quantity of rice processed in Kg.
The coefficients of level of education, income, access credit, access market, processing experience and price of rice product are positive and statistically significant at 5 % level of probability indicating that 5 % increase level of education, income, access credit, access market, processing experience and price of rice product will increase rice value addition by 1.27 %, 4.37 %, 6.36 %, 4.04 %, 4.00 % and 9.35 % respectively. The coefficients for household size and processing cost are negative and statistically significant at 5 % level of probability. This implies that a 5 % increase household size and processing cost would lead to 1.96 % and 4.23 % decrease in rice value addition when other variables are constant. The inverse relationship between rice value addition and cost of processing rice goes to explain the impact of escalating cost of inputs on investment.

CONCLUSION

The study analysed the determinants of value addition among rice processors in Benue state, Nigeria. The result shows that the major challenges confronting value addition among rice processors in the study area are low quality of paddy rice, high transportation cost, and limited access to post-harvest and market facilities. Other challenges that also ranked are high transportation cost, high capital requirement, lack of improved storage facilities, lack of improved rice threshing machines, limited access to working capital, and insufficient modern mechanical drying facilities. The result also shows that majority of the independent variables have positive elasticities as expected which implies that these variables have positive influence on value addition among rice processors in the study area. The coefficients of level of education, income, access credit, access market, processing experience and price of rice product are positive and statistically significant at 5 % significant level. The policy implication is that efforts aimed at enhancing level of education, income, access credit, access market, processing experience among rice processors should be encouraged. Therefore, in order to achieve sustainable value addition in rice processing and strengthening the rice value chain for food security, the escalating cost of production is worrisome and efforts should be made to address these challenges.

RESPONSE SURFACE METHODOLOGY OPTIMIZATION OF CONVECTIVELY DRIED GINGER RHIZOME (*ZINGIBER OFFICINALE)*

A.J. Adeyi
Forestry Research Institute of Nigeria, P.M.B. 5054, Ibadan, Nigeria
***Corroesponence author email address**: adeyi.abiola@yahoo.com

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Drying is an energy intensive process that requires optimization for economic production. This study investigated, modeled and optimized the effect of convective drying factors (temperature (50, 55 and 60^{O}C), steam blanching time (20, 40 and 60 s), and air velocity (0, 1 and 2 m/s)) on the specific energy consumption of Ginger using response surface methodology (RSM). Results showed that all the drying factors considered increased the specific energy consumption during Ginger drying. The determined drying representative model has R-Squared and Adj R-Squared value of 0.9432 and 0.909 respectively. The determined optimum drying condition was drying temperature of 58.71^{O}C, steam blanching time of 20 s, and drier air velocity of 0.82 m/s to give a specific energy consumption of 119.04 kW.h. The results are useful for economic production of dried Ginger.

Keyword: *Ginger, specific energy consumption, response surface methodology, blanching time, drying*

INTRODUCTION
Ginger is an herb in plant habitat. It is consumed in both fresh and dried form because of its stimulating, aromatic, and carminative properties (Hoque *et al*., 2013). The phyto-medicinal importance of ginger is responsible for its large accompanied literature studies. The importance of drying to ensuring shelf stability, preservation, ease of transportation and storage of foods for future use cannot be overemphasized. Drying technology is popular and effective to prepare products for storage purposes (Majdi *et al.*, 2019). Over the years, drying has evolved from traditional open sun drying method to equipment enhanced sophisticated methods such as convective, microwave, freeze-drying, infrared drying and others. Amongst modern drying technologies, convective drying is easily implementable, especially in developing countries. However, a major backdrop of convective drying is the high-energy consumption, which has a detrimental effect on its economic consideration for adoption (Adeyi *et al*., 2022). Therefore, to make convective drying process more economically viable, the optimization of its specific energy consumption is important.

MATERIALS AND METHODS
Materials
Freshly harvested matured Ginger was obtained from a farmland in Ogbomoso Township, Oyo state, Nigeria. Stan gas convective dryer equipped with a temperature regulator, 3000 W heating element and timer was utilized for the drying experiment. A digital weighing balance (0.001 g accuracy) was employed for measurement purposes.

Experimental design
Experiments were designed to understand, model and optimize the individual and interactive effect of drying temperature ((X_1) = 50, 55 and 60^{O}C), blanching time ((X_2)= 20, 40 and 60 s), and air velocity ((X_3)= 0, 1 and 2 m/s) on the specific energy consumption (Y) of convectively dried Ginger. The drying factors and variations were selected based on literature search with special consideration for dried product quality preservation (Mercer, 2012). Design expert software version 8.0.0 (Stat-Ease, Inc., Minneapolis, USA) was utilized to design the experiment using miscellaneous Response Surface Methodology (RSM) and there were twenty-eight experimental runs altogether.

RSM modeling and optimization
Statistical analysis comprising of regression, graphical representation, and analysis of variance (ANOVA) were performed in the design expert software. The developed models were appraised by Mean squares, degree of freedom (DoF), sum of squares, F-value and, P-value are parameters. F-value determines the variance of data about the mean and better model precision is registered when F-values higher than one. P-values determine the model suitability statistically, P-value less than 0.05 is statistically acceptable. Thereafter, the optimum

combination of factors' parameters that best minimizes the process responses was determined. In addition, the RSM's established optimum process condition was experimentally validated. For statistical significance, triplicate validation experiments were conducted and their average is reported. The percentage error between the RSM's established theoretical optimum and its experimental validation was determined using Eqn. (1):

$$\alpha = \frac{Va - Ve}{Ve} \text{ X } 100\% \qquad (1)$$

Where α is the percentage error, *Va* is the experimental value and *Ve* is the theoretical value.

Drying procedure

Gingers were washed with portable water to remove sand and dirt followed by air-drying (28 – 30^{O}C) for 30 mins. The initial moisture content of ginger was determined using oven drying method at 90 ^{O}C for 24 h (AOAC, 1980). Equal sample weight of 10 g was utilized for each drying experimental run and was made to dry at the specified drying temperature, blanching time, and air velocity. The drying was done until equilibrium moisture content of the sample was reached. A digital weighing balance was utilized to measure the pre-drying and post-drying weight of the samples. Thereafter, the specific energy consumption were calculated using the experimental data through Eqn. (2) and (3) (Tunde-Akintunde, 2014), respectively.

$$E_t = Av\rho_a c_a \Delta T D_t \qquad (2)$$

$$E_s = \frac{E_t}{W_0} \qquad (3)$$

Where E_t, E_s, A, v, ρ_a, c_a, ΔT, D_t and W_0 is the total energy required for drying at each experimental run, specific energy consumption, the tray area, air velocity, the air density, specific heat capacity of the drying air, temperature difference, time of drying and initial weight, respectively

Results and Discussions

Effect of drying factors on specific energy consumption

The initial moisture content of ginger used in this study was 86 % (w.b). The effect of the selected drying factors on the specific energy consumption of ginger is represented in Fig. 1.

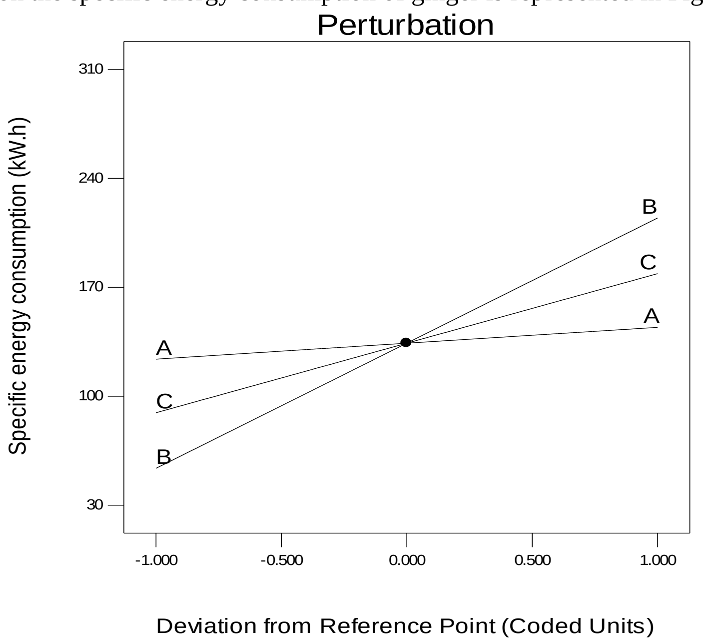

Fig. 1 Effect of the drying factors (A = Drying Temperature, B = Blanching Time and C = Air Velocity) on specific energy consumption

The figure showed that all drying factors led to increment in the specific energy consumption. The blanching time had the highest contribution to the specific energy consumption while temperature had the least contribution. The highest contribution of blanching is due to induced surface moisture on the sample after the blanching process. The least contribution of temperature is due to low electrical energy utilization as a result of low ranged drying temperature applied.

The model that represented the drying characteristics is represented in Eqn. 4

$$Y = +782.24 + 3.48 * A + 603.30 * B + 303.06 * C + 123.45 * A * B - 125.62 * A * C + 359.54 * B * C \quad (4)$$

Where Y= Specific energy consumption (kW.h)
The analysis of the model is represented in Table 1.

Table 1 Analysis of variance for specific energy consumption

Source	Sum of Squares	DoF	Mean Square	F Value	p-value Prob > F
Model	4.288E+006	6	7.146E+005	27.67	< 0.0001significant
A	97.00	1	97.00	3.755E-003	0.9523
B	2.912E+006	1	2.912E+006	112.72	< 0.0001
C	7.348E+005	1	7.348E+005	28.44	0.0003
AB	60963.61	1	60963.61	2.36	0.1555
AC	63122.27	1	63122.27	2.44	0.1491
BC	5.171E+005	1	5.171E+005	20.02	0.0012
Residual	2.583E+005	10	25831.53		
Lack of Fit	1.007E+005	6	16782.92	0.43	0.8323 not significant
Pure Error	1.576 E+005	4	3940	4.44	

R-Squared: 0.9432; Adj R-Squared: 0.9091; Pred R-Squared: 0.8483; Adeq Precision: 19.287

The Model F-value of 27.67 implies the model is significant. There is only a 0.01% chance that a Model F-Value this large could occur due to noise. Values of Prob > F less than 0.0500 indicate model terms are significant. In this case B, C, BC are significant model terms. Values greater than 0.1000 indicate the model terms are not significant. If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model. The lack of fit F-value of 0.43 implies the lack of fit is not significant relative to the pure error. There is an 83.23% chance that a lack of fit F-value this large could occur due to noise. Non-significant lack of fit is good.

Optimization of drying process

The result of the optimization of the drying process is depicted in Fig. 2

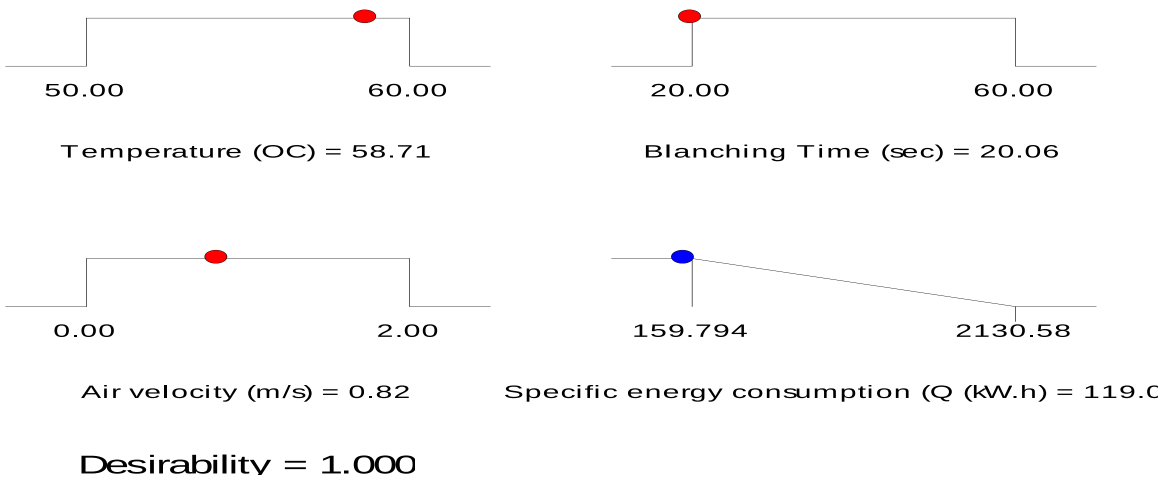

Fig. 2 Optimum drying process condition

The Figure 2 showed that the theoretical optimum drying condition of ginger for optimum specific energy consumption can be achieved at a drying temperature of 58.71^{O}C, blanching time of 20 min, and air velocity of 0.82 m/s. At this optimum drying condition, the dried product will consume specific energy of 119.04 kW.h. The desirability of this optimum drying condition is 1 which is the maximum that can be achieved. In a related study, Majdi *et al*., (2019) reported a desirability value of 0.781 for the optimum drying condition of apple.
The optimization result was validated so that its implementation in a large scale could be trusted. The validation error between the response values of the established theoretical processing condition and the response value of the experimental validation of the theoretical optimum processing condition (using the same input conditions of the theoretical processing condition values) was 0.284. This error is relatively low, and therefore, the RSM's established optimum drying condition can be reliably utilized.

CONCLUSION

The requirement for economic production of dried product is on the rise. Consequently, this study optimized the specific energy requirement during convective drying of ginger in response to selected drying conditions using Response Surface Methodology (RSM). The results implied that the optimal specific energy consumption of the convectively dried ginger was 119. 04 kW.h and could be achieved at drying temperature of 58.71^{O}C, blanching time of 20 mins, and drier air velocity of 0.82 m/s. This result is useful for economic production of dried ginger, which is one of the precursors for its commercialization.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study assessed the training needs of farmers on orange fleshed sweet potato value addition in Abia state, Nigeria. Data were collected from a sample of 120 farmers with the use of structured questionnaire. Frequencies, percentages and means were used for data analysis. The result show that majority (50.8%) were female, Majority (78.3%) of the respondent were married (43.33%) of the respondents fell within the age range of 60-69 years, (42.50%) of the respondents had secondary education. (46.67%) have household size of 4-6. The result also shown that Flour (94.2%), (Orange fleshed sweet potato drinks/juice (91.7%), Packaging (91.7%), Chips (89.2%), Skills for operating processing machines (89.2%), Flakes (86.7%), Meat Pie (85.8%), Selection of varieties for product processing (84.2%), are areas of training needs of the farmers. It was recommended that more awareness creation, training programmes and provision of suitable and necessary incentive should be disseminated by government, non-governmental organizations as well as research institution through extension agents should design programmes to train more sweetpotato farmers how to process sweet potato orange fleshed sweet potato roots into flour and juice for better returns.

Keywords: *Sweet potato, Training needs, Value addition, Farmers*

INTRODUCTION

Sweet potato (Ipomoea batatas) has different names in different languages such as Nduko in Igbo, Dankali in Hausa, Dun odunkun in Yoruba, batata or chaco in Spanish, Patatedouce in French, Patata americanain Italian, Batate in German, among others. It is a herbaceous warm weather creeping plant belonging to the family Convolvulaceae and genusipomomia. Sweet potato is one of the world's most important staple carbohydrate foods. Sweet potato is the fifth most important food crop on a fresh weight basis in developing countries after rice, maize, cassava and wheat. Sweet potato is high in nutritive value, outranking most carbohydrate foods in vitamins, minerals, protein and energy content. Depending on the cultivar, it is high in carotenoids, particularly, the hydrogen carotenoid, and the B-carotenoid which is a potent pro-vitamin A which is very important in nutrition and health of humans (CIP, 2012).

However, the processing of sweet potato into chips, snacks are not common in Nigeria due to inadequate information on processing technologies and various characteristics of products utilization. The poor quality of traditionally dried crop that has retained moisture for too long results from poor processing. This traditionally dried crops result in moldiness, micro toxin contamination and early insect infestation which leads to low or outright rejection of products. Quality sweet potato processing has potential for production of primary products, preservation, conservation and helping or making a way for women and youths in Nigeria to be gainfully employed (Oyebanji, *et al*. 2011)In addition, quality processing holds an opportunity of creating market for sweet potato tubers such as potato chips, potato flour and a lot of confectionaries which will encourage more rural farmers to go into sweet potato production, processing and marketing and invariably lead to increase in production, cost minimization and profit maximization.

Nigeria is one of the largest producer of sweet potato in sub-Saharan Africa with annual production estimated at 4.03 million tons per year with farm size of about 1.7mha and yield of 2.3t/ha (FAO, 2018). Sweet potato is an important food security and early maturity crop that can be intercropped with some crops like yam and maize. It can also be a mono-crop based on the intentions of the farmer. Sweet potato tubers are rich in starch, sugars, minerals and vitamins. Being rich in β-carotene, the orange- fleshed sweet potato (OFSP) is gaining importance as the cheapest source of antioxidant having several physiological attributes like anti-oxidation, anti-cancer and protection against liver injury and is most suiting as bio fortified crop to combat malnutrition in small and marginal farming community.

Skills are vital for an economy to grow and compete particularly in an era of economic integration and technological advancement. Training needs of rural farmers are very essential for the uptake of improved developed technologies for instance Training of rural farmers on value addition of Orange fleshed sweet potato in National root crops research institute Umudike. Training is a direct means of providing workers / farmers with the skills relevant to evolving needs of the economy. Interestingly skill development is an important factor in the drive to enhance OFSP production; processing and utilization which will stimulate economy raise people out of poverty and also ensure food nutrition security (Oguzor, 2017). New innovations are of little or no value unless they are put to use. Many sweet potato farmers are in dare need of training while some needs to be retrained on orange fleshed sweetpotato value addition that will help increase their diversification in sweetpotato production and avoid post-harvest losses. This study assesses the training needs of farmers on orange fleshed sweetpotato value addition in Abia state. The objectives were to describe the socio-economic characteristics of farmers in the study area and to assess the training needs of farmers on orange fleshed sweetpotato value addition in Abia state.

METHODOLOGY

The study was conducted in Abia State. The state has three Agricultural Zones with 38 extension blocks and 27 circles (ADP, 2004). It has a population of 2,833,999 made up of 1,234,193 males, 1,599,806 females, and a population density of about 578 persons per square kilometer. The three agricultural zones (Umuahia, Ohafia, Aba) of the state was involved in this study. A total of 120 respondents was randomly selected using multi stage stratified random sampling technique. One block in each zone was purposively selected because of their involvements in orange fleshed sweetpotato farming, giving a total number of three blocks. Four circles from each block was purposively selected for the same reason. Ten (10) orange fleshed sweetpotato crop farmers was randomly selected giving total of 120 farmers.

RESULTS AND DISCUSSION

Result from table1 shows that 11.67% of the respondent fell within the age range of 40-49, 31.67%were of the age bracket of 50-59 years while 43.33% of the respondent were in the age category of 60-69 years,13.33% were at the age of 70-79years. This implies that young people of active age (75%) dominated the production of sweetpotato in the study area. This findings is in agreement with Olagunji, Fakayode, Babatunde and Ogunwole-Olapade (2013) who noted that majority of sweet potato farmers in Osun State were in their active productive years.

On the sex of farmers, the result indicated that 49.2% were female farmers while 50.8% were male farmers. This implies that both male and females farmers were involved in sweet potato production on almost the same proportion.

Educational level of respondents indicated that 7.50% of the respondents had no formal education, 23.33% had primary qualifications while 42.50% had secondary qualification and 20.83% had NCE/OND, 5.8% had B.Sc/PG qualifications. This means that majority of the farmers were literate, as about ninety two percent of them had one form of formal education or the other. The high proportion of literate people among the farming population implies that majority of them are in a better position to be aware of, understand and adopt the sweet potato production and ultimately value addition technologies. Education also enhances farmer potential to process information and make the best out of any situation hence enable them to minimize risk and face uncertainties (Tura *et al*., 2010).

For household size, farmers that had between one to three people made up 10.83% of the respondents, those with four to six members constituted 46.67%, while those household with seven to nine persons constituted 42.50%. This means that the farmers had relatively large-sized households since they believe that getting married and having children is an alternative source of labour employed in sweet potato production.

For marital status, study findings showed that 21.7% of the respondents were single and 78.2% were married. This implies that majority of sweet potato farmers in the study area were married. This result concurs to the findings of Ejechi (2020) who found out that 78.1% of sweet potato farmers were married in Ebonyi state.

The result for farm size indicated that 29.17% of the respondents cultivated between 0.1-0.9 hectare, 45.83% cultivated between 1.0-1.9 hectares of farm land, 21.67% cultivated between 2.0-2.9 hectares while 3.33% cultivated 3 hectares and above. Majority of sweet potato farmers in the study area are small scale farmers because majority 67.5% of them cultivated between 1-3 hectares of land. This position is in agreement with the findings of studies by Ejechi (2020) who found small-scale farmers predominating the activities of sweet potato production in the Ebonyi state of south east zone of Nigeria. The result also corroborate with the findings of Omoare (2014) who stated that sweet potato farmers in Osun and Kwara states operated mostly on a small scale.

Table .1: Distribution of respondents according to their socio-economics characteristics

Socio-economic variables	Frequency	Percentage	Mean
Age			58.1833
40 – 49	14	11.67	
50 – 59	38	31.67	
60 – 69	52	43.33	
70 – 79	16	13.33	
Sex			
Female	59	49.2	
Male	61	50.8	
Education			10.4034
Non formal education	9	7.50	
Primary	28	23.33	
Secondary	51	42.50

0.1 – 0.9	35	29.17	
1.0 – 1.9	55	45.83	
2.0 – 2.9	26	21.67	
3.0 and above	4	3.33	

Table 2 shows the results of ordinary least square regression analysis of the relationship between socioeconomic characteristics and training needs. The exponential function was selected as the lead equation based on the magnitude of the coefficient of determination, F-ratio and the number of significant variables.

From the result, the co-efficient of determination (R^2) of 0.753 entails that 75.3% of variations in training needs were explained by the socioeconomic characteristics under consideration, while 24.7% of the variations were attributed to error. The F-ratio of 4.029 which was significant at 1% significant level indicates the goodness-of-fit of the model.

From Table 2, age, farm size and education were significantly related to training needs. The coefficient of age (0.021) was positive and significantly related with training need at 5% level of significant. The implication is that the higher the age of the respondents, the greater their training needs. it could also be that older farmers have more experience in farming and are better able to assess the characteristics of modern technology than younger farmers, and hence a higher probability of adopting the practice. Teklewold et al (2006) found out that the older farmers have more experience in farming and adopt new farm practices more than the younger farmers.

The coefficient of farm size (-0.058) was negative and significantly related with training need at 5% level of significant. Implying that the larger the farm size of the respondents, the lesser their training needs. Farm size has a negative influence on value addition training. Increase in farm size reduces respondent's participation in values addition at five percent significance level. This can be attributed to the fact that those with large tracks of land devote large chunks to other competing enterprises such as maize which is considered a staple food in the area. This is contrary to Makhura et al (2001) findings that an increased area of land under cultivation stimulates participation in the market as it allows for an increased production extending beyond the consumption requirements. The findings further contradict Barungi and Maonga, (2011) findings that the fixed transaction costs decrease with an increase in farm size, which explains why the adoption of new divisible technology might begin with larger farms, secondly, because larger farms have a greater ability to raise capital, to bear the cost of the innovations and bear the risk of failure, they are likely to make risky investments compared to smaller farmers.

The coefficient of education (0.049) was positive and significantly related to training need at 5% level of significant. Implying that the higher the educational level of the respondents, the greater their training needs. Education level had a strong influence in the involvement in value addition training. The influence of education levels on technology uptake is well documented. Mishra, (2010) found that farmers with higher education have better access to information and knowledge that are beneficial to farming operation. They also tend to possess higher analytical capability of the information and knowledge necessary to successfully implementation of new technology and realize expected results. Hence, higher education allows farmers to make efficient adoption decision and be the early adopters who can take advantage of new technology and profit most from it.

***, **, * = significant at 1%, 5% and 10% respectively

+ = the lead equation

Table 3 shows that Flour (94.2%), (Orange fleshed sweetpotato drinks/juice (91.7%), Packaging (91.7%), Chips (89.2%), Skills for operating processing machines (89.2%), Flakes (86.7%), Meat Pie (85.8%), Selection of varieties for product processing (84.2%), are areas of training needs. However ranking the training needed shows that training on how to process orange fleshed sweet potato into flour, Drinks/ Juice and Packaging are the most training needs of the respondents in the study area. Therefore training needs of farmers targeted towards processing (Value addition) in the study area should be considered and the area of needs should be treated as the utmost priority.

Table 3: Distribution of respondents based on areas of training needed in OFSP value addition

Competences in Orange value addition	Highly Needed	Needed	Not needed	Mean	Std. Deviation
Skills for operating processing machines.	321 (89.2)	22 (9.2)	2 (1.7)	2.875	0.379
Selection of varieties for products processing.	303 (84.2)	36 (15.0)	1 (0.8)	2.833	0.357
Value added products processing					
OFSP (Drinks/Juice)	330 (91.7)	20 (8.3)	-	2.917	0.278
Flakes	312 (86.7)	28 (11.7)	2 (1.7)	2.850	0.322
Chips	321 (89.2)	24 (10.0)	1 (0.8)	2.883	0.301

Meat pie	309 (85.8)	6 (5.0)	11 (9.2)	2.717	0.219
Packaging	330 (91.7)	14 (5.8)	3 (2.5)	2.892	0.181
Grand mean				**2.863**	

Note: The figures in parenthesis are the percentages, **source**: field survey 2020

CONCLUSION AND RECOMMENDATION

The study investigated the training needs of farmers on orange fleshed sweetpotato value addition in Abia State. The study reveals that most of the processors were female and the respondents were in their productive age. The most paramount training required by the respondents were Flour, Orange fleshed sweetpotato drinks/juice, Packaging, Chips, Skills for operating processing machines, Flakes, Meat Pie and Selection of varieties for product processing. It was recommended that more awareness creation, training programmes and provision of suitable and necessary incentive should be disseminated by government, nongovernmental organizations as well as research institution through extension agents should design programmes to train more sweetpotato farmers on how to process sweetpotato orange fleshed sweetpotato roots into flour , juice, chips and flakes for better returns.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The review examines the impact of climate change on stored product pest (SPP). Factors that contribute to the spread of SPP, the exposure to which they are subjected as a result of climate change and potential consequences of this exposure were reviewed. Climate change is of great concern to Agriculture globally and it is widely discussed presently and climate parameters such as temperature, relative humidity, atmospheric carbon dioxide (CO_2) and precipitation patterns have made significant impact on insect pests. The effect is evident in the increased prevalence of stored product pest by influencing the number of insect species colonizing stored products, development rate, survival, and wider geographic range due high temperature. These had led to increase in infestation rate thereby leading to serious grain damage and economic loss. A long term multi-disciplinary approach is needed to adhere to climate change, ensuring strategic adaptation and mitigation approaches over the unwavering impact of climate change on stored product pest.
Keywords: *Stored Products, Food security, Insect Pest, Stored Product Pests, Climate Change*

INTRODUCTION
Man overtime had engaged in an age-longed practice of preservation of essential commodities to meet different purpose at a particular period of time. These commodities constitute crop, animal and timber products and household goods. Stored agricultural produce is of significant importance being the staple diet of humans inhibiting different parts of the world (Lale, 2002). However, the overall goal for storage is to ensure adequate and consistent food supply (food security). Unfortunately, these stored grains are later infested with many insect pests. These insects are notorious and causes enormous damage to grains, pulses, and many other substances either directly or indirectly by consuming the seeds or seed products or by contaminating food products with their exuviae, cadavers and webbing (Mason *et. al*, 2012). Other sources of concern include accumulation of insect detritus thereby making stored products unfit or unhygienic for human consumption (Rajashekar *et al.*, 2012), boring of seed or grain kernels hence, destroying the germ portion and other several quantitative and qualitative losses (Ahmad et al., 2021). The storage pests often go unnoticed because they infest items that are not regularly used and also being very small in size may not be noticed easily. Storage pest such as weevils, beetles or moths seen flying in large numbers near stored items, or crawling over countertops, walls and ceilings, powdery residues below and surrounding stored items, and stale odours in pantries and closets are all possible indices of their presence and sign of infestation.

Climate change can have a significant impact on the behavior and life cycles of stored product pests, ultimately leading to potential consequences for stored goods. Generally, change in climate is a great concern to agriculture worldwide and it's among the most discussed issues in today's society. Climate parameters such as increased temperatures, relative humidity, rising atmospheric CO2 levels, and changing precipitation patterns have significant impacts on agricultural insect pests (Skendži´*et. al*., 2021). Studies have evaluated the effects of the mentioned atmospheric and climatic factors on the distribution, occurrence and abundance of field pests while areas of stored product pest have been more or less neglected. This has raised concerns because the main reason behind the occurrence of stored grain pests is the presence of favorable climatic condition for their growth and survival (Ahmad *et al.*, 2021).

Climate change continues to present challenges to life and livelihoods globally and amplifies the problems humankind is already facing (Altizer *et al*., 2013; IPCC, 2018). The focus of this paper is to outline the impact of climate change on stored product pest, considering the main drivers of climate change which significantly affect the population dynamics of insect pests and attendant losses and to suggest possible preventive, mitigation and adaptable approaches for SPP management in a changing climate.

Major Economic Stored Insect Pests in Nigeria

Common insect pest species that cause economic damage to stored agricultural products in Nigeria includes *Sitophilus* spp. (Coleoptera: Curculionidae), *Rhyzopertha* sp. (Coleoptera: Bostrichidae), *Trogoderma* sp. (Coleoptera: Dermestidae), *Callosobruchus* spp. (Coleoptera: Bruchidae; Chrysomalidae), *Tribolium* spp. (Coleoptera: Tenebrionidae), *Sitotroga* spp. (Lepidoptera: Gelechiidae), *Corcyra* sp. (Lepidoptera: Pyralidae), *Ephestia* spp. (Lepidoptera: Pyralidae), *Myelois* sp. (Lepidoptera: Pyralidae) and *Plodia* sp. (Lepidoptera: Pyralidae). Majority of SPP belongs to the order of Coleoptera and Lepidoptera that accounting for about 60 and 10 % respectively (Atwal and Dhaliwal, 2008).

The economic losses associated with Stored Product Pest

Stored product pests such as *Plodia interpunctella, Prostephanus truncatus* and *Sitophilus zeamais* are insects of economic importance in stored grains causing substantial losses if not properly managed (Ajayi *et al*., 2021; Kayode et al., 2021). These insect pests cause significant economic losses to crops, with population densities exceeding a pre-established threshold being the main culprit for such losses. For instance, the economic threshold for maize requires two *Cryptolestes ferrugineus* (Stephens), *Prostephanus truncatus* (Horn) per kg of grain while in a maize pest store 0.62 insects/trap/week is the (Economic Threshold Level) ETL for *Sitophilus* spp. (Toews *et al*. 2003). Even though control measures are often applied pre-emptively without considering economic levels, leading to unnecessary costs for farmers. However, determining ETL is important putting into cognizance the climatic factors that could influence serious pest infestation causing food shortages that lead to hunger. This will inform decision on appropriate measures for storage pest management practices which will minimize economic losses.

Impact of Climate Change on Stored Product Pest (SPP)

Generally, changes in climate can affect insect pests in several ways. They can result in an expansion of their geographic distribution, increased survival during overwintering, increased number of generations, altered synchrony between plants/grains and pests, altered interspecific interaction, increased risk of invasion by migratory pests, increased incidence of insect-transmitted plant diseases, and reduced effectiveness of biological control, especially natural enemies (IPPC, 2021).

According to Prakash *et. al* (2014) change in climate has both direct and indirect impacts on pests'; direct includes reproduction, development, survival and dispersal, whereas indirectly the climate change affects the relationships between pests, their environment and other insect species such as natural enemies, competitors, vectors and mutualists. Insects are poikilothermic organisms and undeniably temperature is the most important environmental factor affecting their behaviour, distribution, development and reproduction (Kocmánková et al. 2010).

So many stored pests have expanded their host range or distribution, at least in part globally due to changes in climate (IPPC, 2021). A typical example is the red palm weevil (*Rhynchophorus ferrugineus*) infestation on various palm species, which include coconut and date palm (El-Mergawy and Al-Ajlan, 2011). It was first detected on date palms stored and used for export in the Near East in the mid-1980s, and subsequently spread to other countries in the Near East, and to Africa and Europe (FAO, 2020). The distribution of the red palm weevil may expand because of climate change. Ge *et al.* (2015) predicted that in China the number of areas highly favorable to this pest would increase with climate change, resulting in the expansion of the insect into north China.

Effect of temperature on SPP

Temperature plays an important role in metabolism, metamorphosis, mobility, and host availability, which determines the possibility of changes in pest population and dynamics (Shrestha, 2019). It can strongly influence the life cycle and fitness of ectotherms of insects (Prakash *et. al* 2014). Ectotherms rely on external environment to regulate their body temperature and small changes in temperature can have dramatic effects on insects.

Due to increased temperature causing significant impact on crop pest populations in several complex ways, so also decreased temperature may tend to depress insect populations, although some researchers seem to agree that warmer temperatures in temperate climates will result in increased number of species and higher populations of insects (Lehmann *et al*., 2020). Higher temperature seems to be a double-edged sword as it enhances the multiplication of insects and also declines the efficacy of pesticides to certain insects (Prakash *et. al* 2014). Insect physiology is very sensitive to changes in temperature, and their metabolic rate tends to approximately double with an increase of 10 ◦C (Skendži´*et. al*., 2021).

Dukes *et al*., (2009) reported that increased temperature tends to accelerate insect food consumption, development and movement (distribution), which can affect population dynamics by influencing fecundity, survival, generation time, population size, and geographic range. Hence, this will increase grain damages and serious crop economic loss by the SPP because as temperature increases the insects respond in several ways - adapt, migrate and become cosmopolitan. Human activities in the environment have adverse influence to climatic conditions that apparently affects temperature of storage structures thereby determines the survival and distribution of stored product pest.

Effect of Relative Humidity on SPP

Relative Humidity (RH) influences insect growth and behavior by affecting their ability to regulate water loss (John, 2011). Warm humid condition is favourable for insect growth rate and development and RH in excess of 50% of stored grains especially improperly dried products, have tendency to absorb more moisture from the ambient air and become damp, thereby making it convenient for insect infestation (Lale, 2002). The damp environment influenced by RH is suitable for survival and distribution of stored product pest, as their physiology depends on atmospheric moisture (Patrick, 1982). Certain insects transfer themselves to regions of less evaporation when the air is dry, or when stored products proportion of water has been evaporated from their body. High humidity supports reproductive capacity in insects as percentage of water is correlated with the amount of fats (including eggs in female), which consists of anhydrous molecules and with the amount of cuticle, which has a lower water content than other tissues (Ahmad, *et al*., 2013). While low humidity is often detrimental to insect development, most insects found in desert have adapted to physiological and behavioral mechanism to prevent dehydration (John, 2011). In Nigeria, with warm and dry weather typically in February, March and April one can expect insect activities to increase.

Effect of Increased CO2 Concentration on SPP

Elevated concentrations of atmospheric CO2 can affect the distribution, abundance, and performance of insect pest. Such increases can affect consumption rates, growth rates, fecundity, and population densities of insect in grains or stored products (Fuhrer, 2003). Increased CO2 levels would have a greater impact on cereals especially, therefore, these differential effects of elevated atmospheric CO2 may result in asymmetric effects on stored grains and the response of insects feeding on them (Lincoln *et al*., 1984). Currently some available results suggest that the effect of elevated atmospheric CO2 on stored product pest is not only highly specific to individual insect species, but also to particular insect pest–host plant or grains (Coviella and Trumble, 1999).

Effect of rainfall pattern on SPP

Distribution, intensity and frequency of precipitation are very important indicators of climate change, it affects the incidence of pests directly as well as through changes in humidity levels (Pathak et al., 2012). This event threatens insect survival and affects their diapause but some SPP are found in cracks and crevices of buildings particularly in kitchens and tropical food stores as scavenging pests (Lale, 2002). Variable rainfall can have a major impact on insect populations. Unusual rainfall patterns with either delayed rainfall or early cessation of rainfall have great influence on insect pest resurgence, pest outbreaks and to some extent migration of this pest from one geographical region to another.

Prevention, Adaptation and Mitigation Approaches for Stored Product Pest Management in A Changing Climate

Preventive measure on the effect of climate change is one of the key components needed to maintain and preserve current and future food security. Although the ability to adapt to the impact of climate change through various pest management practices will depend on their physical, social and financial resources (Sutherst, *et al*., 2011). Increasing the ability to adapt rapidly to disturbances and present climatic changes is very important (Barzman *et al*., 2015). Potential adaptation strategies have been identified to reduce the risks of pest infestation and to mitigate the negative impacts of existing pests (Skendži´*et. al*., 2021). Adjustments in grain protection protocols, storage structures modifications are necessary because of recent climatic changes, but further adjustments will become increasingly crucial in the future, assuming the projected climate-change scenarios come true. Modified integrated pest management (IPM) practices are employed in monitoring climate and insect pest populations and the use of modeling predictions tools.

Grain Protection Protocols

Proper sanitation and handling of grains should be ensured during post-harvest operations prior to storage in order to prevent climatic implications that will enhance pest infestation leading to loss of crop products and economic damage (Howden, *et al*., 2007). Drying of grains after harvest to optimal range of moisture content is necessary. Temperature check and regulations should be practiced periodically, temperature below 13^0c slows development while high temperature above 35^0c stops development. In Nigeria, sun drying of infested chips is a major control method used by farmers to manage insect pests in stored agricultural products. However, this method presents several disadvantages. For instance, the sun drying method is the oldest known technique of conservation of agro-alimentary products, and it may not be effective in controlling all types of insect pests (Loko *et al*., 2013; Kayode *et al*., 2021). Additionally, sun drying may lead to product spoilage and decreased product quality because the high temperature damages the nutritional content and flavour of the product. Furthermore, the method is time-consuming and labour-intensive, making it expensive for farmers.

Modified Integrated Pest Management

Integrated pest management (IPM) decisions on the need for control measures should be based on the most modern tools, such as forecasting methods and scientifically validated thresholds. Direct pest control tools are the last resort when economically intolerable losses cannot be prevented by indirect measures (Boller *et al*., 2004).

Modified cropping practices and adaptive management strategies are needed to reduce the impact of insect pests on crops in a changing climate. Practicing the planting different crop varieties, planting at different times of the year to minimize exposure to pest outbreaks and increasing biodiversity at field margins to increase the number of natural enemies (Andrew and Hill, 2017). The use of pheromones and allelochemicals is an important method by which insects sense their environment. They play a substantial role in various IPM techniques such as biological control, mating disruption, push-pull strategies, monitoring and trapping (Heuskin *et. al*., 2011).

Monitoring Abundance and Distribution of SPP

One of the most important prerequisites for determining whether climate change is altering the population dynamics of insect pest species is access to long-term data (Yamamura *et. al*., 2006). Without these important baseline data, it is extremely difficult to fully assess changes in pest populations under changing climate regimes and also to predict future population dynamics (Andrew and Hill, 2017). Long-term monitoring of pest populations and behavior, particularly in climate change-sensitive regions, may provide some of the first clues to biological responses to climate change (Heeb *et al*., 2019). Changes in the dynamics of vectors, diseases and host populations at the local level need to be monitored, as do changes in their geographical distribution. New invasive species are being introduced in many parts of the world, aided by climate change. Effective monitoring and management systems are needed to prevent invasive species from becoming an economic pest in new geographic regions (Hellmann *et al*., 2008). Therefore, adaptive responses in both pest management and biosecurity will be required. Currently available pest management strategies such as detection, prediction, physical control, chemical control, and biological control could be intensified to control pests in response to climate change (Heeb *et al*., 2019).

Climate Forecasting and Model Development

Pest management strategies must tolerate regional climate change and its uncertainties. Some of the available options include sensitivity analyses and combined results obtained by using projected climate change scenarios with sensitivity analyses for a given area over a wide range of variable values. This strategy could become a useful tool in informing pest management personnel when designing adaptation measures for pest management under new environmental conditions (Sutherst, *et al*., 2011). Climate models combined with the environmental requirements of a particular pest species (envelope) can be an effective tool for projecting the possible range of changes on a global scale. Modelling the pest risk together with the responses of its plant hosts to climate change can therefore increase the ability to predict the outcome of an insect infestation (Fleming and Volney, 1995). A comprehensive analysis of climate and historical weather records, together with development of the models described above, will facilitate prediction of pest risks. This could be reflected in the development of proactive strategies for pest prevention and control strategies in a changing climate (Yonow *et al*., 2019)

Storage structures modifications

Modified hermetic or unventilated structures should be used for air-tight storage where oxygen is excluded for insect pest while the environment is monitored overtime. Elevator storage structures are modern facilities composed of large upright concrete bins, grain is moved from bin to bin using horizontal conveyor belts below the bins, a vertical bucket elevator to raise grain to the top of the elevator and spouting or another horizontal conveyor belt to carry grain to the new bin (David and Paul, 2014). According to Hagstrum *et. al.* (2013) the major stored pests *Rhyzopertha dominica* (F.), *Cryptolestes ferrugineus* (Stephens), *Sitophilus oryzae* (L.) and *Tribolium castaneum* (Herbst) in elevators in the USA were managed effectively with elevator equipment. Other improved storage structures such as Aluminum bin, Pusa bin, plastic and metal silos, Polyster polythene bags, jute bags etc (Reed *et al.*, 2003) were also reported to be effective in the management of such insects.

CONCLUSION AND RECOMENDATION

The effects of climate change on insects are complex while it favours such change in climate also inhibits others by negatively impacting on their distribution, diversity, abundance, development, growth and phenology. Researchers have evaluated the effects of several climatic factors – increased temperature, CO2, ozone or ultraviolet-B irradiation, and changing water or humidity patterns on insect pest. Therefore, it is generally expected that there will be an overall increase in the number of pest outbreaks involving a broader range of insect pests.

Despite the wealth of studies on climate-change biology, little have been documented on stored product pest, there are still prominent gaps in research into the impact of climate change on SPP. These gaps include the effect of climate change on the effectiveness of management strategies in stored-product entomology.

With climate change and the acceleration of global trade, uncertainties and frequency of occurrence of existing and new pests will increase. If climate change factors lead to favorable conditions for pest infestation and crop damage, then we will face a high risk of significant economic losses and a challenge to human food security. A proactive and scientific approach will be required to deal with this problem. Hence, there is a great need for planning and formulating adaptation and mitigation strategies in the form of modified IPM tactics, climate and pest monitoring, and the use of modelling tools.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
About 40% of the crops that is cultivated in Nigeria never reach the market/consumers due to post-harvest losses. Therefore, every quantity of farm produce saved from post-harvest losses, usually translates to an added amount of food made available to the consumers. This study focuses on profitability of postharvest management of tomatoes in Kudan Local Government Area (L.G.A) of Kaduna State, Nigeria. Purposive and simple random sampling procedure was employed in selecting sixty (60) tomatoes farmers who adopted tomatoes post-harvest management techniques, and sixty (60) farmers who did not. Primary data were collected with the aid of structured questionnaire, and analyzed using descriptive statistics. Return on investment, net income and gross margin were computed. The results reveals that adopters of postharvest management practices incurred about 3.6% postharvest losses in tomatoes compared to those that did not (24.6% losses). Furthermore, a Net income of ₦1,177,200/ha and gross margin of ₦1,265,200/ha were realized by farmers who practiced tomato post-harvest management techniques, as against a net income of ₦743,900/ha and gross margin ₦814, 900/ha for those who did not. Also, for every ₦1 invested, a return of ₦1.60 was made by farmers that adopted postharvest management techniques as against a return of ₦0.98 made by those who did not. This shows that post-harvest losses reduce the returns of tomatoes farmers in the study area. Therefore, the study suggested that Nigerian Stored Products Research Institute with the mandate of post-harvest management, should sensitize the farmers on the importance of post-harvest management, and train farmers on the developed post-harvest management technologies.

INTRODUCTION
Food and Agriculture Organization (FAO, 2010), opined that the global efforts in the fight against hunger, low farmers income and food insecurity in the developing countries, should give priority to the issues of crop losses. This is due to the adverse effect of crop losses on food quality and quantity, and on the economic development in the developing countries. Thus, post-harvest losses have been identified as one of the major causes of food problems in most developing countries. Post-harvest losses include the rotting of produce and damage during storage, packaging and transportation which leads to consumer rejection (Adeoye *et al.,* 2009). It has been observed that post-harvest loses is much more painful and costlier than pre-harvest loss both in terms of money and man-hours. Adeoye *et al.* (2009) noted that the magnitude of the crop losses depends on the nature of the produce, the condition of the crop at the time of harvesting, the distance travelled, and the nature of the road networks the produce passed through before getting to the consumer.
Tomato which is one of the vegetables that are mostly cultivated in Nigeria is highly affected by post-harvest losses (Adepoju, 2014; Bello *et al.,* 2016). It belongs to the family of solanaceae and originated from the South American Andes. The fruit vegetable is a good source of vitamins and minerals that are essential for healthy human diet. Tomato is not only considered as food but as medicine, flavouring ingredient, nutrient supplement, human system cleanser, and detoxifier (Bello *et al.,* 2016). Tomato production in Nigeria has more than doubled in the last 10 years, being the most widely cultivated vegetable crop (Bello *et al.,* 2016). It is a relatively short duration crop. It is a high yielding crop with high economic benefits (Adepoju, 2014). It accounts for more than 18% of the total daily consumption of vegetables in Nigeria, making it a very important crop in Nigeria (Babalola *et al.,* 2010; Adepoju, 2014). Nigeria is ranked the 13th largest producer of tomato globally (FAO, 2010; Adepoju, 2014). Tomato is grown in the Southern part of Nigeria under the rain-fed systems, while it is grown under the irrigation systems in the Northern part of the country. Tomato is highly perishable in nature (Adepoju, 2014) with

limited shelf life due to its high moisture content. It is prone to pathological, physiological and mechanical damages (Adeoye *et al.,* 2009) as a result of the activities of insect pests, poor handling, rotting/deterioration which reduce the quality and quantity of the produce. Thus, farmers who have no means or facilities to process/preserve their tomato, tends to sell it off at a cheaper rate, which in turn reduces the net income of the farmers. Also, farmers who preferred to transport their produce to the market are faced with the problem of poor road network, and poor means of transportation which usually affect the produce's quality, price, and returns. However, one of the policy thrust of the Nigerian agricultural policy is to encourage farmers to adopt good post-harvest management, and to use on-farm and off-farm storage facilities that are simple and effective. Thus, this study aimed to analyze the profitability of post-harvest management of tomatoes under limited resource-base in the Northern Guinea Savannah Ecology of Nigeria.

METHODOLOGY

The study was carried out in Kudan L.G.A of Kaduna State. The State is located between Latitude 09° 02'N and 11° 32' N and between Longitude 06° 15'E and 08° 38' E. The average annual rainfall and humidity in the study area is 1,272.5 mm and 56.64 %, respectively. The average daily minimum and maximum temperatures are 15.1 and 35.18 °C (Saras, 2021).The State lies in northwest Nigeria and occupy about 5 % of the total land mass of the country with 46,053 km^2 of which 20,220 km^2 is arable. The major crops grown in the area are maize, sorghum, millet, rice, cowpea, pepper, potatoes, yam, tomatoes, leaves/vegetables, and sugarcane. Purposive and simple random sampling techniques were used to select the needed respondents for this study. Kudan L.G.A was purposively chosen for this study due to its peri-urban set up, intensive of tomatoes production, and good evidence of post-harvest management techniques employed by the tomatoes farmers in the area. A simple random technique was used to select 3 villages through balloting system, namely: Jaja, Hunkuyi, and Kudan villages. Then, a snow ball technique was used to identify the N_{ith} tomato farmers who employs post-harvest management techniques, and other i_{th} farmers in each of the villages. A list of $N_{i\text{-}nth}$ farmers who employs post-harvest management techniques was made, as well as those who do not. From this list, 20 tomato farmers who employ post-harvest management techniques and 20 who do not were purposively selected from each of the villages after focused group discussion, to give a total of 60 tomato farmers who employs post-harvest management techniques, and 60 who do not, making a total of 120 tomato farmers selected for the study. Primary data were collected through the use of structured questionnaire administered to the selected farmers. The collected data were analyzed using descriptive statistics such as mean, frequency, and percentage. Gross-margin, return on investments, and net income analysis were also computed.

Net income model

Net income is the difference between the gross return and total cost of farming as stated below

$$Net\ income = GR - TC \quad \ldots\ldots\ldots\ldots \quad (1)$$

Where GR = gross return (value of the useful/sold tomatoes in Naira) and TC = total cost of farming.

While

$$TC = FC - VC \quad \ldots\ldots\ldots\ldots \quad (2)$$

Where FC = fixed cost and VC = variable cost.

Returns on investment (ROI) model

$$Return\ on\ investment\ (ROI) = TR/TC \quad \ldots\ldots\ldots\ldots \quad (3)$$

Where ROI = Returns on investment,

TR = Total revenue in Naira, and TC = Total cost of tomato production in Naira.

Post-harvest losses (PHL) model

This is the differences between what is harvested from the farm and what is useful. It is stated thus:-

$$PHL\ (wasted/damaged) = TPH - TPU \quad \ldots\ldots\ldots\ldots \quad (4)$$

Where PHL = Post-harvest losses, TPH = Total products harvested from the farm at harvest.

TPU = Total products that is useful, that is, the ones sold out, gifted or consumed, the ones from which return is made.

$$\%PHL = \frac{PHL}{TPH}\ x\ 100 \quad \ldots\ldots\ldots\ldots \quad (5)$$

Where PHL and TPH are as stated above in equation 4.

Gross margin model

Gross margin model is expressed as follows:-

$$Gm = TR - TVC \quad \ldots\ldots\ldots\ldots \quad (6)$$

Where: GM = Gross margin, TR = Total revenue made by the farmer, TVC = Total variable cost.

RESULTS AND DISCUSSION

The socio-economic variables of the farmers were grouped into those farmers with Post-Harvest Management Techniques (PHMT), and those without. The results of the analysis are presented in Table 1. The result for age shows that 10% of the respondents are below 21 years, with 5.83% of them employing postharvest techniques to reduce losses, while 4.17% do not. About 32.5 percent of the respondents are 21 to 40 years old, out of which 14.83% employed PHMT, while 17.67% do not. The results reveal that a substantial proportion (46.67%) of the respondents were 41 to 60 years old. Of these, 22.67% employed PHMT, while 24% do not. The average age of the respondents was 43.6 years. This implies that most tomato farmers are within their active and productive age, and can be more flexible to new ideas and risk taking; and are more likely to adopt PHMT. This validates the assertion of Babangida (2016) who opined that youth are more in vegetable production. Table 1 reveals that 36.67% of tomato farmers in the study area were females, of which 28.33% employs PHMT, while 8.34% do not. Of the 63.33% of the respondents who were males, only 21.67% employs PHMT while 41.66% do not. This implies that female tomato farmers employ PHMT more than their male counterpart who dominated the tomato farming business. This is in line with Adepoju (2014) who observed that males dominated tomato production. The results in Table 1 further shows that 28.33% of the respondents had no formal education, while about 51.56% had secondary education, and a lesser percentage (2.5%) had tertiary education. A greater percentage (27.5%) of the farmers who employs PHMT had secondary education. This implies that they are better informed, and literate enough to adopt innovations. The average numbers of years spent in formal education by the farmers was 9. This validates the work of Saras (2021). The mean household size of the tomato farmers was 8, and 23.33% of farmers who employs PHMT have household sizes with 5 – 9 members. Also, the average years of farming were 12, with about 26.67% having farming experience of 11 – 15 years employing PHMT, while 22.33% do not. This implies that farmers with longer experience in tomato farming employ diverse means to reduce postharvest losses. About 33.33% of tomato farmers with land holding between 1 – 2.99 hectares employ PHMT, while 28.33% of them do not. The mean tomato farm size in the study area was 1.6 hectare. This implies that the tomato farmers are largely small holder farmers. Furthermore, Table 1 reveals that about 34.17% of the farmers do not have contact with extension agents, while 65.83% had, of which 43.33% employs PHMT, while 22.5% do not. Extension service is essential in the improvement of farmers' productivity and efficiency as stated by Muhammed (2015).

Table 1: Socioeconomics variables were group according to post-harvest management techniques (PHMT)

Variables	Frequency	Percentage	Mean	With-PHMT	Without PHMT

Post-harvest management Techniques (PHMT) employed by the farmers in the study area.

Focused group discussion was used to source for information with regards to the various postharvest techniques that are employed by the tomato farmers in the study area. The discussion results showed that the various post-harvest management techniques adopted by the tomato farmers in the study area includes; harvesting at what they called "proper time" (when ripening process is setting in), gentle handling of fruits at harvest, use of vegetables crates in collecting the produce at harvest, sorting of fruits on the basis of firmness, sun drying fruits that have lost freshness or showing signs of spoilage, transporting produce in vegetable crates with van/pick-up to the central market for sales.

Profitability of Tomato Production among Farmers with and without PHMT

Return on investment, gross margin and net return analysis were used to ascertain the profitability of tomato production among tomato farmers with PHMT, and those without PHMT. The results of the analysis are presented in Table 2. Table 2 reveals that the total revenue obtained by the tomato farmers who employs postharvest management techniques was higher (₦1,912,000) than that of those who do not (₦1,504,000). Also, the gross margin of the farmers with postharvest management techniques is higher (₦1,265,200) than of those without postharvest management techniques (₦814,900). Likewise, the net return from tomato productions reveals that the farmers who employ postharvest management techniques obtained a higher return (₦1,177,200) than the ones (₦743,900) who do not. This implies that post-harvest losses reduce the net returns of tomatoes farmers in the study area. Table 2 further reveals that the return on investment is ₦2.60 among the farmers with postharvest management techniques, implying that for every ₦1 they invested in tomato production, a return of ₦2.60 kobo was made. While, the return on investment is ₦1.98 among the farmers who does not employs postharvest management techniques. Table 2 reveals also that the farmers who employs postharvest management techniques encountered 3.6% loss of their produce after harvesting, while the tomato farmers who do not, encountered 24.8% loss.

Table 2: Net Returns of Tomato production among farmers with and without PHMT

Variables/ operations	Quantity	With PHMT		Quantity	Without PHMT

CONCLUSION AND RECOMMENDATION

The study which focuses on profitability of postharvest management of tomatoes in Kudan L.G.A of Kaduna State, revealed a net farm income of ₦1,177,200/ha, gross margin of ₦1,265,200/ha, return on investment of ₦1.60 for every ₦1 invested, and about 3.6% post-harvest losses for farmers with post-harvest management techniques, as against a net farm income of ₦743,900/ha, a gross margin of ₦814,900/ha, Return on investment of ₦0.98 for every ₦1 invested, and about 24.8% post-harvest losses for farmers without postharvest management techniques. Thus, the study concludes that post-harvest losses reduce the returns of tomatoes farmers in the study area. The study suggested that agencies like Nigerian Stored Products Research Institute (NSPRI), and others with the mandate of post-harvest management, should sensitize the farmers on the importance of post-harvest management, and train farmers on some of their developed post-harvest management technologies for proper adoption.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
One of the main challenges facing the ever-growing world population is food security. The Food and Agriculture Organization (FAO) of the United Nations suggests that in order to feed the population, food production must increase by 70%. Nearly 1.3 billion tons of food production in the world is wasted as a result of poor postharvest management thereby posing food security threat. Developing countries experience more of postharvest losses; therefore, in order to achieve zero hunger by 2030, the problem of postharvest food loss must be addressed. Reducing post-harvest loss in Sub-Saharan Africa will not only increase the quantity of food available and overall access, but also alleviate poverty, increase agricultural productivity, and improve food utilization and safety in terms of health and nutrition, and reduce unnecessary resource use. Postharvest management strategies therefore need to be applied throughout the food and market value chains.

INTRODUCTION
Postharvest loss poses a serious challenge for food security and agricultural production in developing countries. In developed countries however, postharvest loss is characterized as a consumer behavior while in developing countries it is largely caused by financial, managerial and technical deficiencies (Conteh *et al.*, 2015, FAO, 2011, Premanandh, 2011). Consequently, in developing countries, food loss is mostly ex[rienced at stages 'close to the farm' such as production, handling, and storage (Lipinski *et al*., 2013, Parfitt *et al*., 2010, Premanandh, 2011). The problem of postharvest loss is more prevalent in Sub-Saharan Africa (SSA) where a great portion of the produce is lost as a result poor storage facility, lack of structured markets, limited processing capacity and weather-related factors (Affognon *et al*., 2015, Shiferaw *et al*., 2011, Tefera, 2012, Tefera *et al*., 2011). The global estimate shows that roughly one-third of the food produced for human consumption is lost or wasted FAO (2011). Postharvest loss in SSA is estimated to be about 37%, which is equivalent to an annual per capita food loss between 120 and 170 kgs (FAO, 2011, Sheahan and Barrett, 2017). In Eastern and Southern Africa alone, food losses are valued at $1.6 billion per year, which is nearly 13.5% of the total value of grain production (Abass *et al.*, 2014, World Bank, 2011). This evidence indicates that postharvest loss is a threat to the food and nutrition security and welfare of rural households.

Causes of Postharvest Losses in Sub-Saharan Africa

Employment of Improper Harvesting Methods: Majority of farmers in Sub-Saharan Africa are not exposed to proper and adequate education on advanced agricultural processes and tools. These therefore exposes them to the use of improper harvesting methods.

Lack of Access to Effective Storage Facilities: Many storage facilities in SSA are in poor condition, contaminated or infested with pests such as the larger grain borer, *Prostephanus truncatus* (Horn) or their capacity is inadequate to meet local production. This significantly contributes to the rate of post-harvest loss in Sub-Saharan Africa.

Absence of Proper Packing and Packaging Technologies: Fresh products in Sub-Saharan Africa are majorly transported in unpackaged form or tied in bundles. They are usually placed directly in the trucks and stacked up together, with no cushion against impact and compression. All these greatly reduce the shelf life of such produce if not sold quickly, and thereby contributes to Post-harvest loss in Sub-Saharan Africa.

Lack of Efficient Transporting System: According to a report by Institute of Food Technologists (IFT) wastage begins the moment growers leave their farms because their means for transporting crops are crude. This is frequent especially during the initial steps for getting them across the countryside to the locations where they can be staged for urban markets, all of which contributes to waste.

Unstable Climate Conditions: Climate factors, such as heat, humidity, and altitude, substantially increase post-harvest loss in Sub-Saharan Africa, as Africa is most vulnerable to climate change and its impacts. This contributes to postharvest loss (PHL) at all stages in the food supply chain from the moment of harvesting, to handling, storage, processing and marketing, as well as outside of the chain. Urgent and efficient climate actions are required to improve climate conditions and its impacts.

Strategies for postharvest management for food security

A systematic analysis of each commodity production and handling system is the logical first step in identifying an appropriate strategy for reducing postharvest losses. Also, a cost-benefit analysis to determine the return on investment in the recommended postharvest technologies is essential. It is important to select the technologies that are appropriate for the size of each postharvest enterprise. Marketing companies and cooperatives are essential for handling produce and reducing postharvest losses by providing facilities for accumulating, preparing and transporting produce to markets; by coordinating marketing activities; and by distributing profits equitably to members. Indicated an evolution of priorities within the postharvest sector of developing countries from a primarily technical focus geared towards the reduction of losses, to a more holistic approach designed to link on-farm activities to processing, marketing, and distribution. However, the major constraints continue to be high postharvest losses, poor marketing systems, weak research and development capacity, and inadequacies in policies, infrastructure, and information exchange.

Opportunities in Postharvest Management of Produce

Broad changes in Africa's food markets and value chains point to areas where new ways of operating can reduce food loss and waste.

• *Changing market demand*: Agricultural demand is rising in Africa, fueled by rapid urbanization and the growth of the region's middle class. Increasingly more prosperous and urban consumers are purchasing fruits and vegetables and processed and packaged foods. The production, processing, packaging, and distribution of these crops creates new income opportunities for smallholder farmers and rural people in general and particularly women. Fruit and vegetable production are also characterized by high losses and has high natural-resource intensity.

• *Sustainable local sourcing:* Many large corporations are seeking to make their supply chains more efficient by identifying cost-effective, reliable sources of local supply. Multinational supermarket chains as well as African local and regional entities are increasingly sourcing directly from local smallholders to meet domestic and export retail-related needs.

• *Smallholder participation in value chains:* Local sourcing activities represent an unprecedented opportunity to link farmers to more reliable and consolidated large-scale markets, as well as local ones. These links could generate market infrastructure within which postharvest loss could be more effectively addressed.

• *Loss-reducing technologies:* Many technologies for reducing food loss exist, but they are vastly underutilized. Examples include hermetic bags, heavy molded-plastic containers, and mobile processing units. These innovations have a small unit cost and are suited to individual use. These can also be, easily scaled up to meet growing demand. More complex solutions, such as cold storage, cost more, are better suited to multiple users and are less commonly used but can have a systemic impact under the right conditions.

• *Rising public and private investment in African agriculture, including postharvest loss:* African governments are prioritizing agricultural sectors such as horticulture (Kenya) and value addition to staple food crops (Nigeria). Other public and private organizations, such as the United States Agency for International Development (USAID), the Swiss Agency for Development and Cooperation (SDC), the African Development Bank (ADB), the Food and Agriculture Organization (FAO), the World Food Programme (WFP), and the Gates Foundation, are investing or exploring investments in postharvest activities. Large multinational companies have adopted sustainability goals linked to reducing food loss and waste.

CONCLUSION

Access to safe food remains a critical issue in Sub-Saharan Africa as a result of postharvest losses, which is projected to exacerbate as the Sub-Saharan African population is predicted to double by 2050. Despite the improvement in food production, post-harvest loss in the Sub-Saharan Africa remains an hindrance in the promotion of food security Postharvest technologies can contribute to food security in multiple ways. They can reduce PHL, thereby increasing the amount of food available for consumption by farmers and poor rural and urban consumers. Food availability and accessibility can be increased by increasing production, improving distribution, and reducing the losses. Thus, reduction of post-harvest food losses is a critical component of ensuring future global food security. Generally, significant role food loss reductions could have toward sustainably contributing to global food security.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Transportation is a significant variable input in agricultural development all over the world because it is the only way to get produce and products from farm to market and vice versa. This study was conducted to evaluate the effects of transportation system on income of maize and cassava marketers in Oluyole Local Government Area of Oyo state, Nigeria. The data was collected via interview guide from 150 traders of maize and cassava who were selected through multistage sampling procedure. Descriptive (means and percentages) and inferential (regression) statistics were applied to the data collected. The study reveals that both maize and cassava traders were in their active age with mean age of 49 years. Majority of the traders were educated and married with family size of between 6 and 10 persons. The most popular modes of transportation in the study area were lorries, vans, taxis, and motorcycles. The regression analysis demonstrated that fuel shortages, transportation costs, mode of measurement, and low traffic volume were all significant at various levels and had a significant effect on traders' income. The biggest challenges for traders are fuel scarcity, insufficient vehicles, limited traffic volume, and expensive transportation costs. As a result, governments at all levels should support traders by finding solutions to fuel scarcity to facilitate the transportation of maize and cassava in the research study area.
Keywords: *Effect, Transportation, Maize, Cassava and Trader*

INTRODUCTION
Transport is regarded as an important factor involved in agricultural development all over the world. It is the only means by which food produced at farm site is moved to different homes as well as markets (Tunde, 2018). Transport creates market for agricultural produce, enhances interaction among geographical and economic regions and opens new areas to economic focus. There are complex relationships that vary both spatially and over time between transport and development. However, for any development to take place, transport plays a crucial role. Ogunsanya (2020) observed that there are three types of routes in the rural areas viz; bush paths, unsurfaced rural roads and surfaced rural roads. However, the bush path is very common but the least developed of all the routes. Bush paths link villages with farmsteads and they are usually narrow, winding and sometimes overgrown by weeds especially during the rainy season. In a study carried out by Filani (2019) in rural areas of Nigeria, it was discovered that where motorable roads exist they are mostly of unpaved surface, narrow width, circuitous alignment and with low quality bridges. In most cases, they are either clad with potholes or characterised by depressions and sagging. Such unsurfaced roads are hardly passable during the rainy season when vehicles get stuck in mud or when the improvised bridges of cut-tree trunks get swept away by flood. In another study carried out by Ogunsanya (2021) on relationship between transportation, underdevelopment, and rurality, he observed that the greater the degree of rurality, the lower the level of transport development. Aderamo and Magaji (2010) noted that transportation constitutes the main avenue through which different parts of the society are linked together. Paul *et al.*, (2009) pointed out that the impacts of road infrastructure on agricultural output and productivity are particularly important in Sub-Saharan Africa for three reasons: first, the agricultural sector accounts for a large share of Gross Domestic Product (GDP) in most Sub-Saharan countries (Paul *et al.*, 2009). Second, poverty is concentrated in rural areas; finally, the relatively low levels of road infrastructure and long average travel time's result in high transaction costs for sales of agricultural inputs and outputs, and this limits agricultural productivity and growth. According to Mabogunje (2019), some of the variables that determine the level of development in an environment are easy accessibility and mobility. This study investigated the following objectives: described the socio-economic characteristics of the farm-produce traders; identified the different

modes of transportation of farm-produce; examined the effects of transportation cost of maize and cassava produce on traders' income and identified the constraints faced by maize and cassava produce traders during transportation.

METHODOLOGY

The study was conducted in Oluyole Local Government Area (LGA) of Oyo state, Nigeria. The LGA is made up of 10 political wards divided into two sectors - Idi Ayunre sector and Olode sector. The Olode sector Comprises of ward 1 (Ayegun), ward 3 (Pegba/Egbeda tuba), ward 4 (Muslims/Ifelodun), ward 6 (Latunde) and ward 7 (Olomi/ Olunde). The major activities of the inhabitants is farming and trading. Oluyole Local Government produces virtually all farm produces such as pepper, tomato, maize, cassava, cocoa, cashew, banana, among others.

The population of the study comprised traders of arable crops in Oluyole Local Government Area of Oyo State. One hundred and fifty (150) traders were selected using multi-stage sampling technique. Data were collected using interview guide (structured questionnaire) and analysed using descriptive statistics (frequency, means, and percentages) and inferential statistics (regression analysis).

RESULTS AND DISCUSSION

Table 1 showed the socioeconomic characteristics of the respondents, average age of the respondents in the study area was 49 years and about 41% of the respondents were within their active working ages. Above average (63%) of the respondents were males. Majority (81%) of the respondents were married. It further showed that 42% of the respondents were Christian, 53.33% of the respondents were Muslim. It also showed that majority (90%) of the respondents were literates. It further revealed that 77% have household size of 6-10 members and this was the highest household size. However, all (100%) of the respondents engaged in trading.

Modes of Transportation

Table 2 shows the frequency and percentage of farm-to-farm means of transportation of the respondents. Majority (90%) of the respondents used Lorries as a means of transportation from to farm while 69% of maize and cassava traders in the study area used taxis. This implies that taxis the common mode of transporting maize and cassava from farm to farmstead. It revealed that 32.67% of the respondents used Lorries for transportation from farmstead to village, 52.67% of the respondent used taxis from farmstead to village also 64.00% of the respondents used taxi from village to village. Lorries and taxi were used from village to town transportation at the rate of 45.33% and 49.33% respectively. It further showed 66.00% of the respondents used Lorries as a means of transportation from village to headquarter.

Table 2: Distribution of respondents on different transportation modes in the Study Area.

Types of Trips	Lorry F (%)	Van F (%)	Taxis F (%)	Motorcycle F (%)	Bicycle F (%)	Head porter age F (%)
Farm to farm	135(90.00)	5 (3.33)	6 (4.00)	4 (2.67)	0	0
Farm to farmstead	11 (7.33)	9 (6.00)	103(68.67)	23(15.34)	2(1.33)	2(1.33)

Transportation cost	2.781495	1.492473	1.86	0.064***	
Fuel scarcity	77887.17	15530.21	5.02	0.000*	

Effects of Transportation on Traders Income

The result in table three showed the effect of transport-related variables on traders' income in the study area. The prob>F=0.0000 implies that the linear regression has a good fit for the linear regression. The significant variables for maize include low traffic volume (5%), fuel scarcity (1%) and transportation cost (1%). The significant variables for cassava include modes of measurement (1%), transportation cost (10%) and fuel scarcity (1%). A positive sign on a parameter indicates that the higher the value on the variable the higher the traders' income, similarly, a negative value of the coefficient implies that the higher the value of the variable the lower the merchant income.

Transportation cost was significant at 10% and positively related to merchant income, and the coefficient variable of fuel scarcity for cassava was significant at 1% and positively related to merchant income.

Constraint faced by the respondents during transportation of farm produce.

Table 4 revealed that maize and cassava traders were faced with problems of fuel scarcity in transporting farm produce as it ranked 1st. Insufficient vehicle ranked 2nd among the constraints faced by the traders in the study area. Similarly, low traffic volume, high cost of transportation, and bad road were ranked 3rd, 4th, and 5th respectively.

Table 4: Constraints Faced by the Respondents in Course of Transporting Farm Produce

Constraints	Strongly disagreed. F (%)	Disagreed F (%)	Undecided F (%)	Agreed F (%)	Strongly agreed F (%)	Rank
Bad roads	1(0.67)	0	0	2 (1.33)	147 (98.00)	5th
Insufficient vehicle	1(0.67)	19 (12.67)	2 (1.33)	118 (78.67)	10 (6.66)	2nd
High cost of transport	0	2 (1.33)	1 (0.67)	108 (72.00)	39 (26.00)	4th

Multiple responses.

CONCLUSION

The study reveals that both maize and cassava traders were in their active age with mean age 49. Majority of the merchants were married with medium family size of between 6 and 10 persons and they were also educated. The enterprise is not religiously biased because both Muslims and Christians were much involved with 19 as mean years of experience. The merchants were making use of lorry, vans, taxi and motorcycle as means of transportation, but bicycle and head portage were no longer in folk in the study area. The regression test showed that fuel scarcity, transportation cost, mode of measurement and low traffic volume were all significant at various levels and had serious effect on traders' income. The major constraints facing the merchants are fuel scarcity, insufficient vehicle, low traffic volume and high cost of transportation. Based on the above conclusions, it is therefore recommended that governments at all levels should assist the merchants by finding solution to scarcity of fuel and procure more vehicles to easy transportation of maize and cassava in the study area.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

A research on pest infestation of stored smoked dried fish was conducted to investigate the different types of pests causing damage to stored smoked dried fish and their levels of destruction. In Nigeria, fish is consumed fresh or processed (dried). Dried fish is one of the highly digestible and respectable sources of proteins and essential minerals but it is highly susceptible to insect pest infestation. Published papers on pest infestation of smoked dried fish, types of pests, economic importance of pests, microbial contamination and methods of controlling pests on smoked dried fish were reviewed. Pests commonly found on smoked dried stored fish are: flesh flies (Sarcophagidae), beetles (Dermestes, Cornestes, and Necrobia spp.), and mites (Lardoglyphus spp.). Feeding by larvae and adults of N. rufipes causes quantitative loss of dried cured fish, and also leads to fragmentation and to quality losses due to contamination by insect bodies. Dermestes spp accounts for about 71.5% of dried fish infestation recorded in most of the producing areas with a substantial loss in dry weights of about 43-62.7% from both larvae and adu1ts.). At 6weeks of storage, adult Necrobia spp infested 31% of stored smoked Tilapia spp and 80% of Synodontis spp. Infestation of dried smoked fish by insects and mites may cause public health hazard as they are transmitters of diseases causing pathogens to man that my lead to intestinal disorders and allergies. Pests also causes economic losses to fish mongers and are a threat to them reducing the nutritional, and economic values of the product, therefore the need for this review. It is recommended that fish be salted and dried properly to minimize infestation by pests in order to lengthen its shelf life. Also, fish processors should be educated by extension workers on personal hygiene while handling fish as a measure of reducing contamination with blow flies and other micro-organisms.

Keywords: *Pest, Infestation, Stored, dried and Fish.*

INTRODUCTION

Fish provides an excellent source of protein in the diet of many families in tropical Africa. Of all the animal protein foods produced and consumed in Nigeria, fish is of prime importance as it has remained a major source of protein which is rich in essential-amino acids for both rural and urban poor households. The fish is rich in protein, which is very essential for the health of the body and it account for about 40 percent of the total animal protein of an average person in the tropics (Olatunde, 2003; Reed *et al.*, 2009). Fish is rich in fats, and the following minerals: phosphorus, sulphur, potassium, iron, calcium and copper. Fish fat is characterized by high poly-unsaturated fatty acids, which provides diet low in cholesterol. Its oil has high quantities of vitamin especially vitamin A, B and D, thiamin, riboflavin, nicotinic acid and vitamin B12. Fish contains less than 1% fat and about 10% protein with energy value ranging from 220 – 330 Kilojoules (50 – 80 Kcal/100g) of fish. In Nigeria, fish is consumed fresh or processed (dried) (Horn, 1974).

Dried fish is a highly favoured item of many traditional dishes in Nigeria because of its high proteinous content which is more than fresh fish and other animal proteins like egg, meat and milk. Dried fish is often a good alternative to fresh fish which is readily available in many inland communities because of improved transportation, preservation methods along with growth in inland aquaculture (Eke *et al.,* 2008).

Drying is one of the most popular means of preserving and storing fish. However, drying of fish does not guarantee the ends to the problems of preservation, storage and distribution of fish. Dried fish can suffer considerable loss of weight due to feeding damages caused by insects and mites. Under adverse condition quantitative losses of up to 30 % due to fly damage during processing and up to 50% due to beetle damage during storage have been reported (FAO, 1989).

Some factors responsible for this spoilage or damage includes high temperature, chemical action, enzymes and bacteria (Ojutiku *et al.,* 2009; Oparaku and Mgbenka, 2012). Processing and preservation methods slow down fish spoilage, preserve its quality and also extend fish shelf life (Okonta and Ekelemu, 2005). Several processing and preservation methods have been considered and used to prevent fish from spoilage, including: salting, sun drying, solar drying, smoke drying and canning (Ugwu *et al.,* 2005). The most common method of fish preservation employed in the tropics is smoking; it increases fish shelf life, gives the product a desirable taste and odour, it also provides antibacterial and oxidative effects, lowers pH, imparts colouration as well as accelerates the drying process and acts as an antagonist to spoilage agents (Akintola *et al.,* 2013).

Stored product insects are known in different agricu1tural products including smoked fish products). It was noticed that good storage practices are not observed by most fish-sellers of smoked and smoke-dried fishes such as improper ventilation and easy access of pest into the storage environment (Sani et al., 2016) A number of authors (Nowsad *et al.,* 2009; Babarinde *et al.,* 2012; Lithi *et al.,* 2012; Onyuka and Ofulla, 2013; Zakka et al., 2013) had reported the menace of insect pest infestation on stored smoked fish. Awoyemi (1991) examined the storability of different fish species over a period of 60 days and observed that they were reduced to mere Fras and bones by *Dermestes macu1atus*. The genus *Dermestes* are known for their infestation of dried fish causing qualitative and quantitative damage. The need to protect smoked fish from pests is imperative when the fact that fish plays the crucial role in ensuring food security, income generation and employment opportunities are considered. The large dependence on imported fish can adversely affect the economy (mostly foreign reserves) of some developing countries.

A number of insects infest processed fish but the most important fall into two groups the blowflies and beetles. Insect flies and beetles destroy vast quantity of fish in developing countries while it is being processed or stored (Johnson and Esser, 2005). Insect infestation of cured fish by blowflies and hide beetles is an important cause of post- harvest fish losses in many developing countries like Nigeria. Fish are susceptible to attack by insect pests throughout processing and storage (Reed, 1997). Under prevailing conditions, it is estimated that between 25% and 75% of the nutritional value of fish is lost during attack by insect pests, (Johnson and Esser, 2005). Dried fishery products frequently suffer severe losses due to infestation by flesh flies (*Sarcophagidae),* beetles (*Dermestes*, *Cornestes*, and *Necrobia spp*.), and mites (*Lardoglyphus* and *Lyrophagus s*pp.) (Venugopal *et al*., 1999). These infestations are heavy in dried products containing 7–21% salt and stored under tropical conditions, at 20–32◦C and air humidity of 73–87%. Based on a conservative estimate, the loss represents about 2.75 mt of dry fish for a year in all over the world (Gopakumar and Devadasan., 1982., Wood., 1982) large quantity of dried fish is lost in India due to infestation by earwig, hide beetles, and copra beetles. The most destructive pest is the hide beetle*; Dermestes maculatus*. Infestation of sun-dried fish by the blowfly and beetle larvae caused up to 30 percent loss of the products (Bala and Mondol., 2001; Nowsad., 2005). Dried fish contaminated by both insects and harmful insecticides comprises about 80 percent of the total dried products that is considered unfit for human consumption. The losses have been attributed to net reductions in the amount of nutrients available to the consumer (nutritive quality) resulting to declining consumer acceptability and market prices (economic losses) or both quantitative and qualitative losses (Odeyemi*., et al.,* 2000., Atijegbe., 2004). This study is aimed at investigating the different types of pests causing damage to smoked dried fish and their levels of destruction.

Economic importance of pests

Losses caused by insect infestation are enormous. They include physical loss, whereby the fish available for human consumption is reduced, economical loss where by the physical loss depletes the quantity of fish available for sale, and nutritional loss which is the direct consequences of the physical and economic losses and cause the retail value of fish to increase beyond the purchasing power of the poor (Moses, 1992).

FAO (2019) also reported that insects infest smoked dried fish during storage and cause economic loss to fish mongers and loss in the qualitative and quantitative composition of the fish. Infestation of dried fish by insects and mites may cause public health hazard as they are transmitters of diseases causing pathogens to man that may lead to intestinal disorders and allergies (Busvine, 1980; Osuji, 1985). Furthermore, flies which often perch on dried fish have been implicated as vectors of pathogens causing severe enteric disorders such as dysentery, cholera e t c (Busvine, 1980). Insect pests invade the fish at different stages of processing and storage thereby destroying it (Johnson and Esser, 2005), adult *Dermestes* and *Necrobia* can fly and are thus easily dispersed to new sources of food where they cause food damage, and their infestation also predisposes the infested fish to microbial attack (Adedire and Lajide, 2000).

Types of pests and their levels of destruction

The pests commonly found on dried fish are flesh flies (*Sarcophagidae*), beetles (*Dermestes, Cornestes*, and *Necrobia* spp.), and mites (*Lardoglyphus* and *Lyrophagus spp*.) (Harines., 1989).

Necrobia rufipes: is a beetle of the family *Cleridae* and is the commonest species of *Necrobia* found on cured fish. Two related species, *N. ruficollis* and *N violacea*, are only rarely found on this commodity (Harines., 1989). Feeding by larvae and adults of *N rufipes* causes quantitative loss of dried cured fish, and also leads to fragmentation and to quality losses due to contamination by insect bodies and cast skins. The extent and value of losses due to *N rufipes* infesting dried fish have not been assessed either in the laboratory or the field, but they will of course be directly related to the length of storage of the fish. When associated with *Dermestes* infestations, *N rufipes* is usually in the minority but its contribution to the total beetle damage may be significant (Harines., 1989). At 6weeks of storage, adult Necrobia spp infested 31% of stored smoked Tilapia spp and 80% ofSynodontis spp. (Wahedi and Kefas, 2013). Eyo (2001) reported that long storage periods allow insects more time to breed and consume stored fish, thus leading to ever increasing infestation.

***Dermestes* Species:** belong to the beetle family *Dermestidae*. Several species have been recorded infesting dried fish*: D. maculatus, D. frischii, D. carnivorus Fabr, D. lardarius, D. haemorrhoidalis*, and *D. peruvianus* . Feeding by the larvae and adults of *Dermestes* spp. Causes considerable quantitative loss of dried cured fish, and also leads to fragmentation. (Harines., 1989). According to Uneke (2015) the well-developed mouth parts of adult *D. maculatus* gives them a more destructive tendency than the larvae. The extent and value of quantitative losses caused to dried fish by *Dermestes* spp. have been assessed by various investigators, and estimates range from negligible up to 50% weight loss, depending on length of storage, salt content, moisture content, climatic conditions, and general hygiene during processing and storage. *Dermestes spp* accounts for about 71.5% of dried fish infestation recorded in most of the producing areas with a substantial loss in dry weights of about 43-62.7% from both larvae and adu1ts (Babarinde *et al*., 2012).

***Lardoglyphus Species*:** belong to the family *Acaridae* in the mite group Astigmata. Three species have been found infesting cured fish: *L. konoi*, *L. zacheri and L. angelinae*. Feeding by the adults and nymphs of *Lardoglyphus* spp. will cause quantitative loss of dried cured fish. Quality loss may result from the contamination by live and dead bodies, which can be very numerous. The extent and value of losses caused to dried fish by *Lardoglyphus* spp. have not been assessed in either the laboratory or the field (Harines, 1989).

***Diptera*:** Most flies found on cured fish belong to the subfamilies *Calliphorinae* and *Sarcophaginae* in the family *Calliphoridae.* The commonest of these are various species of *Chrysomia*, but *Calliphora, Lucilia, Sarcophaga* and *Wohlfartia* have also been reported (Harines, 1989). Other families represented in records of flies infesting cured fish are: *Muscidae, Piophilidae, Milichidae, Phoridae* and *Ephydridae*. All these flies are rather similar in general form, though they show a variety of size and coloration, and their identification requires specialist knowledge (Harines, 1989). The feeding of the larvae of *Calliphoridae* on moist fish causes quantitative losses. These losses can be severe if conditions are optimal for fly development: under such conditions, i.e., if unsalted or poorly salted fish is dried slowly because of rain or high humidity, weight losses of 10-30% can be caused by fly larvae. Fragmentation of the fish by fly attack can cause quality loss and may lead to increased risk of damage by beetles and mites. Substantial weight losses due to fragmentation of fish during processing have been recorded, but the contribution of blowfly damage to this has not been separately assessed. Additional costs are implicated in the role of flies as the agents of myiasis and as carriers of pathogens (Harines, 1989).

Microbial contamination

Smoked dried fish are often contamination with microorganisms such as fungi, bacteria, yeast and moulds (Sani, et al., 2016). Saprolegnia is the most important fungal contaminant of fish, although a number of other species have been implicated (Sani, *et al*., 2016). Martin (2008) stated that bacteria (*Staphylococcus aureus*),yeasts (*Saccharomyces cerevisiae*) and moulds (*Penicillium* and *Aspergillus*) are the commonest microorganisms associated with smoked dried fish.

Pathogenic fungi that contaminate fish during processing can also cause considerable hazard to consumer health (Yijia *et al*., 2020). Banwart (2004) also observed that most of the post processing microbial contaminants originate from poor handling practices, while some could be from the air, the source of the fish, or from other degrading substances (Ayuba, *et al*., 2013).

Control of pests

Because of the obvious food, economic and health implications of beetles in smoked fish, several attempts have been made to control them. The major pests on smoked catfish, *Clarias gariepinus* include *Dermestes maculatus* (hide beetle) and *Necrobia rufipes* (copra beetle) which could be controlled by synthesized chemicals. However, there have been Increasing and concerted efforts directed at developing natural pest management control agents that are relatively cheap, safe, biodegradable and environment friendly as alternatives to synthesized insecticides (Mabawonku and Ajayi, 2007).

Development of *Dermestes maculatus* is not possible at 40^0C or above, because, temperature above 40^0C can kill or repel all these beetles. Such temperature can disinfect fish or delay invasion by *Dermestes maculatus* as long as it is achieved throughout the batch. If some of the fish remains at normal temperatures, the beetle will migrate.

Well-dried fish reduces the rate of *Dermestes* population growth. Salting of fish gives protection against *Dermestes maculates*, partly because larval development is prolonged and larval mortality increases with increase in salt content. In experiments at 30^0c, larval development took 37 days on fish with 3.5% salt content compared with 211 /2 days on unsalted fish and mortality reached 100% when the salt content was increased to 9.2% by brining for 11 /2h (Osuji, 1975). This susceptibility to salt may explain the less frequent occurrence of *Dermestes maculatus* in cured marine fish, as salt is more commonly used in marine fish processing. Ashamo and Ajayi (2003) recommended the use of paper cartons and aluminium foils as good packaging materials but the authors noted that any tiny hole in the plastic or foil through which a flow of air can pass will nullify its effectiveness, as insects can pass in and be sustained on the stored fish. Cold treatment or freezing of dried fish at $6\text{-}12^{oc}$ can kill all developmental stages of insects (Boeke *et al.,* 2001) but unreliable electricity supply or lack of the purchasing power makes the use of refrigerator undependable in poor resource-based communities. In addition, mouldiness, rancidity and texture sponginess of such frozen fish have been reported (Ashamo and Ajayi, 2003). The use of contact insecticides is extremely effective against insect infestation, but it is only justified under approved and controlled conditions.

Insecticides are highly toxic and many are dangerous. Only a few are safe to use on foods. One of safe substance is pirimiphos methyl and this has been approved internationally for use on fish. It is extremely effective in controlling blowfly attack during fish drying. When used under specified conditions, it leaves no harmful residues. Pirimiphos methyl is also effective in controlling beetle infection during storage (Khan and Khan, 2002). The uses of plant materials for insect pest control have been reported to be important materials for the control of smoked fish pests. Among the plant materials reported include; Citrus peel oil (Donpedro, 1985), Eugenia aromatica (Akinwumi *et al*., 2006), *Piper guineense, Monodora myristica* and *Tinolia diversipolia* (Fasakin, 2003). Plant-derived materials are more readily biodegradable, less toxic to mammals, retard the development of resistance, easy and cheap to produce by farmers and small-scale industries as crude, or partially purified extracts. It was reported that when dried fish was mixed with leaf bark, seed powder, or oil extracts of selected plants, there was mortality of beetles, reduced oviposition rate, suppression of adult emergence and reduced fish damage rate (Okorie *et al*., 1990; Adedire and Lajide, 2000; Okonkwo and Okoye, 2001; Fasakin and Aberejo, 2002; Anyaele and Amusan, 2003

SUMMARY/RECOMMENDATIONS

Pests that commonly infest smoked dried fish on storage are: beetles (*Dermestes, Cornetes* and *Necrobia* spp.); mites (*Lardophagus spp* and *Lyrophagus spp*) and *Diptera* (flies). These pests cause quantitative loss of dried cured fish and also leads to fragmentation and to quality losses due to contamination by insect bodies, they also cause physical loss where by the fish available for human consumption is reduced, economical loss where the physical loss depletes the quantity of fish available for sale, and nutritional loss which is the direct consequences of the physical and economic losses and cause the retail value of fish to increase beyond the purchasing power of the poor. It is recommended that fish be salted and dried properly to minimize infestation by pests in order to lengthen its shelf life and fish processors be educated by extension workers on personal hygiene while handling fish as a measure of reducing contamination with blow flies.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study analyzed the performance of the cassava producers and processors in Abia State, Nigeria. A multi-stage random sampling procedure was used to select 120 cassava producers and 120 cassava processors making it 240 respondents. Primary data was collected with the use of a structured questionnaire. Data collected were analyzed with descriptive statistics such as frequency, percentage and table, and also cost and returns model. Results showed that the majority of the cassava producers (53%) and (51%) of cassava processors were males. The cost and returns result shows that variable costs accounted for a very large proportion 96% of the total cost of cassava production and 99% for cassava processors. The study therefore, recommends that farmers especially women should be encouraged to grow and process cassava to improve on their livelihood and standard of living as their incomes would have increased. They should also be encouraged to form more cooperatives in order to enjoy credit facilities, increase their performance in cassava production and make high profit in the cassava business.
Keywords: *Performance analysis, cassava producers, processors*

INTRODUCTION
Agriculture provides a living for approximately 70% of Sub-Saharan Africa's rural poor (Moono, 2015). According to Adeoti *et al.* (2014), agricultural expansion is twice as effective as other sectors in reducing poverty. However, primary producers cannot add value to their products due to socioeconomic, environmental, and technological constraints. As a result, low manufacturing efficiency and product diversification has been limited. Furthermore, farmers' insufficient capital development may have hampered farm and household revenues. Cassava production and marketing are difficult for smallholder farmers. This could help smallholder farmers overcome obstacles along the cassava value chain. According to Achem *et al.* (2013) and Abu *et al.* (2014), cassava root processing and value addition are required to extend shelf life (rots within 3-4 days of harvest), improve nutritional content (low in other nutrients, particularly proteins), and convert cassava root into other goods (FAO, 2005). Despite farmers' difficulties in reaching markets, few studies on analyzing the performance of cassava producers and processors in Nigeria have been conducted. Therefore, the specific objectives of the study were to describe the socio-economic characteristics of cassava producers and processors in the study area; to determine the performance of the producers and processors regarding their cost and returns in Abia State.

METHODOLOGY
This study was carried out in Abia State. Latitudes 4°, 41', and 6°, 14' north of the Equator, and Longitudes 7°, 10', and 8° east of the Greenwich median, roughly define the state. This study's population included all cassava producers and processor for market. The respondents for the study were chosen using a multi-stage sampling technique. First, one local government area from each of the three agricultural zones was chosen. Four autonomous communities were chosen from each of these local government areas giving twelve communities. Two villages were chosen from each selected communities, and his takes it to 24 villages. Ten cassava farmers producing for market and ten cassava farmers processing for market were chosen from these villages, resulting in a total of 120 producers and 120 processors. As a result, 240 respondents were used in the study. The primary data were collected directly from the field survey using structured questionnaires. In the data analyses, simple descriptive statistics such as tables, means, frequencies and percentages were used to achieve objective , while cost and returns model was used to analyzed objectives 1 and 2. The cost and returns model is given as:

$$NR = TR - TC \quad .... (1)$$

Where:

NR = Net Returns (₦)
TR = Total Revenue (returns) from the cassava enterprise
TC= Total Costs (₦)
N/B: TC = TVC + TFC
TVC = Total Variable Cost; TFC = Total Fixed Cost
N/B: Equation 1 was analyzed for both cassava producer and processors.

RESULTS AND DISCUSSION

Socio-economic characteristics

The result in Table 1 showed that the majority of the cassava producers (53%) were males while processors had 51% males Generally, it can be deduced that cassava production and processing has little gender bias in the study area against the conventional idea that cassava-based activities are female-dominated (Awerije, 2014 and Amadi *et al*., 2018). The result showed that the majority (47% and 61%) of the cassava producers and processors, respectively, were 41–50 years. The mean age of 46 and 47 years for the cassava producers and processors implies that the respondents are still young, energetic, and in their active years. The result showed that majority (60% and 58%) of the cassava producers and processors respectively had about 4 – 6 persons in their households. This implies that the marketable surplus is obtained with small family sizes, which is not possible in large family sizes where most of what is produced is consumed. The result also showed that 50% and 73% of the cassava producers and processors, respectively, had secondary education. This finding is consistent with Ajok (2016). In addition, the result revealed that 50% and 73% of the cassava producers and processors, respectively, had secondary education. A mean of 12 and 14 years for producers and processors suggest that processors received higher education than producers. Using some machines for processing may require a higher level for their operations (Oni, 2016). The results also indicated that participation in cooperative activities was minimal for both cassava producers (11%) and processors (12%). Cooperatives are very important as they serve as catalysts for several benefits. The computed results also showed that more producers (58%) had access to market information than processors (38%). This is not expected because the producers are only limited to the sales of tubers which in most cases are done at farm gate level, unlike the processors who have a variety of products to sale.

Table 1: Some selected socio-economic characteristics of respondents

	Cassava producers		Cassava processors

Performance analysis of the cassava producers

The entries in Table 2 shows that cuttings accounted for about 42.4% of the total cost of production of cassava in the study area, followed by fertilizer (34.3%) while labour (8.4%) was the least. It is well known that cassava production is labour intensive. However, the lower cost incurred from labour may be related to the utilization of household members in farm activities, while hired labour was for augmenting the family labour. In general, variable costs accounted for a very large proportion (96%) of the total cost of cassava production. Fertilizer utilization in the area of study is generally high, either because of the importance of fertilizer in increasing yield or due to the poor nature of the soils because of continuous use. Agrochemical use is moderate, probably because of the disease resistant nature of the varieties planted.

Table 2a: Performance analysis of the cassava producers

Cost items	Amount (₦)	Percentage
Variable costs		
Stem (₦)	61381.67	42.4
Fertilizer (₦)	49716.67	34.3
Agrochemicals (₦)	15350.27	11.0
Labour (₦)	12206.46	8.4
Total variable cost (TVC)	**138655.28**	**96.0**

Performance analysis of the cassava processors

The result on the cost and returns in processing as reflected in Table 2b showed that roots accounted for about 59% of the total cost of processing. In a similar study conducted by Achem *et al*. (2013), the authors noted that cassava root cost took the largest percentage of the total processing cost. Labour costs about 16% of the total processing cost. The second key element that needed huge investment in cassava processing, as noted by Ajok, 2016 was the element of labour. Costs comprising the labor component are one of the most important contributors to the total production costs in cassava processing. Depreciation cost was only 1% of the total processing cost. This implied that although cassava processing needs huge capital investment in the processing equipment at the initiation of the enterprise, however, once established, processors normally operate at optimum level hence enjoying the economies of scale. The economies of scale enable processors to enjoy better prices (Saediman *et al*., 2015 and Ajok, 2016).

Table 2b: Performance analysis of the cassava processors

Cost items	Amount (₦)	Percentage
Variable costs		
Roots (₦)	209910.5	59
Bags (₦)	6036.67	2
Labour (₦)	58120	16
Firewood (₦)	42226	12
Transportation (₦)	35595.83	10
Total variable cost (TVC)	351,889	99
Depreciation (₦) **(TFC)**	2973.33	1
Total cost, TC = TVC+TFC	**354,862.33**	
Quantity sold (kg) (Q)	18308.5	
Average price/kg (₦)	50

CONCLUSION

The study concluded that the majority of the cassava producers were males while the remaining were females indicating that males slightly dominate cassava production in the study area. The cost and returns result shows that variable costs accounted for a very large proportion 96% of the total cost of cassava production and 99% for cassava processors. The study therefore, recommends that farmers especially women should be encouraged to grow and process cassava to improve on their livelihood and standard of living as their incomes would have increased. They should also be encouraged to form more cooperatives in order to enjoy credit facilities, increase their performance in cassava production and make high profit in the cassava business.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Microbial infection of fruits and vegetables has been shown to impact on economic loss of perishable food crop. Tomato is an important part of a balanced diet. However they are prone to microbial attack responsible for their spoilage. Microbial species on tomato fruit samples obtained from Towobowo market was examined. Standard method of microbial analysis was used to analyze the sample for the presence of bacterial and fungal pathogens. The microbial analysis showed that Pseudomonas fluorescence, Aspergillus flavus and Geotrichum candidum species are associated with spoilage of sampled tomatoes. Inhibitory effect of the aqueous nem leaf extracts (4.0mg/ml, 6.0mg/ml, 8.0mg/ml and 10mg/ml) was observed. The efficacy test revealed that all the isolated pathogens showed maximum and minimum inhibition at 10mg/ml and 4.0mg/ml, respectively. This study confirms that, neem leaves extracts have inhibitory effect on isolated pathogens and has the potential of controlling spoilage causing agents.
Keywords: *Tomato, Microbes, Neem leaf, Concentration, Inhibition*

INTRODUCTION
The existence of microbes in plants and its economic impact did not start today and it poses challenges to post-harvest management in terms of direct and indirect loses in vegetable crops. Tomato is a fruit-bearing vegetable rich in vitamins and minerals that work as medicine in the body for healthy living. However, despite the various benefits of tomato to the body system, their contamination with microbial species could deteriorate their consumption which poses a serious menace to post-harvest management in less developed countries. Absence of appropriate post-harvest storage facilities in underdeveloped countries has contributed immensely to losses of fresh fruit and vegetables. A major challenge of post-harvest storage is diseases facilitated by high temperature and humidity. Tomatoes are identified as perishable farm commodity frequently attacked by field pathogens and surface contaminants. Post-harvest diseases such as dry rot, sour rot, green mold, rhizopus rot, soft rot are among the most important diseases affecting farm produce in developing countries and these are caused by pathogens such as *Fusarium* spp, *Geotrichum candidum, Penicillium digitatum* , *Rhizopus stolonifer* and *Pseudomonas*, respectively. Tremendous microbial post-harvest loss of fruit crops in Nigeria has been reported (Wokoma, 2008; Eni *et al*., 2010) to be between the range of 50 to 90%. They cause economic losses to farmers and sellers of such perishable produce and also health problems for the consumers. The exact negative impact of pathogens on harvested perishable crops includes suppression of their essential dietary nutrients.
Fresh fruits and vegetables sold in different markets are usually obtained from a common source and are predisposed to contamination as a result of poor cultural practices during cultivation by the farmers and after harvesting and poor hygiene level of the handler there by creating avenue for microbial contamination. In the open markets of developing countries, tomato fruits are often displayed in baskets and on benches for the prospective customers, thereby exposing them to opportunistic microbial infections especially mycotoxins (Baiyewu *et al*., 2007). These microbe producing toxins are capable of causing fungal diseases in crop and death for consumers (humans and animals).
Despite the fact that post harvest microbial deterioration of perishable crops is common in Nigeria, there is need to study their diversity in tomato fruits sourced from local markets and retailers. This study examined the post-

harvest species composition of tomato fruit sold in Igboora town, Oyo state in order to create public health awareness and provide useful data to guide in developing management in the study area.

MATERIALS AND METHODS

Collection of sample

Samples of tomato fruits used for this study were purchased from a popular Towobowo market located in Igboora, the headquarter of Ibarapa Central Local Government Area of Oyo State and the traders are made up of peasant farmers, middlemen and retailers from neighboring town and communities. The samples were collected and carried in separate sterile bags with distinct identification tag. The samples were transported to the Biology Laboratory of Oyo State College of Agriculture and Technology for microbial analysis.

Preparation of plant extract

One hundred grams (100g) of leaves (*Azadirachta indica*) at room temperature were powdered with mechanical grinder, macerated in 400ml of ethanol to soak the powdery leaves. The ethanol extraction was carried out according to the method described by Bimakr (2010) with slight modification.

Laboratory preparation of sample

A portion (100g) of each tomato was soaked in 10% normal saline for 24 hours to detach the microbial contaminants of tomato fruit. The solutions were serially diluted. A serial dilution of 1:10 from various dilution were spread out in duplicates on already prepared and solidified Nutrient agar and Sabouraud dextrose agar. Plate count was done on the media incubated at 37^{o}c for 24hours and 28-30^{o}c for 3-5days for bacterial and fungal isolates respectively.

Efficacy concentration tests

To determine the inhibitory effect of the plant extract on microbial infestation of tomato, a 0.1g of the extract was dissolved in distilled water to yield concentration of 10mg/ml, 8mg/ml, 6mg/ml and 4mg/ml. Each of these concentrations was tested against the isolates using agar well diffusion method as described by Babayi *et al*. (2007).

RESULT AND DISCUSSION

Infestation of fruit and vegetable with economic important species of microorganisms causing post-harvest spoilage has become a very important aspect in post-harvest management of perishable food crop. The microbial analysis in this study showed that bacterial and fungal species are associated with the spoilage of selected tomato fruit and this could be attributed to the infestation of the tomato during storage or at the point of purchase from the handlers. Table 1 gives the result of species composition of tomato fruit inducing spoilage microbes. The general observation of the result revealed that 2(66.7%) of the species isolated (*Aspergillus flavus* and *Geotrichum candidum)* were fungi.

Table 1. Species composition of tomato fruit inducing spoilage microbes in the study area

Pathogen	***Pseudomonas fluorescence***	***Aspergillus flavus***	***Geotrichum candidium***
Bacteria	2	-	-
Fungi	-	4	3

This observation corroborates the work of Ibrahim *et al*. (2011), Matthew (2011) and Wogu and Ofuase (2014) which showed that fungal species were more associated to tomato fruit spoilage than bacteria. Similar results was reported by Bello *et al*. (2016). It is important to note that *Aspergillus flavus* are agricultural soil fungus and opportunistic pathogens on crop which produces aflatoxins on infected crop which is harmful to human health. A non-pathogenic saprophytes bacteria isolate, *Pseudomonas fluorescence* is a useful tool in the biocontrol of pathogen causing post-harvest spoilage in crops. Such was reported by Girija and Manoj (2005). Fungal pathogens, *G. candidum*, a common soil borne fungus causing sour rot of tomato fruit is a wound pathogen that get easy chance to enter injured portion of the fruit. Table 2 shows that neem leaves extracts have inhibitory effect on post harvest pathogens. This may not be unconnected with a large number of bioactive constituents in neem.

Table 2. Efficacy of neem leaf aqueous extract at different concentration after 24 hours incubation

Concentration (mg/ml)	**Inhibition (mm)**		
	Pseudomonas fluorescens	***Aspergillus flavus***	***Geotrichum candidium***
40	23.0	24.0	23.5
60	31.5	29.5	25.5
80	32.1	34.5	32.5
100	43.5	36.5	38.3

Previous works have shown that a variety of natural plant extracts play an essential role in reducing the severity of plant diseases by acting either directly or indirectly to inhibit the growth and reproduction of fungal pathogens

(Zaker, 2016; Borges *et al*., 2018; Draz *et al*., 2019; Hassan *et al*., 2021). Another report indicates that plant extracts are effective against other plant pathogens (Elsharkawy and El-sawy, 2015). In this study, the efficacy of neem leaves extract tested at different concentration against identified post-harvest tomato isolates present differences in their inhibitory effect at common aqueous extract concentration of 10mg/ml and 4.0mg/ml on the pathogens. This may be as a result of active phytochemicals in the plant capable of suppressing spoilage causing microbes.

CONCLUSION

The outcome of this study implicated tomato fruits as carrier of species causing post harvest deterioration and the leaves of neem have the capacity to inhibit their growth.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This paper explores the crucial issue of post-harvest losses in the context of developing tropical nations, focusing on Nigeria as a case study. The study highlights the substantial losses that occur across various stages of the post-harvest chain, including harvesting, handling, storage, processing, transportation, and marketing. The impact of these losses on agricultural produce availability is particularly significant for perishable and arable crops like cassava, yam, and sweet potatoes. Estimates suggest that post-harvest losses in Nigeria can range from 35 to 45% of annual production for arable crops, fruits, and vegetables. The implications of these losses for food security are underscored, especially given the challenges faced by individuals in low-income developing countries. To address these issues, the paper emphasizes the urgent need for solutions that minimize post-harvest losses. This is vital for enhancing farmers' profits and ensuring a consistent year-round supply of essential food items. The recommendation put forth is for governments to play a role in facilitating private sector investment in food processing industries, particularly focusing on fruits and vegetables. Such investments can help curb post-harvest losses, foster economic growth, and ultimately strengthen food security. Overall, the paper highlights the importance of mitigating post-harvest losses as a fundamental step toward achieving food security in developing nations.
Keywords: *food supply chain, food waste, pre-harvest losses, post-harvest losses*

INTRODUCTION
While the current administration in Nigeria and some parts of Africa has shown strong support for agricultural development, it's noteworthy that only a mere 5% of investments in agricultural research in the past three decades have been directed toward addressing post-harvest losses (Kader and Roller, 2004; Kader, 2005). This apparent neglect can be attributed largely to a lack of awareness among various stakeholders in the food supply chain. Both buyers and farmers tend to view these losses as an inevitable cost of doing business without fully comprehending the extent of the problem. However, there is a growing realization in the food security community that these losses not only have significant economic repercussions but also jeopardize the long-term sustainability of value chains. According to FAO (2011), the pattern of post-harvest losses in agricultural products differs significantly between developing and developed nations. Developed countries experience fewer losses at the field level compared to developing nations and industrialized Asian countries. However, at the consumption level, developed nations waste a much larger portion of food (22%) compared to developing nations (<5%). In developing countries, pre-harvest losses are primarily due to substantial yield and livestock losses resulting from inadequate resilience and control over natural threats, such as biotic and abiotic stresses, which are characterized by fundamental agricultural inefficiencies and technological limitations. Post-harvest losses in developing countries are substantial due to insufficient storage facilities and frequent infestations by rodents, pests, and diseases. The availability of dry and cold storage facilities provides farmers and growers with increased market flexibility, such as not having to sell their produce immediately after harvesting, and offers economic benefits by reducing losses and enhancing overall produce quality.
The distribution of losses and waste along the food chain varies widely depending on the products and regions. In industrialized regions, significant losses occur early in the food supply chains. Technical, legal, fiscal, and organizational barriers in industrialized countries often hinder more efficient food utilization. For instance, stringent hygiene regulations within European regulations contribute to food waste in the catering industry due to overly cautious safety margins applied by companies (Waarst *et al*., 2011). In medium- and high-income

countries, food waste is prevalent at the consumption stage, where food is discarded even if it remains suitable for human consumption, particularly after cooking or on the plate.

Moreover, considering the limited availability of the world's natural resources, such as soil, water, fossil energy, and nutrients, there is a pressing need for more efficient and responsible resource utilization. In low-income countries, financial management and technical limitations in harvesting, storage, and processing techniques are often responsible for food losses and waste. Economically, these losses directly and negatively impact the incomes of both farmers and consumers. Food security remains a significant concern in much of the developing world, and while efforts to increase agricultural productivity are ongoing in Nigeria, it is evident that the solution extends beyond mere production expansion. Improving farm management practices to reduce post-harvest losses can significantly increase the available food supply by millions of tonnes annually, without the additional demands on labor, land, materials, resources, and biofuel expansion that increased production would entail.

Volume of post-harvest losses of roots and tubers

Globally, an alarming one-third of the food produced today is lost, wasted, or discarded due to inefficiencies in the human-managed food chain, amounting to approximately 1.3 billion tons annually (FAO, 2011). Additionally, studies by Tawose (2008) and Lundqvist *et al*. (2008) have suggested that 30 to 40% of the world's food crops go unconsumed due to various factors like damage, rotting, and pests and diseases that affect crops after harvesting. In Nigeria, the situation is dire, with an estimated excess of over 10 million tons of food grains lost annually due to spoilage and wastage, largely attributed to inadequate post-harvest management (FAO, 2011). Likewise, a study by FAO (2011) focused on animal production and post-harvest losses of roots and tubers in Nigeria, estimating an annual loss of approximately 86,229 metric tons of yams. These recurring losses can discourage farmers and undermine their efforts in food production, ultimately resulting in food shortages and contributing to malnutrition (Hodges *et al*., 2011; Bridget, 2013). Post-harvest losses of roots and tubers are particularly prevalent during small-scale root crop processing. This includes estimated losses during activities such as washing (0-5%), sorting (5-50%), slicing/dicing (5-10%), packaging (0-10%), and rejection (0-5%). Losses of 28% for cassava and 37% for yam, primarily due to damage during harvest have also been reported.

New challenges and strategies in addressing post-harvest losses

Challenges in reducing post harvest loss

Addressing post-harvest losses in developing countries like Nigeria presents a complex challenges, with various interconnected factors contributing to the problem. Key drivers of food loss include the absence of extension services to educate farmers on proper handling, packaging, and storage practices; inadequate post-harvest storage facilities and technologies, and limited market access. Past efforts have primarily focused on technology-based solutions, such as on-farm storage using hermetically sealed bags, solar-powered refrigeration for fruits and vegetables, and mobile grain drying systems. However, more recent approaches have shifted towards a broader market-based strategy to enhance the overall efficiency of the value chain.

Despite these efforts, several emerging issues and obstacles continue to impede progress in reducing food loss and these includes:

i. Insufficient awareness and knowledge about the causes of post-harvest loss and effective prevention techniques.
ii. Disrupted distribution channels for technologies aimed at reducing food loss.
iii. Limited technical expertise among smallholder farmers.
iv. Inadequate access to credit and financing for implementing loss-reducing measures.

To effectively address post-harvest losses and work towards achieving Sustainable Development Goals (SDGs) in Nigeria, there is a need for capacity development. It has been shown that approximately one-third of the country's food production never reaches its intended consumers. To combat this issue comprehensively, it is crucial to not only introduce appropriate technologies but also provide education, training, and support to farmers. While technology improvements are essential, they should not hinder immediate actions that can benefit smallholder farmers and society as a whole. Suitable technologies already exist, and their adoption by farmers can significantly reduce post-harvest losses.

Therefore, a vital aspect of reducing food losses involves educating farmers on improving post-harvest management. Drawing from successful practices implemented by organizations like the WFP in Uganda and Burkina Faso from 2012 to 2014; capacity development and skills training should focus on increasing farmers' awareness of critical biological and environmental factors throughout key stages of harvesting, drying and solarization, threshing, and on-farm storage. Furthermore, efforts should be made to facilitate government and financing agencies' on lending programs, promoting aggregation, appropriate packaging and storage, and facilitating connections with buyers. These initiatives can help alleviate some of the challenges associated with post-harvest losses.

Enhancing food security and economic empowerment

To effectively mitigate post-harvest losses and food wastage, a multifaceted approach is necessary. This approach should encompass raising consumer awareness, altering consumption habits, and reshaping incentives within the private sector's supply chain participants. It's important to recognize that strategies for reducing waste and losses will vary between developed and developing nations due to distinct root causes. Nevertheless, addressing waste and losses in both contexts is crucial for combating hunger and enhancing nutritional security in developing countries while meeting the growing global food demand.

To achieve sustainable food security goals, it's imperative to enhance food availability by minimizing post-harvest losses at various levels, including farms, retail, and among consumers. This involves maintaining adequate infrastructure, expanding cold storage facilities, and effectively disseminating technologies and market information. Striving for a "zero wastage" status in agricultural produce is a key step towards realizing a "Hunger-free Nigeria" and requires dedicated efforts.

Reducing post-harvest losses in developing countries necessitates investments from both the public and private sectors in agricultural research, development, and extension services. This includes allocating resources to suitable storage technologies and enhancing infrastructure to improve the connectivity of smallholder farmers with local, regional, and international markets. Conducting cost-benefit analyses to determine the returns on investment in recommended post-harvest technologies is essential, enabling the selection of technologies appropriate for various post-harvest enterprises across different farmers.

Urgent action is required to establish additional cold storage facilities in various regions for different types of commodities. Governments in affected countries should prioritize foreign direct investment (FDI) and capital injection into this endeavor. Raising awareness about available facilities within the country to reduce post-harvest losses is also crucial. Implementing market innovations and reforms is indispensable for advancing the campaign to reduce food waste.

CONCLUSION AND RECOMMENDATIONS

Given the challenging living conditions faced by many individuals in developing nations like Nigeria, it is of utmost importance to urgently seek solutions to mitigate post-harvest losses. Such efforts can enable farmers to maximize their income and ensure a consistent supply of food, fruits, and vegetables throughout the year. As a recommendation, governments should actively facilitate the development of infrastructure that encourages private sector investments in the food processing industry, particularly for fruits and vegetables. This measure holds significant potential for reducing post-harvest losses, promoting economic growth, and strengthening food security.

Furthermore, it is essential to emphasize the need for practical policies and steadfast leadership to address this issue effectively. To achieve future food security goals, it is crucial to ensure a substantial reduction in post-harvest losses. This requires a collective effort from all sectors of society, including the public sector, private sector, and civil society. Everyone should recognize the pivotal role they can play in establishing and maintaining a robust support system that facilitates decision-making and the adoption of technologies aimed at reducing post-harvest losses in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Cereal grains (maize/corn; Zea mays L. inclusive) are generally the major and least expensive sources of carbohydrate, protein, certain minerals and vitamins in the developing countries. Insect infestation however, has been shown to cause significant quantitative and qualitative damage of stored products. However, due to a dearth of information on the effect of infestation and storage on the nutritional content of maize grains in particular, an investigation into appraising nutritional cost vis-a-viz infestation was carried out. 4 kg of pest free orange coloured maize variety (SAMMAZ 49) and sorted into 2 groups: STM_{01} and STM_{02} and infested with unsexed Sitophilus zeamais Mots. Both samples were stored under ambient laboratory conditions for 3 months after which they were processed and alongside with freshly harvested, uninfested processed samples (FRM_{01}). Significantly ($p<0.05$) higher amount of zinc, copper, sodium, potassium and magnesium was observed in the infested + stored grains (STM_{01}) over and above the uninfested + stored grains (STM_{02}) and freshly harvested + uninfested grains (FRM_{01}) by 10.5 to 97.5%. Vitamin C was at levels below detection in all the samples; while FRM_{01} and STM_{02} had 0.12±0.00 mg/100g and 0.10±0.02 mg/100g Vitamin A content, respectively. STM_{01} had undetectable quantity of Vitamin A. Furthermore, infestation and storage was observed to suppress protein, carbohydrates and dietary fiber content by 24.7 to 77.8%; while a 30.2% increase in moisture content was attributable to S. zeamais infestation + 3 months storage of the grains. Further study is recommended to aid modelling the relationship between infestation and storage vis-a-viz nutritional status of the grains.

INTRODUCTION

Maize or corn (*Zea mays* L.) is a major cereal crop with rising global increase in demand. Having a predicted global increase of ≈ 370 metric tons by 2023 from the initial 967 million metric tons, maize is estimated to account for the greatest share (34%) of the total harvested crop area globally, making maize of inestimable value with regards to global food security (Rouf Shah *et al.*, 2016; Samuel *et al.*, 2021; Medugu *et al*., 2023). Africa produces roughly 7% of global maize production with constant increase in total cultivated land area. The role of maize in the sub-region is enormous as the crop has successfully substituted other staple crops such as sorghum and millet in terms of quantity consumed per household as well as becoming a major source of income for smallholder farmers (Medugu *et al*., 2020; Samuel *et al.*, 2021).

Although, majorly considered as a carbohydrate rich crop, the nutritional composition of maize kernel has generally been reported to consist of important vitamins such as vitamin C, vitamin E, vitamin K, vitamin B_1 (thiamine), vitamin B_2 (niacin), vitamin B_3 (riboflavin), vitamin B_5 (pantothenic acid), vitamin B_6 (pyridoxine), folic acid, selenium, N-p-coumaryl tryptamine, and N-ferrulyl tryptamine (Rouf Shah *et al.*, 2016). Major minerals like Potassium which has a good significance in the human diet as well as about 45–50% of oil that is used in cooking and making of salads is obtained from wet milling process of maize kernel (Kumar *et al.,* 2013; Rouf Shah *et al.,* 2016). These among others is instrumental in maize been referred to as "a life giver" (Kumar *et al.,* 2013).

Considering the global importance of maize and despite high estimation of global production of the crop, attention is drawn towards factors which affect its production vis-a-viz its nutritional composition as there exists evidence of seed and food insecurity arising from storage losses of the crop majorly due to the problem of insect pests. Maize weevil (*Sitophilus zeamais*) and its relatives such as rice weevil (*S. oryzae*), Angoumois grain moth (*Sitotroga cerealella*) and the larger grain borer (*Prostephanus truncatus*) represents the major pre-harvest and post-harvest pests of maize, causing up to 40% losses during cultivation and a whopping 90% postharvest losses (Tefera *et al.,* 2011; Rouf Shah *et al.,* 2016; Medugu *et al*., 2023).

Maize weevil is a primary storage pest which infests intact kernels. Through the feeding activities of adults and the development of immature stages, the insect is able to create holes in whole and undamaged grains, reducing them to powder and causing the grain to lose sufficient nutrient, viability and market value (López-Castillo *et al.,* 2018). The pest has cosmopolitan distribution as it is found in numerous warm and humid regions worldwide (López-Castillo *et al.,* 2018). Of concern is that, among factors that affects productivity and nutrient composition of maize such as geographic location, soil nutrient and others, the effect of insects such as *S. zeamais* have played a more significant role in deterring the productivity as well as the nutrient content of the crop (Rouf Shah *et al.,* 2016; Medugu *et al*., 2020; Samuel *et al.,* 2021).

Wukari is a high maize producing community which is also threatened by *S. zeamais* infestation. The high cost of chemical pesticides used in storage of the crop has also resulted in the high market price of the grain, leaving majority of the poor masses with the only option of purchasing insect infested grains for consumption due to their relatively low prices. In a bid to attract better market price, the crop is stored for a longer time by the growers. Inadequate knowledge of the nutritional value of these consumed damaged and long stored grains exists. Hence while the poor masses are threatened with malnutrition by consistent consumption of damaged maize grains, the bourgeoisies may equally be threatened by same via consistent consumption of "over stored maize grains". Hence this study is designed to determine the effect of storage period and *S. zeamais* infestation on the nutritional characteristics of maize grains.

MATERIALS AND METHODS

Source of raw materials

Four (4) kilograms of pest free orange colored maize variety (SAMMAZ 49) was bought from a registered agrochemical dealer in Wukari and transported to the Biological Science Laboratory of Federal University Wukari for further processing.

Sample preparation

The grains were carefully sorted to ensure that only uninfested ones were used for the study. The sorted grains were divided into 2 main groups and kept in different plastic containers labelled STM_{01} and STM_{02} and covered with a mesh size that would only permit aeration. Forty (40) adult unsexed *S. zeamais* were manually introduced to samples STM_{01} while sample STM_{02} was uninfested. The samples (STM_{01} and STM_{02}) were stored in laboratory condition for 3 months, after which each sample was washed using clean water, air-dried, and milled in an attrition mill and sieved using a mesh with size screen (0.01mm). Fresh maize grain (1kg) labelled FRM_{01} was harvested from the field and processed into flour using the same method outlined for STM_{01} and STM_{02}. This was used as the control. 500g of each flour sample was packaged in high density polyethylene bag, well labelled and stored at (4±2^{o}C) in a refrigerator prior to laboratory analyses (Dereje and Solomon, 2020).

Analytical methods

All samples were safely transported to the Central Laboratory of Federal University Wukari for analysis using standard procedures as described below:

Determination of mineral content

One gram of each maize flour sample was used for analysis of mineral content (zinc, copper, sodium and potassium) present in the samples, following the atomic absorption spectrophotometric method described by Howe *et al.* (2005) where a gram of each samples was accurately weighed and put into 250 ml graduated beakers and labelled. A 3:1 mixture of nitric and hydrochloric acids (20 ml) was added to each beaker, covered with a polyethylene watch glass and allowed to stand overnight. The next day the mixture was digested for 2 hours at 115 ^{o}C. After cooling to room temperature, the digestate was made up to 50 ml. The resulting solutions were analyzed by Flame (for Zn, Cu, Na and K) using a Perkin Elmer 5100PC spectrometer.

Determination of vitamin content

Vitamin content in each sample was determined by High Performance Liquid Chromatography as described by George *et al.* (2015). 2 g sample of each substrate was weighed into separate 50 ml polypropylene tubes and 30 ml of 3% metaphosphoric acid was added and homogenized using a homogenizer. The mixtures were sonicated in ultrasonic bath for 5 minutes, vortexed and centrifuged at 845×*g* for 5 minutes. The supernatants were filtered using 0.25 μm membrane for HPLC analysis. Sample separation was achieved using an Ultra-Performance Liquid Chromatography system. Chromatographic separation was performed on a UPLC system equipped with an auto-sampler column oven, pumps and Prominence Diode Array Detector. The mobile phase composition consisted 0.3 mM potassium dihydrogen phosphate in 0.35% (v/v) phosphoric acid at a flow rate of 0.2 mL/min at ambient temperature. Injections of 20 μL was performed with a total run time of 12 min. Data were extracted at a wavelength of 242 nm while compound identification was based on matching of the retention times with pure ascorbic acid and vitamin A.

Proximate analysis

Determination of moisture content

The moisture content of samples were determined using the procedure described by AOAC (2010). Five grams of the samples was weighed into different aluminium moisture cans. The samples were then dried to constant weight at 105±2ºC and the moisture content was calculated as:

$$\% \, Moisture\ content = (weight\ of\ can + sample) - (weight\ of\ empty\ can) x\ 100/weight\ of\ sample$$

Determination of protein content

The macro Kjeldhal method as described by the AOAC (2010) method was used. Ten grams of the samples were weighed into different conical flasks (250 m1), 0.8 g of the catalyst (potassium sulphate) was poured into each of the conical flask and 5m1 of sulphuric acid and three glass beads (anti bumps) were dropped inside the conical flask and swirled. The mixture was heated on the Kjeldhal apparatus for 2-3 hours at 100°C, until it turned bluish white. The digest was allowed to air cool, then diluted with 10 ml distilled water. These were distilled using Markham distillation apparatus where l00 m1 conical flask containing 5 ml of boric and 2-3 drops of mixed indicator was attached. The 5 ml of the digest was introduced into the body of the apparatus and followed by l0 m1 of 40-45% sodium hydroxide solution. The distillate was collected as ammonium sulphate which was titrated against 0.1 M hydrochloric acid. A blank titration will be carried out using distilled water instead of the distillates. Percentage nitrogen was calculated using the formula:

$$\% \, Nitrogen = Titre\ value - \ blank\ x\ 0.0014g\ x\ 100\ x\ 25/weight\ of\ sample\ x\ 5\ ml$$

$$\% \, Crude\ protein = \% \, N\ x\ \ 6.25\ (conversion\ factor)$$

Determination of ash content

The ash contents were determined by the AOAC (2010) method. Two grams each of the samples was weighed into a dried pre-weighed porcelain crucible. Each sample was transferred into a preheated muffle furnace (carbolite Bamford S30 2AU) and heated at 550°C for 2 hours. The ash was removed, cooled in a desiccator and weighed, while the percentage ash content was calculated as:

$$\% \, Ash = Weight\ of\ ash\ x\ 100/Weight\ of\ sample$$

Determination of fiber content

Crude fiber of the samples was determined using the method described by the AOAC (2010) method. 2g sample was weighted into 500 m1 beaker and in 200 m1 boiling sulphuric acid for 1 hour 30 minutes. The suspension was filtered using a white filter paper and rinsed with hot water to obtain the filtrates. The residue obtained was transferred into a crucible and placed in an oven for 30 minutes. The dried residue was cooled in a desiccator and weighed. Percentage crude fiber was calculated using the formula:

$$\% \, Crude\ fiber = Loss\ in\ weight\ after\ incineration\ x\ 100/Weight\ of\ sample$$

Determination of carbohydrate content

Carbohydrate was calculated by difference as described by Ihekoronye and Ngoddy (1985).

$$\% \, Carbohydrate = 100 - (\% \, Moisture + \% \, Fat + \% \, Protein + \% \, Ash + \% \, Crude\ fibre)$$

Statistical analysis

The experiment was carried out on completely randomized design (CRD). The data were analyzed by one way analysis of variance using Statistical Package for Social Sciences (SPSS) software version 20. Means that were significantly different, were separated by the Least Significant Difference (LSD) test. Significance was accepted at $p < 0.05$.

RESULTS AND DISCUSSION

After 3 months of storage, results as shown in Table 1 revealed that infested + stored grains (STM_{01}) had significantly ($p < 0.05$) higher amount of zinc, copper, potassium, and magnesium than the other 2 treatments by an average of 10.5 to 97.5%. The result further showed that, differences in zinc, copper and magnesium content between uninfested + stored (STM_{02}) and freshly harvested + uninfested (FRM_{01}) were due to random variation ($p > 0.05$). However, while sodium content in STM_{02} (16.30±0.40 mg) was significantly ($p < 0.05$) higher than that in FRM_{01} (15.17±0.30 mg); the reverse was the case with respect to potassium with 0.13±0.00 mg and 0.40±0.00 mg values, respectively.

The analyses of Vitamin A and C carried out on the samples showed that Vitamin A was insignificantly ($p > 0.05$) higher in freshly harvested + uninfested maize grains (FRM_{01}) with a concentration of 0.12±0.00 mg/100g vis-a-viz uninfested + stored grains (STM_{02}) which had (0.10±0.20 mg/100g). The insect infested and stored grains (STM_{01}) had an undetected amount of Vitamins A and C across all the samples (Table 2).

Table 3 shows that infestation + storage significantly ($p < 0.05$) depletes protein, carbohydrate and fibre content of the maize grains by an average of 77.8, 72.3 and 24.7%, respectively. On the other hand, infestation was noted to significantly ($p < 0.05$) favour moisture rise by up to 30.2%.

Table 1. Mineral content of stored infested, stored uninfested and fresh uninfested maize grains

Mineral content (mg)	STM_{01}	STM_{02}	FRM_{01}
Zinc	$0.25^{a}\pm0.01$	$0.15^{b}\pm0.00$	$0.10^{b}\pm0.35$
Copper	$0.27^{a}\pm0.30$	$0.02^{b}\pm0.20$	$0.05^{b}\pm0.25$
Sodium	$17.58^{a}\pm0.00$	$16.30^{b}\pm0.40$	$15.17^{c}\pm0.30$
Potassium	$0.72^{a}\pm0.20$	$0.13^{c}\pm0.00$	$0.40^{b}\pm0.00$
Magnesium	$0.80^{a}\pm0.12$	$0.02^{b}\pm0.00$	$0.02^{b}\pm0.00$

Means bearing different superscript on the same row differ significantly at ($p < 0.05$)

Table 2. Vitamins A and C content of stored infested, stored uninfested and fresh uninfested maize grains

Vitamin content (mg/100g)	STM_{01}	STM_{02}	FRM_{01}
Vitamin A	$0.00^{b}\pm0.00$	$0.10^{a}\pm0.02$	$0.12^{a}\pm0.00$
Vitamin C	ND	ND	ND

Means bearing different superscript on the same row differ significantly at ($p < 0.05$)
ND: Not detected

Table 3. Proximate composition of stored infested, stored uninfested and fresh uninfested maize grains

Proximate (g)	STM_{01}	STM_{02}	FRM_{01}
Protein	$0.10^{c}\pm0.20$	$3.47^{b}\pm3.55$	$8.07^{a}\pm3.77$
Carbohydrate	$10.04^{c}\pm0.22$	$24.60^{b}\pm2.55$	$71.10^{a}\pm2.46$
Ash	$1.28^{b}\pm0.82$	$2.30^{a}\pm0.30$	$1.17^{c}\pm1.01$
Moisture	$12.50^{a}\pm0.3$	$7.37^{c}\pm3.47$	$10.08^{b}\pm0.94$
Fiber	$0.90^{b}\pm0.94$	$1.30^{a}\pm1.01$	$2.92^{a}\pm0.09$

Means bearing different superscript on the same row differ significantly at ($p < 0.05$).

Factors such as storage condition and duration, as well as pest infestation among others have been reported to greatly influence the nutritional composition of maize (Tefera *et al.*, 2011; Rouf Shah *et al.*, 2016; Stathas *et al.*, 2023). In this study, value of the mineral content obtained from FRM_{01} samples largely agreed with the reports of Rouf Shah *et al.* (2015) for freshly harvested maize samples. However, the comparative higher values of the minerals (Zinc, Sodium, Copper, Potassium and Magnesium) as observed in STM_{01} sample can only be attributed to the combined effect of both storage duration and insect infestation. Insect infestation has been shown to increase mineral content as indicated by the study of Jood and Kapoor (1994) in their research with *Trogoderma granarium* and *Rhyzopertha dominica*. Although intake of these minerals is of immense health benefits (Rouf Shah *et al.*, 2016), excessive consumption of Zinc and Magnesium has been reported to be associated with health problems such nausea, headache, vomiting and stomach upset (Rouf Shah *et al.*, 2016).

Of interest is the undetectable level of Vitamin A level in STM_{01} sample as against what was obtained in STM_{02} and FRM_{01}. This largely suggests that the activities of insect infestation on maize grains, suppress Vitamin A content. Further, the undetectable level of Vitamin C in all the samples analyzed showcased the deficiency of the grains in Vitamin C. This buttresses the findings of Garg *et al.* (2021) and Galani *et al.* (2022) who reported that maize grains have insignificant quantity of Vitamin C.

Proximate properties of the maize samples used in this study had similar results in FRM_{01} values for Protein, Carbohydrate, Moisture, Ash and Fiber reported by Rouf Shah *et al.* (2015). However, the significant lower nutrient value of protein, carbohydrate and fiber in STM_{01} sample vis-a-viz the other samples may be attributed to the combined effect of storage and *S. zeamais* infestation, and this buttresses the finding of Tefera *et al.* (2011) which showed that insect infestation reduces nutrient quality of maize. A study conducted by Ojimelukwe *et al.* (1999) showed a 19 – 28% decrease in protein content of cowpea as a result of insect infestation. They attributed the depletion to the utilization of the protein nutrient by the insect pest. Our findings however showed a far greater (≈ 77.8%) reduction attributed to infestation and storage. This apparently shows the extent infestation and storage could deplete proteins in grains. In contrast however, Jood *et al*. (1993) observed a 75% increase in mean protein content in infested cowpea which was suspected to be due to the presence insect excrements and body fragments. Approximately, we noticed 77.8 and 77.2% increase in protein and carbohydrate content in the infested and stored maize samples. This was in contrast with the observation of Stathers *et al*. (2020) who noticed a decrease in carbohydrate and an increase in protein content as a result of insect infestation. This difference may be due to differences in grain varieties, analytical methods or experimental procedures. The ≈ 24.7% decrease in dietary fiber in sample STM_{01} in our study could be attributed to the insect feeding on the soluble portion of the fiber. Hence, the freshly harvested maize grains (FRM_{01}) which had significantly higher fiber content could be adjudged to have better physiological and health advantages by way of lowering cholesterol level, regulating blood sugar, and prevention of diabetes and certain forms of cancer (Akah and Onyeka, 2017). High moisture content was observed in STM_{01} following the 3 months storage. This also suggests that insect infestation and activities could possibly be responsible for increase in moisture content of the maize sample as earlier reported by (Stathers *et al*., 2020).

CONCLUSION

Although storage duration also influenced the nutritional composition of the maize samples used in this study, a combined effect of insect infestation was observed to be more deleterious on the nutrient content. This suggests that consumption of insect infested maize may not only lead to malnutrition, but also contributes to some disease cases such as gastro-intestinal dysfunction, liver and heart diseases among others, due to a disproportionately higher amount of minerals. More extensive studies are thus recommended to enable modelling the association between infestation and storage on one hand against nutritional losses.

ACKNOWLEDGEMENT

We are grateful to the staff of Senator Bwacha Memorial Central Laboratory, Federal University Wukari who carried out the laboratory analyses.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Roots and tubers play a significant role in ensuring food security, especially in developing countries where they are staple crops for millions of people. However, improper harvest and postharvest management practices often result in substantial losses, reducing food availability and contributing to food insecurity. This paper highlights the importance of enhancing food security through improved harvest and postharvest management of root and tuber crops. Improving harvest management involves implementing appropriate techniques to ensure the timely and efficient collection of roots and tubers. Traditional methods, such as hand harvesting, are often labour-intensive and time-consuming, leading to delays that can negatively impact the quality and quantity of crops. Introduction of mechanised and semi-mechanised harvesting technologies can significantly enhance efficiency, reducing losses and improving food security. Postharvest management plays a crucial role in minimizing losses and extending the shelf life of root and tuber crops. Common challenges faced during postharvest handling include physiological deterioration, sprouting, pest infestation, and improper storage conditions. Implementing improved postharvest practices, such as cooling, packaging, and the use of other appropriate storage technologies can significantly reduce losses and improve food availability. More so, enhancing food security through improved harvest and postharvest management requires the involvement and capacity building of smallholder farmers. Providing them with training, technical support, and access to improve technologies can empower them to adapt best practices and reduce losses during harvest and postharvest stages. Overall, enhancing food security via improved harvest and postharvest management of root and tuber crops is crucial for reducing food losses, increasing availability, and ensuring a stable food supply. By addressing the challenges associated with these key stages, policymakers, researchers, and farmers can work together to achieve sustainable food security for the growing global population, particularly in vulnerable regions that are highly dependent on roots and tubers.
***Keywords:** Root and Tuber crops; Food Security; Harvest; Post Harvest Management*

INTRODUCTION.
Roots and tuber crops, including yam (*Dioscorea* spp.), cassava (*Manihot esculenta* Cranz), potato (*Solanum* spp.), sweet potato (*Ipomoea batatas*) and edible aroids (*Colocasia* spp. and *Xanthosoma sagittifolium*) can contribute significantly to meeting the nutritional needs of vast majority of people and reducing hunger. Hence, roots and tuber crops can play crucial role in sustainable food security. These crops are the second most important food crops after cereals in many regions of the world. They are grown in varied agro-ecologies and production systems ranging from highland densely populated regions to lowland drier areas prone to droughts or floods. These crops account for about 95% of the total root and tuber crops production in Africa and produce more than 240 million tons annually on 23 million hectares (NRCRI 2008; FAO, 2009; IITA, 2015).

Root and tuber crops such as yam, cassava, cocoyam, potato and sweet potato are cheap but nutritionally rich staple foods that contribute starch or carbohydrate, protein, minerals, vitamins (like vitamin C, vitamin A etc), zinc, and iron towards the dietary demands of the region's fast-growing towns and cities. They are referred to as poor man's crops and have considerable unrealized potential for processing into high end products for food, animal feed and industrial uses (Nteranya, 2015).

Root crops such as potato and sweet potato crops have short life cropping cycle that may range from three to four months. They are suitable for double cropping seasons especially in rain-fed systems, with significant advantage over cereals which have longer time to harvest. Due to root crops short growing periods, they have flexible planting and harvesting period which may allow quick food availability to sustain hunger. Tuber crops like yam

and cassava, with long cropping cycles, are good for annual cycle of food production. They are grown in marginal environments as well as having diverse maturity period with storage capability that allows flexible planting and harvesting periods which helps to sustain food production (FAO, 2009).
The crops can be traded locally and nationally even exported internationally. As such, they significantly contribute to a more stable food system and predictable source of income. Their perishable nature, coupled with challenges in long distance conveyance, storage and marketing creates major threats for small scale farmers. Root and tuber crops are affected by many pathogenic and physiological disorders during the post harvest storage periods resulting to great economic loss. These crops are still living organisms when harvested and their losses during storage occurs mainly as a result of its physical and physiological conditions (Scott *et al.*, 2000). In order to maintain their freshness, farmers, in different parts of the world, have developed several simple, low-cost traditional methods to store these root and tuber crops. To ensure effective storage of root and tuber crops, these major causative factors need to be properly understood, and be properly controlled, taking into account the socio-economic factors which prevail in the areas of production and marketing. For most root and tuber crops, a significant proportion of the crop is processed. Transformation of the crop into a more storable form reduces physical losses as well as providing income and employment. Where processing leads to increased value of the product it can effectively change a situation of postharvest loss to one of net economic gain (Karya, 2019).
Harvest and Post Harvest Management Strategies.
1). Timely Harvesting: Proper timing of harvest is critical as it affects the quality and storage life of root and tuber crops. At their maturity time, these crops show signs and indications of their readiness for harvesting. Harvesting too early or too late can result in yield losses and reduced storability. Therefore, harvest at the right maturity stage to ensure their economic value, maximum yield and quality. Delayed harvesting can lead to spoilage, loss of nutrients, and reduced market value. Table 1 showed the harvesting period of these crops, and their harvesting period mainly depend on the type of crops, varieties and growing conditions (Krishnakumar *and* Sankarakutty, 2021).
There are commonly used criteria to ascertain the harvesting time root and tuber crops. For cassava; as soon as the foliage begins to dry, it shows that the crop is due for harvest. Same applies to sweet potato. For sweet potato however, the production of white gum but not green or black by the crop indicates readiness for harvest. Yams are harvested when their foliage begin to wilt with a corresponding enlargement of the tubers. Over maturity of yam may be tough and fibrous tubers. In Cocoyam; harvest is due when the foliage turns yellow and start to wither.

Table 1. Harvesting Period of root and tuber crops (RTCs)

Root and tuber crops	Maturity period
Cassava	6-10 months
Sweet Potato	5-6 months
Potato	3-4 months
Cocoyam	5-7 months
White Yam	9-10 months
Yam Beam	4-5 months

2. Efficient handling method: After harvest, root and tuber crops should be handled with care to prevent physical damage and bruising, which can lead to harvest losses such as rotting. Many causes of postharvest losses can be suppressed by minimizing mechanical injuries during harvest, avoiding harvesting at high temperature and preferably harvest in dry weather. The use of proper tools and techniques and carefully lifting or digging the tubers could reduce harvest losses. The use of manual means either by digging or lifting is time-consuming but it results in healthy harvest produce as compared to that from the mechanical means of harvesting. Root and tuber crops, when cultivated in commercial quantity are handled and harvested by mechanical means. However, careful handling to prevent cuts and bruises to the tubers during harvesting is critical. The crops should be harvested along with their vines or stems to slightly prolong the shelf life (Oke-Okoro *et al.*, 2014).
3. Cleaning and sorting: Clean the harvested crops to remove dirt, debris, and any damage or diseased parts. Sort them based on size, shape, and quality to ensure uniformity and marketability (Scott *et al.*, 2000).
4. Transportation of root and tuber crops: Proper transportation of root and tuber crops can preserve and maintain the quality and freshness of the produce. More than 10 to 20 % postharvest losses in fresh produce can happen due to improper transportation methods. To maintain quality and reduce loss, the crops should be packed in cartons or sacks/bags with cushioning materials like paper pieces, crop hays/straws etc. to prevent mechanical injury during transport. While transporting the crops, the produce must be protected against the sun, rain and dust by covering it with a light-coloured tarpaulin or enclosing it in a refrigerated truck. Over speeding, and unnecessary jumping into pot holes must be avoided, as they cause squeezing and bruising of the crops. Loading

and offloading of produce must be done with carefully. Packed produce must be handled gently to avoid bruises (Krishnakumar *and* Sankarakutty, 2021).

5. Pre-cooling of root and tuber crops: Pre-cooling aids to conserve the weight of the tubers and prolong the storage life. Pre-cooling could be handled either by using hydro-cooling means, air cooling or vacuum cooling method for quick removal of heat from produce. This depends on the perishability and refrigeration equipment of the produce, its adoptability to a specific method and the availability of facilities (Scott *et al.,* 2000).

6. Curing: Curing involves subjecting harvested crops to specific temperature and humidity conditions to toughen their skins and heal any minor injuries and to reduce water loss and spoilage during postharvest. Curing improves shelf life and quality, especially for crops like sweet potato, yam and cassava. Curing is an important practice for these crops. If ventilation is poor, uncured tubers may start to rot. Curing can be done in a well-ventilated shed or in the sun. Curing period depends on the type of the root and tubers and varied between four to six days. Curing operation is to be carried out as soon as possible after harvest (Krishnakumar *and* Sankarakutty, 2021). Curing periods depends on the species/variety of crops, condition of the crop at harvest, type of wound, season, storage temperature and relative humidity. The best conditions for curing vary among crops as shown in the Table 2.

Table 2. Optimal temperature and relative humidity for curing of different RTC

Root and tuber crops	Temperature($0^{o}{}_{C}$)	Relative humility (%)	Days
Cassava	30-40	90-95	2-5
Sweet potato	30-33	85-95	5-7
Yam	29-40	90-95	5-7
Cocoyam	26-330	-	7-15

7. **Improved packaging practices and marketing**: Use appropriate packaging materials that provide protection against moisture, pests and physical damage. Proper ventilation should be maintained for the packed tubers. Proper selection of packaging materials is important to increase the shelf life of the product without affecting its quality. Multi-layered packing material can be used for long term storage of flours/starch. For tuber crops, packaging materials like gunny bags, palm baskets, paper cartons, perforated plastic bags for pre-packaged tubers, solid black crates and polyethylene bags can be useful. Proper labelling and branding can also facilitate marketability, and ensure consumers are aware of the quality and nutritional value of the products. This can enhance their market value and provide economic opportunities for farmers. Develop efficient supply chains and linkages between farmers, processors, and consumers. Improve the transportation infrastructure and establish market information systems to facilitate timely and profitable sales (Magbalot-Fernandez and Umar, 2018).

8. Storage facilities: Invest in proper storage facilities such as warehouse, cold rooms, or ventilated containers to main the quality and freshness of root and tuber crops. These facilities should have controlled temperature, humidity and ventilation to prevent spoilage and pest infestation. At room temperatures, fresh produce can spoil quickly, there is need to sell them as soon as harvested. However, these crops could be stored under cold storage facilities for longer periods. Tubers are protected at safe optimal temperature from chilling injury, which cause internal browning, surface pitting and increased susceptibility to spoilage (Okunneye, 2002). Best storage practices include: Storing only sound and good quality crops: clean, mature, and disease free, injury free produce. They Should be stored immediately after harvest for better storage life. The containers and the storage rooms should be clean to prevent contamination and spoilage of fresh produce. Also, inspect the stored produce on regular basis to remove spoiled ones. Table 3 showed that there are different storage techniques which are practiced by farmers to ensure prolonged shelf life of tuber crops.

Table 3. Recommended storage conditions for shelf life extension for root and tuber crops

Root and tuber Crops (RTC)	Temp. (0^{0c})	Relative humidity (%)	Potential Storage duration
Cassava	5-8	80-90	2-4 wks
Sweet potato	12-14	85-90	6 months
Yam	13-15	95-100	6 months
Cocoyam	13-15	85-90	4 months

9. Processing and value addition of RTC: Explore processing techniques such as drying, milling, and fermentation to extend the shelf life of root and tuber crops. Processed products like flour, chips, and snacks can increase their market value and reduce postharvest losses. Root and tuber crops can be consumed after boiling the peeled and sliced tubers in water and eaten with some spicy curry. They should not be eaten in raw state as they contain anti-nutrients like cyanide in cassava, oxalates in yam and cocoyam. Their processed products are packaged and stored to achieve their potential shelf life of up to two to twelve months. Dried food products made from tuber crops must be packaged in air-tight containers. Dried products take up much less space than their fresh equivalents, further reducing transport and storage costs (Christopher, 1995).

10. Postharvest loss reduction: Addressing postharvest losses is crucial to maximize the amount of food available for consumption. Measures such as improved infrastructure, including access to efficient transportation systems and adequate storage facilities, can help reduce losses due to spoilage and damage during transportation. Implementing postharvest technologies, such as low-cost cooling systems and modified atmospheric packaging, can also prolong the shelf life of root and tuber crops (Okunneye, 2002).

11. Training and capacity building: Providing training and technical assistance to farmers on best agricultural practises in harvest and postharvest management techniques, can improve their knowledge and skills in handling root and tuber crops. Capacity building initiatives can also focus on educating farmers about market requirements, grading, quality standards and value-added processing techniques to enhance the economic value of their produce (Oke-Okoro *et al.*, 2014).

12. Research and innovations: Support research and development efforts to improve postharvest technologies, storage methods, and value addition for root and tuber crops. Encourage innovation and adoption of new technologies to enhance food security and reduce postharvest losses (Oke-Okoro *et al.*, 2014).

CONCLUSION

Enhancing food security through improved harvest and post-harvest management of root and tuber crops is crucial for communities and countries that rely on these crops as staple food sources. By implementing better practices and technologies, we can reduce post harvest losses, increase yield and quality, and ensure a stable food supply throughout the year. Improvements in harvest and post-harvest management can include the use of appropriate machinery and tools, such as mechanical harvesters and storage facilities, to minimize damage and losses. Training and education for farmers on proper harvesting techniques, cleaning, grading, and storage methods can also greatly contribute to reducing losses and maintaining crop quality. Again, investing in research and development for better varieties of root and tuber crops that have higher yield potential, resistance to diseases and pests, and improved storage life can further enhance food security. Promoting sustainable farming practices such as the use of organic fertilizers and integrated pest management, can protect crops from post-harvest losses, increase productivity, and ensure a steady supply of nutritious food for all.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Marketing and distribution of leafy vegetables is very crucial for sustainability of the whole value chain. This study was conducted to evaluate the postharvest handling practices of vegetable handlers in Ilorin and environs in order to assess their level of awareness of Nigerian Stored Products Research Institute (NSPRI) developed technologies for green leafy vegetables and their challenges. A total of 30 respondents were purposely selected from five locations (150 respondents). Structured questionnaires were administered to respondents for data collection and their responses were analysed through the use of descriptive statistics. Results showed that 48% of respondents were within their active productive years (26–45), 90% were female, and 83% were married while 56% had no formal education. The average annual income of respondents was ₦243,333.00 and many (41%) were from Ilorin-West Local Government Area. Technologies known and/or adopted include: bunching, vegetable baskets and vegetable shed. Challenges faced during postharvest handling of green leafy vegetables include: wilting, discolouration with an average storage time of only 25h. Although, high level of awareness (70%) was recorded among holders, there was low level of adoption (less than 40%) of postharvest technologies. Factors responsible for low adoption included: cost, technical know-how and ease of use.

INTRODUCTION
Green leafy vegetables (GLV) are plants with edible leaves, roots or tubers and they are used as supplementary food, side dishes or main stable dishes in Nigeria (Adekalu, 1999). They are functional foods with high nutritional content, essential for growth, health, and good skin (Al Saqqa 2021; Mungofa *et al*., 2022). They reduce risks of obesity, heart diseases, high blood pressure, cancer, and mental decline (Carballido, 2022; Autumn, 2023). They are low in calories, high in fiber, and rich in vitamins A, B, C, E, K, potassium, magnesium, and calcium. Leafy vegetables contain antioxidants like chlorophyll, beta-carotene, and rutin (Shetty *et al*., 2013; Ambuko *et al*., 2017).
Leafy green vegetables, due to their high moisture content, are highly susceptible to postharvest losses (Atanda *et al*., 2011; Workineh and Enyew 2021). According to Elemasho *et al*. (2021), the primary cause of losses is majorly due to inadequate awareness and prevention methods. Other factors include physiological deterioration, mechanical damage, poor handling, diseases, and pest infestation (Atanda *et al*., 2011). Nigeria needs to adopt affordable and adaptable technologies for postharvest loss reduction (Iwuagu *et al*., 2014).
The Nigerian Stored Products Research Institute (NSPRI) has developed some technologies for effective handling of leafy vegetables which include: Vegetable Baskets (VBs) for harvesting, handling and transportation of leafy vegetables, Vegetable Shed for on-farm handling of vegetables and vegetable bunching. Some of these technologies are forms of Evaporative Cooling System (ECS) or controlled atmosphere storage which majorly relate to the environmental conditions of the storage area (Liberty *et al.*, 2013). The VBs as developed can preserve some vegetables for between 5–7 days (Babarinsa, 2001). This study investigated the handling practices of leafy vegetable handlers in Ilorin environs to identify causes of postharvest losses, determine the level of awareness and adoption rate of NSPRI postharvest technologies in the study area and identify the constraints faced by handlers.

MATERIALS AND METHODS

The study was carried out in four (4) Local Government Areas (LGAs). Leafy vegetables sellers and/or holders in the study area constituted the population for data collection in this study with a multistage sampling procedure (Dire *et al*., 2016; Amurtiya and Adewuyi, 2020). The first stage involved purposive selection of four (4) LGAs in Kwara State. The second stage involved purposive selection of five locations (Lasoju, Kodi, Mandate, Ipata and Yoruba road market). The third stage sampling consists of random selection of 30 respondents from each location to make a total of 150. Data were collected from the respondents through the use of structured questionnaires. Descriptive statistics (frequency, percentage and mean) were used for data analyses. Results were presented in tables and charts for clarity and understanding.

RESULTS AND DISCUSSION

The socio-economic characteristics, challenges of storage and level awareness of NSPRI technologies by green leafy vegetable handlers in Ilorin is presented in Table 1. It showed that 29.3% of respondents were between the ages of 26-35 and 19.3% between ages of 36-45 years. Therefore, 48% of respondents are still within the active age and productive years. This corroborates the findings of Elemasho *et al*. (2021). Age is an important factor in the study of individuals because it reflects the physical strength to perform a task and the psychological disposition for imbibing behavioural change or otherwise (Dire *et al*., 2016). The gender distribution was predominantly female, with 90% being married and having a large household size (6-10). This suggests that women are more involved in postharvest activities, which are influenced by division of labour and cultural beliefs (Adejo, 2019). The average annual income of the study population was ₦243,333.00 which apparently is an attraction for the business. The challenges experienced during storage include; wilting and colour change. These challenges could adequately be taken care of by the use of available simple technologies.

The results showed that majority (about 51%) of the respondents have no contact with any extension agents. Further, despite the facts that more than 70% of the respondents were aware of NSPRI postharvest technologies for green leafy vegetables, only few of them had adopted them. The technologies adopted include: bunching (1.3%), vegetable basket (1.3%) and vegetable shed (28%). These results largely indicate that the adoption rate of NSPRI technologies for leafy vegetables is low in the study area. This finding agreed with the report of Adebayo *et al*. (2018) which showed a positive relationship between contact with extension agents and the rate of adoption of technologies. The constraints faced by respondents include; cost (64.7%), technical know-how (19.3%), and ease of use (7.3%).

Table 1. Distribution of respondents according to socio-economic characteristics, challenges of postharvest handling and level of awareness (N=150)

Characteristics	Frequency	Percentage	Mean	Characteristics	Frequency	Percentage
Gender				500,001 and above	5	3.3

CONCLUSION

The study has shown that indigenous methods of packaging and transportation of leafy vegetables are still in operation among holders in the location visited. Awareness of modern technologies was high but adoption was very low. Among the constraints for lack of adoption of the technologies was cost or finance. Whereas the cost of these items may not be unaffordable for the users, we recommend that more education should be provided to enlighten them about these technologies. The institute should also make some of these materials available to users at subsidized or no cost.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The study investigated the effect of different drying techniques: air, oven and sun drying) on the proximate composition of three aquatic Macrophytes, Common cattails (Typha latifolia), white lotus (Nymphaea lotus) and Oryza sativa. Nymphaea lotus was at 60^{0}C oven dried for 24 hours. Samples of each aquatic macrophytes were and subjected to the three different drying methods in the oven in triplicate. Determination of proximate composition was carried out on the dried sample of each aquatic macrophytes following the methods described by the moisture content of the samples were determined using standard methods. The moisture content of air dried Nymphaea, Oryza sativa, and Typha latipolia leaves are 8.0, 6.0 and 5.5%, respectively. The effect is significant, p=0.5. Relatively high protein content of 16.98, 12.25 and 11.2% were observed for Nymphae lotus, Typha latipolia and Oryza sativa, respectively. Oven dried samples of the three aquatic Macrophytes have the least ash and crude fiber. Research work showed that oven drying is most effective in team of moisture removal and nutrient retention Furthermore, the Study recommends a feeding trial to access the potential of these aquatic Macrophytes subjected to various drying methods on growth and nutrients utilization of cultivable fish species.

INTRODUCTION

Animal's feedstuffs have been in the decline in recent years, because of the diminishing output of certain traditional crops. Statistics show that most country relies on imports to meet the needs of an expanding livestock and aquaculture industry (FAO, 2008). This has caused increase in prices of feed resources which intensify the already high cost of fish feed which have been a major problem to fish farmers in Nigeria (Eyo *et al*., 2004). The feed cost constitute 40 to 60 percent of the recurrent cost of the most intensive fish farm ventures which affect the economic viability of the farm when cheaper alternatives are not available (Madu *et al*., 2003). Fish meal is the most commonly used in fish feed which is consider to be the best in ingredients due to its protein requirement of fish (Alam *et al*., 1996).

Aquatic Macrophytes are among those factors which a fishery manager should try to understand and include in his strategies for optimizing capture fisheries in inland waters. The species composition, distribution and percentage cover of aquatic plants may determine the fish species composition, individual-fish species production, access to fish stocks by fishermen, fishing gear and sometimes also boat access and transport possibilities for getting the fishery product to the markets. Aquatic plant are important component of freshwater ecosystems, affecting diverse ecosystem functions and services (Hilt, *et al.*, 2007), many aquatic Macrophytes species have a high invasion potential due to their high profagule pressure, rapid growth, wide environmental tolerance, high phenotypic plasticity and ability to reduce allelophatic compounds (Riis, *et al*., 2010; Heidbuchel, *et al.*, 2020, Hussner, *et al*., 2021). Macrophytes help to stabilize sediments and shorelines, form breeding ground for some fish and many invertebrate species and are a food source for waterfowl and mammals such as beavers and moose (Walker *et al*., 2013).

Aquatic Macrophytes are present in virtually all freshwater bodies. In lakes they occupy predominantly the littoral shallows, and their importance in a lake ecosystem generally declines with increasing lake size. Emergent and floating-leaved aquatic Macrophytes seldom grow in waters exceeding a depth of 3m (Canfield and Hoyer, 1992) in small lakes where the littoral region with aquatic Macrophytes occupies a literally large portion of the lake;

there is relatively low intensity of competitive interaction among consumers that move from the pelagic zone to use littoral resources (Gasith and Gafny, 1998). The cross-boundary movers are typically adult or large fish that move between deep and shallow water for feeding, cover and seasonally for breeding.
Macrophytes and bryophytes are plants that have structures that are usually more complex, interdependent, and physically substantial than benthic algae. In this chapter, we describe the characteristics and roles of Macrophytes and bryophyte species that can thrive in submerged and flowing conditions. Macrophytes and bryophytes are often important components of stream ecosystems, providing an important physical substrate for periphyton, habitat, and refuges for benthic macro invertebrates and fish, and ultimately detritus that provides food and fuel to heterotrophic bacteria. Individual Macrophytes and bryophyte species are differentially responsive to environmental conditions and have been widely used to define stream community types and to monitor responses of stream ecosystems to terrestrial and anthropogenic drivers. In this chapter, we describe the specific characteristics that define Macrophytes and bryophytes, discuss their role in stream ecosystems, and provide instructions for common methods to sample them. Macrophytes may be used as fish food components and replace costly commercial feed owing to their potential nutrients profile: moisture ranges between 84.1-95.9%, dry matter 4.1-15.9%, crude protein 8.7-26.8%, crude fat 2.2-5.1%, carbohydrate 9.3-35.6%, ash 8.0-25.3%, and crude fibre 15.0-28.1%. The objective of the study is to assess the effect of different drying methods on the chemical composition of aquatic Macrophytes in Shagari Dam, Sokoto State.

MATERIALS AND METHODS

Description of the Study area

The study was carried out at the Shagari Dam and Agric Chemical Laboratory of the Faculty of Agriculture, Usmanu Danfodiyo University, Sokoto. The experimental site is located in Sudan Savanna vegetation zone of Nigeria on latitude 13° 07' 78 N and longitude of 5° 12' 25" E and on 275m above sea level. The study area is characterised by a long dry season which start from October to May, 2022; with cool dry air during the harmattan; (November - February) and hot dry air during (March - May). Raining season start in June and ends in September. Annual rainfall in the area ranged from 500 to 725mm. The mean relative humidity range between 14.9% and 40% during March and June, 2022, respectively. The ambient temperature can reach up to 41° during April and May and may fall 20°C during December and January.

Sample Collection

Samples were collected from Shagari Dam, Shagari local government Sokoto, Sokoto state, around the study area.

Identification of Sample

The samples collected were identified using a book written by Akobundu and Agyakawa (1987).

Processing of Macrophytes

Sun drying

The samples were dried on clean concrete surface flour to prevent being blown away by wind. Samples were sun-dried for 8 hours, at a relative humidity of 780 mm HG and the temperature readings were as follows: 30.25^{0}C, 34.50^{0}C, 35.23^{0}C, and 34.750C at 10am, 12.00pm, 4.00pm and 6.00pm respectively. This was aided by the use of mercury glass thermometer.

Air drying of samples

The samples were air dried indoor and the temperature was monitored. A building, room, etc., where goods or materials are dried in an artificially raised temperature; a drying-chamber. Temperature readings were 29^{0}C, 32.5^{0}C, 30.5^{0}C, 29.8^{0}C at 6.00am, 12.00pm, 4.00pm and 8.00pm respectively. This was aided by the use of Mercury glass thermometer.

Oven drying

The oven drying samples were oven dried at the Agric. Chemical Laboratory using UniscopeSM9053 Laboratory Oven at 65^0 C for 48hrs.

Proximate Analysis

Samples collected were analysed using the A.O.A.C (2000) methods. The proximate composition analysed were moisture content (Mc), ash content, crude protein (Cp), ether Extract (EE), Crude fiber (Cf), and the carbohydrates contents (CHO).

Moisture content (Mc)

Empty can (Petri dish) was weighed empty (W_0) and 2g of a Macrophytes sample were added and weighed (W_1) again. The W_1 was placed in the hot air drying oven at 105°c for 24hours and then allowed to cool off in a desiccator. The dried sample was weighed again (W_2) and then returned back into the oven for another 24 hours to maintain a constant weight. The weight (W_2) was constant and the moisture content was calculated as:

$\%MC = W_1 – W_2/W_1 –W_0 \text{ X } 100$

Crude Protein (Cp)

The estimation of Crude protein involved the determination of total nitrogen usually by the Kjedahl procedure (Digestion, Distillation, and Titration).

%Nitrogen = TV x 0.01m x 0.014m x 50x100/ Weight of sample x Mol. of aliquots

The crude protein was determined by multiplying the nitrogen value by 6.25.

Ether Extract (EE)

A known weight of prepared sample was poured into a thimble and covered with a cotton wool and the thimble was placed into the Soxhlet apparatus, before this was carried out, the thimble was washed, dried and weighed (W_1). Petroleum ether was added into the flask and heated to extract the fat from the sample for 7-8 hours. The lipid is then collected from the flask and dried in the oven for 1 hour at 100-105^{0}C, the flask is then weighed again together with the lipid (W_2). The percentage lipid is calculated thus

%EE =W_2 –W_1/weight of sample x 100

Crude fiber

A known weight of sample was poured into one liter conical flask and 200ml of boiling 1.25% H^2SO^4 was added and boiled for 30 minutes using cooling fingers to maintain constant volume. The sample was then filtered over a 9cm Buchner funnel and rinsed with hot distilled water and 10% was added and rinsed with petroleum ether (BP 40-60^{0}C). The residue was dried overnight in oven at 100^{0}C and cooled in a desiccator (W_1); this was then ashed at 550^{0}C for 90 minutes in a muffle furnace and cooled in a desiccator before weighing again (W_2). The percentage crude fiber was calculated using

%Cf= W^1-W^2/weight of sample x 100

Nitrogen Free Extract

This was not determined directly but was obtained as the difference between the crude protein and the sum of Ash, protein, crude fat and crude fiber.

Nitrogen free extract (NFE) =100- (%Ash+%Cf+%EE+%CP)

Statistical analysis

The determination was made in triplicate, parameters obtained were subjected to analysis of variance (ANOVA) and, the treatment means was separated for significant differences following the procedure of Duncan Multiple Range Test (Steel and Torrie, 1980). All the analysis was carried out using the computer software Statistical Package for the Social Sciences (SPSS) version 9.0 windows (SPSS, 2007).

RESULTS AND DISCUSSION

Proximate Composition of Water lily common cattails and *Typha latifolia*

Result of the analysis showed oven dried and sun dried samples with the lowest moisture content compared to air dried samples. The effective moisture removal for Nymphaea leave is in the order of air dried>oven dried, sun dried. The results also showed that Nymphaea leaves had crude fiber content within the range of 3.0 to 18.5 which is in order of sun dried>air dried>oven dried. Similar trend was also reported in the leaves of *Cratera religiosa* (Hassan *et al*., 2007).

Results of the analysis showed that oven dried and sun dried samples with the lowest moisture content compared to air dried samples. The effective moisture removal for Typha leave is in the order of air dried>oven dried and sun dried. The results also showed that Typha leaves had crude fiber content within the range of 35.5 to 39.5 which is in order of oven dried>sun dried>air dried.

Results of the analysis showed that sun dried and oven dried and samples with the lowest moisture content compared to air dried samples. The effective moisture removal for Oryza leave is in the order of air dried>oven dried>sun dried. The results also showed that Typha leaves had crude fiber content within the range of 21.5 to 35.5 which is in order of air dried>oven dried>sun dried.

Aquatic Macrophytes leaves

The investigation showed that some fish species feed on some plants. This was in line with Opuszyski (1972), who said herbivorous fish feeds on aquatic plants. Another writer Shell (1962) also writes that certain species feed on aquatic plants. Although Boyd (1968), Bates *et al*. (1976), Oyakawa *et al*. (1965) and Scunthorpe (1967) writes on different aquatic plants eaten by man, most of the mentioned plants were not however found here. But Scunthorpe (1967) writes on different aquatic plants eaten who he said the seeds, rhizomes and petioles of Nymphaea species.

Gaevskaya (1966), Moore (1969) and Sharma (1971) also wrote on the uses of aquatic Macrophytes as livestock feed. Other uses are included in this write up which was not explained by the writers. Aquatic Macrophytes harbour certain pests and diseases. Aquatic Macrophytes have been to serve as foodfor livestock, and could also serve as host for pest and disease (Uka and Chukwuka, 2011).

Macrophytes serves as fish hideouts, fish nets, reduces catch. Breeds mosquitoes and causes malaria was higher (80%).

Obeng (1969), Or *et al.* (1987), Baker *et al*. (1984), Pet (1968), Paperna (1970) and Odei (1979) among other writers on the effects of aquatic Macrophytes which confirms results obtained from the study. Weight of aquatic Macrophytes varies due to their differences in their different moisture content. This is because their classification varies as some are free floaters while others are emergent. The mineral composition varies also among aquatic Macrophytes. A good reason is because of the environment where they are found and also the type of plant. National Council for research (1976) writes on the chemical composition of aquatic Macrophytes which results of obtained from the analysis is similar.

Table 1 Proximate composition of Sample ingredients in **different drying methods**

Aquatic Macrophytes	Nutritional values %					
	Moisture	Ash	Lipid	Fiber	Protein	NFE
Typha latipolia						
Air dried	8.0[a]	10.0[a]	1.5[a]	35.5[a]	10.15[b]	35.85[b]
Oven dried	4.5[b]	5.0[c]	1.5[a]	39.5[a]	12.25[a]	37.25[a]

	SE=0.63	SE= 0.75	SE = 0.10	SE= 3.64	SE = 0.37	SE = 0.40
Nymphaea lotus						
Air dried	5.5[a]	14.5[a]	2.0[a]	19.5[b]	16.98[a]	41.52[c]
Oven dried	4.0[b]	12.5[b]	2.0[a]	12.0[c]	16.98[a]	52.52[a]
Sun dried	4.0[b]	3.0[c]	2.0[a]	26.5[a]	16.1[a]	48.4[b]
	SE = 0.28	SE= 1.78	SE = 0.14	SE= 2.10	SE = 0.20	SE = 1.61
Oryza sativa						
Air dried	6.0[a]	12.5[c]	1.5[a]	35.5[a]	12.6[a]	33.9[c]
Oven dried	5.0[ab]	15.5[a]	1.0[a]	22.0[b]	11.2[a]	45.3[b]
Sun dried	4.5[a]	14. 0[b]	1.0[a]	21.5[b]	7.88[b]	51.12[a]
	SE = 0.28	SE= 0.48	SE = 0.16	SE= 2.30	SE = 0.73	SE = 2.53

Values in a column denoted by same letters are not significantly different (P>0.05).

CONCLUSION

The results of this study shows that *Nymphaea lotus* leaves and *Oryza sativa* leaves are good sources of carbohydrate and moderate protein. However, *Typha latifolia* had relatively low carbohydrate lipid and lower protein contents together with *Oryza sativa*. drying methods were found to have effects on moisture, ash, crude fiber, crude protein crude lipid and soluble carbohydrate in all the three aquatic Macrophytes, but protein retention was highest in oven dried samples.

RECOMMENDATIONS

Research should be carried out on these leave as possible source of feed for fish and other uses. Enlightenment should be carried out to keep the communities around the study area at alert and inform the public benefits behind the maximum utilization of these plants. Based on the findings the following recommendations were drawn: It is recommended that drying under shade be adopted for drying these leaves.

23rd – 27th Oct., 2023

ABSTRACT
The study examines the analysis of crayfish marketing in Bonny Local Government Area of Rivers State. A total of 110 respondents made up the sample size for the study. Data were collected using copies of structured questionnaire and analyzed using descriptive statistics such as frequencies, percentages, mean score Likert scale, and gross margin. Results from the study showed that majority (94.5%) of the respondents were female and most (50%) of them were between the age of 31-43 years and also 73.6% of the respondents received formal education. Further findings showed that 67.3% of the sampled respondents earned ₦41,000-₦80,000 per month while 22.7% of them earned between ₦10,000-₦40,000 per month. Results on the methods of crayfish processing showed that the most common method were sorting and salting which had 21.3% and respectively. Gross margin analysis showed that a monthly average gross margin earned in the study area was ₦72508.77 and the profit stood at ₦75939.49. In respected to the constraint to crayfish marketing, results from the mean score showed that, the most prevalent constraint to crayfish preservation was the inhaling of Co2 (means score 3.381818) and that for crayfish marketing was price fluctuation (mean score =3.272727). The study recommended that Medical outreach should be organized to crayfish marketers/processors to assess the level of harm CO_2 causes to their health and educate them about the dangers of CO_2, and further suggesting preventive measures to the effect of CO_2.
Keywords: *Crayfish marketing, Crayfish processing, Costs and returns*

INTRODUCTION
Crayfish is one of the aquatic animals and dominant decapods in many freshwaters and even terrestrial habitats playing important community roles through their wetlands (burrowers), and cave ecosystems (Reynolds et al., 2013). Being an important crustacean consumed all over the world, they are usually prepared for consumption by smoking, and occasionally preserved by sun-drying. It is also a common delicacy in the diet among the people of the Southern Western Nigeria (Chinasa, 2017). It is a clean and very low carbohydrate food and has a super healthy combination of nutrients from its almost pure form of protein to its healthy amount of omega-3 fatty acids which we now know are among the most beneficial fats we can eat (FAO, 2009). Meals containing crayfish play a great role in the development of humans in the world especially in the lives of people in the developing countries where other protein sources are grossly inadequate and comparatively costly (Ele and Nkang, 2014). Experimentally, protein derived from crayfish and fish-based diet is as good as that obtained from meat. Consumption of crayfish together with products of plants origin which are poor in some amino acids such as lysine and thiamine enables not only a complete utilization of plant protein, but also improves the content of the diet (Ele and Nkang, 2014). Crayfish key roles and attributes in ecosystems include indicators or surrogates for water quality, bio-indicators for communities or habitats, keystone controllers of trophic webs and ecological engineers.
Crayfish has been used as a major source of income because of its high demand in the markets. Its market shifted from local consumption in rural areas to higher volume markets in cities such as Baton Rouge, New Orleans and beyond (Taylor, 2009). In the study area (Akwa-ibom State, Nigeria) crayfish has provided business and economic activities for the fishermen, crayfish dealers as well as consumers of crayfish (Ele and Nkang, 2014). It is estimated that about 12,000 metric tonnes of crayfish is produced annually in Nigeria and although the artificial rearing and

production of crayfish in Nigeria is not common compare to the production of fish, processing and marketing of crayfish is gaining ground because of the seasonality of supply with the peak harvest occurring 891from March through June (Robert *et al*., 2005). Marketing of crayfish passes through various market participant and exchange of crayfish point before they reach the final consumers (Baba *et al., 2015)*. The longer the chain of people involved in a marketing process, the more the costs incurred.

The demand for crayfish globally in Nigeria has been on the increase with the supply not meeting up with the demand (FAO, 2004) even though, especially inthe knowledge that Nigeria is blessed with a vast expanse of inland fresh waters and marine brackish ecosystem, which are very rich in aquatic life (Chukuigwe *et al.*, 2021; Tall,2004). It is estimated that about 12,000 metric tonnes of crayfish is produced annually in Nigeria and although the artificial rearing and production of crayfish in Nigeria is not common compared to the production of fish, processing and marketing of crayfish is from March through June (Robert et al, 2005). Thus, there is need to strike a balance between production (catching, processing, and marketing) and consumption of crayfish. One of the ways of doing this is by improving the processing and marketing system, since production, processing and marketing work together. (Mendoza and Rosegrant, 2000). The specific objectives of this study were to:

i. describe the socioeconomic characteristics of crayfish marketers;
ii. identify the methods of crayfish processing prevalent in the study area;
iii. estimate the costs and returns of crayfish marketing in the study area; and
iv. identify the constraints associated with crayfish processing and marketing in the study area.

METHODOLOGY

The study was conducted in Bonny Local Government Area (LGA), Rivers State Nigeria. Bonny Local Government Area of Rivers State is situated in South Nigeria. It is on the Bight of Biafra within latitude $4^0 26^1 0^{11}$N and Longitude 7^0 $10^1 0^{11}$ E. It is approximately 56 km from upland Port Harcourt, the capital city of Rivers State Niger Delta (Abere & Opara, 2018 cited by Harry and Brown, 2020). The LGA was estimated to have 215,358 inhabitants in the 2006 national census (NPC, 2006). Boats are the main form of transport to and from the island. The local language spoken in Bonny Island and Bonny Town is Ibani, though many natives there also speak Igbo language.

Survey research design was employed in this study where copies of structured questionnaire was used to generate data. According to the information gathered from Crayfish union in 2022 there are 151 registered Crayfish marketers in the Bonny LGA. *Taro Yamene Formula* was employed in determining the sample size of 109 marketers. However, for the purpose of equal allocation across the 10 communities in the study are, the study thus increased the sample size to 110 marketers. Multi-stage sampling was used in selecting the sample size of the study. In the first stage, the purposive selection of ten (10) communities out of the seventeen (16) communities in Bonny LGA was employed. This was owing to the fact that there was more Crayfish marketers concentrated in them. The second stage involved the simple random selection of eleven (11) crayfish marketers respectively across the following communities; Adamakiri, Agbala, Akpakpasu, Amanadama, Biemekiri, Bilemekiri, Atabakiri, Alaasiakiri, Asaramatoru, thus making a total of 110 respondents. In respect to the analysis of the data, objective (i) as achieved using tabular presentation of frequency distribution, and percentages. Objective (ii) and (iv) were achieved viz., 4 point Likert scale, and. objective (iii) was achieved using gross margin analysis.

Likert Scale Rating Technique

The study utilized the 4-point scale rating technique presented in the following order:

Strongly agreed (SA) = 4; agreed (A) = 3; disagree (D) = 2; strongly disagree (SD) = 1.

The mean scores of the respondents based on the 4-point scale would be 4 + 3 + 2 + 1 = 10, 10/4 = 2.50.

Benchmark: The benchmark using the four- point Likert Scale to analyze the constraints militating against pepper production was 2.5. The 2.5 constraint benchmark indicated the constraints that militated against farmer's production, mean values from 2.5 and above shows that the parameter is a constraint.

Gross Margin

Gross margin mode was used to determine the costs and returns from gross margin obtained; further analysis was conducted to obtain profit associated with the trade in the study area. The model is specified as:

GM = TR – TVC……………………………………………………………………eq 1.

Where: GM = Gross margin; TR = Total revenue; TVC = Total variable cost; TFC = Total fixed cost; and π (profit) = GM- TFC

RESULTS AND DISCUSSION

Socio-Economic Characteristics of the Respondents

The result from Table 1 shows that 94.5% of the respondents were females, while 5.5% of them were male. On age, it shows that 50% of the respondents were between the ages of 31-43yrs, 24.5% of them were between the ages of 18-30 years, 20.09% of them were between the ages of 44-56 years and 4.5% of the respondents were between the ages greater than 57yrs. This implies that majority of the marketers were young and vibrant people who could carry out the tedious work involved in crayfish marketing. Individuals who are in their active ages have the tendency to be more productive (Olasunkanmi *et al.*, 2012; Agbagwa, *et al*, 2021). Entries on marital status showed that 72.7% of the respondents were married, 20.9% of them were single and 6.4% of then were separated.

Furthermore, Table 1 shows that on the household of the respondents, 53.6% of the respondent had household size of 5-7 persons, 31.8% of them had household size of 2-4 persons 10% of them had household size of 8-10% and 4.5% of them had household size greater than 10 persons. This indicates that majority of the respondents had household size of 5-7 persons. This result also shows that since they had a large household size, they had the responsibility of taking care of them. Entries on years of experience showed that majority (59.1%) of the marketers had 4-6 years marketing experience followed by 20.9% of them who had 1-3 years of experience. Sadiq *et al.* (2015) posited that experience enhances risk management. Entries on educational attainment show that majority (53.6%) of the respondents had secondary school educational attainment while 26.4% of them received no formal education. On monthly income earned by the marketers, 67.3% of the respondents earned ₦40,000-₦80,000, 22.7% of them earned ₦10,000-₦40,000, 5.5% of them earned ₦81,000-₦120,000, and 4.5% earned greater ₦120,000.

Field Survey, 2022

Methods of Processing Crayfish

Result in Table 2 shows that 21.30% of the marketers utilized sorting as one of the methods in the processing of crayfish. In addition, 20.40% and 18.80% respectively utilized salting and smoking of crayfish as methods of crayfish processing. While 18.80% marketers engaged in washing 10.20% utilized cleaning while 10.40% employed sun drying as one of the methods of crayfish processing.

Table 2: Methods of Crayfish Processing Prevalent in the Study Area

Method	N	Percent	Percent of Cases
Smoking	85	18.80%	77.30%
Sun drying	47	10.40%	42.70%
Salting	92	20.40%	83.60%
Washing	85	18.80%	77.30%
Cleaning	46	10.20%	41.80%
Sorting	96	21.30%	87.30%

Profitability of Crayfish Marketing

The result in Table 3 shows that variable cost of marketing per month was ₦151,611. Total revenue was ₦224119. The Table further shows that ₦72508.77.00 was obtained as the gross margin (GM=TR-TVC). The average monthly profit form crayfish marketing in Bonny LGA was ₦75,939.49. This is evident that the marketing of crayfish in Bonny is profitable. More so, the rate of return of return on investment was ₦1.45 which would imply that for every ₦1 invested in crayfish marketing, ₦1.45 was gained by the marketer.

Table 3: Average Monthly Costs and Returns on Crayfish Preservation and Marketing

ITEM	AMOUNT (₦)
Total Revenue (TR)	**224119.8**

Constraints to Crayfish Preservation

The constraints to crayfish processing are presented in Table 4. The result shows that inhaling of carbon dioxide (CO_2), undesirable odour and drudgery were seen by the marketers as a constraints as they had mean scores greater than 2.50. The marketer also admitted that drudgery associated with the processing of crayfish was a constraint in the business. In another vein, lack of processing facilities, inadequate knowledge and lack of finance were not considered as constraints as they had mean scores less than 2.50.

Table 4: Constraints to Crayfish Processing

Constraints	**SA**	**A**	**SD**	**D**	**Total Score**	**Freq.**	**Mean**
	4	**3**	**2**	**1**			**($\bar{X}$)**
Lack of processing facility	20	48	136	21	225	110	2.045455
Inadequate knowledge	0	18	126	41	185	110	1.681818

$\bar{X}$ >= 2.50 = important; $\bar{X}$ < 2.50 = unimportant

Where: SA = Strongly Agree A = Agree, D = Disagree, SD =Strongly Disagree

Source: Field Survey, 2022

Constraints to Crayfish Marketing

The constraints to crayfish marketing as identified by the respondents are presented in Table 5. The result shows that poor infrastructure, price fluctuation and loss of capital due to debtors were considered by the marketers as constraints to the trade as they had mean scores greater than 2.50. This indicates that poor infrastructure, price fluctuation and loss of capital due to debtors were the major constraints to crayfish marketing in the study area. However, marketing location and perishability were not seen as constraints.

Table 5: Constraints to crayfish marketing

Constrains	**SA**	**A**	**SD**	**D**	**Total Score**	**Freq.**	**Mean**
	4	3	2	1			**($\bar{X}$)**
Poor infrastructure	20	150	110	0	280	110	2.545455
Marketing location	60	60	140	5	265	110	2.409091

$\bar{X}$ >= 2.50 = important; $\bar{X}$ < 2.50 = un important

Where: SA = Strongly Agree A = Agree, D = Disagree, SD =Strongly Disagree

Source: Field Survey, 2022

CONCLUSION

The study showed that that crayfish marketing is profitable in Bonny LGA and is highly dominated by females. The most dominant method used in the processing of crayfish in the study area was sorting. The study further adds that while inhaling of CO_2, undesirable odour stood as the major constraint to crayfish processing, Price fluctuation and Poor infrastructure were adjudged the major constraints to crayfish.

RECOMMENDATIONS

Based on the findings obtained, the study recommends that:

i. Medical outreach should be organized to crayfish marketers/processors to assess the level of harm CO_2 causes to their health and educate them about the dangers of CO_2, and further suggesting preventive measures to the effect of CO_2.

ii. Modern processing facilities that emits less of CO_2 be provided to the marketers to enable them process crayfish with lesser health risk.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study assessed the effect of artisanal fisheries on the livelihood of fishing communities along Kainji dam, Nigeria. Questionnaire schedule was used to collect data from 460 respondents. Multi-stage and proportionate sampling techniques were used in selecting the respondents. Descriptive statistical tools (frequency distribution count, percentages and mean) and inferential statistics (logit regression) were used for data analysis. The Logit regression estimates of the effect of artisanal fisheries on livelihood sustainability status of the fishers shows that the coefficients with respect to household size X^1, access to credit X^2, age X^3, fishing experience X^4, livelihood diversification X^5 and income from fishing X^6 were statistically significant at 1% level of significance while access to extension X^7 was significant at 5% level of significance. The estimated fish catch per unit effort has declined to less than 2 kilograms compared to more than 8 kilograms realized by 42.5% of the fishermen before the establishment of the dam. In conclusion, the research showed that, artisanal fishing activity is important in the lives of the fishers along the two dams and thus need to be sustained. The study therefore, recommended that financial institutions should grant credit facilities to practicing fishers with easy collaterals.. Government should provide improved fishing and processing postharvest inputs to fishers at subsidized rate to avoid spoilage during storage and transportation. Fisheries extension agents should facilitate awreness and adoption of improved fishing techniques.

Keywords: *Effect, Artisanal Fisheries, Livelihood, Fishing Communities, Kainji Dam*

INTRODUCTION

The fisheries subsector of the Nigerian agriculture is an essential tool for rural development through its provision of income, high-quality protein, and socioeconomic development of fishing communities in Nigeria (Anko and Eyo, 2001). The relevance of the fisheries sub-sector to the Nigerian economy and benefits derived by Nigerians from fish and other fish products has led to the high consumption and hence the increased demand for fisheries products. In order to meet up with increasing demand for fisheries products, Nigerian federal government have tremendously implemented series of projects targeted at increasing the local supply of fish. Some of the projects include second and third phases of Fadama programme, source although some improvements were recorded in terms of output levels of fish, the gap between the demand and supply of fish keeps increasing as a result of the use of traditional fishing methods, as is the artisanal fishery, which has the major source of protein from fish relied on, despite the increasing growth rate of the Nigerian population. Fisheries production in Nigeria especially from marine is important for the socio-economic development of Nigerians and it contributes to the nation's economic growth through the Gross Domestic Product (GDP) (Shehu and Kafayat, 2017).

METHODOLOGY

Kainji Lake is located between latitudes 9°5' and 10°55'N and longitudes 4°21' and 4°45'E. It cuts across the Niger and Kebbi states, and is mostly located in Niger state. Kainji is the second largest lake and the largest man-made lake in Nigeria (Umar and Illo, 2014). It was created in 1968 following the impoundment of the Niger River by the construction of the Kainji Dam at New Bussa, in Borgu Local Government Area of Niger State. It has a maximum length of 134km, a maximum width of 24.1km, a mean and maximum depth of 11m and 60m, respectively, a surface area of 1,270sqkm, a volume of 13 × 10^9m^3, and a catchment area of 1.6 × 10^6sqkm. The climate of the Kainji Lake usually alternates between dry and rainy conditions. The total annual rainfall for the Lake ranges between 1,100 mm and 1,250 mm, spreading from April to October (Salami *et al.*, 2011). The highest (about 30°C) and the lowest (about 25°C) monthly temperatures are recorded in March and August, respectively. Fishing is the major traditional occupation of these people whereas other occupations include: farming, livestock breeding and local entrepreneurship such as pottery, mat weaving, gear/craft making and servicing (Alamu, 2000). Both primary and secondary data were used for the study. The study identified 550 fishing communities along Kainji dam. The fishing communities have a fishing population of 3,823 along Kainji. This figure 3,823) represents the sampling frame out of which the sample size of the study was drawn. The study employed multi-stage and proportionate sampling techniques. Firstly, Kainji dam in North central region where artisanal fisheries activities are widely practiced was purposively selected. Secondly, 50 Villages were randomly drawn along Kainji dam for the study. Thirdly, proportionate sampling technique was then employed to select 460 respondents along the dam to be used as the sample size for the study.

Data were analyzed using both descriptive and inferential statistics. Descriptive statistics such as frequency distribution count, percentages and mean were used to analyze objectives 1. Similarly, Logit registration were used to analyze objectives 2.

Logit Regression Analysis

Specification of the Model

Logit Regression Analysis (LRA) was employed to analyze objective 2. The Logit model is an inferential statistical regression model that describes the relationship between a censored continuous dependent variable y_i and a vector of independent variables x_i (Amamiya, 1998).

Y_i is the dependent variable and X_{i} – X_{14} are the independent variables

The general Logit regression model is mathematically expressed as:

$Y = \alpha + \beta o + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \ldots + \beta_{11} X_{11} + U$………………. (1)

Where Y = Livelihood (Implying a binary dependent variable valued as 1= when household has sustainable livelihood and 0= when otherwise.

X_i =Fishing technology (1 for local, 2 for modern, 3 for combined)
X_2 =Income from fishing (₦)
X_3=Processing method (1 for traditional processing method, 0 for otherwise)
X_4=Quantity of fish caught (Kg)
X_5=Household size (Number)
X_6=Period of fishing (1 for dry season, 0 for otherwise)
X_7=Experience in fishing (Years)
X_8= Membership of association (1 for member, 0 for otherwise
X_9=Access to credit (1 for access, 0 for otherwise)
X^{10}= Access to extension (1 for access, 0 for otherwise)
X_{11}= Age of fishers (Years)
X^{12} = Packaging method (1 for local, 2 for modern)
X^{13} = Livelihood diversification (1 diversified, 0 no diversification)
X^{14} = Distance to fishing site (Km)+
U=Error term
βi =Constant term
$\beta i - \beta_{10}$=Regression coefficient to be estimated (Amamiya, 1998).

RESULTS AND DISCUSSION

Table 1 shows the logit regression estimates of the effect of artisanal fisheries activities on livelihood sustainability of fishers along Shiroro and Kainji dams. The study found that artisanal fishing is a viable and a profitable enterprise capable of providing employment opportunities among the fishing communities of the two dams. The model predicted the livelihood sustainability status of fishers with 85.3 percent accuracy, according to the results of the logit regression provided in Table 1 in terms of predictive efficacy. The results also demonstrated that in understanding the effect of artisanal fisheries activities on livelihood sustainability status, the model was adequate. Six of the eleven factors in the model (Household size, Access to credit, Age, Fishing experience, Quantity of fish caught, Income from fishing) were found to be significant at 1% level of significance and one other variable (Access to Extension) was significant at 5% level in explaining the variation in the livelihood sustainability status of fishers in the study area. Household size of the fishers has a negative coefficient but statistically significant (t = -3.42, p0.01). As a result, the effect of artisanal fisheries on livelihood sustainability of the fishers in households would decline as the size of the household increased. A unit increase in the size of the household will result in a 0.06 reduction in the likelihood that livelihood will be sustainable. This outcome was anticipated because more homes means more people are consuming the same resources. Larger households experience unsustainable livelihood more frequently than smaller ones (Jared, 2021). This findings is in line with Umunna *et al.*, (2020) who reported that the household size of the respondents was observed to have a positive significant ($p<0.1$) influence on the likelihood of livelihood sustainability. The coefficient of household size have a positive and significant relationship with the possibility of the fisher's household's livelihood sustainability. This study is in congruence with the findings from previous similar studies (Toyosi *et al.*, 2019). The marginal effect of household size revealed that the likelihood of livelihood sustainability will increase by 4.3% with an additional member in the household. Findings of this study agrees with that of Ifeanyi-obi *et al.*, (2018) who confirm a positive association between household size and on-farm livelihood sustainability. The results show further that for every unit increase in household size, there is a 0.83 increase in the log odds of on-farm livelihood sustainability by households, holding all other independent variables constant. These findings suggest that as household size increases, so does on-farm livelihood sustainability. The model confirms a positive association between the fishing experience and livelihood sustainability of the fishers. The results indicates that for every unit increase in the years of fishing experience of the fishers, there is a 0.06 increase in the log odds of livelihood sustainability, holding all other independent variables constant. These findings therefore suggest that as years of fishing experience increases, so doe's livelihood sustainability.

Access to extension contact has a positive coefficient ($t = 2.17$, p 0.05) that is significant at 5% level. This outcome is anticipated since extension agents are expected to communicate information and/or enlighten fishers on improved fishing technologies that can enhance productivity (fish catch) of the fishers. This is in turn expected to translate to a higher income and livelihood sustainability. This result is in disagreement with the result of Ismail (2014) who reported that the coefficient of extension contact correlated negatively with livelihood sustainability with a t-value of 2.476 which was significant at both 0.01 and 0.05 probability levels respectively. This implies that the more the rural dwellers come in contact with extension agents the more they engage into other livelihood activities. The model results confirm a positive relationship between access to credit and fishers livelihood sustainability. The results showed that holding all other independent variables constant, for every unit increase in credit accessibility, there is a 1.67 increase in the log odds of livelihood sustainability of the fishers. It is believed that access to credit promotes the use of risky activities through relaxation of the liquidity constraint as well as through boosting of a household's risk-bearing ability. With an option of borrowing, a household can do away with inefficient risk reducing income diversification strategies and concentrate on more risky but also more efficient investments.

The coefficient of age of household has been found to have a significant ($t<4.24$) and negative influence on the probability of livelihood sustainability. In other words, the multiplicity of livelihood activities the fishing households engage in decreases with advancing age. This study in in congruence with George *et al.*, (2012) who reported that the age of the fishers positively and significantly affect income at 5% level of significance with coefficient of 0.004 and p value of 0.001. This implied that the income of the fishers increased by 4% as the fishers age increased by one year. The coefficient of monthly income correlated positively with livelihood activity with a t-value of 2.21 which was significant at 0.01 probability level. This could imply that rural dwellers who earn higher monthly income have their livelihood activities enhanced and sustained other than fishing. This may be as a result of having more money which can enable them invest in other livelihood activities other than fishing.

Table 1: Logit regression estimates of the effect of artisanal fisheries on Livelihood sustainability of fishers (n = 460)

Variables	Parameters	Coefficient	Standard Error	t-Value

Source: Field Survey, 2023 *significant at 10% level, **significant at 5% level, ***significant at 1%level

Result from table 2 shows that majority of the respondents (42.5%) indicated that their fish catch per unit effort before the establishment of Kanji Dam was more than 8 kilograms while majority (47.5%) of the respondents indicated that their fish catch per unit effort after the establishment of the dam was less than 2kg. The result of the study agreed with the findings of Ita (1982) who reported that early fish yield after the impoundment reached 28,639 metric tons in 1970, after which the yield declined to 4,500 metric tons in 1978 (Ekwemalor, 1978). Balogun (1985) attributed the decline in fish catch per unit effort to presumed increase in fishing pressure and use of undersized fishing gears. As a result, Juvenile of most fish species are indiscriminately accepted, thus preventing smaller fish to grow to adult or marketable size. Results of the study also showed that 71.9% of the respondents who engaged in fishing attributed the declining fish catch recorded over the years to construction of Kainji dam while 28.1% attributed it to the migratory fishermen who engaged in massive fish catch using sophisticated fishing equipment such as beach seine (*Dala*). Discussions additionally revealed the following as causes of declining fish catch: Use of beach seine (*Dala*) which catches eggs and juvenile fish and prevent the growth of smaller fish, Menace of storms, and water hyacinth which causes tearing of fishing nets, Cutting of Niger grass by fishermen in order to catch all fish species that inhabit the particular surrounding water body, High wind turbulence caused by massive cutting of Niger grass which displaces fishing nets, Use of fish fencing (*dumba*) which catches small-sizes of fish. This is made from rows of trap with nylon net of fine mesh with size of about 1 inch (25mm) and arranged in rows of several kilometers to form barrier to fish passages. The total declining yield estimates reported by Erinne (1989) are shown on table 24.Furthermore, 68.8% of the respondents indicated that there are certain fish species that disappeared from the waters of Yauri after Kainji dam construction.

Table 2: ***Distribution of Fishermen Based on Estimated Fish Catch per Unit Effort n= (460)***

Fish Catch Per Unit Effort (kg)	Before the Dam	After the Dam
Less than 2	30(6.5)*	190(41.3)
2-4	21(4.6)	18(3.9)
4.1 – 6	23(5.0)	24(5.2)

CONCLUSION

The research work was carried out on the effect of artisanal fisheries on livelihood of the fishing communities along Kainji dam, Nigeria. From local to global levels, artisanal fisheries play important roles in food supply, income generation and nutrition. Encapsulating appropriate instruments that may enhance artisanal fish catch levels is one of the most intractable challenges in developing countries, Nigeria inclusive. The outcome of this study shows that fishers do not receive adequate extension services which should have exposed them to better fishing techniques. To conclude, the research showed that, fishing activity is important in the lives of the fishers along the two dams. The constraints that faced the industry such as high cost of fishing gears, lack of credit facilities, lack of modern technology, poor storage facilities, inadequate extension services, shortage of manpower and lack of government incentives hinder full realization of the potentials of the artisanal fishing industry

Based on the effect of artisanal fisheries on livelihood of fishers, findings indicated that artisanal fishing had an effect on the livelihood of the fishers because it is a viable and profitable enterprise capable of providing employment opportunities in the rural communities. Government organs responsible for fishery development should promote the development of both artisanal and aquaculture so as to meet the fish demand supply deficit in Nigeria.

Fisheries extension agents should advise fishers to properly use their wealth of experience in fishing to drive home more fish landings. This could be achieved through the use of fisheries membership association, accessing credit facilities and costing all the resource inputs used in the fishing activities including fishing gears used with the view to genuinely assess the economic worth of fishing enterprises.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was designed to assess the constraints faced by artisan fishermen in Yauri Emirate, Kebbi State, Nigeria. Ninety (90) artisan fishermen were selected using two-stage sampling techniques. Questionnaire and interview schedule were used to obtain information from the respondents. The data obtained were analyzed using frequency distribution tables, percentages and mean. On the socio-economics characteristics of the artisan fishermen, it was found that the majority (58%) of the respondents were male; 36% of the respondents were having secondary school Education as their highest level of education. Also,31% have fishing experience of below 10 years with yearly fish output of above 1000kg and yearly income of greater than ₦200,000.00. While 81% belong to one form of co-operative society or the other. Extension agents have visited none of the respondents. The constraints faced by artisan fishermen were seasonal changes in the volume of water, inadequate finance, and poor sales. Based on the findings of the study, it was recommended that, the government and other appropriate authorities should enforce the fishing laws and regulations to avoid illegal exploitation of fishing grounds and ensure the sustainability of artisan fishing by making extension services available to fishers in the Emirate.
Keywords: *Assessment, Artisan fishermen, constraints, Yauri Emirate.*

INTRODUCTION
The existence of enormous water bodies offers great potentials for the development of the fishing industry in Nigeria. Fisheries development began in 1914 in Nigeria when the first fisheries office was established as a component of the Agricultural office of the colonial administration (Anko & Eyo, 2003). Artisanal fishery subsector accounts for over 80% of total fish output in Nigeria as evidenced by available data from the Federal Department of Fisheries. An artisanal, traditional or small scale fishery is used to characterize those fisheries that were mainly non-fishery in tropical developing countries (Berkes,*et al* 2007). Ekpo and Essien-Ibok (2013) noted that artisanal fishing is a major producer of fish for the teaming population of Kebbi State and Nigeria at large though in the recent times, there has been a significant drop in the quantity of fish catch in the area. Generally, artisanal fishing operation is tedious and characterized by low individual productivity. The problems faced by artisanal fishers in Nigeria are not far from what is experienced by artisanal fishers in Yauri Emirate. Some of the problems faced by artisanal fish farmers in Yauri Emirate include lack of enforcement of fishing regulation, changes in the volume of water and climatic factors, the use obnoxious means in fishing, poor mesh size regulation (the use of wrong type of fishing gear by trawlers and fishers) and continuous increase in the price of fishing gears (Anko & Eyo, 2003). This research was designed to assess the socio-economic characteristics and constraints faced by artisanal fishers in Yauri Emirate.

METHODOLOGY
Study Area
Yauri is an emirate in Nigeria's occupying the Yauri Local Government Area. Kebbi State, it is located at latitude 10^0 44' 33.59" N and Longitude 4^0 46' 23.99" E, it is one of the smallest historical emirates in Northern Nigeria. In 1972, the population was about 112,000 people inhabiting a land area of about 1,306 square miles (3,380 km^2) and scattered over six major districts. The area was first settled by an eastern group around early 1000-1200 AD. Farming is the major occupation of early settlers because of the fertile land and gradually fishing because of the river (Salamone 1980).

Data Collection and Analysis

Ninety (90) artisanal fishers were selected using two-stage sampling techniques. Questionnaire and interview schedule were used to obtain information from the respondents. The data were analyzed using percentages, mean and regression analysis.

RESULTS AND DISCUSSION

Socio-economic Characteristics of the Fishers

Table 1 showed the socio-economic characteristics of artisanal fishers in the study area. The majority (58%) of the respondents were male. This is an indication that males were more in artisanal fishing in the study area. This agrees with the findings of Okeowo, *et al* (2014) which revealed that males dominate artisanal fishing. The table further showed that 76% of the artisanal fishers were 50 years and below. This is an indication that majority of the proportion of the artisanal fishers in the study area are still in their active age. This agrees with the findings of Shettima *et al* (2014), which indicated that most of the fishers were in their youthful age. The table also reveals that the majority (73%) of the artisanal fishers were married. This indicates that many of them are saddled with family responsibilities and as such have the tendency of abandoning fishing if there is no enough financial proceed to take care of their family. This also agrees with the findings of Okeowo *et al.* (2014) who revealed that majority of the respondents in Epe and Badagry were married. Only 27% did not have any formal education, the remaining 73% had primary, secondary or tertiary education. The majority of the artisanal fishers are literate enough to adopt new technologies that can improve their fishing activities since education is known to increase fisherman's tendency to adopt new technologies. (58%) majority of artisanal fishers have household size of 5 persons and above. They maintain moderate number of persons in the households. The table revealed that 69% have fishing experience of over 10 years and had stayed long enough in the enterprise to have acquired the necessary knowledge and skill involved in the fishing enterprise. Only 9% of the artisanal fishers have yearly fish output of 400kg and below. The rest have more than 400kg. Only few proportion (31%) produce above 100kg. this shows that the majority of the fishers don't produce substantial quantity. (53%) a good number of fishers earn N200, 000 and above on yearly basis. This is an indication that many of them are still living below the poverty index. It was also shown in Table 1 that 81% of the artisanal fishers are members of co-operative society. This indicates that a cordial relationship exists amongst the fishers and as such extension services if and when available would be easy. All (100%) of artisanal fishers agreed that no extension agent has ever visited them. This is surprising as agricultural extension agent are supposed to extend their services to these group of fishers.

Constraints faced by artisanal fishers in Yauri Emirate

Table 2 showed the constraints faced by artisanal fishers in Yauri Emirate, Kebbi State. It showed that out of the thirteen variables used to capture the constraints artisanal fishers faced in the fishing activities; only four were not seriously affecting the fishers namely; religious barriers, increased on fisheries resources, lack of extension services and unfavorable union activities and levies. The fishers do not even know what extension services are all about as they have never seen any extension agent around and such do not appreciate the need and use of extension information to improve their fishing activities. Other factors including conflict amongst fishers, type of instrument used, shortage of man power, inadequate finance, poor storage facilities, poor sales, and high cost of instruments were some of the constraints found to be affecting the fishers in the seriously in the study area. Shettima *et al.*, (2014) revealed that 24% of the respondents were constrained by breeze (wind), 14% of the fishers indicated unavailability of fish during windy periods and when there is high water volume as the constraint they faced in the study area. It was ranked second most important constraint by the respondents. The other constraints faced by the fishers in the study area were unavailability of fishing equipment (20%), lack of formal education (15%) and insufficient fund (18%) ranked fourth, fifth and sixth respectively.

Table 2: Constraints faced by artisanal fishers in Yauri Emirate

S/N	Factors	Standard deviation	Mean
1.	Religious barriers	0.00	1.0
2.	Conflict amongst farmers	1.17	3.4*
3.	Use of crude tools	0.00	5.0*
4.	Type of instrument	0.99	3.2*
5.	Shortage of man-power	0.94	3.1*
6.	Increased pressure on fisheries resources	1.06	2.0
7.	Inadequate finance	0.77	4.6*
8.	Poor storage facilities	1.10	3.9*
9.	Poor sales	0.72	4.4*

Relationship between artisanal fishers' socio-economic characteristics and constraints

Table 3 showed the result from ordinary least square regression analysis to determine the relationship between the artisanal fishers' socio-economic characteristics and the constraints faced. The linear functional form was chosen as the lead equation based on the high value of R^2, number of significant coefficients, appropriateness of signs and highest F-value, ($F=10.51$; $P\leq0.5$). The coefficient of multiple determination (R^2) value of 0.58 indicates that about 58% of the variation in the constraints faced in artisanal fishing could be explanatory variables while the remaining 42% was due to other factors not specified in the model. The coefficient of age (x_2) correlation positively and significantly with the constraints faced in artisanal fishing. This could imply that older fishers face more constraints in their fishing activities than the younger ones. This may not be surprising as older fishers who have passed their productive age are known to be physically weaker than younger ones and may find it more difficult to face the challenges in fishing activities. Educational attainment (x_4) and fishing experience (x_6) were negative and significant at 5% significant level. More educated fishers are known to possess more skills and knowledge to tackle challenges, adopt new technologies and adapt to changing environment. Also, fishers who have spent more number of years in fishing activities are known to have gathered more skills and knowledge to tackle challenges and constraints more vigorously than ones with less experience. Furthermore, yearly income of the fishers was negatively significant at 10% probability improved practices that could lessen the constraints and challenges faced in their fishing activities.

Table 3: Relationship between artisanal fishers's socio-economic characteristics and the constraints faced.

CONCLUSION AND RECOMMENDATION

The constraints faced by fishers in Yauri Emirate, Kebbi State are Fluctuation in the volume of water, inadequate finance, Lack of extension services, poor storage facilities, poor sales, and high cost of instruments. These constraints need to be addressed to improve productivity of artisanal fishers in Yauri Emirate. It is recommended to enforce fishing laws and regulations to avoid illegal exploitation of fishing grounds, mesh size regulation, access to fund to improved their fishing equipment or instrument and access to information through extension serves in Yauri and other parts of Kebbi state and beyond.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
African catfish (Heterobranchus bidorsalis) is cultured as food fish and is also used to control overpopulation in tilapia ponds. High demand for catfish fingerlings has resulted in many farmers venturing into the fingerling production business. In this study, the performance of three different feeds: live zooplankton (Moina micrura), Artemia and coppens on the growth performance of H. bidorsalis fry, were assessed. H. bidorlis fry were raised in 9 plastic tanks for a period of 16 days. M. micrura was in a mono specific state and were harvested washed clean from algae and fed to fish. Feeding was done for five days to satisfaction with the treatments (Artemia, Coppens and live M. micrura). Data analyzed showed that there was significant difference (p<0.05) in all the growth parameters assessed. Result of the study further revealed that percentage mean weight gain, specific growth rate, increase in length and condition factor were highest (116.45%, 4.83, 2594.4% and 5.28) in fry fed live zooplankton (M. micrura) whereas survival rate was not significantly different between LPZF1 and LPZF2 respectively. Water quality parameters monitored were within the acceptable range (temperature; 27-30°C, dissolved oxygen; >3mg/L, pH; 7.3-8.5 etc) for fry production. Commercial fish farmers practicing H. bidorsalis fry culture are recommended to raise their larvae on live M. micrura as starter feeds for the purpose of enhancing faster growth performance.
Keywords: *Heterobranchus bidorsalis, Moina micrura, Artemia and coppens*

INTRODUCTION
Many fish larvae require live food at the onset of exogenous feeding. Nutrient assimilation studies in fish larvae at the onset of exogenous feeding are limited by a number of factors. The composition of artificial diets can be modified easily but their acceptance by the larvae is often low (Schlechtriem, *et al*., 2004). When fishes raised in semi-intensive ponds are supplemented with low protein feeds, dietary protein is largely provided by the natural food. Hepher (1988) and Schroeder *et al*. (1990) reported that natural food contributed between 300 and 500 g/kg of growth when tilapia was supplemented with artificial feeds in fertilized ponds. The protein content of natural food ranges between 550 and 700 g /kg on a dry matter basis (Hepher, 1988). For many fish species, the larval period is considered critical in their life history. Success of larval rearing depends mainly on the availability of suitable diets that are readily consumed, efficiently digested and that provide the required nutrients to support good growth and health (Giri, *et al*., 2002). Larvae, especially first-feeding larvae, generally depend on live food. While live food is difficult to sustain and requires considerable space and expense, micro diets are easier to maintain and usually have lower production costs (Jones *et al*., 1993, Person-Le Ruyet *et al*., 1993). The development of formulated diets allows for production of valuable fish larvae without using live prey. The possibility of replacing live feed with manufactured diets from the onset of exogenous feeding has been investigated in several studies (Jones *et al*., 1993, Person-Le Ruyet *et al*., 1993). Limited success has been achieved in first feeding larvae with the complete replacement of live feeds. In freshwater zooplankton, cladocerans are important because many of them are voracious predators, feeding on algae, ciliates, rotifers, larval insects, and small cladocerans (Monakov 2003), thereby structuring plankton communities.
Several cladoceranss, are facultative predators and grow better on animal diets (Williamson and Reid, 2001). Wang *et al*. (2005) found that the survival was significantly higher in larvae fed live food than in larvae fed the three formulated diets. Introduction of live zooplankton is therefore being investigated as an alternate to pond

fertilization for increasing fish yields while avoiding water quality deterioration, (Jha, *et al*., 2007). A variety of environmental factors are known to affect zooplankton production. Recent research has focused on the relative importance of food quantity and quality. Among zooplankton, brine shrimp (*Artemia spp*) and moina (*Moina micrura*) have been used most extensively as a live food for rearing of marine and freshwater fishes (Bengtson *et al*., 1991). The use of *Artemia nauplii* is well established due to its many advantages: year-round availability as on the shelf cysts; good nutritional value for some fish; and relatively easy improvement through simple enrichment techniques (Leger *et al*., 1986). Aquaculture production of *Heterobranchus bidorsalis* has been practiced for a long time in Africa. Increased productivity of fry and fingerlings with attributes of faster growth rates and better environmental tolerance, and ensuring fish food security in Africa. *Heterobranchus* exhibits many qualities that make it suitable as aquaculture candidate. These include ability to withstand stress, disease resistant, fast growth rate, high yield potentials, high fecundity and good taste among others. They can also withstand low dissolved oxygen (D.O.) and pH level and grow on turbid water. Growth and survival data are powerful tools for understanding the effects of both live and manufactured diets on first-feeding fish larvae (Wang *et al*., 2005). The present study was conducted to evaluate the growth performance and survival rate of *H. bidorsalis* fed live zooplankton and processed feeds.

MATERIALS AND METHODS

Procurement of Experimental Fish.

Heterobranchus bidorsalis broodstocks were sourced from a reputable fish farm and they were acclimatized for a period of seven days, during which they were fed four times daily. The broodstocks were used for breeding to obtain the fry that was used for the study. Nine hundred (900) *Heterobranchus bidorsalis* fry was used for the study.

Collection, Identification and culture of *Moina micrura*

Moina micrura was collected from the Department of Aquaculture and Fisheries Management fish farm of the Faculty of Agriculture, Nasarawa State University Keffi, Shabu- Lafia Campus. Lafia is located on latitude 8° 35'N, longitude 8° 32'E, altitude 181.53m above sea level with a mean temperature of 34°C, relative humidity of 40-86% and average day light of 9-12h (NIMET, 2011).

Moina micrura was cultured in mono-specific state on filterate of manure according to the method Okunsebor (2014) for 14 days. Plankton net was used to harvest the *Moina micrura* to feed the fry four (4) times daily to satiation. The *Moina micrura* were collected and used for the feeding of the fry after they were washed clean from algae.

Experimental Procedure

The experiment was carried out in three treatments and three replicates comprising of: live *Moina micrura*, processed artemia and coppens for the period of 16 days. The fry were selected at random from the acclimatized population and stocked at 100 fry per 30 litres of borehole water in a rearing bowl. Water was changed regularly after four days and aerator was used to maintain dissolved oxygen required. Water quality parameters (pH, dissolved oxygen, temperature, carbon dioxide etc) were monitored using water testing kits.

Statistical Analysis

Data collected in this experiment was analysed using Analyses of variance (ANOVA) and significant mean was separated at 0.05 probability level as described by (Steel *et al*., 1997).

Results and Discussion

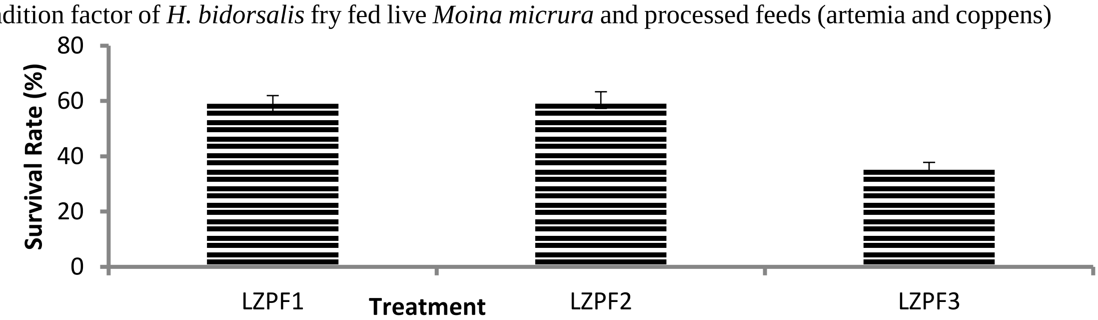
Figure 4: Condition factor of *H. bidorsalis* fry fed live *Moina micrura* and processed feeds (artemia and coppens)



LZPF1 = *Moina micrura* LZPF2 =Coppens LZPF3 = Artemia

Figure 5: Survival rate of *H. bidorsalis* fry fed live *Moina micrura* and processed feeds (artemia and coppens)

Growth of the *Heterobranchus bidorsalis* fry was significantly affected by different diets. Fry fed on *Moina micrura* showed superior growth over those fed on artemia and coppens. This results agrees with the findings of Lim *et al*. (2002) and Paulet (2003) for larval of goldfish, *Carassius auratus*. These workers found that the larvae fish grew best on live zooplankton than other first feed used in larvae culture. Adeyemo *et al*. (1994) similarly reported that *Heterobranchus bidorsalis* and *Clarias gariepinus* grew better when fed with *Moina dubia* (a freshwater zooplankton) than when fed with *Artemia nauplii*. On the contrary, Hung *et al*. (1999) reported that larvae of Mekong catfish, *Pangasius bocourti* exhibited lower growth performance when fed with *Moina sp*. compared with *Artemia nauplii*. Also, Kerdchuen and Legendre (1994) reported a better growth performance of *Heterobranchus longifilis* fed with *Artemia nauplii* than *Moina sp*. The poor growth of African catfish larvae fed artificial diet had also been reported for other catfishes: *Heterobranchus longifilis* (Kerdchuen and Legendre, (1994), *Clarias gariepinus* (Adewolu and Ossai 2001), Mekong catfish, *P. bocorti* (Hung *et al*., 1999) and *Chrysicthys nigrodigitatus* (Adewolu, 1998).

The reason for the poor growth may be related to the texture of the dry feed, its digestibility and nutrient leach in water. In addition, may also be related to lack of functional stomach, particularly the absence of proteolytic enzymes during the first few days of exogenous feeding (Kerdchuen and Legendre, 1994; Mills *et al*. (1996). Dabrowski (1982) reported that many fish fry do not have enzymes for digesting artificial diets and digestion in these fish larvae is carried out by enzymes present in their live diets.

The specific growth rate obtained in this study was between 3.09 – 4.83. This result is very close to the maximum average SGR values (4.07 – 4.19) calculated in *Clarias gariepinus* after a 10-day feeding period with decapsulated cysts of *Artemia* (Verreth and Den Bieman, 1987) and suggests that *H. longijïlis* and *C. gariepinus* fry have a similar growth potential. Significant differences were found among treatments in total length (TL) over the culture period. Fish growth for the culture duration appears to have been influenced by the type of diet. The growth in length of fry in this study was considered to be significantly higher than what has been reported in the literature. Verreth *et al*. (1993) reared *Clarias gariepinus* larvae for 10 days on decapsulated Artemia cysts. They obtained a mean TL of (15.954 ± 1.021 mm) after 10 days.

Condition factor of fry fed live zooplankton (*Moina micrura*) was above 3.0 which is an indication that the fish have better well-being compared to fry fed artemia and coppens with condition factors below 3.0. Condition factors value from 3 and above indicates a robust fish while values below 3 indicates a lean fish (Le Cren, 1951). In this work, it was observed that survival rate of fry fed with Artemia and coppens were similar and higher than survival rate of fry fed live zooplankton (*Moina micrura*). The lower survival rate recorded in fry fed *Moina micrura* could not be attributed to diet composition but could be as a result of differential growth which causes cannibalism among the fish in the treatment (Nyina-Wamwiza *et al.,* 2007).

CONCLUSION AND RECOMMENDATIONS

In conclusion, this study has shown the superiority of live *Moina micrura* over Artemia and Coppens, as live food for the *Heterobranchus bidorsalis* fry. Fry fed with live *Moina micrura* had better growth survival rate and increase in length compared to fry fed artemia and coppens.

Artemia and Coppens are imported and may be expensive for an average fish farmer, therefore *Moina micrura* may be a better alternative to them as this zooplankton is locally available in most freshwaters in Africa. Commercial fish farming practicing *Heterobranchus bidorsalis* fry culture are recommended to raise their larvae on live *Moina micrura* as starter feeds for the purpose of enhancing faster growth performance. Environmental conditions along with water parameters should be monitored and checked when breeding African catfish like other fish species for higher survival rates and higher growth performances.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted on growth performance, nutrient utilization and carcass composition of African catfish juveniles fed with processed watermelon seed meal-based diet. Four (4) treatments in three replicates were stocked with 30 juveniles of Clarias gariepinus under flow through system and were fed supplemented watermelon seed meal diet at 0%, 25%, 50% and 75%. Feeding was done 8:00am in the morning and 7:00pm in the evening at 3% body weight/day for 70 days and was adjusted fortnightly at new weight. Water quality parameters was monitored and maintained. The result revealed that mean weight gain (11.98±0.00) percentage mean weight gain (91.24±0.00), specific growth rate (0.17±0.00), and feed intake (592.05±36.64) were significantly higher in treatment fed T2 (25% watermelon seed meal inclusion) whereas feed conversion ratio (2.90±0.000) and survival rate (90.00±0.00) were significantly higher in T1 (0% watermelon seed meal inclusion). The use of watermelon seed meal as supplementary feed for C. gariepinus juveniles is highly recommended at 25% inclusion.

INTRODUCTION
Aquaculture production is becoming more and more intensive; this is because production from capture fisheries has reached its maximum possible potential, as the catch is dwindling with each passing day (Gabriel *et al*., 2007). Jamiu and Ayinla (2003) had stated that feed management determines the viability of aquaculture as it accounts for at least 60 percent of the cost of fish production (Akinrotimi *et al*., 2007), therefore the establishment of economically viable fish culture ventures requires the incorporation of agricultural wastes or by-products as feed ingredients or direct feed (Shang and Costa-Pierce, 1983) to replace conventional feed stuffs whose dwindling supply has resulted into arbitrary hike in prices. Conventional ingredients used in fish feed are in high demand for human consumption and their yields are currently insufficient to match their demands, hence out of concern for and the implications for food security as well as water and land use, there is urgent need to get local materials especially agricultural by-products of lower price to replace these costly feed materials.
Watermelon (*Citrullus lanatus*) seed meal (WMSM) is one of such agricultural by-product whose nutritive potential has not been effectively taped in animal nutrition, especially fish. Watermelon a creeping annual cash crop which belongs to the family Curcurbitaceae. It grows successfully in the tropics and sub tropics (Mohr, 1989). Watermelon seed is rich in minerals, protein, vitamins, carbohydrate and fibre (Duke and Ayensu, 1985; Tarek and Khaled, 2001). Watermelon seeds are rich in oil and protein (Mustafa *et al*., 1972; Alkhalifa, 1996). Watermelon seed oil proved to be good source of high quality edible oil characterized by low free fatty acid content (Mustafa *et al*., 1972). The experience with watermelon seed cake or meal in rations for animals, showed that it is a good source of digestible protein comparable to other oil seed cakes like cottonseed, linseed etc hence can be safely incorporated in animal feeds (Singh *et al*., 1973). In view of the increasing demand for fish and high cost of conventional feed ingredients, it is therefore necessary to investigate the appropriate method of processing water melon seed for better utilization by *C. gariepinus* juveniles. The main objective of the study is to determine the growth performance and survival rate of *Clarias gariepinus* fed with processed *Citrullus lanatus* seed meal.

MATERIALS AND METHODS

Experimental Site

The study was conducted at the Department of Aquaculture and Fisheries Experimental Farm, Faculty of Agriculture, Nasarawa State University Shabu-Lafia Campus. Lafia is located on latitude 8° 35' N and longitude 8° 32' E, altitude 181.53 m above sea level NIMET (2011).

Procurement and Acclimatization of Experimental Fish

A total of One Hundred and Twenty (120) *Clarias gariepinus* juveniles were obtained from a recognized fish farm. The experimental fish were acclimatized for a period of 7days under experimental conditions in an outdoor concrete tank of the Departmental Fish Farm.

Experimental Design

The source of water for the experiment was from the experimental farm borehole, four (4) concrete tanks of 1.5x1x1.5m³ were filled with water uniformly and 30 *Clarias gariepinus* juveniles were randomly stocked in each pond. The design of the experiment was completely randomized design. The experiment consisted of four (4) treatments which are sun drying alone, fermentation and boiling and the control diet that does not contain WMSM. The fish were starved for twenty four (24hrs) to maintain uniform stomach condition and to induce their appetite prior to the use of experimental diets. The fish were randomly distributed into four (4) concrete tanks in three replicates. The fish were assigned randomly to each tank, and they were fed with the formulated feed for ten (10) weeks. They were fed 3% of their body weight for 70 days. During the experimental period, water quality parameters (Dissolved oxygen, pH, Temperature, Carbon dioxide and Ammonia) were kept within acceptable range for fish culture.

Proximate analysis of fed

The proximate analysis of the experimental feeds were also carried out for Crude protein content, ash content, lipid/ether extract, nitrogen free extract (NFE), and moisture content following the standard by AOAC (1990).

Carcass Analysis

At the end of 10 weeks, one fish per treatment and replicate was selected at random and starved for about 18 hours to empty their Gastro-intestinal tracts. They were sundried and grinded into fine powder and packaged into separate polythene bags. The carcasses were analyzed at the laboratory of Animal Science, Faculty of Agriculture, Nasarawa State University Keffi, Shabu-Lafia Campus.

Statistical analysis

Data obtained were analyzed using one way Analysis of variance (ANOVA) and significant mean differences were separated at 0.05 probability level as described by Steel *et al*. (1997).

RESULTS AND DISCUSSION

Proximate composition of experimental diets is presented in Table 1 below. The result revealed moisture content of the diets ranges from 5.00% to 5.37% with T3 having the highest moisture content of 5.37%. Crude protein contents of the diets ranges from 40.00% to 40.89% with T1 having the highest crude protein value. Lipid (Ether extract) value of the diets was from 7.15% to 9.69%. The highest lipid value of 9.69% was obtained in T4 followed by 9.62% in T3. Crude fibre content of the feeds ranges from 5.19% to 6.41% with T1having the lowest crude fibre content and T2 having the highest value of 6.41%. Ash content of the feeds ranges from 7.14% to 8.19% respectively. T1 had the highest ash content value of 8.19% followed by T4 with 7.92% and T3 with 7.53% while the lowest as content value of 7.14 was obtained in T2. Nitrogen free extract content of the feed in this study ranges from 30.98 to 33.58 with T1 having the Highest NFE value of 33.58% followed by T2 with 32.68% and T3 with 31.23% while the least value 30.98% was obtained in T4.

Table 1: Proximate composition of experimental diets

Parameters	T1 (0%)	T2 (25%)	T3 (50%)	T4 (75%)
Moisture (%)	5.00	5.00	5.37	5.00
Crude protein (%)	40.89	40.47	40.00	40.13
Lipid (%)	7.15	8.30	9.62	9.69
Crude fibre (%)	5.19	6.41	6.26	6.28
Ash (%)	8.19	7.14	7.52	7.92
NFE (%)	33.58	32.68	31.23	30.98

Mean weight gain of Clarias gariepinus juvenile fed watermelon seed meal is shown in Table 2. Result from Anova table shows that the treatments were significantly different ($p<0.05$) from each other. Fish feed T2 (25% watermelon seed meal inclusion) had the mean weight gain of 11.98+0.00 followed by fish feed T1 (0% inclusion) with 11.57+0.00. The lowest mean weight gain of 9.07+0.00 was recorded in T3 (50% inclusion). Percentage mean weight gain (%) of *Clarias gariepinus* juvenile fed watermelon seed meal presented in Table 3 revealed that the highest percentage mean weight gain 91.24+0.00 was obtained in fish fed T2 (25% inclusion), followed by

T1 (0% inclusion) and T3 (68.71+0.00) while the lowest percentage mean weight gain 44.92+0.00 was obtained in fish fed T4 (75% watermelon seed inclusion). The results showed that there was significant difference ($p<0.05$) in percentage mean weight gain among the treatments.

Table 2: Growth performance of *Clarias gariepinus* juveniles fed with differently processed watermelon seed meal based-diet

Parameters	T1	T2	T3	T4
Initial weight (g)	132.6	131.3	132.0	132.3
Final weight (g)	248.3	251.0	222.7	240.2
Mean weight gain (g)	11.57±0.00^{b}	11.98±0.00^{a}	9.07±0.00^{d}	10.79±0.00^{c}
Percentage mean weight gain (%)	87.25±0.00^{b}	91.24±0.00^{a}	68.71±0.00^{c}	44.92±0.00^{d}
Specific growth rate	0.16±0.00^{b}	0.17±0.00^{a}	0.13±0.00^{c}	0.16±0.00^{b}
Feed conversion ratio	2.90±0.00^{a}	2.85±0.00^{b}	2.82±0.00^{c}	2.67±0.00^{d}
Feed intake (g)	523.84±31.06^{b}	529.05±34.64^{a}	404.10±20.17^{d}	432.66±42.29^{c}
Protein efficiency ratio	0.54±0.02^{d}	0.55±0.04^{c}	0.56±0.03^{b}	0.62±0.05^{a}
Survival rate (%)	90.00±0.00^{a}	86.67±0.05^{b}	76.67±0.05^{d}	83.33±0.15^{c}

Mean with different superscript along the row are significantly different

Specific growth rate (SGR (%) of *C. gariepinus* juvenile watermelon seed meal is shown in Table 2. The highest specific growth rate (0.17+0.00) was recorded in T2 and it was significantly different ($P<0.05$) from other treatments. T1 and T4 (0 and 75%) were not significantly different ($p>0.05$) from each other. Feed conversion ratio of *C. gariepinus* juveniles fed watermelon seed meal is shown in Table 3. Results from the ANOVA shows that the treatments were highly significant from each other. T1 (0% watermelon seed meal) had the highest 2.90+0.00 feed conversion ratio and it is significantly different ($P<0.05$) from the treatment. T4 had the lowest feed conversion ratio 2.67+0.00. Feed intake results as presented in Table 3 below showed that feed intake among the treatments were significantly different ($p<0.05$). Highest feed intake value 529.05+34.65 was obtained in fish fed T2 (25% watermelon seed meal inclusion) followed by 523.84+31.06 in fish fed T1 (0% inclusion), 432.66+42.29 in fish fed T4 (75% inclusion) while the least feed intake value of 404.10+20.17 was obtained in T3 (50% inclusion of watermelon seed meal).

Protein efficiency ratio of *C. gariepinus* juvenile fed watermelon seed meal is shown in Table 3. Results from the ANOVA table shows that the treatment were significantly different ($p<0.05$) from each other. T4 had the highest protein efficiency ratio (0.62+0.05) and it is significantly different ($p<0.05$) from other treatments followed by T3 with 0.56+0.03 and T2 with 0.55+0.04. The lowest protein efficiency ratio 0.54+0.02 was obtained in T1. Survival rate of *C. gariepinus* juvenile fed watermelon seed meal is shown in Table 2. Result from the ANOVA shows that the treatments were not significantly different from each other. T1 had the highest survival rate of 90% followed by T2 with 86.67% and T4 with 83.33% while the lowest survival rate 76.67% was obtained in T3 respectively.

Proximate composition of carcass of *C. gariepinus* juveniles fed differently processed watermelon seed meal is presented in Table 3. The result showed that carcass values were higher than the initial values recorded. The crude protein content values increase ranges from 15.15 – 15.71% as compared with the initial 13.44%. Diet 1 had the highest crude protein value of 15.71% while diet 4 had the lowest crude protein value of 15.13 but were higher than the initial. Crude fat content of the diets increases from 6.55 – 8.66% compared with the initial 6.22%. The highest crude fat value of 8.66% was obtained in T2 followed by 7.70% in T4.

Table 3: Carcass composition of *Clarias gariepinus* juveniles fed differently processed watermelon seed based-diet.

Parameters	Initial	T1	T2	T3	T4
Crude protein (%)	13.44	15.71	15.41	15.09	15.13
Fat (%)	6.22	7.20	8.66	6.55	7.70
Crude fibre (%)	1.63	1.87	2.00	1.60	2.10
Ash (%)	1.89	2.00	2.02	2.79	2.14
NFE (%)	22.69	9.10	7.64	10.99	10.71
Moisture (%)	54.13	64.12	64.27	62.98	62.22

Crude fibre content values of the fish carcass ranges from 1.60 – 2.10%. The crude fibre content values in this study increases as compared with the initial but the initial crude fibre content was higher than that recorded for T3. Ash content of the carcass ranges from 2.00 -2.79% and were higher than the initial value. Nitrogen Free

Extract values of the carcass ranges from 7.64 – 9.10 and were lower compared to 22.69% recorded for the initial value while moisture content was also higher from 62.22 – 64.27% compared with 54.13% initial value. The result of this study indicated that there was no weight loss in the present study compared to the weight at initial, observation on growth and nutrient utilization revealed that growth significantly reduced as watermelon is increased in the diet. However since there was no significant differences in the protein content of the diet, differences in performance of experimental fish may be linked to superiority of protein quality of Groundnut cake which reduced as level of replacement increase. Characteristic feed utilization efficiencies and consequent growth rates has earlier been reported and attributed to dietary protein quality by Sotolu and Faturoti, (2008), however, anti-nutritional factor in raw watermelon seed may also be implicated as possible cause of significant reduction in growth. Watermelon seeds possess chemical compounds such as alkaloids, lectins and phenolic compounds such as lactones, tannins and flavonoids which probably function in the protection of seeds from microbial degradation until conditions are favourable for germination, hence, may have led to prevention of digestion in the gut of the fish (Cai *et al*., 2004; Komutarin *et al*., 2004).

It has been reported that toxic component or anti-nutritional factors in most agricultural by-products may cause irritation of digestive tract which is capable of decreasing feed intake and growth (Fakunle *et al*., 2013). Hence inclusion beyond the tolerable level of the fish lead to adverse growth consequences. Many other authors have similarly reported varied replacement level of about 50 % (Babatunde *et al*., 2001; Falaye *et al*., 1999), 60% (Olubamiwa *et al*., 2000) and 100% (Tiamiyu *et al.,* 2014) of waste and by-products with conventional once. It can be correctly inferred then that replacement of convention feeds by alternate sources of plant and animal origin, depends on the nature and composition of the unconventional feedstuffs, inclusion levels, anti-nutritional factor of feed ingredients, method of processing and the tolerance levels of the experimental fish species. Similarly, Lovel and Leary (1990) pointed out that increasing fibre content beyond the basal level could cause reduce growth of fish owing to poor digestion of cellulose. Hence, this is likely to be responsible for the poor growth performance of fish fed inclusions beyond 25% watermelon seed meal containing high crude fibre. However the result of the present study show that *Clarias gariepinus* cannot tolerate inclusion levels beyond 25% and fiber content beyond 5% as negate agreed with the recommendations of Sawaya *et al*. (1986) who stated that watermelon seed should not be included at levels higher than 20%, because these levels brings up the fiber content of the ration over 10%, which reduce feed intake. The protein efficiency ratio obtained in this study is in line with 0.31-0.52 reported by Orire and Ozoadibe (2014) for *Clarias gariepinus* fingerlings fed soybean waste. The results of feed conversion ratio in this study is higher than 1.10-1.60 reported by Ogbonna and Orire (2015) for *Clarias gariepinus* fingerlings fed graded inclusion levels of raw locust bean as replacement for fish meal and 1.02 – 1.85 as reported by Adewumi and Ola-Oladimeji (2016) on performance of catfish fed varying inclusion level of fermented mulberry leaf. The specific growth rate in this study was between 0.13 – 0.16.

Despite the significant effect observed in growth, survival of the fish fed the different diet were also affected, Basavarajah and Anthony (1997) had reported a survival rate of 98% for common carp fry fed conventional feed and 100% for fry fed supplementary feed for a 35 days feeding trial. Survival likely depend strongly on tolerance level of different fish species to the nature and level of anti-nutritional factor in the feedstuff. Carcass composition of the fish fed the experimental diets were higher in values than the those recorded in the start (Initial) of the study, protein retention was higher for the control and T2 suggesting that the protein to energy ratio used in the feed was at the right level and as a result, there was no sparing of protein for energy. The lipid content increase in this study is likely due to the fact that both groundnut cake and watermelon seeds oil seeds added to the lipid contents of the feed (Mustafa *et al*., 1972). Abbas (2007) and Manjappa *et al.* (2011) had opined that better nutrients utilization in fish carcass fed high lipids diets is related to both the dietary protein level and availability of non-protein energy sources.

CONCLUSION AND RECOMMENDATIONS

The findings of this research revealed that mean weight gain, percentage mean weight gain, specific growth rate, and feed intake, were significantly higher in treatment fed T2 (25% watermelon seed meal inclusion); however, feed conversion ratio and survival rate were significantly higher in T1 (0% watermelon seed meal inclusion). The use of watermelon seed meal as supplementary feed for *Clarias gariepinus juveniles* is highly recommended at 25% inclusion.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

Eight (8) weeks feeding trial was conducted to evaluate the effect of processed termite meal as a replacement for Artemia in the diet of Clarias gariepinus fry. The effects of three treatments: Artemia (WGT1), processed termite mixed with moringa extract (WGT2) and processed termite mixed with pumpkin extract (WGT3) on the growth performance, survival rate and condition factor of C. gariepinus fry were studied. Each treatment was replicated three times in a completely randomized design. One hundred (100) C. gariepinus fry were stocked per replicate. Feeding was done ad-libitum for 14 days. Water quality parameter was monitored and maintained at optimum levels for freshwater fish culture throughout the experiment. Result elucidates the significant difference in Percentage weight gain which was highest in WGT1 (396.60+0.00) and lowest in WGT3 (120.21+0.00), Specific growth rate (SGR) was significantly different among the treatments, with mean values of 11.424, 6.506 and 5.635% in WGT1, WGT2 and WGT3 respectively. The survival rate was highest in WGT2 with mean value 69.00% and least in WGT1 (66.67%). Condition factor of the fry was not significantly different among the treatments. It was concluded that Artemia significantly improved the growth of C. gariepinus fry compared to processed winged termite, but survival rate of the fry fed processed winged termites meals was significantly better than fish fed Artemia. It is recommended that processed winged termites meals can be used for feeding C. gariepinus fry in fish seed production; however, there is need for further research to improve on weight gain of the processed winged termites meals comparatively to Artemia.

INTRODUCTION

At present human population stands at 6.4 billion. It is estimated that the world's human population will be 8.1 billion in 2030 and 9 billion in 2050. The greatest increase will occur in developing countries (Roppa, 2007). This increase will lead to the animal protein requirements and demand also increasing. Therefore, there is a need to exploit not only the known unconventional feed ingredients but also to determine and introduce new and lesser known plants and animal feed resources. The availability of high-quality, low-cost feed is a crucial prerequisite for aquaculture production. Presently, the protein sources such as fishmeal are very expensive, especially for smallholder farmers. As a result, the demand for low cost fish feed is high, due to the rising cost and limited supply of commercial feeds (Mupeta *et al.,* 2003). Gope and Prasad (1993) mentioned that insects represent the cheapest source of animal protein.

Insects are believed to have a higher proportion of protein and fat than beef and fish with a high energy value. According to Bernard and Allen (1997), protein concentrations in invertebrate species range from 40 to 70% on a dry matter basis (DMB). However, little research has been conducted on the use of winged termite "Shinge" (as called in Hausa language) in the feeding of *Clarias gariepinus* fry. Therefore this study intends to provide empirical information on the use of winged termite as major ingredients in the diet of *C, gariepinus* fry.

MATERIALS AND METHODS

Experimental Set Up

The experiment was conducted at the Fisheries unit of the Experimental Farm, Nasarawa State University. Nine hundred (900) *Clarias gariepinus* fry was used for the study. Fresh pumpkin and *Moringa oleifera* leaves was obtained from Lafia central market and transported to the experimental location for extraction. Both the pumpkin and moringa juice were extracted separately. The leaves were washed with clean water, squeezed with little quantity of water and sieved with a fine sieving cloth to collect the juice.

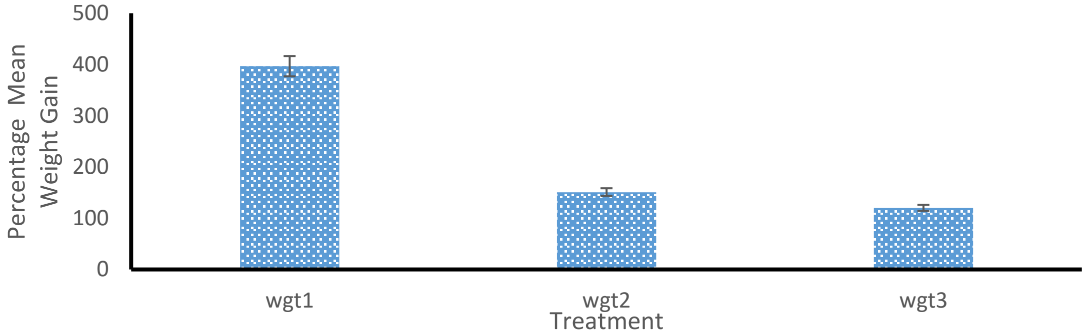
Winged termite popularly known as "*Shinge*" was obtained from Thursday market in Lafia (Alhamis market). The termites were washed with clean water so as to remove dirt and sand particles, and oven dried and grounded into powder. The grinded termite was divided into two equal portions. One part was mixed with pumpkin leave juice and dried at room temperature while the second part was mixed with moringa leave juice, dried at room temperature. These were used as the processed winged termite meals.
Water was pumped from the University's farm borehole into over-head tanks for settling after which water is released into the experimental units. Plastic bowls were used for the study. The bowls were filled with water uniformly and 100 *Clarias gariepinus* fry were randomly stocked in each bowl. The fish were starved for twenty four (24hrs) to maintain uniform stomach condition and to induce their appetite prior to the use of experimental diets.
The experiment consists of three treatments replicated three times in a completely randomized design. Treatment 1 which was the control was fed with artemia and is labeled as WGT1, treatment 2 was fed with processed winged termite mixed with pumpkin leave juice and industrial vitamin C and was labeled as WGT2 while treatment 3 was fed with processed winged termite mixed with moringa leave juice and industrial vitamin C and was labeled as WGT3. The fish was fed to satiation for two (2) weeks.
Water quality parameters (D.O, pH, temperature, carbon dioxide and ammonia) were monitored throughout the period of the experiment.

Statistical Analysis

Data obtained was analyzed using one way Analysis of variance (ANOVA) and significant mean differences was separated at 0.05 probability level as described by Steel *et al*. (1997).

RESULTS AND DISCUSSION

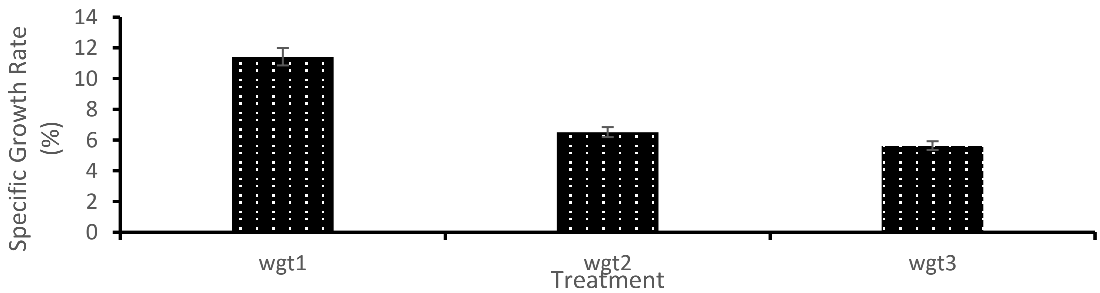
The result revealed WGT 1 feed with highest gain in specific growth rate, followed by WGT 2 feed. The better performance of WGT 1 WGT 2 could mainly be attributed to the rate of processed winged termite fed alongside with the Artemia feed, which might have led to the acceptability and efficient utility by fish.



Keys: WGT1 = Artemia, WGT 2 = winged termite mixed with moringa, WGT 3= winged termite mixed with pumpkin

Fig. 1: Percentage mean gain of C. *gariepinus* fry fed with Artemia and processed winged termite diets

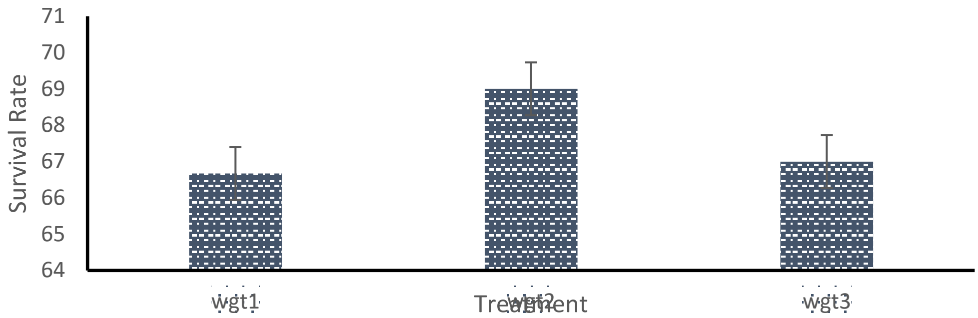
The growth of fish depends on the ingredient and it percentages in the formulated feed (Giencoss *et al.*, 1997). The result of percentage mean gain (Fig. 1) also compare well with comparative feed trials of Rahman *et al*., 1997 an Henken *et al*., 1986 who recorded best growth result for feed containing 40% and 58% crude protein respective in Clarias spp. The result agree with that of Giri *et al*., (2003) who reported an increase in body weight gain specific growth rate in post larvae of Clarias hybrid feed increase level of protein. In previous studies by (Lim *et al*., 2003) involving the larvae of African catfish, *C. gariepinus*, Artemia also gave the best growth performance in terms of weight gained. Artemia have also been reported as a good starter diet for freshwater and marine fishes (Person, 1989) because of its balanced nutritional composition.



Keys: WGT1 = Artemia, WGT 2 = winged termite mixed with moringa, WGT 3= winged termite mixed with pumpkin

Fig. 2: Specific growth rate of C. *gariepinus* fry fed with processed winged termite diets

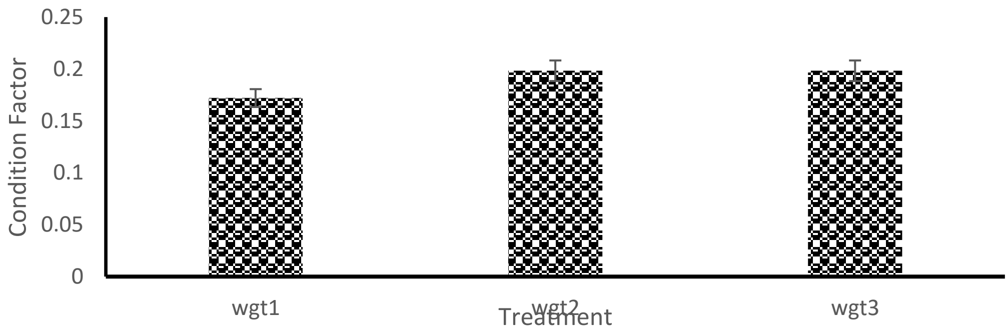
The specific growth rate (Fig. 2) obtained in this study was between 3.17 and 11.66. This result is higher than the maximum average SGR values (4.07–4.19) calculated in *Clarias gariepinus* after a 10-day feeding period with Artemia (Verreth and Den Bieman, 1987). This study agree with Agokei *et al.* (2001) who reported a higher specific growth rate value of 3.19%d^{-1} using Coppens, Multifeed, Eurogold, Vital and feed Ajanla which may be due to feeding frequency and the type of feed.



Keys: WGT1 = Artemia, WGT 2 = winged termite mixed with moringa, WGT 3= winged termite mixed with pumpkin

Fig. 3: Survival rate (SR) of *C. gariepinus* fry fed with processed winged termite diets

Survival rate (Fig. 3) was better in *C. gariepinus* fry fed with winged termite and moringa leave. This result agrees with the report of Abduraheem *et al.* (2012), who obtained lower survival in *C. gariepinus* larvae fed live feed (Artemia) and higher in artificial feeds. Like other live feeds such as Artemia, this implies that the fry did not have fully developed guts, as well as poor perception organs such as the olfactory. Even fry could die with guts full of food, suggesting their inability to digest formulated diets. Artemia showed superior growth over those fed on winged termite with Moringa leaves extract.



Keys: WGT1 = Artemia, WGT 2 = winged termite mixed with moringa, WGT 3= winged termite mixed with pumpkin

Fig. 4: Condition factor of *C. gariepinus* fry fed with processed winged termite diets

Condition factor (Fig. 4) recorded in this study is in line with the findings of Cassius *et al.* (2017) in *C. gariepinus* fed on different diets. The lower growth observed in *C. gariepinus* fry fed winged termite with pumpkin leave can be as a result of high crude protein content. Dupree and Huner (1984), reported that weight gain in fish is directly proportional to the protein content of the diet provided the levels of protein does not exceed 50%. Cho *et al*. (1985) reported a 25% crude protein in diet as adequate for catfish fry rearing in order to obtain optimum growth in intensive culture.

Table 1: Water Quality Parameters when feeing with Processed Winged Termite Diets and Artemia

Treatment	DO (mg/l)	T (°c)	pH
WGT1	7.22±0.03	27.30±0.04	7.24±0.02
WGT2	7.21±0.03	27.23±0.06	7.25±0.03
WGT3	7.22±0.03	27.3±0.02	7.23±0.03

The water quality parameters monitored were within the normal range for optimum performance of culture fish (Table1).

CONCLUSION AND RECOMMENDATIONS

It is concluded that Artemia significantly improved the growth of *C. gariepinus* fry compared to processed winged termite; however, survival rate and condition factor is significantly better than fish fed Artemia. More efforts are required to develop and test other feed ingredients or manufactured feeds of the same or better ingredients of the feed used in the study to further reduce the cost of feeds in seed production. Based on the result of this study, it is recommended that processed winged termites meals can be used for feeding *C. gariepinus* fry in fish seed production.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Parasites are a menace to cultured fish affecting the health status, creating entry for secondary bacterial infection that results in economic losses, making fish production by culture unsustainable. The knowledge of the various parasites associated with hatchery propagation of fish seeds becomes important to the development of effective health management strategies, and this study seeks to investigate the occurrence and intensity of these parasites in catfish hatcheries. A total of 150 seeds of Clarias gariepinus comprising of 80 fry, 55 fingerlings and 15 juveniles were sampled from thirty randomly selected farms, and observed for the presence of parasites using standard parasitological methods. The percentage of fry, fingerlings and juveniles infected were 41.1%, 46.4% and 12.5%, respectively. The parasites observed comprised of 5 protozoans (Trichodina sp, Vorticella sp., Tetrahymena sp., Icthyobodo sp., and Chilodonella sp. and 3 metazoans (Gyrodactylus sp., Dactylogyrus sp. and Salmonichus sp.). Trichodina sp had the highest occurrence and load in all developmental stages (fry: 22.6 and 46.5 %; fingerling: 60 and 86 %; juvenile: 33.3 % for both), than the other parasites, especially under the intensive system. However, the occurrence of Dactylogyrus sp (Monogenea) was higher (48.4 %) than Trichodina sp in the fry, under the intensive system. The occurrence and load of the parasites were more on the gills than the skin. The predominant source of water was borehole (86.7%), and the prevalent values of water quality parameters (pH, water temperature, dissolved oxygen, ammonia, nitrite and iron) were within acceptable range. Parasite occurrence and load were generally higher under the intensive rearing system for the various developmental stages of Clarias gariepinus..
Keywords: *Parasites, Clarias gariepinus, management, hatcheries, fish seeds.*

INTRODUCTION
The sustenance of aquaculture industry depends on production and availability of quality fish seeds ranging from fry, fingerlings and juveniles. The production yield may be influenced by certain factors such as availability and effective utilization of water, quality feeds, intensification of fish production and other production inputs (Oladosu *et al.*, 2012). However, increase in the level of culture intensification subjects fish culture to higher risk of disease occurrence (Schlotfeldt, 1981). The persistent build up of organic wastes coupled with poor water quality requires regular water renewal to possibly prevent susceptibility of cultured fish to rapid transmission of occasional pathogens (Oladosu *et al*., 2012 and Paperna, 1991).

Parasites occur in different groups ranging from protozoans, helminthes, arthropods and other miscellaneous taxa producing harmful effects on their host (Paperna, 1996). Although, ectoparasites are fondly found in tropic water than endoparasites (El-Seify *et al*. 2011). All the parasites derive food and nutrient from their host which could possibly lead to decrease in growth rate and atime mortality resulting to loss of investment (Khalil and Polling, 1997). The outbreak of disease in fish farming is one of the raging challenges that can easily devastate production processes and cause economic loss (World Bank, 1997), as buttressed by the global estimate loss in aquaculture to disease, to the tune above US$ 6 billion per annum (World bank, 2014). Recently, attention has been shifted gradually to fish parasites in culture systems due to increase in aquaculture practices. Parasites of fish negatively affect the immune system of their host, resulting to nutritional deficiency, susceptibility to secondary infections, energy loss, mortality and economic loss (Onyedineke *et al.*, 2010). The fish seeds as a product of infected hatcheries could be a pathogen carrier to the grow–out systems where disease can manifest rapidly and cause mortality of the stocked seeds.

Incidence of parasitic infestation on *C. gariepinus* fry reared under different culture systems has been previously reported (Oladosu *et al.*, 2012), the juveniles of *Clarias* sp and H*eterobranchus* sp in hatcheries in southern Nigeria (Obiekezie and Ekanem 1995) and high mortality of fry, fingerlings and juveniles of carp, eel and catfish reared under intensive water recirculating system (Schlotfeldt and Alderman,1995). However, information on parasitic infestation in fish seeds (fry, fingerlings and juvenile) production under different culture intensity (Intensive and semi - intensive culture systems) in tropical environment is by no means exhaustive, necessitating this study.

MATERIALS AND METHODS

Fish Sampling

A total of 30 fish hatcheries were randomly selected. The fish seeds at the point of visit were collected to erode bias, resulted to 80 fry, 55 fingerlings and 15 juveniles using scoop nets. Five samples of each developmental stage of fish seeds were collected for laboratory analysis. A labeled 10 – litre kegs used for respective collection of the fish seeds prior to clinical examination.

Water Sampling

Physico-chemical parameters of water collected from the rearing facilities where the fish seeds were sampled were measured. Dissolved oxygen (DO) and water temperature were measured *in situ* using a digital oxygen meter (Hanna HI9146 – 04 with a probe HI76407/4F). The pH was measured using a pocket-type Hanna digital pH meter ((HI98103). A commercial colorimetric test kits Hanna – H13824 – 025 and HC960475 were used respectively to measure the ammonia and nitrite content according to the instruction of the manufacturers. The values of water quality parameters were recorded for the hatcheries, culture systems and the different developmental stages.

Clinical examination of fish seeds samples

Five samples of each fish seed type were collected and examined for parasitic infections. The fingerlings and juveniles were immobilized by severing the vertebral column with a pair of scissors just behind the head, while the fry slightly compressed with the aid of forceps to restrain the specimen for examination. The whole fry was placed on glass slides, two drops of normal saline were placed on each fry prior to microscopic examination to avoid dryness thereby preserving the parasites to be examined (Oladosu *et al*., 2012).

Five fingerlings and juveniles were clinically and microscopically examined from selected farms. On each sample, skin smear was collected using cover slip to longitudinally scrape the body of the fish, placed on a clean glass slide and kept moist by applying a drop of saline at the edge of the cover-slip covering the smear on the glass slide. The opercula plate of each of the fingerlings and juveniles was slit opened and a gill arch was detached using forceps and scissors. One gill arch each from respective fish seed was placed on a glass slide and kept wet with a drop of saline to prevent dehydration of the parasites by the microscope light before completing the microscopic procedure. The procedures for clinical examination carried out followed the descriptions of Noga (1995) and Oladosu *et al.,* (2012).

Identification of parasites

Parasites from the skin smears and gills collected from fingerlings, juveniles, and fry were observed under a binocular microscope (Olympus). The parasites were captured using a digital camera (Scopephoto DCM 35E – 350K Pixels) inserted into one of the eyepiece holders of the microscope. The camera was connected to a laptop computer unit to capture the image of the parasites. The images of the parasites obtained were compared with those earlier described (Paperna, 1980 and Noga, 1995). Parasites were identified to genus level according to the description of (Noga, 1995 and Schlotffeldt and Alderman, 1995), and ascertained with the identification keys by Paperna (1980). Microscopic observation was done at magnification of x40 and x100.

RESULTS

One hundred and fifty fish seeds comprising of 80 fry, 55 fingerlings and 15 juveniles were sampled from thirty randomly selected farms, out of which 23, 26 and 7, respective fish seeds were infected (Table 1). Table 2 shows the culture practices management of the catfish hatchery visited. The culture system used by the respondents were intensive farming (66.7%) and semi – intensive (33.3%). No fish breeder used extensive system of farming. The major source of water was borehole (86.7%) while 13.3% depended on well water. Majority of the breeders (46.7%) adopted tarpaulin vats compared to concrete tanks (26.7%) and plastic tanks (26.7%) with 60% farmers operating flow through rate of water renewal.

Table 1: Occurrence of parasitic infestation in different seeds of *Clarias gariepinus*

Developmental Stage of fish Seeds	Numbers of fish farms	Number of fish examined	Numbers of fish infested	Percentage of infested fish (%)
Fry	16	80	23	41.1
Fingerlings	11	55	26	46.4
Juveniles	3	15	7	12.5
Total	30	150	56	100

Table 2: Culture / management practices observed in the hatcheries

		Freq.	%
Source of water:	Borehole	26	86.7
	Well	4	13.3
Culture facilities	Concrete tank	8	26.7
	Plastic tank	8	26.7
	Tarpaulin vats	14	46.7
Level of intensification:	Intensive	20	66.7
	Semi – intensive	10	33.3
Water exchange/week:	Flow-through	18	60
3 – 4 times		8	26.7
1 – 2 times		4	13.3

The parasitic fauna observed in this study (Table 6) comprised of 5 protozoans (*Trichodina* sp, *Vorticella* sp., *Tetrahymena* sp., *Icthyobodo* sp., and *Chilodonella* sp.) and 3 metazoans (*Gyrodactylus* sp., *Dactylogyrus* sp. and *Salmonichus* sp.). Production of fry under intensive culture showed 23 infected fry from 11 farms with highest prevalence of *Dactylogyrus* sp., (48.5%) but the highest load of trichonids (180) (Table 3). Twenty – three (23) infected fingerlings from 9 farms recorded *Trichodina* sp., both for highest prevalence (60%) and load (414) followed by *Dactylogyrus* sp (20% and 48) respectively (Table 4). Other parasites identified on the fry reared under intensive culture were *Vorticella* sp (25.8%) and *Salmonichus* sp (0.3%). The fingerlings reared under intensive culture revealed more parasites with 2.9% minimal prevalence of *Gyrodactylus* sp., *Ambiphyra* sp., *Tetrahymena* sp., *Ichthyobodo* sp., and *Chilodonella* sp., respectively while *Vorticella* sp. recorded 5.7%. No parasite was obtained from juvenile produced under intensive culture (Table 4).

The semi – intensive production recorded 30% parasitic infections in fingerlings from 2 farms with 28.6% prevalence in *Trichodina* sp., *Dactylogyrus* sp., and *Gyrodactylus* sp., respectively but highest load of 101 *Trichodina* sp. was recorded. 46.7% of juveniles were infected under semi – intensive production with highest prevalence of *Dactylogyrus* sp. (55.6%), but the lowest prevalence of *Gyrodactylus* sp. (11.1%) recorded the highest parasitic load of 13 individuals (Table 5). No breeder produced fry under semi – intensive system during the time of study.

The distribution of parasites on the sites of infection on the fry, fingerlings and juveniles showed that *Trichodina* sp was most prevalent parasites followed by *Dactylogyrus* sp. while the least was *Salmonichus* sp. (Table 6). *Trichodina* burden was found more on the skin of the fry (117) and fingerlings (366) while *Dactylogyrus* burden was recorded more on the gills of fry (120) and fingerlings (56). *Gyrodactylus* sp invaded the skin of fingerlings and juveniles with prevalence rate of 85.7% and 100% respectively. Other parasites were found to be site specific as recorded on the skin of the fry (*Salmonichus* sp.,), and the fingerlings (*Vorticella* sp., *Ambiphyra* sp., *Tetrahymena* sp., *Icthyobodo* sp., and *Chilodonella* sp.).

Table 3: Parasitic infestations and load of parasites on *Clarias gariepinus* fry under different levels of culture intensity

Culture Intensity	Numbers Examined & infested	Taxa of parasites	Freq. of occurrence	Percentage of occurrence	Total loads of parasites	Percentage loads of parasites(%)
Intensive	55/23 (41.8)	*Trichodina* sp	7	22.6	180	46.5
		Dactylogyrus sp	15	48.4	132	34.1
		Vorticella sp	8	25.8	74	19.1
		Salmonichus sp	1	3.2	1	0.3
Semi - intensive	25/0 (0)	Nil	0	0	0	0

Table 4: Parasitic infestations and load of parasites on *Clarias gariepinus* fingerlings under different levels of culture intensity

Culture Intensity	Numbers Examined & infested	Taxa of parasites	Freq. of occurrence	Percentage of occurrence	Total loads of parasites	Percentage loads of parasites (%)
Intensive	45/23 (51.1)	*Trichodina* sp	21	60	414	81
		Dactylogyrus sp	7	20	48	9.4
		Gyrodactylus sp	1	2.9	4	0.8

The prevailing environmental conditions for fry, fingerlings and juveniles reared under the different culture systems in this study were reported in table 7. The water quality parameters recorded were water temperature, pH, dissolved oxygen, ammonia, nitrite and iron. They were all at acceptable range except the lowest dissolved oxygen and highest nitrite values recorded in juveniles produced in plastic tank.

Table 7: Mean physico – chemical parameters of infected hatcheries operating under different culture systems

Culture Systems	Fish Stage	Water temp. (°C)	pH	Dissolved Oxygen (mgl^{-1})	Ammonia (mgl^{-1})	Nitrite (mgl^{-1})	Iron (mgl^{-1})
Concrete tanks	Fry	30.2	6.92	4.57	2.80	0.36	0.60
	Fingerlings	31.1	6.76	7.67	2.70	0.47	0.27
	Juveniles	30.8	5.87	9.74	2.90	0.60	0.00
Plastic tanks	Fry	29.8	6.90	3.69	0.30	0.51	0.00

	Juveniles	26.4	7.30	10.24	2.80	1.31	0.80

pH = Hydrogen ion concentration, Water temp. = Water temperature

DISCUSSIONS

Infestation of parasites spread through the culture systems in various degree despite the efforts of the breeders to maintain high water budgets by using borehole (86.7%), flow through (60%), fish seeds fed with imported feeds and feeding regime of 3 – 4 times daily. This may suggest that other prevailing factors related to production process such as usage of contaminated hatchery materials, rearing conditions, stocking density, handling, availability of oxygen and seasonality may be contributing to parasites propagation (Firmino *et al.*, 2019). The prevalence of protozoans and monogenean trematodes recorded in the study possibly complied with the research report that parasitic infestations are often recorded in ponds used every year to rear fry especially where infections have been previously noticed which commonly increase rate of mortality (Paperna, 1963a). The distribution of parasites recorded in this study predominantly found on the skin, gills or both which agreed with the reports of *Abowei (2011). Trichodina* sp was commonly found on the skin and gills of fry (117, 63) fingerlings (366, 144) and juveniles (5,2) respectively which conformed with the report that trichonids are true parasites of fish mostly found on the skin and gills of culturable fish species (Paperna, 1980).

The second most distributed parasites was *Dactylogyrus* sp., found on the gills of all the fish seeds with atleast 90% occurrence but only found on fry skin with 12 individuals. This reports agreed with the study carried out in Delta State with *Dactylogyrus* sp absent on the skin of *Clarias gariepinus* fingerlings but contrary to its presence on the gills of fry and fingerlings (Okunade *et al.*, 2018). *Gyrodactylus* sp., was found both on the skin and gills of the fingerlings and only the skin of the juveniles with no record on the fry. The finding was contrary to the reports obtained on *Clarias gariepinus* in Delta State probably because of geographical location and other factors (Okunade *et al.*, 2018). Moreover, Monogenea are found to exhibit both host and organ specificity indicating that some species could attack the skin while some on gills of freshwater fish (Öztürk and Özer, 2014). Nevertheless, *Dactylogyrus* sp commonly infest the gills while *Gyrodactylus* sp on skin (Reed *et al*., 1996). Infestation rate of monogeneans were higher in this study which could be as a result of high reproductive capacity of the parasite reported by Paperna, (1996).

Other parasites were found to be skin specific on fry (*Vorticella* sp and Suspected *Salmonichus* sp.,) and fingerlings (*Vorticella* sp., *Ambiphyra* sp., *Tetrahymena* sp., *Icthyobodo* sp., and *Chilodonella* sp.). These parasites were not recovered on juveniles skin or gills. The finding was contrary to the report that most of these parasites were found on both the skin and the gills of culturable fish species (Hoffman *et al.*, 1979; Imai *et al.*, 1984, Paperna and Van As, 1983). The absence of these parasites on juveniles may be that they developed more defensive mechanism than others.

The higher intensification (intensive culture) recovered more load of parasites like *Trichodina* sp., *Dactylogyrus* sp. and *Vorticella* sp., on fry and *Trichodina* sp., *Dactylogyrus* sp., and *Ambiphyra* sp., on fingerlings which may be due to polluted water environment as a result of overfeeding, overcrowding and stress caused by frequent handling through sorting. However, the juveniles suffers less parasitic load of *Trichodina* sp than fingerlings under semi – intensive culture which may be as a result of better environment created after sorting in terms of low stocking density and better innate immunity with growth as a factor in parasitic resistance.

The water quality recorded were within the acceptable range for *Clarias gariepinus* in all the cultured systems except the high depletion of dissolved oxygen in juveniles reared in plastic tanks which may be due to utilization of more oxygen for their metabolic activities and ability to use the lung like structures to breathe – in atmospheric air. The fish were able to withstand the varied water values in different culture systems because of reasonable water renewal pattern adopted.

CONCLUSION

Some of the hatcheries encountered parasitic infestations despite the used of borehole as their major source of water and quality feeds which depicted the possibility of other factors responsible for parasitic infestations such as inoculation of uninfected culture water with infected water, overstocking, inadequate and untimely sorting and usage of non-disinfected hatchery materials. The study showed that ectoparasites are highly prevalent in *Clarias gariepinus* fish seeds production. As fish breeders usually channeled their resources and efforts to maximize their productions, intensive culture systems must be adequately regulated within the required inputs to avoid pathogenic infections that can expose their investment to unguided risk leading to economic loss. Therefore, good aquaculture practices are recommended to improve the welfare of the fish in the hatcheries.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Non-timber forest products (NTFPs) play a significant role in the livelihoods of the rural households through trade. In this study the profitability analysis of selected non-timber food products in Enugu state of Nigeria was examined. Specifically, the study aimed to identify the socio-economic characteristics of the respondents; it also determined the current income from marketing of the selected non-timber forest products. Furthermore, the study focus was to ascertain the profitability of selected NTFPS marketing as well as the constraints facing marketing of NTFPs in the study area. Sampling technique used was purposive where (102) marketers were interviewed. Data collected came from primary sources with well-structured questionnaire. Multiple regression, gross margin and descriptive statistics were used to analyze collected data. The findings show that it is profitable to commercialize selected non timber forest product in the study area. From to the study, 75% of the respondents involved in marketing are females, as 87% of the respondents were unaware of extension agent. Added to this, only 78% of the respondents stated that most non-timber forest products are seasonal but 73% of the respondents indicated that their reasons for marketing of NTFPs are as source of livelihood. The study indicated from cost and return analysis that marketer realizes for every ₦1 invested in the marketing of selected NTFPs, ₦12.3, ₦7.3, ₦3.5, ₦1.0, ₦2.0 and ₦3.8 for achi, akpalata, African bush pear, African oil bean, African bread fruit, and bush-meat respectively. Additionally, the research shows the coefficient of age, marital status, seasonality, access to extension agent and household size were significant variables that influences the profitability of marketers of selected NTFPs in the study area. The constraints identified include seasonality of products, lack of funds, extension services, and price fluctuation amongst others. The study recommended that the government should offer credit facilities through commercial banks and bank of agriculture to motivate young people in marketing of selected NTFPs business since it is a profitable and sustainable enterprise. Besides, government should implement good pricing system, relevant laws and harvest guide regulation for sustainability of non-timber forest products. Finally, modern storage, processing and preserving facilities should be provided to improve shelf-life which in turn increases availability of NTFPs after harvest by different levels of government.
Keywords: *Profitability, Marketing and NTFPs*

INTRODUCTION
The NTFPs constitute an important source of livelihood for millions of people across the world, and research have shown that there are more than 500 million people that are highly dependent on forest resources, particularly the NTFPs, in Latin America, sub-Saharan Africa, (SSA) and South- eastern Asia (Shackleton *et al*., 2007). The NTFPs provide about 17 million and 30 million full-time jobs in the formal and informal sectors as well as 13-35% of all rural non-farm employment in developing countries like Nigeria and in Enugu state (Duong, 2008).
In addition to their wide industrial applications in developed countries, non-timber forest products (NTFPs) are consumed locally and are used in religious and cultural rituals (Chikamai et al., 2008). Non-timber forest products represent income opportunities from forest that do not involve cutting down trees for wood products. In forest with low timber production potential, non-timber forest products represent the major or potential source of income, traditionally used and appreciated by people of many cultures worldwide (Odeyale and Olawuyi, 2018). The significance of these products for sustainable economic growth, cultural endurance and environmental health is receiving increasing recognition by government and other official agencies (Bonet et al., 2009).

According to Nzeh and Eboh (2007), forest contribute directly and indirectly to rural household livelihood through the generation of income and employment from the sale and exchange of gathered and unprocessed non-timber forest products such as firewood. The term non-timber forest products (NTFPs) emerged as an umbrella to recognize the products derived from these various forest resources as a group such as bush meat, fuel wood, herbs, fruits etc. (Ibrahim et.al., 2016). The commercial potential of non-timber forest products (NTFPs) has received increasing interest throughout the world, not only in the developing and emerging economies, where NTFPs are an important means to alleviate poverty and address conservation concerns. Therefore, forest resources, particularly the non-timber forest products (NTFPs) have been established as an essential source of livelihood income for the majority of forest dependent communities among others. Non-timber forest products (NTFPs) - have the potential to become substantial sources of revenue, but in many communities they are underexploited. In some cases, people make considerable use of the products, but their commercial value is low.

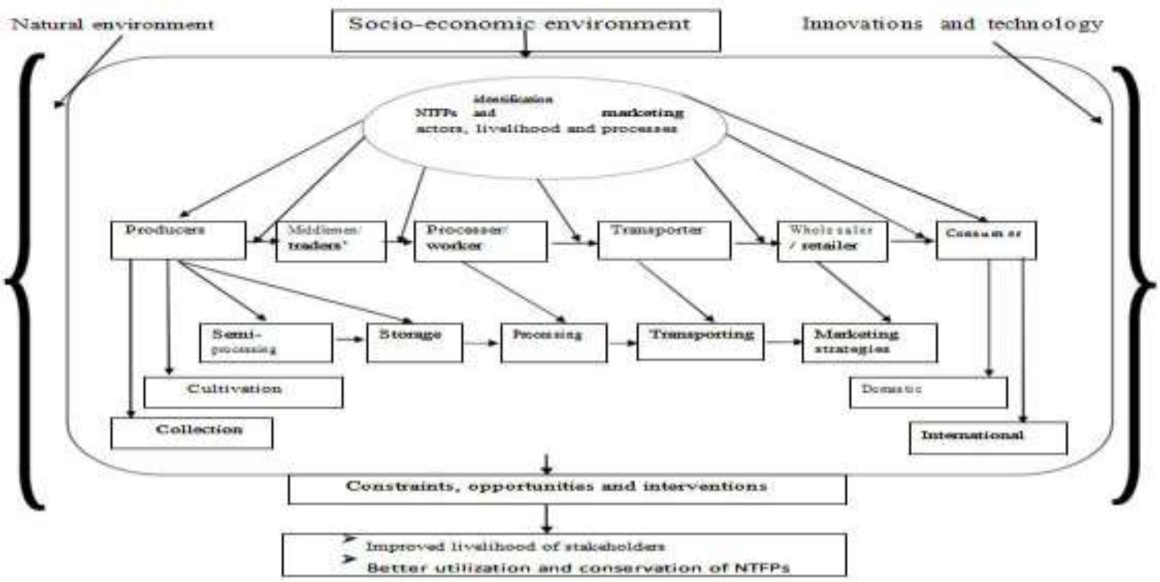
One of the difficulties for small-scale producers who seek to commercialize NTFPs is that often the markets for these products are relatively complex compared to those for timber and more traditional agriculture goods. Many NTFPs occupy "niche" markets, which tend to be small and dispersed. In addition, there are few established standards for NTFPs, and consumer preferences for products may vary considerably depending on such factors as the type of market (tourist or local) and the time of year. Prices for NTFPS vary from place to place as well as over time. Buyers may impose different quality control standards. All of these factors contribute to the complexity of NTFPS markets.

Despite the increasing research efforts, the business potential of NTFPs is still strongly underutilized; there are various challenges that hinder the development of the NTFP sector in Nigeria and the study area. Studies on the supply chains of NTFPs have revealed the key challenges at specific points of the chain, these challenges are scarcity of raw material (in terms of both quantity and seasonal availability), low market transparency, lack of business and marketing skills, small market size and high production and transport costs. In addition, it is however noted that NTFPs are continually diminishing resources as a result of their dependency on land which is usually under the pressure of depletion from agriculture and development of public infrastructures. The NTFPs constitute a critical component of food security and they are important sources of income for the rural poor in Nigeria even in the study area.

Despite their importance to forest-dependent people worldwide, accurate information on income effect on marketing of NTFPs is limited and often mixed with agricultural production statistics. This study therefore is designed at assessing the profitability of marketing of selected non- timber forest products in Enugu state. The research specifically examined the socio- economic characteristics of respondents in the study area, identify the availability status of non- timber forest products in the study area, determine the current income of marketers of selected non-timber forest products in Enugu state, analyzed the profitability indicators of non- timber forest products marketers in the study area and lastly, identify the constraints associated with marketing of non- timber forest products in the study area.

Literature Review

Conceptual Framework

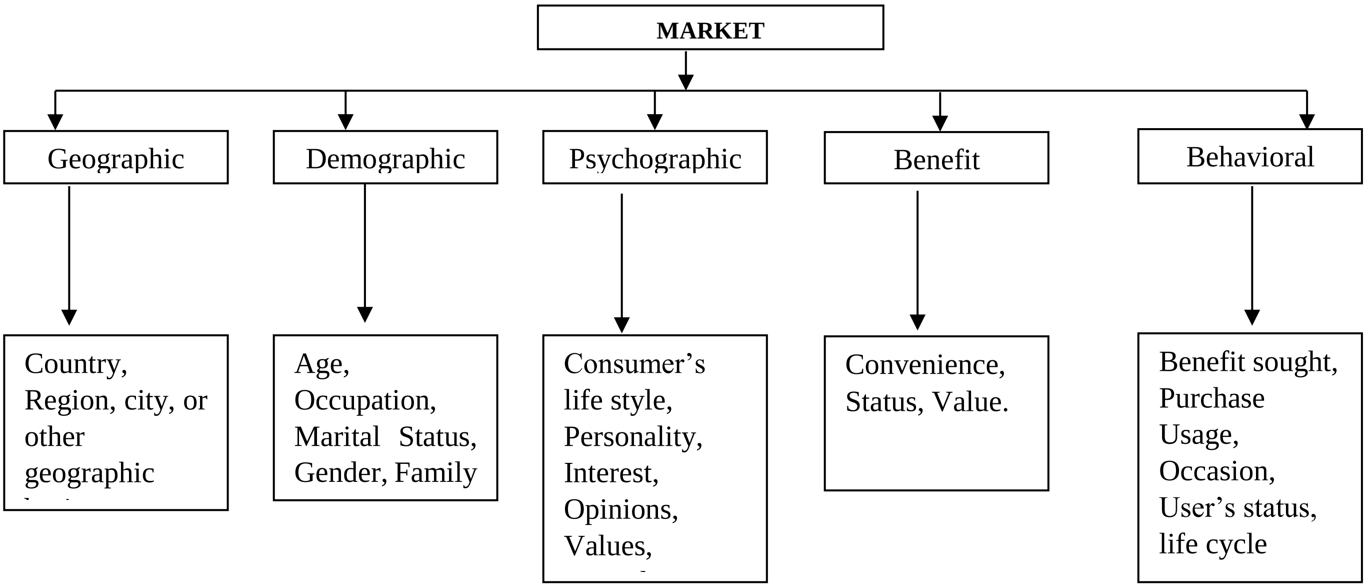


Source: Adapted from Nzeh et al (2018)

In Figure 1 above, using the production consumption system approach (PCS),it analyses the full range actors and function that are involved in all activities of NTFPs production and it encourages development of basic understanding of the system and helps to identify the most important stakeholders, their constraints and opportunities. It shows a framework within which to organize issues that needs to be considered in developing NTFPs. Its attention is focused on the market, with emphasis on the linkage between a point of transformation amongst firms at any particular point of transformation, which distinguishes PCS approach from other analytical tools such as market chain analysis and subsector analysis.

Theoretical Framework

This study is anchored on two theories. The first is production theory, Production refers to the principle to be applied in making production decisions (Oji, 2002), production decision include the decision to acquire resources, utilize resources, organize production, distribute the product of the productive activity in general to manage the services of production resources. According to Saari (2006) production theory is the study or the economic process of converting inputs into outputs including that of the NTFPs. Therefore, production talks about the act of creating an output, goods and services which adds value and contributes to utility to the society at large and also the firm itself. The second theory, marketing discusses the strong linkage between the producers and customers.



Source: Adapted from www.marketingguide.com (retrieved 2021)

Segmentation based on consumer is a definable characteristic, identity or behavior of an individual consumer that can be utilized to classify consumer into related groups. A market segmentation base is simply the factor that is used to define overall market up to into its individual market segments. These factors include description of the consumer, usually relating to their lifestyle, purchasing behavior, goals or life stage attributes.

Analytical Framework

The analysis for the study involved using descriptive statistics and other analytical tools. Meanwhile, budgetary analysis was used to determine the profitability of NTFPs marketed i.e.

TC = TFC +TVC
GM = TR – TVC
NI = TR -TC
PI = NI/ TR
BCR =TR/TC

Where:

TC = Total Cost
TVC = Total Variable Cost
TFC = Total Fixed Cost
TR = Total Revenue
GM = Gross Margin
NI = Net Income
PI = Profit Index
BCR = Benefit Cost Ratio

Furthermore, multiple regression model was used to analyze some critical objectives in the study, and it is represented below as:

$Y = b_o + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + b_8X_8 + + b_9X_9 + b_{10}X_{10} + \mu.$

Where,

Y = Income of forest marketers (annual sales in Naira),

X_1 = Age (number),

X_2 = Gender (dummy),

X_3 = Educational level (number of years in formal school),

X_4 = Martial status (dummy),

X_5 = Years of experience (number of years in marketing NTFPs),

X_6 = Access to market [distance from home to market (Km)],

X_7 = Seasonality of forest products (dummy),

X_8 = Access to extension agents (frequency of visit),

X_9 = Household size (number),

X_{10} = Access to credit (in Naira),

μ = error term

RESULT AND DISCUSSION

The socio-economic status considered in study includes, gender, age, marital status, educational status, religion, household-size, awareness of extension to the marketers and years of experience.

Table 1: Distribution of respondents according to socio- economic characteristics.

Variable	Frequency	Percentage (%)	Mean(X)
Gender			
Male	21	21	
Female	81	79	
Age			
≤ 15	7	7	
16- 30	33	32	
31 – 45	45	44

Source: Field survey, 2022.

The Table 1 above shows that 79% of the respondents that are involved in NTFPS marketing are females and as only 21% of the respondents are male. The greater number of females does not presuppose out-rightly that females outnumber the males in the study area. This implies that greater proportion of the marketers of NTFPs were females. Rather it can be attributed to females being more interested in marketing of NTFPs than males (Nzeh 2012). This confirms the findings of (Patience e.t.al 2019), that generally the women are more active in marketing, the high presence of women in NTFPs marketing is an indication that this activity is an important source of livelihood to generate income.

Furthermore, Table 1 reveals that 44% of the respondents falls within the age bracket between 35-45years, as it can be seen that 32% of the respondents falls within the age bracket between 25-35years. The age bracket of $\geq$45years and above constitute 17 % but barely 7% of the respondents falls within the age brackets between $\leq$18-25years. The result shows the high proportion of marketers of NTFPs in the study area falls within the middle-age bracket. From the above table 1, the youths appear uninterested in marketing of NTFPs. However, the proportion of people engaged in marketing of NTFPs with respect to age should favor both income and employment generation.

Generally, education broadens the horizon of human activities, operation and understanding of his/her environment. The educational status of individuals assist the person more access to government programmes, production credit, improved technologies and membership of rural institutions (cooperatives). According to table 1 above, it revealed that 43% of the respondents indicate no formal education in the study area. Also the same table 1 shows that 24% of the respondents agreed that they had primary education as 20% and 13% of the respondents respectively stated that they had secondary and post-secondary education. This means, NTFPs marketing constitutes a source of livelihood for both the literates and illiterates in the study area.

From the table 1 above, it illustrates that majority 90% of the respondents are Christians while 10% of the respondents are traditionalist. However, one should not be quick to assert that Christians dominate the study area, even though this seems to be the picture. In any case, both Christianity and traditional religion dominate other types of religion in the study area.

More critical findings as revealed in table 1 shows that greater proportion of the respondents (87%) are not aware of forest extension agent while 13% of the respondents are aware of the forest extension agent. This simply indicates that the few percentages of respondents with forest extension services knowledge may not be connected with those living nearer government forest reserve areas. Also as indicated that many respondents are not knowledgeable about extension services, it will result to either over exploitation or under exploitation of forest product resources thereby resulting to reduction in income generated by them. It implies that there is need for more extension agent to visit the study area.

Table 2: Distribution of some major NTFPs in the study area.

S/N	Common names	Scientific name	Part used
1	Achi	*BrachystegaEurcyloma*	Seed
2	Mushroom	*Agaricus bispous*	Plant
3	African breadfruit (ukwa)	*Treculia Africana*	Fruit
4	Rabbit (ewi ani)	*Oryctolagnus cuniculus*	Meat / bones

5	African bush pear (ube)	*Darryodes Edulis*	Fruit
6	African oil bean (ugba)	*Pentaclethra macrophylla*	Fruit
7	African oak (Akpalata)	*Afzelia Africana*	Seed
8	Grasscutter (Nchi)	*Throyonomisswinderianus*	Meat /bones
9	African Guinea pepper (uda)	*Xylopia aethiopica*	Seed
10	African nutmeg (ehuru)	*Mandora myistica*	Seed

Summarily, Table 2 above shows some of the very fundamental NTFPs in the study area. These listed NTFPs are marketable in the state. They help to generate income and employment in Enugu State as reported by Nzeh, Eboh and Nweze (2018). Literature shows that as these NTFPs create both income and employment to the rural households it assist in the poverty reduction in these communities.

To ascertain the current amount of income provided by marketing of NTFPs, a multiple regression analysis was carried out. The four functional forms – linear, double-log, semi-log and exponential were used to test. The double logarithmic was chosen since it provided higher number of variables with significance levels and also based on it records of having best R^2, F-ratios and also the best coefficients when signs and significant are considered. The results of the multiple regression analysis are shown in tables 4.3. R^2 indicates the percentages variation in the independent variables. The higher the R^2, the better the equation fits the data.

The four functional form of the model linear, semi-log, double- log and exponential were tested and out of the four functional form, double- log functional form was selected as the lead equation it has the highest significant variables and highest co-efficient of determination R^2 (47%) and F-ratio 9.047. According to the table above, independent variables (age (X_1), (marital status (X_4), (seasonality (X_7), (access to extension agent (X_8) and (household size (X_9) were positively significant. The co-efficient age X_1, marital status X_4, seasonalityX_7, and access to extension agent X_8 were positively correlated with income of NTFPs and were highly significant at 1% while household size X_9 was positively correlated to income of NTFPs marketers and significant at 5%.

SUMMARY, CONCLUSION AND RECOMMENDATION

From the study, it has been observed that marketing of selected non-timber forest product is profitable in Enugu State. These products make direct and indirect contributions to household economy, through the generation of income from the sale of gathered and processed non-timber forest products such *achi*, bush meat, *utazi*, *ukwa*, *ugba*, African bread fruit and numerous others.

However, from the discussion so far in this study, it should be easy to deduce that marketing of non-timber forest project suffers from both governments and policy makers' apathy. Therefore, there is need for improved policy on forest product activities if the government hopes to generate both local and international revenue from this sector. This is because the contributions of this sector would not be made without efficient and effective provision of improved modern forest harvesting/processing technology which will reduce under and over exploitation of the resources. But since some natural forest resources are still in existence, all hope is not lost. There is need to address the concerns of the rural marketers that are involved in non- timber forest marketing. hence these activities add to the economy of the areas.

Based on the above premise and other relevant issues raised in this study, it is therefore considered very necessary that to meet with the demand of the society (concerning non-timber forest product activities), the government and other interested policy makers may find the following recommendation useful.

- The government and other community development organization should regularly host workshops, seminars, and training programs for rural farmers and marketers to increase their understanding of how to preserve and use non-timber forest products and adopt practices for sustainable harvesting.
- The government should provide credit facilities through commercial banks and bank of agriculture to motivate young people in marketing of NTFPs business since it is profitable and sustainable.
- Government should implement good pricing system, relevant laws and harvest guide regulation for sustainability of non- timber forest products, modern storage, processing and preserving facilities should be provided to improve shelf-life, which in turn increase availability of NTFPs after harvest.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study assessed the impact of climate change on fish production in Nigeria. The model made use of time series data spanning from 1981 to 2021. Data on the variables for the study were collected from the archives of Food and Agriculture Organization (FAO) and World Bank database. Data for the study were analyzed using descriptive statistics, Johansen Co-integration test after testing for unit root and Vector Error Correction Model (VECM). The result of Augmented Dickey Fuller (ADF) test for unit root indicated that the variables temperature, rainfall and fish production were found to be integrated of order one and became stationary on first differentiating. The use of Johansen co-integration mechanism indicated that the computed trace statistics (24.66229) is greater than the critical value at 0.05 level (21.13162). The result of the VECM indicated that in the long run, the coefficient of rainfall (5.395) and temperature (-58.523) were statistically significant at 1% which indicated the existence of long run effects of climate change on fish production. In the short run, change in the coefficient of rainfall (0.234) and temperature (0.067) were significant which implies that rainfall and temperature have significant effects on fish production in the short run. The study therefore, recommended that there is need for proper extension services to educate fish farmers on how to mitigate the long-term impact of climate change.

Keywords: *Rainfall, Temperature, Fish Production, Climate Change, Vector Error Correction Model, Augmented Dickey Fuller, Food and Agriculture Organization*

INTRODUCTION
According to the African Partnership Forum (2011), the Intergovernmental Panel on Climate Change (IPCC) has identified climate change as a paramount challenge in the 21st century. Today, climate change stands out as the most pressing global issue, surpassing even the threat of global terrorism (Maduekwe, 2014). Two interconnected challenges facing humanity in this century are human-induced climate change, caused by an increase in greenhouse gas (GHG) concentration in the atmosphere, and agricultural production. Increasing temperatures have led to a surge in extreme weather events, intensifying the impact of climate change (Agba *et al.,* 2017). As climate conditions shift, aquatic life is also affected, leading to potential outbreaks of protein deficiency-related diseases. The agricultural sector bears the brunt of climate change through alterations in rainfall patterns, temperatures, and agro-climatic conditions, which can disrupt growing seasons, water availability, and increase the prevalence of pests and diseases. Moreover, the Niger Delta region of Nigeria experiences acid rains caused by emissions from oil-producing companies, further influencing the type of rainfall in the area (Zievegel *et al*., 2008).

Rainfall is undoubtedly the most significant aspect of climate change in Nigeria and plays a crucial role in determining the country's water resources potential (Lokonon, 2018). The northeast region of Nigeria is experiencing a rapid transition into an arid environment due to a considerable decline in surface water, as well as diminishing flora and fauna resources on land (Obioha, 2008). This consistent reduction in rainfall adversely affects the natural regeneration rate of land resources and contributes to a decline in water levels (Fasona and Omojola, 2005). In contrast, the southern region of Nigeria, known for its high rainfall, is currently facing irregularity in rainfall patterns, and the Guinea Savannah zone in the country is witnessing a gradual increase in temperature. Moreover, the northern zone is under the looming threat of desert encroachment (Federal Ministry

of Environment, 2004). These climatic changes pose significant challenges for various parts of the country and have considerable implications for agriculture, water availability, and overall ecosystem stability.
Disruptions of existing food and water systems will have devastating implications for development and livelihood. These are expected to add to the challenges climate change already poses for poverty eradication (Maduekwe, 2014). According to (Obioha 2009), the sustainability of the environment to provide all life support systems and the materials for fulfilling all developmental aspirations of man and animal is dependent on the suitability of the climate which is undergoing constant changes. The effect of these changes is posing threat to fish production and agricultural output in general within the country. Therefore, there is a necessity to study the impact of climate change on fish production in the country. However, even though climate change is a global phenomenon, the negative impact is unevenly felt depending on the adaptive capacity of individual nations.

METHODOLOGY

Study Area

The research focuses on Nigeria, a country situated on the Gulf of Guinea in West Africa, covering an area of 923,768 square kilometers. As one of the most populous black nations globally, it had an estimated population of around 140 million in 2006 (NPC, 2006). With a population growth rate of 2.6%, the population is projected to be approximately 210.87 million in 2021 (www.statista.com). The country's topography varies, ranging from mangrove swamps along the coast to tropical rainforests and savannah in the north. Its geographical coordinates are approximately between latitude 4°16' and 13°53' north and longitude 2°40' and 14°41' east (Central Intelligence Agency, 2009). Given its highly diverse agro-ecological climate, agriculture plays a crucial role in Nigeria's economy. The climate varies, with the southern region being equatorial, the central area being tropical, and the northern part experiencing a savannah climate.

Data Collection and Analytic Techniques

The research relied on secondary data obtained from the Food and Agriculture Organization (FAO) database covering from 1981 to 2021. The study employed advanced statistical techniques, such as Johansen co-integration, which helps identify long-term relationships among variables. The Augmented Dickey Fuller (ADF) test was used to assess "stationarity" in the time series data, which is essential for conducting meaningful econometric analyses. Lastly, the Vector Error Correction Model (VECM) was employed to examine dynamic relationships between variables and to analyze short-term deviations from long-term equilibrium.

Model Specification

Vector Error Correction Model (VECM)

The study utilized VECM to analyze the causal influence between non-stationary I (1) variables, while also identifying evidence of a long-run relationship among them. The VECM is particularly useful in assessing short-term adjustments that move towards the long-run equilibrium in each time period. When variables are found to be co-integrated, a VECM is estimated because a co-integrating relationship focuses solely on the long-run relationship between variables without considering the short-run dynamics. This approach offers a significant advantage as it enables the determination of both long-run and short-run influences of the endogenous variables in the model. Additionally, it allows the evaluation of the mechanism that maintains the variables in equilibrium.

$$\Delta \ln \mathrm{FIP_t} = \varphi_2 + \sum_{i=1}^{p} \beta_{2i} \Delta \ln RAIN_{t-i} + \sum_{i=1}^{p} \emptyset_{2i} \Delta \ln \mathrm{TEMP}_{t-i} + \sigma_2 + \sigma_2 ECT_{t-i} \dots \dots \dots \dots (1)$$

where: φ *and* σ are mx1 vector of parameters; $\alpha, \beta, \emptyset,$ μ and γ are mx1 and m x p vectors of parameters respectively; p is the optimal lag order that minimizes Information criteria; n is the number of endogenous variables under investigation (rainfall, temperature and fish productivity); ξ_{jt} is an mx1 vector of random variables assumed to be normally distributed white noise process.

RESULTS AND DISCUSSIONS

Unit Root Test

As shown in Table 1, a necessary preliminary test, the Augmented Dickey Fuller (ADF) test for unit root was employed to test whether or not a variable is stationary and also determine the order of integration of the variable. The result indicated that the variables (temperature, rainfall and fish production) were found to be integrated of order one and became stationary on first differencing. This indicates that the variables exhibit random walk (unit roots) or the future values of these variables do not converge from their past values.

Table 1: Results of Augmented Dickey-Fuller (ADF) Test

Variable	ADF	Level			ADF				First Difference
		1%	5%	10%		1%	5%	10%	Inference
Fish Production	0.215	-3.606	-2.937	-2.607	-6.594***	-3.611	-2.939	-2.608	I(1)
Temperature	-2.668	-3.606	-2.937	-2.607	-9.745***	-3.610	-2.939	-2.608	I(1)
Rainfall	-0.224	-3.606	-2.937	-2.607	-6.319***	-3.610	-2.939	-2.608	I(1)

*** Significant at 1%; Source: Data Analysis, 2023

Co-integration Test

According to Engle and Granger (1987) regressing a non-stationary series on another non-stationary series yields spurious regression, but if the linear combination of the series is stationary, we could say the variables are co-integrated and the regression is no longer spurious. Variables are said to be co-integrated if they have long run association. Since the variables are non-stationary, it becomes imperative to test whether or not the variables are co-integrated. Using trace statistics, the result revealed that combination of these variables has one co-integrating equation and this means that linear combination of these variables has a single long run linear combination of relationship or one co-integrating equation.

Table 2: Unrestricted Co-integration Rank Test

Hypothesized No. of CE(s)	Eigenvalue	Trace Statistic	0.05 Critical Value	Prob.**
None *	0.468667	24.66229	21.13162	0.0152
At most 1	0.073737	2.987305	14.2646	0.9476
At most 2	0.00012	0.004677	3.841466	0.9445

Trace test indicates 1 co-integrating equation(s) at the 0.05 level; Source: Data Analysis, 2023.

The results in Table 2 elucidated the computed trace statistics (24.66229) is greater than the critical value at 0.05 level (21.13162). Since the computed trace statistics is greater than the critical value at 0.05 level, therefore, co-integration exists among the variables. This implies that long run relationship exists among climate change (temperature and rainfall) and fish production in Nigeria.

Long Run and Short Run Effects of Climate Change on Fish Production in Nigeria

Given the presence of one co-integrating equation among the variables, indicating a long-run relationship, the study proceeded to estimate the Vector Error Correction Model (VECM). The VECM provides insights into both short-run and long-run effects of rainfall and temperature on fish production in Nigeria. The results of the VECM estimation are presented in Table 3, offering valuable information on how changes in rainfall and temperature impact fish production over different time horizons. The short-run effects provide an understanding of the immediate adjustments that occur in fish production in response to fluctuations in rainfall and temperature. On the other hand, the long-run effects reveal the sustained impacts of changes in these climatic variables on fish production over extended periods.

Table 3: Long and Short-run Effects of Rainfall and Temperature on Fish Production

Long run	Estimates		
Regressors	**CointEq1**

Source: Data Analysis, 2023

The result of the VECM indicated that in the long run, the coefficient of rainfall (5.395) was positive and statistically significant at 1%. This implies that a unit increase in rainfall will increase fish production by 5.395 units. This may be due to the fact that increase in rainfall may leads to increase in water availability which encourages fish production. More so, the result showed that in the long run, the coefficient of temperature (-58.523) was negative and statistically significant at 5%. This implies that a unit increase in temperature will decrease fish production by 58.523 units. The result indicated the existence of long run effect of rainfall and temperature on fish production. This gives credence to the finding of Ugwumba *et al.* (2020) who found a positive relationship between rainfall and fish yield in the Anambra River basin.

According to the results of the VECM, in the short run, there is a positive and statistically significant relationship between rainfall and fish production. Specifically, a unit increase in rainfall leads to an increase of approximately 0.234 units in fish production during the first lag period. This suggests that changes in rainfall have an immediate positive impact on fish production in Nigeria, indicating the sensitivity of the fisheries sector to short-term variations in precipitation. It's important to note that the significance at the 1% level indicates a high degree of confidence in the statistical relationship between rainfall and fish production in the short run. These findings can be valuable for policymakers and stakeholders in the fisheries industry to make informed decisions regarding climate adaptation measures and sustainable fisheries management, considering the importance of rainfall in influencing fish productivity in Nigeria. This is in line with Fafiolu *et al.* (2020) found that water temperature was a significant predictor of fish yield in the Ogun River, with higher yields observed during cooler months when temperatures were below 27°C.

The short-run results of the VECM analysis showed that the Error Correction Term (ECT) at lag (-1) is statistically significant and negative (-0.004). The negative sign of the Error Correction Term indicates that there is a tendency for the system to correct deviations from the long-run equilibrium position. In other words, the system is self-correcting when it moves away from the long-run equilibrium.

The magnitude of the Error Correction Term (-0.004) indicates the speed at which the system adjusts back to its long-run equilibrium after a deviation. Specifically, a 0.4% deviation from the equilibrium position is corrected within a year. This implies that the fisheries sector in Nigeria is relatively stable and has a slow adjustment process, with only minor deviations from the long-run equilibrium position being rectified within a short time frame. The significance of the Error Correction Term suggests that there is a strong mechanism driving the system back to its long-run equilibrium, ensuring that any temporary imbalances in the short run are gradually corrected. This information is essential for understanding the dynamic behavior of the fisheries sector in response to climate variables and for developing effective policies and strategies to promote sustainable fish production in Nigeria.

CONCLUSION AND RECOMMENDATIONS

The study investigated the impacts of climate change, specifically focusing on changes in rainfall and temperature on fish production in Nigeria. The study concludes that there is a long-run relationship between rainfall, temperature and fish production in the country. In the short term, fluctuations in rainfall and temperature have a notable impact on fish production, leading to immediate adjustments in fish yields. In the long run, changes in these climate variables continue to exert meaningful and sustained effects on fish production in Nigeria. These conclusions offer valuable insights into the complex interactions between climate change and the fisheries sector in Nigeria. Policymakers, researchers, and stakeholders can utilize these findings to develop effective strategies for climate adaptation, sustainable fisheries management, and enhancing food security in the face of changing climatic conditions.

Based on the findings of this study, the following recommendations were made:

i. There is need for proper extension services to educate fish farmers on how to mitigate the long-term impact of climate change.
ii. It is important to have early warning systems in place to alert fish producers on potential risks of climate change. This could include monitoring weather patterns and ocean conditions, and providing timely information and advice to help stakeholders make informed decisions about their livelihoods.
iii. Given the complex and interconnected nature of climate change and its impact on fish production, it is important to promote collaboration and knowledge sharing among different stakeholders. This could include sharing best practices in sustainable fishing, as well as working together to develop new technologies and approaches to mitigate the impact of climate change on fish production.

ABSTRACT

Life after retirement becomes a very difficult period for individuals. This literature review looked at retirement plan and engagement of retirees in aquaculture (fish farming) Retiree are expected to have more time at hand for themselves and it is a period for them to rest due to old age. However,, due to some situation of financial disposition that affect retiree at retirement, retiree is expected to engage in one activity or the other in order to earn extra income to complement their pension. It is expected that many retirees are engaged in aquaculture (fish farming) in Nigeria, considering the high demand of fish because of its nutritional value and health benefits to human especially the elderly and because some of our retirees had attended agricultural extension training sessions during their active service.. However, most of them were found out not engaging in fish farming butr other activities. The decision of those who are engaged in aquaculture was influenced by level of education, marital status, household size, personal interest, extension training. The decision of those who were not engaged in fish farming was informed by their age and gender. It is recommended that workers should be trained and encouraged to engage in fish farming after retirement Agricultural extension training programs for workers should be sustained and workers need to be encouraged to engage in fish farming some years prior to their retirement.

Keywords: *Aquaculture, Agricultural Extension Training, Fish Farming, Retirees*.

INTRODUCTION

Good number of retirees return to their villages because of lower cost of living to avoid financial difficulty and high cost of living in urban settlement (Ofuoku, 2012). Those who retire from government and private organization also face some financial constraints on retirement. This is because they are no longer to receive their full salaries and allowances. Retirees do not stay idol however they engage in one activity or the other. Ofuoku (2012) found out that most retirees who embarked on return migration engaged in agriculture and agricultural related activities.

Bur (2001) posits that retirement is the act of leaving one's service either voluntary or compulsorily where such an employee has completed a specified period of service years or is removed from office by way of compulsory retirement, lay-off, dismissal (for acts of insubordination or misconduct), death, illness, disability or by voluntary withdrawal from service.

Rogers (2008) said retirement is a golden time in the life of a worker, where he/she stops working and does the things that he or she had always wanted to do but had never had the time. Thus, for the first time, the individual has the leisure and freedom to travel and do other things of interest freely. Lee and Law (2004) further explained that even the relatively affluent and employees with private pension schemes need to give some attention to this matter, given the increasing proportion of the population that is unable to stay in employment after its mid-50s because of corporate downsizing brought on by the economic recession and slowdown of the global economy. According to Kasschau (as cited in Lee and Law, 2004), a comprehensive retirement planning policy should include all levels of society. He further argues that at the individual level, pre-retirement planning should be the primary responsibility of the individuals so that he or she will have sufficient resources for his or her desired lifestyle and standard of living. At the family level, Kasschau (as cited in Lee and Law, 2004), further posits that because the family is still the main pillar for informal care, individuals should plan and prepare for retirement together with family members.

Fisheries and Aquaculture

Fish is a major source of animal protein and, according to FAO estimates, fish accounted for 17 percent of the global population's intake of animal protein in 2010 (FAO, 2016). In addition to protein, certain micronutrients from animal-source foods, like iron and vitamin A, are more easily absorbed into the body, while vitamin B12 is only available from animal-source foods.

Fisheries and aquaculture sector play a crucial role in food security, nutrition and health, it contributes directly by providing micronutrient- rich fish and other aquatic foods and it indirectly provide a source of full-time, part-time or supplementary income for over 100 million people in fishing, aquaculture operations, processing, trading, retailing and ancillary industries (HLPE, 2014). Local and international fish trade and licenses to access fisheries resources or fees to lease sea areas for aquaculture also provide important contributions to national trade balances and government revenues. Profits from businesses that range in size from household economies to multi-national vertically integrated seafood companies derive business profits from the capture, farming, processing, trading and retailing of fish. These profits in turn contribute to growth and prosperity from local to national levels.

Importance of Fish and fish product

Aquaculture can be defined as the farming and husbandry of aquatic organisms, such as fish, crustaceans, mollusks, and seaweed, and the production of freshwater and marine pearls and a variety of other aquatic species, such as crocodiles, frogs, sponges, and sea cucumbers. (The word "fish," unless otherwise stated, is used throughout in the generic sense to cover all aquatic animal production, including fish, crustaceans, and mollusks). Fish and fish products are known worldwide as a very important diet because of their high nutritive quality and significance in improving human health (Amao *et al*, 2006). Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein intake of billions of the populace (Amao *et al.*, 2006). On a global scale, almost 16 percent of total average intake of animal protein was attributable to fish in 1988 (FAO, 1990). The Food and Agriculture Organization (FAO, 1991), recommended that an individual takes 35 grams per caput of animal protein per day for sustainable growth and development. Fish contributes 36.6 grams per day of net protein utilization in Nigerian homes (Adekoya, 2004). Fish and fish products provide more than 60% of the total protein intakes in adults especially in the rural areas in Nigeria (Adekoya, 2004).

Fish and fish-related products also provide a primary source of income and livelihood for many communities worldwide, as an estimated 45 million people are directly engaged in the production and harvesting sector. Small-scale fisheries are a key source of employment opportunities and related income. Globally, over 90 percent of those depending on commercial fisheries value chains operate in the small-scale fisheries sector (World Bank, 2012). In addition, secondary sectors such as handling and processing provide employment for millions more. Altogether, it is estimated that fisheries and aquaculture support the livelihoods of some 10 to 12 percent of the world's population (FAO, 2014).

Planning on retirement

Planning for retirement should begin while the individual is still in the middle age; however, persons on the verge of retirement can benefit from planning programs as they learn how to reduce the risk of making poor decisions that may be costly and irreversible (Lee and Law, 2004). Hence, the state has a moral responsibility to educate the public on the importance of retirement planning and to provide resource and planning guides for individuals, groups, and organizations.

According to Lee and Law (2004), planning can be worthwhile and effective only if a person has sufficient resources, knowledge, and the ability both to generate alternative options and take advantage of them in a supportive institutional environment.

Many plans for retirement and start to do something else to earn extra income when they retire from active service. On retirement, the retirees have much time. Hurd and Rohwedder (2003), Ward-Batts (2008) state that before retirees have more available time, they get engaged in more-time intensive production of commodities.

Potentials in fisheries

In Nasarawa State, fish is consumed when roasted, boiled, fried or dried etc. The skin of some cat fish makes useful leather and polishing material; the stem of fish yield substances that when coated are used as glass beads (Iwena, 2008). Fish oil is used for human consumption as well as in the manufacturing of soap. Some species of fishes are used for aesthetic purposes, they are also used for educational and research purposes, Whale fish especially clupeid, anchovy and other species are used for fish meal or condiment (Olaitan and Omomia, 2009). For these reasons, the market and demand for fish is very high and could engage retirees for sustainable livelihood.

Constraints in fisheries activities by Retirees

According to FAO (2004) the challenges that most immediately and directly threaten the sustainability of fisher folk's livelihoods in Africa are poverty, vulnerability and social exclusion. These factors apply not only to fishing communities but generally to the rural poor living in remote areas with little access to social services, infrastructure and markets. According to UN Committee on Social, Economic, and Cultural Rights (2001), poverty is a human condition characterized by sustained or chronic deprivation of the resources, capabilities, choices, security and power necessary for the enjoyment of an adequate standard of living and other civil, cultural, economic, political and social rights. Vulnerability is understood in terms of people's exposure to risks, the sensitivity of their livelihood systems to these risks and limited assets to cope with and adapt to them (UN Committee on Social, Economic, and Cultural Rights (2001)). According to FAO (2004) while poverty and vulnerability are sometimes thought of as end results of a country's policy failures of various kinds, marginalization or social exclusion is conceived as resulting from negative social and power relations with others. The marginalized are excluded from political, social and economic opportunities enjoyed by other citizens.

Constraints experienced by fish farmers, one will not be surprised that many retirees are not involved or engaged in fish farming. This implies that the work force is dominated by the males. However, women also make an encouraging percentage of fish farmers especially in the aspect of fish processing, among the retirees.

Challenges to fishery resources management

Akankali and Jamabo (2011) observed that several empirical evidences existing in literature shows that the fisheries yield from artisanal sources is on the decline in Nigeria. The greatest challenge to fishery is that it is operated by artisans who have learnt the art of fishing informally from their parents.

Most of the fishermen are not educated and can hardly read or write. They lacked modern fishing equipment and can hardly maximize their catch in the face of declining fishery resources, climate and small fishing gears.

Some fish species are fast disappearing and the number of stocks caught is decreasing in average size due to over fishing and other harmful fishing practices. Fishermen use small eyed-nets which catch small and immature fish. The increasing cost of fishing gears in recent times is making it difficult for most fishermen to afford. This increases the cost of fishing in the area.

Etim (2010) attributed the problem of overexploitation to invention and increased sophistication of fishing gear in recent times. The number of fishermen has been increasing while the average catch per week continue to declined, the sizes of individual fish in the catch are also becoming smaller and large sized fishes becoming rare to encounter.

Education as a factor

Level of education was significantly and positively related with retiree's decision on fish farming. The implication is that education is a variable that encourages people to venture into fish farming as Madukwe (1995) states that educational level of farmers is one of the salient variables related to the use of important farm practices. That is how education is also related to the decision by retirees to engage in fish farming. Most retiree should have one level or the other of formal education. Education is expected to be an influencing factor for decision to engage in fish farming after retirement. Education will expose them to useful information on fish farming. Education therefore influences the behavior of retirees' behavior (positive towards fish farming).

Household Size

Marital status will significantly and positively influence the decision of retirees to embark on fish farming. With the responsibility over their spouses their need to earn extra income to cater for the short fall in pension paid to them as pension. Most of retirees have large household sizes. These forms of responsibilities to them as more often than not, most household are dependents. This is in consonance with Ofuoku (2012) who stated that in household size. Household size proved to positively and significantly influence the decision of retirees to engage in fish farming. This means that the larger the household size the more likely a retiree will engage in fish farming activities. This is attributed to the fact that the monthly pension paid cannot adequately cater for the needs of their household members. In order to make up for the reduced income in the name of pension they took the decision to embark on fish farming. Hard and Rohwdder (2003), Ward-Batts (2008) found that retirees have more time available to them and so they shift toward more – time intensive production of commodities.

Retirees and Training

Most retirees should receive extension training in various agricultural enterprises. Ofuoku (2012) suggested extension training for urban – rural migrants most of who are retirees who embarked or return migration to their respective villages. Extension training will have positive and significant influence on the decision of the retirees to embark on fish farming. This implies that the retirees who had extension training tends to be more likely to decide on going into fish farming. Ofuoku (2012) suggest that retirees should be given preretirement years so that they can take to farming after retirement.

Age and Retiree

Age always have a negative but significant relationship with the retiree's decision to get involved in fish farming. This is in consonance with a priority expectation. It implies that older retirees are at risk averse as fish farming is not void of the risk of poaching and the cost of inputs is high. This is congruent with Lemchi *et al*. (2003), Maduakor (2001) who opined that as one becomes older bone becomes more risk averse. This can also be alluded to the fact that sometimes the labor required is intensive.

CONCLUSION

Many retirees find it difficult to make ends meet as a result of reduced income to their households. In order to provide for this shortage in income it is expected that most of them engage in activities that will earn them extra income to supplement the pensions received by them.

Most of the retirees were males and most of them are also married and had one level of formal education or the other. They had average household size of 5 persons and had agricultural extension training. Many retirees were not engaged in fish farming. However, their decision to engage in fish farming was influenced by their gender and age negatively but positively by their level of education, marital status, household size and agricultural extension training they had prior to retirement.

RECOMMENDATIONS

Workers should be encouraged to prepare for retirement by giving them training on fish farming and other agricultural activities.

Retirees should be encouraged to engage in fish farming no matter the level of production, some years before retirement, this will enable them to master the intricacies involved in fish farming so that they can be fully prepared before retirement.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted to investigate fish handling, processing, preservation and socio-demography of fishers in Gubi dam, Nigeria. Structured questionnaire was used for the assessment. The questionnaire was designed to gather information on the management of handling and processing practices which include fish mortality, quality of fish, method of harvesting, fishing gears used, type of fish processing methods, fish storage and duration of fish storage. Percentages were used to analyse the data. Majority of fish processors (73.6%) were males while 26.4% were females. Most (41.5%) of the respondents had primary school education while 11.3% had tertiary education and 18.9% had no formal education. Most (37.6%) of the respondents fell within the ages of 15 – 25. Fishing experiences are mostly (37.7%) within the range of 6-10 years. Most (60.4%) of the fishers were not trained on fish handling techniques while 39.6% were trained. Majority (71.7%) of the gears used in harvesting fish in the dam do not injure the fishes while 28.3% do cause injuries. Daily catches of 60.4% of the fishers is 3 – 4kg with dominant use of scoop net (64.2%). The landed fish were usually in poor hygiene conditions (92.5%) but the post landing handling techniques are generally good (96.2%) with mostly 5 – 6 hours' time of harvesting and handling (43.4%). Fishers in the study area had moderate skills in fish handling and processing techniques. However, such skills can be improved sustainably through regular training such as by fisheries extension workers' services.
Keywords: *Gubi dam, Socio-demography, Fish Handling Techniques, Daily Catches*

INTRODUCTION
Fish is a major and relatively cheap source of animal protein. According to Food and Agricultural Organisation (FAO) in 2010, fish accounted for about 20% of the global population's intake of animal protein (FAO, 2016). Fish is also rich in micronutrients like iron, vitamin A, vitamin B12 and so forth. Globally, more than 90% into commercial fisheries value chains are small-scale ventures with about 45 million people directly engaged in fish production and harvesting sector while secondary sectors such as handling and processing provide employment opportunities and related income for millions more (World Bank, 2012). Fish is one of the protein foods that need careful handling (Eyo, 2002). This is because fish spoils easily after capture due to the high tropical temperature which accelerates the activities of bacteria, enzymes and chemical oxidation of fat in the fish. Due to poor handling of Fish species, about 30 – 50% of fish harvested are wasted in Nigeria (FAO, 2014). These losses could be minimized by the application of proper handling, processing and preservation techniques (Bate and Bendall, 2010).The purpose of processing and handling fish is to get fish to an ultimate consumer in good, usable condition. The fish's gut is a rich source of enzymes that allow the living fish to digest its food (Lima Dos Santos *et al.*, 2011). Fish farmers are faced with the challenges of how to process and handle fish for better consumption as poor quality raw fish produces poor quality end products. Processing can only help to slow down the rate of deterioration. The main aim of this research was to investigate and provide an insight on the activities of fishers and fish processors on the quality assurance of fish caught in Gubi dam through the following objectives: to assess the socio-demographic characteristics of the fishers, fish handling techniques, fish processing and preservation in Gubi dam.

MATERIAL AND METHODS
Study Area
Gubi dam is located at Piro Village, Ganjuwa Local government Area, Bauchi state. The dam is mostly recharged by rivers whose main sources of water are rainfall added water. The rivers are seasonal and dry out during the dry period of the year. it is the largest fresh water body in Bauchi state (latitudes 9° 3' - 12° 3' north and longitudes 8°

50' - 11^0 east). Gubi dam is an earth filled dam with clay core. It has a total storage capacity of 3.84 x $106m^3$. The maximum depth of the dam is 27 meters (m), Length of the embankment is 3.8 kilometres (Km), free board is 3 meters (m) and the spill way is 70 meters (m). The dam has catchment areas of $179km^2$ and reservoir area of 590ha (Anon., 2005).

Data collection

A validated questionnaire was used to gather information from 53 respondents which have been involved in fishing, handling, processing and preservation of fishes caught in Gubi dam. Site inspections were carried out as well for critical observations.

Data Analysis

Descriptive statistics were used in analysing the data with result presented in percentage.

RESULTS AND DISCUSSION

Those surveyed included the fishers, processors, the dry fish producers and the buyers of landed fish. In most instances, an individual may be involved in multiple activities.

Table 1: Socio –Demographic Characteristic of Respondents

Parameters	Percentage (%)
Gender	
Male	73.6
Female	26.4
Level of Education	
Primary	41.5
Secondary	28.3
Tertiary	11.3
None	18.9
Occupation	
Fishing	37.7
Crop Farming	5.7
Crop Farming and Fishing	30.2
Fishing, Crop Farming and Fish Processing	26.4
Age	
15 – 25	37.6
26 – 36	28.3
37 – 50	19.0
51 – 70	15.1

Table 2: Fishing Gears Technology, Hygiene, Catches and Mortality

Parameters	Percentage (%)	Parameters	Percentage (%)	Parameters	Percentage (%)
Fishing gears used in catching Fish		**Injuries to fish due to fishing gears**		**Fish mortality**	
Drag net	20.8	Yes	71.7	10 – 20 fish	50.9
Scoop net	64.2	No	38.3	30 – 40 fish	41.5
Hook and line	3.8	**Exposure to pesticides**		50 – 60 fish	7.6
Cast net	11.3	Yes	92.5	70 – 80 fish	0
Hygienic condition of landed fish		No	7.5	**Time of fish harvesting and handing**	
Yes	7.5	**Adherence to good fish handling techniques.**		1 – 5 hours	15.1
No	92.5	Yes	96.2	3 – 4 hours	32.1
Experience In Fish Handling		No	3.2	5 – 6 hours	43.4
Yes	39.6	**Washing canoe frequently**		7 – 8 hours	9.4
No	60.4	Yes	24.5	**Fishing experience**	
Keeping fish on		No	70.7	1 – 5 years	35.8

floor					
Yes	9.4	**Total weight of fish caught daily**		6 – 10 years	37.7
No	90.6	1 – 2 kg	18.9	11 – 15 years	20.8
Quality assurance (inspection)		3 – 4 kg	60.4	16 – 2 0 years	5.7
Yes	83	5 – 6 kg	15.7		
No	16.6	7 – 8 kg	5.7		

Abdulkarim *et al.*, (2005) investigated fish and fisheries of Gubi dam thereby providing a baseline data. However, the approach of this research in focusing on the socio-demographic characteristics of fishers and on fish handling techniques, processing and preservation is expected to also provide another set of data for future evaluation and monitoring of such fisheries activities in the dam.

Table 3: Fish Processing, Preservation and Handling

Parameters	Percentage (%)	Parameters	Percentage (%)	Parameters	Percentage (%)
Types of fish processed		**Number of years in fish processing**		**Way raw fish are kept before processing**	
Marine fish	0	1 – 5 years	85.7	At room temperature	92.9
Fresh water	100	6 – 10 years	7.2	In a fridge	7.1
Brackish water fish	0	11 – 15 years	7.1	In a freezer	0
The source of raw fish		16 – 20 years	0	**Storage of processed fish**	
Fishers	71.4	**Do you wash hands before processing**		Sold immediately after processing	35.7
Fisher mongers	28.6	Yes	85.7	Refrigerator	0
Cold store	0	No	14.3	Wire mesh (Basket)	42.9
Open market	0	**Materials used to wash hands**		Others	21.4
Others	0	Only water	71.4	**Storage of processed fish before selling**	
Processed Fish Species		Water and soap	14.3	Less than one day	50
Tilapia	57.1	Water and ash	14.3	More than one day Less than one week	42.9
Cat fish	42.9	**How long fish are kept before processing**		One week – 1 Month	7.1
Fish inspection before purchase		Less than 30 minutes	64.3	More than a Month	0
Yes	92.9	30minuts to 1 hour	35.7		
No	7.1	More than one day less than one week	0		
		More than one week	0		

Table 1 elucidates the socio-demographic characteristics of the respondents. Majority (73.6%) were males while 26.4% were females. All the females are in the processing activities as there was no female fisher. Most (41.5%) of the respondents had primary school education; 11.3% had tertiary education while 18.9% had no formal education. This is an indication that new technologies could be easily adapted as just less than 20% of the respondents were not educated more than 80% are enlightened. Although, just 11.3% attended tertiary schools, because others do not have access to further their education due to limited resources and a belief that education has no connection to their income, job opportunities and general success in life. Most (37.7%) engaged only in fishing, followed by 30.2% into both fishing and crop farming and 26.4% were into Fishing, Crop Farming and Fish Processing while few (5.7%) were only into Crop farming. Fishing occupation dominates the society and most (37.6%) of the respondents fell within the ages of 15 – 25 years while few (15.1%) were within 50 – 70 years. These implied that youths dominated the occupation and was observed that most of them inherited it from their fathers and likely that might be the reason which their fishing experiences are mostly within the range of 6-10 years (37.7%) and 1-5 (35.8) as in Table 2. Daily catches of 60.4% of the fishers is 3 – 4kg with dominant use of scoop net (64.2%) which unlike what Emmanuel (2009) opined based on considerable literature review that gill nets is the most important gear used by indigenous fishers followed by long lines and cast nets.The landed fish are usually in poor hygiene conditions (92.5%) but the post landing handling techniques are generally good (96.2%) with mostly 5 – 6 hours' time of harvesting and handling (43.4%).

From Table 3, the hygiene condition of fish and fish handlers were usually assured before purchasing. This hygienic condition of the fish and fish handlers were not satisfactory due to lack of extension services to educate the fish handlers about fish handling and hygienic practice and its importance. Most of the respondent reported that the fish were usually not placed on the ground directly rather they were placed on tarpaulin before sorting the fishes into different species and sizes. The respondent stated that the gears used during fishing does not caused injuries to the fish. The gears used by the fishers were made from simple materials which agree with the baseline study reported by Abdulkarim *et al*., (2005) that the fishing is artisanal small scale in Gubi dam.

CONCLUSION AND RECOMMENDATIONS

Fishers in the study area had moderate skills in fish handling and processing techniques. However, such skills can be improved sustainably through regular training such as by fisheries extension workers' services.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The Study of length weight relationship and stomach content analysis of Synodontis schall from Oyan Reservoir, Ogun State was carried out between May and July 2021. Two prominent fishing ground/ landing sites: Ibaro and Apojola were selected for the sampling. 120 specimens of S. schall consisting of fifty- eight (58) male and sixty-two (62) female was examined to determine the length weight and stomach content of the fish. The stomach content analysis using numerical method revealed that S. schall from Oyan dam feed more on phytoplankton and detritus (26.27%) respectively in Apojola and Ibaro landing station. These studies shows that S. schall examined are in good condition and feed very well as the length increases with body weight while most of the stomach content analysed have food materials in them. Majority of the fish examined fed on phytoplankton and detritus due to their benthic feeding characteristics and are carnivorous in nature by feeding on varieties of feed ranging from algae to fish scale. The fishes caught during the research are more of smaller sizes indicating young fishes, further research should be carried out to capture larger fish species.
Keywords: *Stomach content, Synodontis schall, Phytoplankton, Detritus.*

INTRODUCTION
Fishes are sources of food for human beings and other animals, rich in proteins and vitamins, especially, vitamin A (Retinol) (Fayeofori, 2013; Osuigwe and Obiekezie, 2007). It is unfortunate that the protein requirement of most African countries still grossly outweighs its supply (Adakai *et al.,* 2014). In Nigeria, less than 40% of the total protein requirement by the people is met, out of which fish constitutes about 41% (Bernard *et al.,* 2011). The fish Family Mochokidae is one of prominent fish species in Africa and represented mainly by Genus Synodontis commonly referred to as squeaker or upside-down catfish, is widely distributed in African freshwaters ranging from the Nile basin, Chad, Niger and much of the West African region (Paugy and Roberts, 1992). This genus has over 112 species (Daget *et al*., 1991) and some of the species are commercially important comprising up to 40% of the total landings by weight in some regions of Africa (Willoughby, 1974; Sanyanga, 1996) cited by Elias *et al.* 2012. Lowe-McConnell, 1987 reported Synondontis schall (Bloch & Schneider) as the most tolerant species to adverse environmental conditions in the genus and has the widest distribution in Africa. Twenty species of Synodontis species were reportedly found in Northern Nigeria (Reed *et al.*1967) while twenty-one species were identified in Niger (Holden and Reed 1972). The Length Weight Relationship is used in determining condition factor (*k*) is used to compare the "condition", "fatness" or wellbeing of fishes (Seher and Suleyman, 2012). According to Carey and Lawson, 2003, this is based on the hypothesis that heavier fish of a particular length are in a better physiological condition. The food and feeding habit of fish species usually determine the condition and wellbeing of fish as the heavier fish is considered to be in a better condition. The dietary habit of fishes, based on stomach analyses, is widely used in fish ecology as an important method to investigate trophic relationship in aquatic communities (Abdul *et al.* 2016). This study is aimed at providing information on food and feeding habit of *Synodontis schall* from Oyan reservoir as there is paucity of knowledge of this fish species from the reservoir.

MATERIALS AND METHODS
The study was carried out at Oyan reservoir, Ogun State Nigeria. Oyan Reservoir is located at lat. 7°14'N, long. 3°13'E near Abeokuta, the capital city of Ogun State, Nigeria. The reservoir was established in 1984 with, lying adjacent, two resettlement communities named Abule-titun and Ibaro. The dam has an embankment crest length of 1044m, a height of 30.4m, four spillway gates (each 15 m wide and 7m high), and three outlet valves (each 1.8m in diameter). The reservoir has a surface area of 40 km^2, a gross storage capacity of 270 million m3, and a dead storage capacity of 16 million m^3(Ofoezie and Asaolu, 1997).

Samples Collection

A total of One hundred and twenty samples of *S. schall* were collected from local fishermen from two landing sites (Ibaro and Apoojola) in Oyan reservoir. The Total Length (TL) was measured to the nearest 0.1centimetre using measuring board while the Weight (W) was measured into the nearest 0.1g using sensitive scale. The gut of the fish was carefully removed by making a longitudinal incision along the mid ventral line from the mouth to the anus in order to expose the visceral organs. The stomach was later removed carefully by detaching it from other internal organs and fatty tissues. The stomach was removed and immediately preserved in 4% formalin in pre-labeled sterile bottles for subsequent food items examination and analysis in the laboratory. The stomachs were rated 0, ¼, ½, ¾, or full according to their fullness as described by Olatunde (1978). Each stomach sample was opened in the laboratory and the content emptied into a petri dish. The food items were identified using hand lens while others with the aid of light microscope using magnification of X10 and X40 for proper identification. The stomach contents were analyzed using Numerical method.

Numerical Method: Percentage number of a food item

$$= \frac{\text{Total Number of the particular food item}}{\text{Total number of all food items}} \times 100$$

RESULTS AND DISCUSSION

Tables 1 shows different food items recorded in the stomach content of *S.schall* from the two landing sites. Phytoplankton and Detritus accounted for the most occurred food item with 119 items respectively. Unidentified food materials from the two stations were small ranges from 6 to 9 materials. The detritus was the highest food materials recorded in all the month ranges from 78 to119. The lowest food item was the fish scales which range between 48 to 63 food samples.

Table 1: Monthly diet composition of *Synodontis schall* from Oyan reservoir, Ogun State

Month	Blue green algae	Protozoans	Fish scales	Phytoplankton	Detritus	Unidentified materials
May	56	58	48	69	78	7
June	61	60	55	83	95	9
July	81	65	63	119	119	6

The stomach content analyses of *S. schall* from Oyan reservoir using Numerical method was shown in Table 2. This result of stomach content analysis revealed that *S. schall* feeds on various food items such as Blue green algae, protozoans, fish scales, phytoplankton and detritus. Some unidentified food item was also recorded in small quantity.

Table 2: Stomach content analysis of *Synodontis schall* from Oyan reservoir, Ogun State (Numerical method %)

Month	Blue green algae	Protozoans	Fish scales	Phytoplankton	Detritus	Unidentified materials
May	17.72	18.35	15.19	21.84	24.68	2.22
June	16.80	16.53	15.15	22.87	26.17	2.48
July	17.88	14.35	13.91	26.27	26.27	1.32

DISCUSSION

The food items recorded from stomach content analysis of *S. schall* were Blue green algae, protozoans, fish scales, phytoplankton, detritus and unidentified food items. The phytoplankton and detritus accounted for the highest food item of 26.27% respectively using Numerical method of stomach content analysis. Unidentified food item recorded the least with 1.32% of the food item. Fish scales also have the lowest percentage of 13.91%, this is in line with lowest percentage of it recorded by Elias *et al.* 2012 in Lake Chamo and this shows the carnivorous feeding habit of the fish. The varieties of food items found in stomach content of *S. schall* shows the omnivorous feeding habits of this genus as reported by Shinkafi *et al.*(2010). Feeding on larger percentage of detritus indicate a demersal or bottom feeding characteristics of the genus Synodontis as reported by Shinkafi *et al.* (2010).

CONCLUSION

The stomach content of *Synodontis schall* in Oyan reservoir, Ogun State showed that the fish species is an omnivorous feeder indicated by the verse varieties of food items found in their stomach.

ACKNOWLEDGEMENT

We are grateful to Almighty God for the wisdom, knowledge and understanding bestow on us in researching and writing this article. Also our sincere appreciation goes to TETFUND aid of OYSCATECH for their financial support during the conference activities.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT.
The effect of pre-treatment on the drying behavior of Tilapia (Oreochromis niloticus) fish was investigated. (pre-treatment at 0 min, 5 min and 10 min steam blanching respectively) In addition, the economic analysis of the optimal drying period of Tilapia fish in consequence to applied pre-treatment was studied. Results showed that the drying behavior of samples occurred at a single falling rate period signifying a heat and moisture permissible microstructure of the fish. The drying time for 0, 5- and 10-min steam blanched samples were 750, 630 and 570 min, respectively. The economic metrics showed that the commercialization of 10 min steam blanched convectively dried Tilapia fish has a payback period of two and half years within ten years maximum operational period of the drier. The results can assist citizen's capacity development, empowerment and food security.
Keywords: *Tilapia fish, drying, pretreatment, economic, convective, food*

INTRODUCTION

Tilapia (*Oreochromis niloticus*) fish is a freshwater fish species that belongs to the Cichlidae family (Lee *et al.*, 2014). It is a popular fish species worldwide due to its high nutritional value, fast growth rate, high productivity and adaptability to different environmental conditions (Adeyi *et al.*, 2022). Tilapia fish also have high protein content and several medicinal usefulness, which makes it an excellent dietary source of protein for humans (Mahbub *et al.*, 2019).

Tilapia fish like other foods, is perishable and therefore need processing for preservation and storage. Amongst processing methods, drying is simple, effective, and economical. Drying increases product acceptability, shelf life, concentrate protein content and add market values. Traditionally, open sun drying is one of the most commonly utilized methods to preserve Tilapia fish (Lee *et al.*, 2014), however, the inconsistency, and unhygienic characteristics of open sun drying makes it unacceptable in the modern times. Nowadays, drying technologies such as solar or solar tunnel, convective oven, freezer, infra-red, microwave, amongst others have emerged. Amongst the many emergent drying technologies, convective dryer is technically fulfilling for commercial purposes (Adeyi *et al.*, 2022).

A notable challenge of convective oven drying is the long drying time; however, literature has it that this challenge could be significantly handled if adequate pretreatment methods such as blanching were applied (Adeyi *et al.*, 2022). It is important to minimize agro produces' drying time to lower energy utilization for process sustainability, products' economic production and environmental preservation, products' undesirable fermentation and dried products' quality preservation.

Furthermore, most research outputs are usually not implementable due to dearth of knowledge about its commercialization economic implications. Economic analysis helps in determining the cost drivers of the drying process (Fudholi *et al*., 2016). By conducting an economic analysis, such as for drying process, investors can make informed decisions and take steps to improve the overall efficiency and profitability of operations (Poonia *et al*., 2017).

Therefore, the aim of this study is to conduct a techno-economic analysis of Tilapia fish drying through the following specific objectives: (1) investigate the effect of steam blanching as pretreatment on the drying time of Tilapia fish, and (2) conduct economic analysis of the Tilapia fish drying process based on least drying time.

MATERIALS AND METHODS

Fresh *Oreochromis niloticus* Tilapia fishes (harvested on the same market day) were purchased from Waso market in Ogbomoso Oyo State Nigeria. The fishes were degutted, de-scale and washed with potable water. The prepared

fishes were air-dried at room temperature prior to drying in Stangas (SG-9052G, Stangas Luxury Modern Appliances, Italy) convective dryer.
The Stangas convective dryer is equipped with temperature regulator, 3000 W heating element, fan and vent. Digital weighing balance (0.01 g accuracy) was utilized for measurement purposes. Tuneable heater (1000 Watts) was utilized for heating during sample pretreatment.

Pre-treatment procedure

Samples of Tilapia fish (100 g each) were cut out from the fleshy part of the fish for steam blanched. The first sample was steam blanched by exposure to steam from Tuneable heater with the aid of expanded wire mesh for 5 min in the laboratory in accordance with the method of Taiwo and Adeyemi (2009). The second sample was also steam blanched in the same way for 10 min. After blanching, the samples were allowed to air dry and attain room temperature. Thereafter, the samples were subjected to drying.

Drying Procedure

The contribution of steam blanching pre-treatments to the drying time of Tilapia fish was determined. The pre-treated Tilapia fish were dried in the Stangas convective oven at nutritive quality preserving temperatures of 70 ^{O}C, and at a constant dryer air velocity of 2.0 m/s. The ambient air temperature varied between 29 and 31 ^{O}C. The dryer was allowed to operate for 30 min prior to insertion of the pre-treated sample. The instantaneous weights of the sample undergoing drying were determined at reasonable intervals (10 min at the drying onset, 20 min at mid drying times and 30 min at later drying times). This was achieved by discontinuously weighing the sample on digital weighing balance and repeated severally until a constant sample weight was observed (Adeyi *et al*., 2022). Drying experiments were done in replicates for the purpose of data integrity, and the mean of the replicates were used to describe the drying characteristics and time of the pre-treated Tilapia fish samples. The initial moisture content of fresh Tilapia fish used in this study was 241.3 % d.b as determined by oven drying method at 105 ºC for 24 h in accordance with the report of Kaveh *et al*, (2021). Equations 1 – 2 assisted in empirical drying data analysis.

$$M_a(d.b) = \frac{W_F - W_D}{W_D} \text{ X } 100\% \quad (1)$$

Where M_a = initial moisture content in percentage dry basis (%), W_F = fresh weight of the sample (g) and W_D = dried weight of the sample (g)

$$MR = \frac{M_t - M_e}{M_a - M_e} \quad (2)$$

Where, MR is the moisture ratio, M_t = moisture content at a given time t during drying (g of water/g of dry matter) and M_e = final equilibrium moisture content (g of water/g of dry mater).

Economic Analysis

Financial consideration to assist potential investor take decision on commercialization of Tilapia fish drying was investigated. Usually, conducting economic analysis starts from market research where information is gathered regarding the demand for the intended product in the targeted market, understanding the preferences, purchasing behavior, and potential competitors for the intended product. Thereafter, a cost analysis that includes all aspect of production is undertaken with particular interest in drying procedure that results in least drying time with the assistance of Eqn. (3) - (8).

$$\text{Energy consumption} = \text{dryer power} * \text{drying time} \quad (3)$$

$$\text{Cost of fresh fish per batch} = \text{fresh fish per batch} * \text{Cost of fresh fish per kg} \quad (4)$$

$$\text{Cost of electricity used} = \text{dryer power} * \text{drying time} * \text{cost of electricity} \quad (5)$$

$$\text{Revenue per batch} = \text{dried weight} * \text{selling price per kg of dried fish} \quad (6)$$

$$\text{Net income per batch} = \text{Revenue per batch} - (\text{Electricity cost} + \text{Labor cost} + \text{Maintenance cost} + \text{wet weight cost}) \quad (7)$$

$$\text{Payback period} = \text{Initial investment on dryer} \div \text{Net income per batch} \quad (8)$$

RESULTS AND DISCUSSION

Effect of blanching on drying characteristics

The effect of pretreatment (un-blanched, 5- and 10-min steam blanching) on moisture removal profile and drying time of Tilapia fish in this study is represented in Fig. 1. The three represented profiles showed a single drying falling rate period. This represents a non-reluctant drying rate which can be related to the permeable microstructure of the sample. The unblanched sample showed the longest drying time of 750 min, followed by the 5 min steam blanched sample (630 min drying time) and 10 min steam blanched sample (570 min drying time). These showed that steam blanching reduced drying time as blanching time increased.
The point of deflection from the steep slop signifies a point moisture removal reluctance. This is related to change in texture or case hardening phenomenon in the sample. The last points of the profiles signify equilibrium stage where the samples have low/safe moisture content that is required for storage and shelf stability. Taiwo and Adeyemi (2009) observed a similar result.

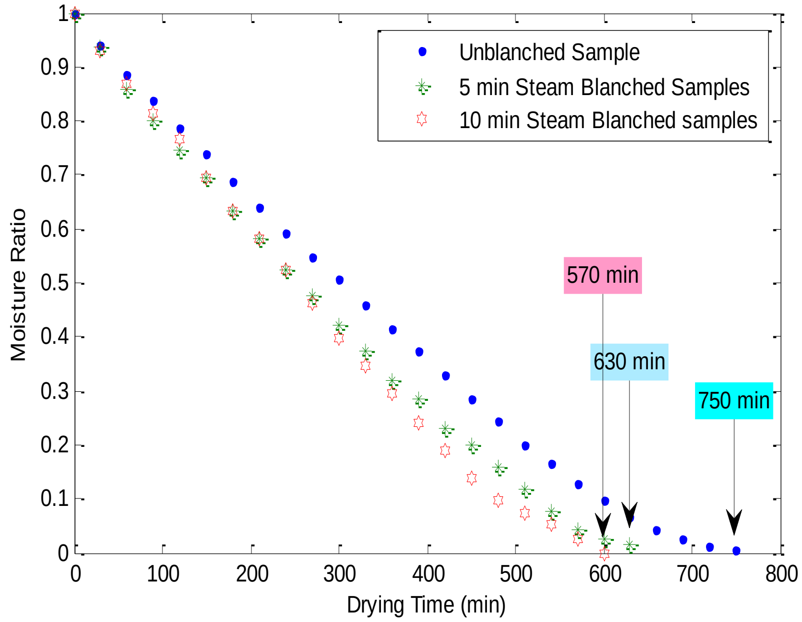

Fig 1. Drying profile of Tilapia fish in convective oven

Economic metric

The economic analysis of Tilapia fish drying (steam blanched at 10 min) is represented in Table 1. The 10 min steam blanching was utilized because of its lowest drying time).

Table 1 Table of economic analysis

Parameters	Amount	Unit
Dryer cost	100000	1
pcs		
Dryer capacity	50	kg
Fresh fish/batch	50	kg
Dried fish/batch	16.5	kg
Dryer power	3	kW
Drying time	12	hr
Number of batches in a year	52	
Batch		
Cost of electricity per kWh	26	₦
Cost of labor/batch	1000	₦
Cost of dryer maintenance/batch	100	₦
Selling price/kg of dried fish	3200	₦
Cost of fresh fish/kg	1000	₦
Energy consumption	36	
kWh		
Cost of fresh fish per/batch	50000	₦
Cost of electricity used	936	₦
Revenue/batch	52800	₦
Net income/batch	764	₦
Payback period	130.89	
Batch		
Number of year equivalent of Payback period	2.51	
Years		

The assumptions used includes unchanging price of fresh Tilapia fish, constant availability of fish, electricity, demand for dried Tilapia fish, labor cost, and dryer maintenance cost for 5 years. Therefore, sensitivity analysis was not necessary. Furthermore, the tax or other government levies that might affect the cost or benefit of the project are ignored, and that inflation rate will be zero for the five-year analysis-covering period.

The results showed that the revenue per batch is significantly higher than production cost, which is desirable. At this revenue per batch, results showed that the payback period for the initial investment is about two and half years, which is also desirable. It therefore means that the rest of eight and half years will be for gain making. Therefore, the business is worthwhile.

CONCLUSION

In this study, the effect of steam blanched pre-treatment on drying time of Tilapia fish was undertaken. In addition, economics metrics of the drying process consequent to pretreatment was investigated. The results implied that increment in steam blanching time reduced the drying time significantly. This was attributed to increased tissue loosening as a result of steam blanching. The economic analysis with reasonable assumptions and in connection with present market prices showed that 10 min steam blanched plus convectively dried Tilapia fish hold a profitable commercial potential. It is concluded that the results of this study can aid citizen's capacity development, economic empowerment, and thus contribute to food security.

RECOMMENDATION

It is recommended that a similar study of Tilapia drying should be replicated using a smoking kiln instead of the electrically powered convective dryer due to the erratic nature of electricity in Nigeria.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study was conducted to investigate the organoleptic characteristic and polycyclic aromatic hydrocarbon in smoked eviscerated catfish using four different energy source of wood charcoal: Gmelina (Gmnelina arborea), Parkia (Parkia biglobosa), Neem (Azadirachita indica) and charcoal from commercial market in Ogbomoso (mixture of different wood types). Overall acceptability was based on 5-point Hedonic scale (excellent (5) -poor (1). Chemical test was on Polycyclic Aromatic Hydrocarbon (PAH) contents (benzo (α) pyrene, Fluoranthene, Napthalene, Acenapthalene, Benzo (k) pyrene). Smoked fish sample produced with Parkia and Neem had higher mean scores for overall acceptability followed by charcoal and Gmelina respectively. Smoked catfish samples produced with charcoal had the lowest level benzo (α) pyrene followed by Neem, Gmelina, and Parkia. The concentration is within the EC'S recommended maximum limit of 5µ/kg for benzo (α) pyrene which has been classified as carcinogens. Conclusively, it can be drawn that fish produced by charcoal among other sources investigated is the best and most suitable for human consumption.
Keywords: *Cat fish, Smoked fish, wood sources, organoleptic characteristic*

INTRODUCTION
Fish is one of the most important sources of animal protein available in the tropics and has been widely accepted as a good source of protein and other elements for the maintenance of healthy body (Andrew, 2001). There are various reasons that trigger smoking and preservation of fish, chief of which is its high susceptibility to deterioration without any preservative or processing measures (Okonta and Ekelemu, 2005). Soon after death, fish begins to spoil. In the healthy live fish, all the complex biochemical reactions are balanced, and the fish flesh is sterile. After death, however, irreversible changes that results in fish spoilage begins to occur. The resultant effect is the decomposition of the fish (Akinola *et al.,* 2006; Singh and Heldman, 2013; Pigott, 2015).
A considerable effort has been directed to extend the shelf life of fish using preservation and processing techniques, such as refrigeration, freezing, canning, salting, drying and smoking (Okonta and Ekelemu, 2005; Singh and Heldman, 2013; Pigott, 2015, Davies and Davies, 2005). Smoking is the preferred cheap method to preventing fish spoilage. This is carried out-over smoldering wood, sawdust or other local source of energy using traditional kilns constructed with locally sourced materials. All these methods have the effect of imparting pleasant flavour to the product beside the preservative effect of the smoke itself (Burgress *et al*., 1965; Tull, 1997). This experiment aims to evaluate the effect of different types of energy sources on organoleptic properties and polycyclic aromatic hydrocarbons (PAHs) composition on smoked African catfish.

MATERIALS AND METHODS
Experimental Procedure
A total of hundred (100) table size African catfish *Clarias gariepinus* were obtained from a reputable fish farm in Ogbomoso. The modern smoking process (using charcoal oven) experiment was carried out at the fishery unit, Ladoke Akintola University of Technology (LAUTECH) Teaching and Research Farm, Ogbomoso. African catfish samples were eviscerated washed with clean water and smoked using four different fuel sources Beachwood *(Gmelina arborea*), African locust bean tree *(Parkia biglobosa*), Neem (*Azadirachita indica*) and charcoal.
The fish were smoked to complete dryness and the time taken for complete dryness was recorded (state the time) using a digital stopwacth, the smoking temperature for all treatments was maintained between 80^0C and 100^0C. The time taken for fish to be smoked using the Gmelina, Parkia, Neem and charcoal smoked fish was 8 hours,

6.5 hours, 7 hours and 5 hours, respectively. The smoked samples were kept at room temperature after complete dryness and about 5g samples for each treatment were taken to the laboratory for analysis.

Organoleptic Test

The smoked fish samples were assessment based on scoring system by Emokpae (1979) which involved measurement of certain parameters on a 5-point hedonic scale (excellent (5), very good (4), good (3), fair (2) and poor (1) for colour, texture, taste, flavour and overall acceptability.

Chemical Analysis

Smoked fish samples were analyzed for Polycyclic Aromatic Hydrocarbon PAHsBenzo(α)pyrene, Fluoranthene, Napthalene, Acanapthalene, Benzo(k)pyrene) according to the methods of the proximate composition of the wet and smoked fish were analyzed for proximate composition according to the method of A.O.A C (2000).

Statistical Analysis

Data collected were subjected to one way analysis of variance (ANOVA) using general linear model (GLM) of factorial experiment design and means were separated by Duncan's multiple index (P< 0.05).

RESULTS

Table 1: Sensory score for Smoked Catfish (*Clarias gariepinus*) using four different sources of Energy in ogbomosho.

Parameters	GSS	Judgement	PSS	Judgement	NSS	Judgement	CSS	Judgement

Pyrene (µg/kg)	1.92^{b}	1.86^{b}	0.23^{a}	0.18^{a}	0.26
Benzo(α)pyrene (µg/kg)	2.74^{a}	2.75^{a}	0.73^{a}	0.32^{b}	0.34
Fluoranthene (µg/kg)	2.04^{a}	2.19^{b}	0.25^{b}	0.19^{b}	0.33
Naphthalene (µg/kg)	2.89^{a}	3.83^{a}	0.83^{b}	0.79^{b}	0.46
ΣPAH(µg/kg)	15.25^{c}	11.91^{b}	2.27^{a}	2.19^{a}	1.75

GSS: Gmelina smoked sample; PSS: Parkia smoked sample; NSS: Neem smoked sample;
CSS: Charcoal smoked sample.

Sensory Evaluation

African catfish samples produced using Charcoal as smoke source had higher average score for colour (4.63) than other samples. Charcoal smoked samples had a bright appearance and conform to consumers' preference for smoked fish. Smoked catfish samples produced with Neem and Parkia woods had a medium firm texture compared with other samples. Average scores of texture for smoked samples produced Gmelina, Parkia and Neem wood were 2.63, 2.54, 2.81 and 2.27 respectively. Fish samples produced by the four smoke sources; Gmelina, Parkia, Neem and Charcoal had organoleptic characteristics which appeals to consumers preference.

PAHs Concentrations

Benzo(α)pyrene (BαP) concentrations in charcoal samples was lower than other treatments. There was significant difference (p<0.05) in the concentration of BαP present in samples smoked using other smoke sources. Values of BαP in Charcoal wood-smoked catfish samples was significantly (p<0.05) low at 0.32µg\kg compared to other samples of Neem (0.34µg\kg), Gmelina (2.74µg\kg) and Parkia (2.75µg\kg)

Total PAHs concentration present in smoked African catfish samples was higher in samples produced with Gmelina (15.25µg\kg) than other treatments. However, total PAHs concentration found in Charcoal (2.19µg\kg) produced smoked fish was significantly ($P<0.05$) lower than others.

DISCUSSION

Organoleptic evaluation score for charcoal smoked Fish was higher than others in colour (4.63), taste (3.82) and acceptability (3.27) other samples.

Generally, all fish samples processed using Charcoal smoke recorded less PAHs. This may be due to the short drying time as a result of the high heat and less smoke produced by Gmelina. This is consistent with the findings of Silva *et al*., (2011), who observed in their study that at high temperatures, less smoke was produced and at lower temperatures, more smoke was produced during the smoking process. The results of concentrations of total PAHs in smoked African catfish samples presented in table 2 revealed that all the samples dried using Gmelina wood as smoke sources recorded the highest levels 15.25 µg/kg followed by the samples dried using Parkia and Neem with total PAHs content of 11.91 µg/kg to 2.27µg/kg respectively. The samples dried using Charcoal as smoke source recorded the lowest total PAHs concentration (2.19µg/kg). The trend of the concentrations of the total PAHs of the fish from high to low based on the processing methods is presented in the following order: Gmelina>Parkia >Neem> Charcoal. This is in agreement with Moret *et al.,* (1997) postulation that the actual levels of PAHs in smoked foods depend on several variables in the smoking process, including type of smoke generator, combustion temperature, and degree of smoking.

CONCLUSION

The results of this study revealed that eviscerated African catfish samples smoked using Gmelina had the highest concentrations of PAHs followed by Parkia, Neem and charcoal. Although for a sustainable fuel source, charcoal smoking produced the healthiest smoked fish product in terms of PAHs contamination. Benzo (α)pyrene concentrations of 0.32µg/kg and 0.37µg/kg respectively were detected in the smoked fish samples produced with Neem and Charcoal. These levels are within the European Commission (2006) regulatory limit of 5µg/kg. This indicates reduced consumer health risks associated with using charcoal in smoking fish.

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Ficus exasperata leaf is a terrestrial afro-tropical shrub found to containing nutrients such as protein, carbohydrate, fiber, vitamins, carotenoids and minerals which are essential for growth. This occurrence suggested the investigation of the effect of F. exasperata leaf on growth performance and egg production when included in the diet of Clarias gariepinus. Leaves of F. exasperata were plucked, air dried for four weeks, blended and stored in airtight dry bags. Proximate composition of blended leaves revealed that F. exasperata leaf is high in crude protein (21.35%). The blend was used to formulate diets at varying inclusions which was used to feed the experimental fishes. Five treatments namely T1 (0.00g inclusion/100g), T2 (0.02g inclusion/100g), T3 (0.03g inclusion/100g), T4 (0.04g inclusion/100g), and T5 (0.05g inclusion/100g) were created and duplicated in a complete randomized design. Feeding trial revealed that treatment four (T4, 0.04g/100g of feed) had the highest level of growth performance parameters for Final Mean weight (FMW), Mean Weight Gain (MWG), Percentage Mean Weight Gain (PMWG), Specific Growth Rate (SGR) and Protein Efficiency Ratio (PER). T4 was significantly different to T1 at p<0.05. Highest egg parameter (EW= Eggs Weight, EN= Egg Number, EV= Egg Volume) values were observed in treatment five (T5, 0.05g/100g of feed), showing significant increase in the parameters more than other treatments, with values significantly different at p<0.05. Hence, it is recommended that F. exasperata leaf at 0.04g/100g inclusion in the diet of C. gariepinus gives optimum growth performance as well as egg production and can be adopted by fish farmers as well as feed millers.
Keywords: *Clarias gariepinus, Ficus exasperata, growth performance, egg production.*

INTRODUCTION
Many scientific studies revealed that leafy vegetables are good sources of nutrients such as protein, carbohydrate, fiber, vitamins, carotenoids and minerals which are essential for growth (Afolabi *et al*., 2012). The presence of secondary metabolites such as Steroids, polyphenols, flavonoids, phlobatannins, tannins, saponins and in appreciable levels in plant leaves could contribute to their medicinal properties (Oulai *et al*,. 2014).
Ficus exasperata leaf is found to be natural delicacy to goats and other ruminants in south western Nigeria, among the yorubas (Weladji *et al*., 2004). *F. exasperata* have also been proven to be medically useful in the treatment of many health disorders (Bafor *et al*., 2009; Sonibare *et al*., 2006). Adebayo *et al*., (2009), stated that the presence of steroids, flavonoids, phlobatannins, tannins and saponins, give the leaves, stem back and roots of *F. exasperata* the pharmacological qualities.
This work therefore aimed at investigating the level of nutritive elements in the leaves of *F. exasperata*, the effects this leaf may have on growth performance of *Clarias gariepinus* (Burchell 1822) when included at varying levels in the diet and the effects on egg production and parameters.

MATERIALS AND METHODS
Experimental Site
Research was conducted at Fisheries and Aquaculture unit of Ladoke Akintola University of Technology, Teaching and Research Farm, Ogbomoso, Oyo state, Nigeria.
Experimental Fish
One hundred and fifty (150) *Clarias gariepinus* (400g to 500g) were procured from a reputable farm and acclimatized for two weeks while been fed extruded feed twice daily (7.00hrs and 16 .00hrs).

Collection of Experimental Leaves (*Ficus exasperate)*

Healthy leaves of *Ficus exasperata* were obtained from Ladoke Akintola University of Technology Teaching and Research Farm demonstration plots and were further identified at the Department Pure and Applied Biology of the university. Samples were air-dried at room temperature (27.5 ± 2.6^{0}C) for a period of 4 weeks and were regularly turned to ensure homogeneous drying. Samples were blended into powder form and kept in dry air-tight bags.

Proximate Analysis

The proximate composition of *Ficus exasperata* leaves were determined according to the method of Association of Official Analytical Chemists (A.O.A.C, 2002)

Formulation of Experimental Diet

Feed ingredients namely; maize, wheat offal, groundnut cake, fishmeal, soybean meal, vegetable oil, oyster shell, bone meal, salt, methionine and lysine were purchased from a reputable feed mill in Ogbomoso. Five (35% CP) diets containing varying levels (0g, 0.02g, 0.03g, 0.04g and 0.05g inclusions) of *F. exasperata* powder were formulated. Feeding trials were conducted for twelve weeks.

Experimental Set-up

Experimental design was complete randomized design (CRD). There were five treatments of *Ficus exasperata*, namely; control diet 1 (0g), diet 2 (0.02g), diet 3 (0.03g), diet 4 (0.04g) and diet 5 (0.05g) per 100g of feed. Each treatment was duplicated and seven healthy juvenile were assign to each experimental unit.

Determination of Growth Parameters

Fish weight changes and feed intake data were monitored and documented. Mean Weight Gain (MWG), Percentage Weight Gain (PWG), Specific Growth Rate (SGR), Feed Conversion Ratio (FCR), Protein Intake (PI) and Protein Efficiency Ratio (PER) parameters were calculated from the data collected using the mathematical relations below.

- MWG= Final Mean Wt – Initial Mean Wt
- PMW =(Mean Wt gain/Initial Mean Wt)*100
- SGR = (Log FMW – Log IMW/No of days)*100
- FCR = Feed Intake/MWG
- PI = Feed Consume * %CP in Feed
- PER = MWG/PI

Eggs Collection

The oval egg sacs were excised and kept in 10% formalin prior to the analysis. Egg Parameters observed were Egg volume, Egg weight and Egg number.

Statistical Analysis

One way analysis of variance (ANOVA) was used to analyze data collected. Means were separated by Duncan's multiple range test (Duncan 2020).

RESULTS AND DISCUSSION

Table1: Proximate Composition of *F. Exasperata* Leaf

Proximate Constituents	DM	MC	ASH	CFT	CF	CP
(%)	92.50	7.50	16.20	3.30	11.40	21.35

DM= Dry Matter; MC= Moisture Content; CFT = Crude fat; CF= Crude Fibre; CP= Crude Protein.

Proximate analysis of *F. exasperate* on in Table 1 revealed that dry matter content was highest at 92.50%, followed by crude protein content 21.35%, ash content 16.20%, crude fibre content 11.40%, moisture content 7.50% and crude fat 3.30%. The result showed that leaf of *F. exasperata* is rich in crude protein, a constituent of interest while formulating feed for *Clarias gariepinus* with crude protein requirement range of 30% to 40% (Tadesse, 2019).

Craig and Helfrich (2002) also stated that crude protein level in aquaculture feeds generally are within average 35% to 40% for African catfish.

Table 2: Growth performance of *C. gariepinus* fed with varying inclusion levels of *F. exasperata*

Parameters	T1 (Control)	T2 (0.02g)	T3 (0.03g)	T4 (0.04g)	T5 (0.05g)	SEM
IMW (g)	223.15	223.86	223.65	223.29	223.72	1.48
FMW (g)	321.79^{b}	341.13^{b}	347.18^{a}	359.19^{a}	339.96^{a}	3.81
MWG (g)	98.65^{b}	117.27^{ab}	123.54^{a}	135.90^{a}	116.22^{ab}	3.43
PMWG(%)	44.31^{c}	55.92^{ab}	54.78^{ab}	60.73^{a}	50.15^{bc}	1.56
SGR(%/day)	0.16^{c}	0.20^{ab}	0.19^{ab}	0.21^{a}	0.18^{bc}	0.00
FCR	2.48^{a}	2.10^{b}	2.21^{ab}	2.05^{b}	2.41^{a}	0.05
FI(g)	229.26^{b}	246.36^{b}	269.63^{a}	273.78^{a}	278.93^{a}	4.31
PI(g)	80.24^{b}	86.21^{b}	94.37^{a}	95.83^{a}	97.63^{a}	1.51
PER	1.21^{bc}	1.37^{ab}	1.31^{abc}	1.42^{a}	1.19^{c}	0.27

All the parameters with different superscript are significantly different ($p<0.05$)

IMW= Initial Mean weight; FMW=Final Mean Weight; MWG= Mean Weight Gain; PMWG= Percentage Mean Weight Gain; SGR= Specific Growth Rate; FCR=Feed Conversion Ratio; FI = Feed Intake; PI= Protein Intake; PER=Protein Efficiency Ratio; SEM= Standard Error of Mean.

Table 2 revealed that highest Final mean weight, Mean weight gain, Percentage mean weight gain, Specific growth rate and Protein efficiency ratio were observed in treatment 4 (0.04g/100g) while the lowest Final mean weight, Percentage mean weight gain, Specific growth rate were observed in treatment 1 (0.01g/100g). The eventual decrease in the values of the parameters listed above and observable in treatment 5 may be an indication that a further increase in the inclusion of *F. exasperata* above 0.04g/100g will be limiting to growth performance of *Clarias gariepinus* juveniles.

The results on table 2 also showed significant differences at $p<0.05$ between values of treatment 4 (0.04g/100g) and treatment 1 (0.00g/100g) for mean weight gain, percentage mean weight gain, specific growth rate and protein efficiency ratio.

Table 3: Effect of *F. exasperata* leaves on egg parameters of *C. gariepinus*

PARAMETERS	T1(0g)	T2(0.02g)	T3(0.03g)	T4(0.04g)	T5(0.05g)	SEM
EW	53.49^{b}	26.43^{c}	62.25^{ab}	67.88^{ab}	78.66^{a}	4.05
EN	39128.02^{b}	19335.40^{c}	45536.57^{ab}	49658.97^{ab}	57545.30^{a}	2960.00
EV(m/s)	605.50^{a}	362.00^{b}	639.50^{a}	646.50^{a}	699.50^{a}	29.53

Parameters with different superscripts are significantly different at $P< 0.05$
EW= Eggs Weight, EN= Egg Number, EV= Egg Volume

The highest values of egg weight, egg number and egg volume were observed in treatment 5 (0.05g/100g), while the lowest values of egg weight, egg number and egg volume were observed in treatment 2 (0.02g/100g). There is an observable increase in the values of parameters from treatment 2 (0.002g/100g) with increase in the amount of *F. exasperata* inclusion per 100g. Further increase in inclusion per 100g may yield noticeable increase in egg weight, egg number and egg volume. There are also significant differences between values of parameters in treatment 5 and treatments 1 and 2, however there is no observable significant difference at $p<0.05$ in egg volume for treatments 1 and 5.

CONCLUSION

The results obtained in this study revealed that, inclusion of 0.04g/100g *F. exasperata* leaf (treatment 4) in the diet of *C. gariepinus* had the best growth performance in terms of MWG(Mean Weight Gain) and PER (Protein Efficiency Ratio) as well as an optimal utilization and conversion of feed into flesh and muscles.

Egg quality parameters were observed to have optimal results at 0.05g/100g inclusion level. Therefore, it can be concluded that 0.04g *F. exasperata* leaf-based diet can be included in the diet of African catfish (*C. gariepinus*) to enhance a better growth performance and egg production.

RECOMMENDATION

Based on the findings of this research, *F. exasperata* leaf at 0.04g/100g inclusion in the diet of *C. gariepinus* gives optimum growth performance as well as egg production. Therefore it is recommended that fish farmers and feed mill owners can adopt the use of sandpaper leaf meal (*F. exasperata*) in fish diet at the recommended level.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
This study analysis the factors influencing catfish production in Nsukka Local Government Area of Enugu State. The primary data were obtained using structured questionnaire from 120 catfish producers. Descriptive statistics such as frequency distribution, percentages and multiple regression analysis were used to analyzed the data. Majority (73.7%) of the catfish farmers were within the economically active age (30-59 years) and will contribute significantly to catfish production, 58.3% having more than 5 years of production experience. Most (93.7%) of the respondents had primary education, 62.5% of the sampled farmers had family sizes of more than 5 persons. The majority (78.0%) of the respondents do not belong to cooperative societies and 1001- 2000m² pond size mostly used by the respondents. Education of the farmers, production experience, feed used, stock density and labour used were the factors that positively and significantly influenced catfish production in the study area. Catfish producers should pay special attention to the identified factors to boost production.
Keywords: *Factors, Catfish production, Nsukka, Area*

INTRODUCTION
Fish farming is the fastest-growing animal husbandry industry in Nigeria and many parts of the world. In most parts of Africa, the most cultured species is Tilapia and Catfish. In Nigeria, the demand for fish is 2.66 million metric tones and only 1.4 million metric tones is available of which the country imports over 500 000 mt annually. Therefore, the importance of the fishing industry to the sustainability of animal protein supply in the country cannot be over-emphasized.
Regrettably, the supply of fish (an essential food) has been on the decline. This is due to consistent declines from the country's major source of fish supply, the artisanal fisheries, from 90% in 1990 (Tobor, 1990) down to 40% in 2006 resulting to about 300,000 metric tonnes (Global Agriculture Information Network (GAIN), 2007). Currently, domestic fish production is put at 551,700 metric tonnes as against the present national demand of about 1.5 million metric tonnes estimated for 2007 (Osawe, 2007). The shortfall is said to be bridged by the importation of 680,000 metric tonnes annually consuming about N 50 billion in foreign exchange (Odukwe, 2007). To close the gap existing between the demand and supply of fish in Nigeria, catfish farming should be encouraged. Adediran (2002) and Ugwumba (2005) asserted that the only way of boosting fish production and thereby move the country towards self sufficiency in fish production is to boost catfish production. Traditional fish farming practices have been prevalent in the study area. Farmers fish on natural bodies and this led to a problem of decline in the catch per unit effort. Greater improvement in catfish production can be achieved with a proper analysis of the factors that influence catfish production.

METHODOLOGY
This research was carried out in Nsukka Local Government Area of Enugu State. It has an area of 1,810 km² and a population of 309,633 at the 2006 census. Nsukka Local Government Area comprises nine communities which are Alor, Iheakpu-Awka, Eha- Alumona, Edem, Opi, Nsukka, Lejja, Obimo and Ibagwa. The Local Government Headquarters is located in the hilly and green sites which Nsukka is known for close to colonial quarters of the pre-Independence years. The era is bordered in the east by Ede- Oballa, in the west by Obino, in the north by Aku and in the south by Enugu-Ezike and Uzo-Uwani. Nsukka Local Government Area occupies an area of 1810km² It is located between latitude North of the Equator and longitude 7^0 39' and 7 ^{0}99' East of the Greenwich Meridian (www.nimet/nsukka.org). The people are mostly farmers who take advantage of the rich and abundant farm land to engage in both crop production and animal husbandry. Many people engage in animal husbandry which includes: piggery, fishery and rearing of cattle. Others cultivate yam, rice, cassava, cereals and vegetables, among

others. Others engage in trading and skill work such as wood work, mat weaving, basket weaving and blacksmithing. Data was generated from respondents by the use of structured questionnaire and oral interview. Multistage random sampling technique was used to select communities, villages and respondents. First, four (4) communities in the study area were randomly selected from six (6) autonomous communities. Secondly, three (3) villages were randomly selected from each of the selected communities. Lastly ten (10) catfish farmers were randomly selected from each of the selected villages to make a total of one hundred and twenty(120) respondents for detailed study. Descriptive statistical tools such as frequency tables, mean and percentages was used to analyze the socioeconomic characteristics of respondents. Gross margin analysis was used to estimate the cost and returns of catfish farming. Multiple regression analysis was used to determine the effect of socio-economic characteristics of farmers on their output. The multiple regression model is stated thus: $Y = f(X_1, X_2, X_3, X_4, X_5, X_6, X_7, ei)$

The four functional forms of the model are explicitly specified as follows:

Liner: $Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + ei$.

Semi-log: $Y = \text{In}b_0 + b_1\ln X_1 + b_2\ln X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + b_7X_7 + ei$

Double- log: $\text{In}Y = \text{In}b_0 + b_1\ln X_1 + b_2\ln X_2 + b_3\ln X_3 + b_4\ln X_4 + b_5\ln X_5 + b_6\ln X_6 + b_7X_7 + ei$

Exponential: $\text{In}Y = b_0 + b_1X_1 + b_2X_2 + b_3X_3 + b_4X_4 + b_5X_5 + b_6X_6 + b_7X_7 + ei$.

Where Y= Catfish Output (kg), bo = intercept, b_1-b_6 = Coefficient to be estimated, X_1 = Age of the famer (years), X_2 = Stock Density (number of fish in pond), X_3 = Educational level (years spent in formal education), X_4 = Fish farming experience (years), X_5 = Feed used (Kg), X_6 = Labour (Mandays), ei = error term.

RESULTS AND DISCUSSION

The socio-economic characteristics of the respondents such as: age, gender, level of education, marital status, household size, membership of association, pond size and farming experience are presented in Table 1 below.

Table 1: Distribution of respondents according to socioeconomic characteristics

Variable	Frequency	Percentage
Age		
20 -29	16	13.3
30 -39	18	15
40 -49	70	58.3
50 -59	8	6.7
60 and above	8	6.7
Education level		
No formal	8	6.7
Primary	17	14.2
Secondary	51	42.5
Tertiary	44	36.6
Production experience		
1 -5	50	41.7
6 -10	42	35.6
11 -15	15	10.0
Above 15	16	13.3
Household size		
1 -5	56	46.67
6 -10	58	48.33
11 and above	6	5.0
Membership of Association		
Yes	42	35.0
No	78	65.0
Source of working Capital		
Formal sources	48	40.0
Informal sources	72	60.0
Pond size		
100 – 1000M^2	36	30.00
1001 – 2000M^2	58	48.33

2001 – 3000M^2	26	21.67

Source: Field data, 2021

Result in Table 1 revealed that majority (73.3%) of the respondents were within the age bracket of 30-49 years, implying that most of them are within the economically active population and therefore constitute a good labour force for fishery enterprise. Amazon et al (2000) indicated that farmers in their active age would be good managers of limited available resources. Most of the respondents acquired formal education. Only 6.7% of the total respondents had no formal education. This education attributes of the respondents will help extension agents in effective dissemination of innovations to the farmers. Educated individuals are usually innovative, adaptive and prudent in resource use. Majority (58.3%) of catfish farmers had more than 5 years production experience, which is good enough to understand the production techniques. This is in line with apriori expectation, the more years of experience a farmer has, the ability to overcome challenges of production as well makes them be willing to adopt improved technologies that would earn a better profit. About 53.33% of the respondents had more than 5 persons in their household.. This result reveals that the Catfish farmers household size is relatively moderate. Household size is a principal determinant of labour availability in small- scale farming system given the relatively soaring cost of hired labour (Nwosu et al 2012). Majority (65%) of the respondents had no contact with extension agents. This implies that many catfish producers in this study area do not participate in any new innovation disseminated by the agricultural extension agents. It could be also as a result of inaccessible roads in the study area that hinders entrance of the agents. Only 35% of the respondents obtained capital from formal sources (banks, Governments programmes , etc. This implies that majority of the farmers relied on informal sources . Majority of the farmers avoided borrowing from the banks because of the high interest rate charged by the banks as well as the demand for collateral. According to Balogun (2011) inadequate access to credit facilities is a major problem limiting large scale agricultural production and marketing activities. Pond size of 1001 - 2000m^2 was mostly used by most of the farmers. What matters most is the stock density, to ensure that fish are not congested in the pond and there is adequate space for their growth.

Table 2: Regression estimates of the determinants of Catfish output in the study area

* = significant at 10%. **= significant at 5%. *** = significant at 1%.

Figures in parentheses are t – values

Table 2 shows result of multiple regression on the determinants of catfish production

The four functional forms of linear, exponential, semi-log and double log were tried. Cobb Douglas production function was chosen as the lead equation because of the higher number of significant variables and highest value of coefficient of determination (R^2) and also agreement with a priori expectation. The R^2 value of 0.772indicates that 77% of the variation in the output of catfish was explained by the independent variables considered in the model. The F- value was 38. 175 and significant at 1% probability level indicating that the model gave a good fit. The coefficient of age was negative and significant at 5% probability level. This is consonance with a priori expectation. Nwane reported that the risk bearing ability, innovativeness of farmers and even his mental ability decreases with advancing age. The coefficient of stock density was positive at 5% probability level. This is in line with a priori expectation. Fish ponds should be appropriately stocked to avoid over-crowding. Lagos State Agricultural Development Agency (LSADA, 2005) recommended 1000 juveniles per 10 x 10 M ^{2} pond.

Education level was positively signed and statistically significant at 5% alpha level. Result is in line with a priori expectation. The higher the educational level of the farmer the higher will be the production, ceteris paribus. This result is in consonance with Anozie et al (2014) who reported that, the higher the educational attainment the efficient the person is in resource use and less risk averse and more readily innovation are adopted. The coefficient of production experience was positive and significant at 1%. Years of farming experience helps to enhance farmers capacity of maximizing their farm output and profit at minimum cost.

The coefficient of feed used was positive and statistically significant at 1% level. This implies that any increase in quantity of feed used by the catfish farmers will increase quantity of catfish produced while any decrease in feed used will lead to reverse. This is in line with the a priori expectation since a well fed fish will grow faster, be presentable and marketable. Ebukiba and Luka (2019) stressed the importance of feeding fish adequately and with quality feed for good returns. Labour used was another significant variable at 1% level of probability and have positive sign. This implies that the amount of labour applied in farming determines the quantity of output produced. This could be the reason for low production for the small holder farmers when compared to the large scale or commercial farmer who can afford and employ skilled workers.

CONCLUSION AND RECOMMENDATIONS

Based on the findings of this research it may be concluded that: Age of the producers, their educational level, production experience, stock density and feed used were the factors that significantly affect catfish production in the study area. Also the following recommendations were proffered based on the research findings: Catfish producers should pay special attention to the identified factors. They are encouraged to form cooperative societies. Cooperatives are important in capacity building, acquisition of credit and procurement of quality production inputs at subsidized rates.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

The review evaluates the current state of Fish production in Nigeria, particularly aquaculture, challenges to aquaculture development and provides solution to them. It assesses the current fish demand which stands at 3.61 million Metric tons while the supply stands at 1.84 million and production from Aquaculture stands at 350,000 MT. The production from this sector has consistently grown over the years, the largest aquaculture producer in Sub-Saharan Africa. The paper highlighted the progressive development of Aquaculture from its inception in 1949 and various government efforts that culminated to improved production of aquaculture. The paper further highlighted some of the challenges of aquaculture production which includes high cost of fish feed, inadequate supply of high quality fingerlings, poor data for planning and high cost of energy. It stated the role climate change has on fish breeding And production as well as poor marketing system. Several remedies were provided for these challenges highlighted. They included the replacement of fish meal which had hitherto been a limiting factor with insect meal and cassava leaf concentrate at varying inclusion levels. On the inadequate fingerling supply, it noted the there is need for improved hatchery management which include the use of live food, introduction of 3% salt solution in the rearing facility of the hatchery, which serves as anti-stress as well as maintaining good temperature. It ended by recommending the use of solar energy to replace fossil fuel to reduce energy cost as well as training and retraining of farmer, particularly on farm record keeping.
Keywords: *Fish production, aquaculture, solar energy, fossil fuel*

FISH DAMAND, SUPPLY AND POTENTIAL

Nigeria has a population of about 200 million people providing a large market for fish. Fish plays a significant role in human diet, well being and commerce of many growing economies. It is a good source of animal protein and income in many countries. In Nigeria, fisheries sub sector contributed 0.88 % to the Agriculture GDP and contribution of Agriculture to Nigeria GDP is 22% (FDF, 2018). FDF 2018 also stated that the sub-sector provides employment for 8.632m million people in the primary sector and 19.55 million people in the secondary sector. Agricultural production is the generally enhanced through genetic improvement and this generally lead to improved varieties (Megbowon *et al*., 2009) Fish demand stood at about 3.61 million MT while supply is about (FDF, 2018). The Fisheries sub-sector provides job for 8.632 million people in the primary sector and 19.55 million people in the secondary sector (Giwa *et al*., 2018). Nigeria has an estimated annual per capital fish consumption of 17.5 kg (FAO, 2018). Fish demand stood at about 3.61 million MT while supply is about 1.84 million MT and production from Aquaculture was 350,000MT in 2018 (FDF, 2018). In 2020, Nigeria was the second largest producer of Aquaculture in Africa (FAO,2020) and it is a well-known fact that aquaculture is one of the world's leading food production sectors globally (Megbowon *et al*., 2013).

Fish production in Nigeria comes basically from artisanal fisheries obtained from inland rivers, lakes, coastaland brackish water, industrial fishing and Aquaculture. The bulk of fish production comes from capture and artisanal fisheries. In 2015, the gross domestic production was 1.027million metric tons. The artisanal fishery alone contributed about 67.7% (694,867.00 MT); aquaculture contributed 30.8% (316,727.00 Metric tons) while industrial fishery contributed 1.5 % (15,464.00) (Giwa *et al.,* 2018) Table 1 shows the trend of fish production by sectors and export from 2006-2015. The table reveals the inconsistency in the production from artisanal and industrial sectors making the sectors unreliable in driving fish production. Fish farming continues to develop in techniques as well as operation and and utilization of inputs, even though there is high cost and scarcity of such inputs they are affecting the overall development of fish farming. The table equally shows consistent growth of the aquaculture sector. This has been the trend in recent times, indicating that aquaculture sector is the most

reliable sector to improve domestic fish production. Several fish species are available in Nigeria. They include mud catfishes (*Clarias* spp.), Tilapias snake head (*Channa* spp.*)* head, slap water (*Heterotis niloticus*), trunk fish (*Gymnarchus niloticus*), Marine fishes such as Niger perch (*Lates niloticus*), Bonga (*Ethmalosa fimbriata*), Croakers (*Pseudotholitus* spp.), grunter *(Pomadasys jubelini*), barracuda (*Sphyraena barracuda*) among others.
Nigeria has consistently depended on importation of fish to meet the rising fish demand. It was reported that Nigeria is a net importer of fish and fishery products (FAO, 2013). A number of government interventions were made to implement policies that are capable of bridging the gap between demand and supply of fish and fishery products in Nigeria. Aquaculture has made tremendous impact in recent time to scale up Nigeria's domestic fish production. It has grown from 84,533 MT in 2006 to 316,727.00 MT in 2015, making Nigeria the largest aquaculture producer in Sub-Saharan Africa. This should make the nation to do everything possible to improve aquaculture development. The table 1 shows the data of fish production by sector.

Table 1: Data of Fish Production by Sector from 2006 to 2015 the table should cover a ten or five year period from 2019 to date or 2017 2022 as the case may be.

YEAR	Artisanal Production (MT)	Industrial Production (MT)	Aquaculture Production (MT)	Total Domestic Prod. (MT)	Fish Import (MT)	Total Fish supply (MT)	Fish Export (MT)
2006	518,538	33,778	84,533	636,848	646,484	1,283,332	7,738

There is great potentials in fish culture Nigeria Inland due to Water Surface Area of 14 million hectares available for cage culture, Available land for Aquaculture, put at 1.7 million hectares and Estimated Aquaculture Potential of 2.5 million MT,

TREND OF AQUACULTURE DEVELOPMENT IN NIGERIA

The culture of fish in Nigeria began in 1949 at Onikan, Lagos, Nigeria, as a small experimental system, with tilapia as the cultured fish (Longhurst, 1961). The interest in fish farming led to the construction of Panyam Fish located in Plateau state of the North central Nigeria in 1951 with interest in the common carp, *Cyprinus carpio* (Anetakhai, *et al.*, 2004). Between 1951 and 1971, fish farming continued to expand, being dominated by the Governments, both at state and Federal level. This implies that governments and their agencies were involved in direct production of fish. From 1971-1981, government established demonstration farms in Agodi, Ibadan (South West), Okigwe, Itu and Opobo (South East) and Mando, Kaduna State (North west). Other efforts at promoting fish farming in the country included the establishment of fish seed centres across the country by Federal and State governments in addition to the establishment of the African Regional Aquaculture Centre, assisted by Food and Agriculture Organization at Aluu, Portharcourt, River state. The Centre was to serve as research support and training of middle class fisheries officers .From 1981-1991 government stimulated efforts in developing fish farming led to private sector participation. Between 1991 and 2010 it became apparent that fish farming should be seen as a business. During this period, Agriculture Development project which was supported by the World bank came into existence. During the period the formation of Fish farming cooperatives and cooperative Estates brought about rapid development in the industry. For instance, Eriwe Village fish farm estate started in 2003 with 30 fish farmers, has grown to over 1,500 farmers, providing job for over 3,000 persons by 2020. Each farmer allocated 2 ponds (0.02 Ha), stocking at 15-20 fish/m^2. A group of 20 fish farmer formed a cooperative in the scheme. Purchases of input, construction of ponds and sales of fish are centralized where funding could be sourced through cooperative loan at 18% P.A In the scheme, earthen ponds were used. Similar to these is the Ikorodu fish farm Estate, using concrete tanks,.These models has facilitated rapid development in the industry in Ogun and Lagos States and Should be replicated across the region

CHALLENGES OF AQUACULTURE IN NIGERIA AND REMEDIES

The culture of fish is bedeviled by a number of challenges. These include high cost of feed. Feed constitutes 75% of operating cost of fish culture. While some producers depend on imported feed which is not sustainable, other rely on local feed. However, the limiting ingredient in this feed is fishmeal which is often imported. It is generally assumed that catfish require High Crude protein of 40% and above but experience has shown that 30-35% is adequate (Mohanta *et al*., 2023), thus reducing cost. Furthermore there is need to explore local sources of protein which can replace fishmeal and close alternatives is insect meal. Studies were conducted on other alternatives to fishmeal which are more ecofriendly. They include; Cassava leaf concentrate (45% CP), Black soldier fly meal; *Hermatia illicens (*47% CP*)*, mopane larvae meal; *Imbrasia belina* (56% CP), grasshopper*; Gastrimargus acrinidae (*62% CP*)*, Rhinoceros beetle larvae; *Orectyes rhinoceros (*51% CP) and poultry processing waste and blood meal.

Another major setback for catfish farming is inadequate seed production. For sustainable production of fish there must be steady supply of good quality fingerlings on regular basis. This has however been hampered by a number of factors such as poor quality broodstock due to inbreeding depression, inadequate live food and locally produced fry feed to reduce cost, heavy mortality during growing process (Matthews-Mbokane *et al*., 2022). On this there are 2 schools of thought. Some believes that mortality is due to feed while others attribute this to Climate change, global temperature rising, taking its toll on catfish breeding. To ameliorate this there is need to develop broodstock bank. This is because the quality of the broodstock determines the quality of the fingerlings. Similarly, it must be understood that breeding is a 24/7 business operation. It should equally be borne in mind that the rearing medium should have 3% salt solution to reduce stress and lower water temperature (Wurts, 1995). We need to equally explore vigorously production of live foods like Moina and Daphnia as alternative to artemia to reduce cost and ensure survival as the larvae grow better and have better survival on live food (Das *et al*., 2021).

Another critical challenge faced by farmer is power. Electricity has been a major problem in Nigeria for tank rearing of fish. Public electricity supply is rarely available where fish farms are located in the rural areas. Framers therefore have to rely on alternative power source, by generating the required energy themselves using fossil fuel. The cost of fossil fuel, particularly diesel, is very high, thus affecting cost of production and profit. To overcome this, farmers may need to resort to the use of solar energy for sustainability. Other solution includes the rearing of fingerlings to about 200 g and transfer to earthen for fattening. Furthermore, where there are large expanse of water, fish could be cultured in cages as this does not require water exchange as seen in pond or tank culture. It may be necessary to increase the scale of operation to 100 tons per annum to enhance economy of scale where farmers need to rely on fossil fuel.

Others include non-availability of data for planning. Most farmers don't keep farm record, thus making planning and government's intervention difficult. Another problem is that of fish marketing which makes middle men take advantage to exploit the farmers due to unorganized market structure. Formation of farmers into cooperative society will go a long way to enable farmers to negotiate price better. Farmers can as well go to value addition in order to increase profitability.

CONCLUSION

The potential of fish farming in Nigeria is high but production at the moment is lower than expected. The data available are not reliable for effective planning because farmers are not keeping records. No country ever developed without research. Government need to provide adequate funds for Aquaculture research to facilitate service delivery. The challenges of Aquaculture are surmountable if appropriate mechanism is put in place to address them.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Phytobiotics are plant based compounds that promote growth, improve the innate immune system and overall productivity of fish. The beneficial effects of Phytobiotic powders; moringa leaf, ginger, garlic and a combination of the three, as well as a control diet without additives on innate immune gene expression of Clarias gariepinus juveniles were investigated in this study. Significant differences in the expression level of immune gene have been identified between the phytobiotics fed supplements and the control diet. Furthermore, differential gene expression analysis revealed upregulation of TNF-α gene expression in fish fed with a control fish-fed diet (no Phytobiotics fed supplements) having a fold change of 1.436 ± 0.791. However, the innate immune gene TNF-α was observed to be downregulated in Clarias gariepinus fed with Phytobiotics supplements of garlic, ginger, moringa based diets and a combination of all having a fold change of; 0.288 ± 0.088, 0.196 ± 0.145, 0.124 ± 0.034 and 0.097 ± 0.30 respectively. These results revealed that the fish fed phytobiotics leaf-based diet compromised the action of the innate immune gene TNF-α, despite being shown to have phytochemical properties improving fish health while the upregulation observed in fish fed with the control diet presumes there is a significant expression of TNF-α which is advantageous in pathogen resistance.
Keywords: *Phytobiotics, immunity, gene expression, Clarias gariepinus*

INTRODUCTION
Phytochemicals are natural plant dietary supplementation in aquafeed which could be used as an effective way for increasing growth and the immune-competency of fish. Most common phytochemicals are Moringa (*Moringa oleifera*), Garlic (*Allium sativum*) and Ginger (*Zingiber officinale*) which are both perennial crops, natural, readily available, affordable and have been reported to promote various health activities (Wahab *et al*., 2022). Moringa leaves, fruits, barks and roots have high nutritive value and possess immunostimulant, anti-inflammatory, antiulcer, antibacterial, hypoglycemic, antihypertensive, and hepatoprotective properties (Kazeem *et al.*, 2017). According to Abayomi *et al.* (2018), garlic contains variety of bioactive compounds and phytochemicals such as flavonoid, saponins, alkaloids and allicin. Nutritional and phytochemical analyses revealed that garlic contains about 17 amino acids, 33 sulphur compounds, several enzymes, minerals and vitamins. Ginger has been reported to be rich in mineral elements, vitamins, and phytochemicals which have a high anti-inflammatory and antioxidant effect (Iheanacho *et al.*, 2017).
Results have suggested that *M. oleifera* leaf powder-supplemented diets could enhance the immune response of *Oreochromis niloticus* fry and prevent disease caused by *A. hydrophila* (El-Gawad *et al*., 2020). Dietary inclusion effect of ginger and garlic have also been shown to induce growth in *Clarias gariepienus* (Nyadjeu *et al*., 2021) and feed formulated with these supplements fed to Common carp has shown significant increase in RBCs, WBCs, PCV, Hb and total plasma protein (Ajeel, and Al-Faragi, 2013). Feed supplements used in feed formulation having anti-oxidative and inflammatory active components triggering inflammatory response is of an advantage to Fish immune system. Cytokines are commonly thought to play a role in the creation of immunological and inflammatory responses. One of these cytokines is Tumor Necrosis Factor Alpha (TNF-α), which is involved in innate immune response in Fish.
Understanding the interaction between fish nutrients and its immune system are critical for the new product development to increase aquaculture production efficiency; hence necessitated this study.

MATERIALS AND METHODS

Fish Tissue Sample Collection

The experimental fish were divided into five groups (4 representing fish fed phytobiotic leaf-based diet and 1 control) and were fed twice a day with 2% phytobiotic diets inclusion. Fish tissue samples were collected from each group after feeding trial which lasted for Ten weeks. In the molecular Biology Laboratory Nigerian Institute for Oceanography and Marine Research (NIOMR), tissues samples (1 g) were collected from the ventral region Cordero *et al*. (2017) of *Clarias gariepinus* and immersed in 1 ml of RNALater buffer, contained in well labeled 2 ml Eppendorf tube to maintain RNA stability, and stored in the Refrigerator at -20° C until further use.

RNA extraction, cDNA synthesis and PCR amplification

Total RNA was isolated using JENA mini kit (Jena Bioscience, Germany) according to the manufacturer's protocol. The purity and concentration of RNA extract was determined using a Thermofisher 1000 C Nanodrop spectrophotometer. Reverse Transcription Polymerase Chain Reaction (RtPCR) was carried out using Fire script RT cDNA synthesis kits (FIREScript®, Estonia, using Oligo dt primer with the thermal profile: 65˚ C for 5 mins for denaturation, followed by Primer annealing at 25˚ C for 10 mins and 85˚ C for 5 min to inactivate RT enzyme). The housekeeping Gene, Glyceradehyde 3 Phosphate dehydrogenase (GAPDH) and the immunity gene, tumor necrosis factor alpha (TNF-α) were used to quantify the complementary DNA (Primer sequence shown in Table 1), amplification was done with initial denaturation at 2 min at 94ºC followed by 30 cycles of the following; denaturation at 94ºC for 30s, annealing at 54ºC for 30s and extension at 72ºC for 30s.

Table 1: Primers used for Nucleic acid qualification in this study

Primer	Forward Sequence	Reverse Sequence	Tm (°C)	Band Size (pb)
GAPDH	GCCCTCTGGTAAAATGTGGA	ATTCCCTTCATGGGTCCTTC	54	450
TNF-α	GGATGGTGGTGTGTGTTGTG	CTGGTACTCTGGTCACGACTC	60	150

Data Analysis

GraphPad Prism software 20.1 was used to carry out one-way analysis of variance (ANOVA) to test for significant differences ($p < 0.05$) among fed treatment groups and control and data were presented as mean ±SD.

RESULTS AND DISCUSSIONS

Recently, research findings suggested phytobiotics as potential antimicrobial agents having bioactive compounds to stimulate immunity and fish resistance against diseases unlike antibiotics that sometimes have potential negative effect on the fish produced, the consumer and the environment when used by fish farmers in fish health management (Zulhisyam *et al*., 2022). In the current study, the quantified cDNA gel capture (Figure 1) shows GAPDH PCR amplicons on 2% agarose gel electrophoresis of reverse transcribed RNA sample. The gel band suggests the presence of TNF- α (immunity) gene in all the treatment groups indicating that the immunity gene is expressed in them all at different levels. The expression of the TNF-α gene was upregulated in experimental Fish fed with the control-fed group (CT) having a fold change of 1.436±0.791. However, TNF-α expression was downregulated in Phytobiotics Fish fed leaf-based diet, with garlic (C) fed group having a higher fold change of 0.288±0.0880, ginger (B), with fold change of 0.196 ± 0.145, moringa (A) with a fold change of 0.124 ± 0.034 and a combination of the supplements (D) with a fold change of 0.097 ± 0.30 (Table 2). These results revealed that the Fish fed Phytobiotics leaf-based diet compromised the action of the innate immune gene TNF-α, despite being shown to have phytochemical properties improving fish health while the upregulation observed in Fish fed with the control diet presumes there is a significant expression of TNF-α, which is advantageous in pathogen resistance. This finding is contrary to Aklilu *et al.* (2020) who stated that medicinal plants have different activities such as growth promotion, increased immunity, disease resistance, antistress, appetite stimulation, aphrodisiac and antimicrobial properties due to the presence of bioactive components such as alkaloids, flavonoids pigments, phenolics, terpenoids, steroids and essential oils.

Subsequently, TNF-α plays a crucial role in the rapid inflammatory response against environmental pathogens, this indicates that the garlic and ginger supplements possess anti-inflammatory properties.

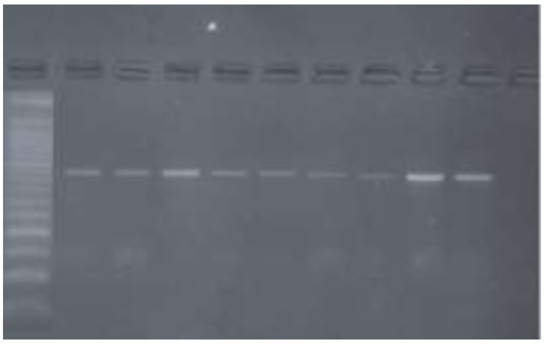

Figure 1: Gel Image capture of TNF-α PCR amplicons ran on 2% Agarose gel electrophoresis, with expected bands size 150bp. Samples were loaded in Triplicate from left to right CT, A, B, C, D

Table 2: The gene expression level of different experimental Fish fed with different Phytobiotics supplements

Sample	Fold change
CT	1.436±0.791
A	0.124±0.034
B	0.196±0.145
C	0.288±0.088
D	0.097±0.30

57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study compared production of fish in plastic tanks at both homestead and commercial farm levels in Jos metropolis, Plateau State. Purposive and Snow balling sampling techniques were employed to identify 44 Fish farmers as respondents. Field visits were conducted; oral interview and farm records were employed for data collection. Physicochemical parameters of water were measured in three commercial fish farms A, B and C. Data collected was analysed using percentages and means. Majority (66%) of the fish farmers did not receive training on fish farming while few (34%) did. More males (66%) than females (34%) were into the business. The age range of the respondents was mostly 35-45 (52%) then 25-35(27%) and 45-55(21%). The highest educational qualification of the respondents was mostly at the level of secondary (45%), followed by primary (39%), then tertiary (16%). Most (77%) were small scale/subsistent farmers while few (23%) were commercial. 73% of the fish farms had experience of 1 – 3 years on the business. Farms A and B had low stocking densities (fish/litre) of 1:3 and 1:1 respectively while farm C was overstocked with 4:1; 84% of the respondents reported high rate of incidence of fish mortality with the leading cause being poor water quality (31%) then diseases (21%) followed by fish stocking density (15%). Fish mortality occurred at all stages of growth but highest at fry (40%) then at fingerlings (34%) followed by juvenile (17%) and adult (9%). Majority (59%) of the farmers culture their fish for a period of 4 – 7 months before harvesting. The mean values of the physicochemical parameters of water in plastic tanks of the commercial farms for pH (7.0±1.96), temperature (28.0±3.55ºC) and dissolved oxygen (5.0±1.4ppm) were within the normal range for the growth and survival for fish. The farmers were observing good sanitary habits on the farms. Since mortality was highest at fry stage of fish growth and development; therefore, measures to mitigate this should be further investigated and success of which should be disseminated to the farmers.

INTRODUCTION
According to World Review of Fisheries and Aquaculture (WRFA) (Anon, 2012), world fish food supply has grown tremendously from period 1961–2009 with an average growth rate of 3.2% per year therefore, outpacing the increase of 1.7% per year in the world's human population. This is an indication of the great potential in fisheries if properly harnessed, to solve world hunger. FAO (2014) reported that international trade recorded in 2012, 37% of the total fish production in value, with a total export value of 129 billion United State dollars, of which 70 billion dollars constituted mostly tropical countries' exports. Estimates indicate that small-scale fisheries contributed about half of global fish catches.

If aquaculture's potentialities are well explored, it can reduce over dependence on importing fishery products; one of the most important animal proteins in terms of food availability in the tropics, poverty alleviation, form of employment, income generation and foreign exchange earnings is fish (FDF, 2005). Fish farming implies some sort of intervention in the rearing process to enhance production, such as regular stocking, feeding, protection from predators and so forth. This can involve individual or corporate ownership of the stock being cultivated. In recent times, aquaculture technology allows the commercial and viable production of a number of aquatic organisms through the management of their entire life cycles by developing all aspects of fish husbandry, such as the facilities required for the various life-cycles stages (brood stock holding tanks/sea cages, nursery tanks/cages and grow-out facilities). Others may include feed production, fish handling systems, and disease control. Such procedures and techniques have been developed for several fish species (Eze *et al*., 2011). Three types of fisheries management strategies have been identified as Traditional, Modern and Mixed (Yildiz *et al*., 2011) while culture methods could be monoculture or polyculture which any could be semi-intensive, intensive or super-intensive system (Abdulkarim and Yusuf, 2015).

Kolo (1996) observed inadequate environmental conditions as one of the major factors that limit fish production. Such factors include water quality relating to physical, chemical and biological properties of the ponds. Physical factors that are important in domestic fish farming include shape and size of fish pond, types of substrata material, temperature, turbidity and pond transparency while the chemical factors include, dissolved oxygen (DO) alkalinity, hardness of water, hydrogen ion concentration (pH), conductivity and mineral constituents such as nitrates and phosphates; these are often referred to as physicochemical parameters. The objectives of this study were to investigate fish farms rearing fish in plastic tanks within Jos metropolis in order to assess the water quality; determine the causes of fish mortality and evaluate the hygienic conditions of the farms.

MATERIALS AND METHODS

Study area

The study was conducted in Jos the capital of Plateau state, Nigeria. Plateau state get its name from the Jos plateau, a mountain area in the North of the state with Captivating rock formation. The altitude range from around 1, 200 meter to a peak of 1,829 meter above sea level in the Shere Hills range near Jos. Plateau state is located between latitude 8^{0}24' N and 10^{0}30'N and longitude 8^{0}32'E and 10^{0}38'E. It has an area of 26,899km^2. Average monthly temperature range from 21 – 25^{0}C and from mid-November to late January, night temperature is 7^{0}C. The state also has a total population of 1,586,679 at a growing rate of 2.7% per annum (National population commission, 2006). Plateau state shares boundary with Bauchi State to the North-east, Kaduna State to the North-west, Nasarawa state to the South-west and Taraba state to the South-east (Wikipedia, 2023).

Data Collection

Data were collected on several parameters such as age of the fish, management and physiochemical parameters of water in plastic tanks. The data were also obtained from oral interview and fish farm records. Field visits to the farms were done twice a week throughout the period of the study. The commercial fish farms used in Jos Metropolis remain anonymous as Farms A, B, and C. Purposive and snow balling sampling techniques were used to identify 44 Fish farmers as repondents.

Data analysis

All data generated during the research were analysed using percentage and mean

RESULTS AND DISCUSSIONS

Results achieved through this study are presented in Tables below:

Table 1: Distribution of respondents by their demographic features in Jos Metropolis

Demographic features	Categories	Percentage (%)
Sex	Male	66
	Female	34
Age (Years)	25-35	27
	35-45	52
	45-55	21
Highest Educational qualification	Primary	39
	Secondary	45
	Tertiary	16

Table 1 elucidates the demographic features of the respondents. The results revealed that there are more males (66%) than females (34%) in the business. The age range of the respondents was mostly 35-45 (52%), 25-35(27%) and 45-55(21%). The highest educational qualification of the respondents was mostly at the level of secondary (45%), followed by primary (39%), then tertiary (16%) which indicates that no qualification is required in the business; however, from another perspectives if fisheries is emphasised on as a trade subject in secondary schools, it can promote self-employment, economic productivity and self-reliance at a very tender age of youths. This study was similar to those obtained by Dirican *et al.* (2008) in his evaluation of aquaculture in the Sivas.

Table2: Profiles of the three commercial fish farms purposively sampled in Jos Metropolis

Fish Farm	Capacity of Tanks (Litre)	Number of Fish Stocked	Number of Sorting Tanks	Daily Feeding Schedule	Number of fish/Litre
A	4500	3000	2	2	1:3
B	7500	15,000	2	2	1:1
C	2500	10,000	1	2	4:1

From Table 2, it could be observed that the highest stocked fish was in farm B (15,000) with though 15,000 litre capacity tanks (7500 x 2) giving a stocking density of one fish per litre (1:1) of water; however, this is luxurious or under stocking while one fish per 3 litres (1:3) of water as obtained in farm A was too luxurious as the ideal stocking density for a table size *Clarias gariepinus* based on recommendation of Abdulkarim and Yusuf (2015) is 2 fish per litre of water. On the other hand the stocking density of farm C (4 fish per litre of water) is overstocking.

Table 3: Some Management Skills of Fish Farmers in Jos Metropolis

Description	Class	Percentage (%)
Professionally Trained on Aquaculture skill	Yes	34
	No	66
Experience (Years)	1 – 3	73
	4 – 7	20
	>7	7
Type of fish farming	Commercial	23
	Homestead	77
Time of Harvest (Months)	2 – 3	29
	4 – 7	59
	>7	12

Table 3 elucidates the present status of fish farming in Jos Metropolis the result revealed that 73% of the fish farms were established between 1 – 3 years ago followed by 20% that were between 4 – 7 while 7% were those that have been in the business for more than 7years . The result also revealed that the level of operating was mostly homestead (77%) which production were mainly for consumption 23% were commercial fish farmers. Majority (59%) of the farmers culture their fish for a period of 4 – 7 months before harvesting which corroborates with the commonly reared period of *Clarias gariepinus* to table size (0.5 – 1kg or >1kg) among fish farmers as reported by Abdulkarim and Yusuf (2015).

Table 4: Respondents' reports on Incidence of Fish Mortality, Causes and Fish Growth Stage of Occurrences

Parameter	Category	Percentage (%)
Incidence of Fish Mortality	High (Frequently occurring)	84
	Low (Less frequently occurring)	16
Causes of Fish Mortality	Aquatic Environment (Predation, injuries, and so forth)	10
	Natural/ Unknown	10
	Poor Water Quality (Pollution)	31
	Feed Contamination	13
	Fish Stocking Density (Overstocking)	15
	Diseases	21
Fish Mortality at Stages of Growth	Fry	40
	Fingerling	34
	Juvenile	17
	Adult	9

Table 4 elucidated that 84% of the respondents reported high rate of incidence of fish mortality with the leading cause being poor water quality (31%). The second leading cause was reported to be diseases (21%) followed by Fish stocking density (15%). The report further elucidated that the respondents experienced significant fish mortality at fry stage of growth (40%) then at fingerlings stage (34%) while fish mortality occurred less at juvenile (17%) and adult (9%) stages. The sanitary habits of the farmers were observed to be generally commendable in terms proper disposal of used water from the plastic tanks.

Table 5: Mean Water Quality (Physicochemical) Parameters

Parameter	Farm A	Farm B	Farm C	Mean ±Standard Deviation
Temperature	26.2	27.8	26.5	28.0±3.5
pH	7.7	7.1	7.2	7.02± 1.9
Dissolve Oxygen (D.O.)	4	5	5	4.0±1.4

Table 5 revealed the mean water quality parameters of fish reared in plastic tanks from the three purposively sampled commercial farms in Jos metropolis. The study showed that the water parameters such as the pH (7.0±1.96), temperature (28.0±3.5) and dissolved oxygen (5.0±1.4) are good for fish production as they are within the tolerable ranges for the survival and growth of the fish (Abdulkarim and Yusuf, 2015).

CONCLUSIONS AND RECOMMENDATIONS

The mean values of the physicochemical parameters of water in plastic tanks of the commercial farms were within the normal range for the growth and survival of fish. As water pollution was reported to be the first leading cause of mortality in plastic tanks reared fish among homestead fish farmers; hence, monitoring of water quality parameters is hereby recommended as a critical practice in fish farming. Mortality was found to be most occurring at fry stage of fish growth and development therefore; measures to mitigate this should be further investigated and disseminated to the farmers. Furthermore, Agricultural Development Project or any Non-governmental Organization should embark on extension services delivery and training to the fish farmers in order to build adequate skills required for sustainable fish farming among homestead and commercial fish farmers. The hygienic practices should be sustained as observed amongst farmers.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Bioaccumulation effects of heavy metals through food chains are of great public health concern as the heavy metals are toxic, at certain mean concentrations (MC), to humans that are at the top of food chains and webs. The aim of this study was to determine heavy metals' concentrations in samples of water, fish (Clarias gariepinus and Oreochromis niloticus) and sediments of Dadin Kowa dam. Temperature and pH of the water were measured with digital pen type thermometer and pH meter respectively. Atomic Absorption Spectrophotometer was used to measure the concentrations of the heavy metals: Copper (Cu), Nikel (Ni), Cadmium (Cd), Zinc (Zn), Chromium (Cr) and Lead (Pb). The water has ranges of mean values of temperature (30.90˚C– 32.0˚C) and pH (6.53 – 6.84). MC (mg/L) of Zn was highest (1.447and 0.944) in the gills and muscles for O. niloticus, while lowest (0.391 and 0.179) for C. gariepinus respectively. O niloticus bones and muscles had the same (0.012) MC of Cr which were higher (0.006 and 0.010) than in same organs of C. gariepinus. MC of Cu was observed to be relatively higher (1.165 – 0.11) in sediments while lowest (0.59 and 0.48) in water. MC of Cd in the sediments ranged from 0.11-0.01 and was 0.112 – 0.105 in water. The Temperature and pH of Dadin Kowa dam were suitable for fish survival; however, MCs of Pb, Zn, Ni and Cd in the fish species, sediments and water samples were observed to be higher than the World Health Organisation (WHO) permissible limit. Therefore, we call on relevant governmental and non-governmental agencies to further investigate our findings for proper action to be taken in order to save guard the public health.
Keywords: *Pollution, Health Risk, Heavy Metal Concentration, Dadin Kowa Dam*

INTRODUCTION
Improper discharge and uncontrolled applications of industrial wastes and pesticides on land and in water bodies containing pollutants such as zinc, cyanide, copper, lead, mercury and cadmium cause death and an increment in toxic level of fish species and aquatic ecosystem health. These and many other contaminants and waste product contribute high levels of synthetic organic compounds and heavy metals which subsequently find their wayfr3 into the Dadin kowa Dam. However, the incorporation of these heavy metals by aquatic organisms into their body systems during feeding may remain for a very long time and these can pass on in the food chain. Heavy metal refers to any metallic elements that has a relatively high density (4mg/cm^3) and is toxic or poisonous even at low concentration. The concentration of essential heavy metal under acceptable limit is good for health. However, if it exceeds the acceptable limit, these heavy metals may become harmful and extremely toxic to human and it result to deficiency diseases or syndromes if not in adequate amounts. The American Heart Association recommended consumption of fish at least twice per week in order to reach the daily intake of omega-3 fatty acids (Kris-Etherton *et al.,* 2002). However, fish normally accumulate heavy metals from food, water, and sediments (Yilmaz *et al.,* (2007), Zhao *et al.,* (2012) this reported that it is a good indicator of heavy metals contamination in water (Voegborlo *et al.,* 2012). Rivers support large proportion of fish species of varying composition; these fish species provide affordable sources of food and quality protein to the surrounding communities. The study aimed at assessing the concentrations of some heavy metals in commercially important fish species from Dadin kowa Dam, Gombe State so as to establish a baseline data on the current pollution status of the Dam.

MATERIALS AND METHODS

Study Area

Dadin kowa dam is 37 km from Gombe town and about 5 km North of Dadin kowa village in Yamatu- Deba Local Government Area (L.G.A) of Gombe state. It shares common boundary with Akko L.G.A in both the south and west, Yamaltu-Deba to the East and Kwami to the north. The Dam is situated between latitude 10 19' 19''N and longitude 11 28' 54''E of the equator (Nigeria Galleria, 2021).

Sample Collections

Samples (water, fish, and sediment) were collected to determine the concentration of heavy metals from Dadinkowa dam, Gombe State, Nigeria. Samples from different sources were collected around the head, middle and tail of water of the dam. Plastic containers, washed with de-ionized water, were used in collecting water samples. Samples of fresh fish species: two *Clarias gariepinus* and two *Oreochromis niloticus* were obtained randomly from fishers fishing in the dam. The Fish species were kept in polythene bag and stored in the ice box for transportation to laboratory for analysis. Sediment samples were collected (1-2 cm) from the bottom of linnet zone with a spade and stored in a sealed polythene bag.

Digestion of samples

Digestion of water, fish species and sediments were carried out according to the method described by Öztürk *et al.*, (2009) in triplicates while the heavy metal analysis was done using Atomic Absorption Spectrophotometer (AAS) model: 210 VGP from the Department of Engineering, Abubakar Tafawa Balewa University Bauchi (ATBU) Bauchi. The instrument (AAS) operating conditions were set in line with the manufacturer's specifications.

Data analysis

The data were analyzed using Statistical Package and Service Solution SPSS version 25.0 for Windows (SPSS, IBM. 2017) whereby the means, standard deviation and standard error were obtained.

RESULTS AND DISCUSSION

Table 1 revealed the mean temperature and pH of Dadin Kowa dam water. Tail water of the dam had the highest (32.0^0C and 6.84) mean temperature and pH while the middle water had the lowest (30.9 and 6.53) mean temperature and pH respectively. Dadin kowa dam water was slightly acidic.

Table 1: Mean Temperature and pH of Dadin Kowa Dam Water (Jan, 2023)

Month	location	Temperature (^{0}C)	pH
January, 2023	Head	31.3	6.61
	Tower (Middle)	30.9	6.53
	Tail water	32.0	6.84

Table 2 elucidates that, the mean concentrations of Zn were highest (1.447 and 0.944) in the organs (bones and gills) of *Oreochromis niloticus* while lowest (0.391 and 0.179) in the organs (bones and gills) of *Clarias gariepinus* respectively.

Oreochromis niloticus bones and muscles had the same (0.012) mean concentration of Cr, and were higher than in the bones (0.006) and muscles (0.010) of *C. gariepinus* (Table 2).

Table 3 revealed that, the mean concentration of Cu was the highest (1.165) in the head of sediment while lowest (0.590) at the tail of the dam water. Mean concentrations of Cd in the sediments (tail and head) ranged from (0.11 -0.91) and the mean concentration of Cd in the dam water range from (0.112 – 0.105) in the tail and head respectively.

Table 2: Mean Heavy Metals' Concentrations (mg/L) in Organs from Fish in Dadin Kowa Dam (Jan, 2023)

Samples	Fish organs	Cu	Ni	Cd	Zn	Cr	Pb

Physical and chemical parameters of Dadin Kowa Dam water

The mean temperature recorded in Dadin Kowa dam water were within the recommended temperature range for 'warm water fishes' which was 25-32^{0}C and 14-18 °C for 'cold water fishes' (Trivedi, 2020). According to the author temperature of Dadin kowa dam water may be suitable for fish survival, growth, and reproduction. Temperature of water had a potential implication on the oxygen retention capacity (CWT, 2004). A pH range of Dadin Kowa dam water ranged from 6.53 to 6.84 (Table 1). This indicated that, Dadin kowa dam water was slightly acidic. These values were suitable for domestic and drinking water purposes (WHO, 2017). This lower value of pH may be attributed to runoff of inorganic fertilizer from adjacent farms within the dam. Spellman (2017) stated that, pH is one of the most important parameters of water quality.

Heavy metals mean concentrations in some organs of fish species (*Clarias gariepinus* and *Oreochromis niloticus*) from Dadin Kowa Dam

The following heavy metals were identified in both *C. gariepinus* and *O. niloticus*: Copper (Cu), Nickel (Ni), Cadmium (Cd), Zinc (Zn), Chromium (Cr), and Lead (Pb) (Table 2). Mean concentrations of Zn was found to be highest in the bones and gills of *O. niloticus* and lowest in *Clarias gariepinus*. The mean value of the heavy metals obtained in the fish species were above the permissible limits (WHO, 2017) respectively.

Zinc (Zn) is an essential trace element whose threshold value in surface and groundwater normally do not exceed 0.01 and 0.05 μg/l, respectively (Vinodhini and Narayanan, 2009). Deficiency of zinc causes several physiological disorders such as poor pregnancy rate, cardiovascular diseases and cancer; but it becomes toxic in excess amount (Azaman *et al.,* 2015). However, concentrations in tap water can be much higher as a result of dissolution of zinc from pipes. WHO (2003) stated that, drinking water containing zinc levels above 3 μg/l may not be acceptable for consumption.

The mean values of Cu and Cr obtained in the fish species were below the permissible limits (2.0 and 0.05) recommended for fish consumption (WHO, 2017). High concentration of Cu in dam water may be due to mining activities close to the dam water, similar findings indicate that, the major source of copper (Cu) in water was due to mining activities within the dam (Adelekan, 2011). Higher concentrations Cu in organism can lead to neurological complications, hypertension, abdominal pain, diarrhea, kidney and liver dysfunctions (Tirkey *et al.,* 2012).

O. niloticus bones and muscles had the same mean concentration of Cr; while *C. gariepinus* bones and muscles had different concentrations Cr obtained in the fish species were below the permissible limits (0.05) recommended (WHO, 2017). Furthermore, O'Brien *et al.,* 2001, Matsumoto, 2006) and WHO, (2015) implied Chromium have been associated with slow healing ulcers in organisms. It has also been reported that Chromate compounds can destroy DNA in cells. Recommended safe limits for Cr (hexavalent) in wastewater and soils used for agriculture are 0.05 and 0.1 ppm respectively (Chiroma *et al.,* 2014, Aneyo *et al.,* 2016). Lead (Pb), Zinc (Zn), Nikel (Ni), Cadmium (Cd) was above permissible limits in all the fish species. These heavy metals were the major causes of water contamination and poison in Zamfara state (Mahuta, 2020). The WHO, (2011) recommended 0.01 and 0.1 ppm as the safe limits of Pb in wastewater and soils used for agriculture. The high mean concentration of Nickel (Ni) in dam may be due to wastewater runoff from farms in to the dam. WHO recommended safe concentration of Ni to be 0.02 and 0.05 (Chiroma *et al.,* 2014, and Aneyo *et al.,* 2016). The recommended safe limits of Cd were 0.003 ppm in both waste water and soils for agriculture by World Health Organisation (Chiroma *et al.,* 2014, and Aneyo *et al.,* 2016).

The mean concentration pattern of heavy metals in fish species of all the organs obtained in Dadin kowa dam (muscles, bones and gills) for *C. gariepinus* and *O. niloticus* were Zn>Cu>Ni>Cd<Pb>Cr. Ekpo *et al.*, (2013) mentioned the target organs of heavy metals in fish was the metabolically active ones which accumulate high level of metals gills, bones and muscles of fish species.

Mean concentrations of heavy metals in sediments and water (head and tail of the water) in Dadin Kowa Dam

Mean concentration of Cu and Zn in the dam sediments were higher while in the tail water lowest (Table 3). Lead (Pb), Zinc (Zn), Nikel (Ni), Cadmium (Cd) was above permissible limits in sediments and water, while Cupper (Cu) and Chromium (Cr) were below permissible limits in domestic and drinking water (WHO, 2017). Some of these heavy metals such as cobalt, chromium, copper, magnesium, iron, molybdenum, manganese, selenium, nickel and zinc are essential nutrients that are required for various physiological and biochemical functions in the body. When heavy metals were not in adequate amount in the feed, it may result to nutritional diseases. Furthermore, when they are in large concentrations in the feed, they may cause acute or chronic toxicities (WHO, 1996).

Contamination of sediments with heavy metals is an environmentally affecting aquatic organisms and human health. However, heavy metals accumulation in the sediment and bottom of dam, did not have any possibility of flowing out, outflow from the dam, outflows of heavy metals usually occur at the surface level. Sediments act as the main pool of metals in the aquatic environment. Presence of heavy metals in sediments indicates the status of water pollution (Zahra *et al.*, 2014).

CONCLUSION

The study elucidates that, Dadin kowa dam water is slightly acidic due to pollution. The following heavy metals were detected in the dam water Zn>Cu>Ni>Cd>Pb>Cr. Zinc is the most abundant heavy metal in the bones of *O. niloticus* and muscles of *C. gariepinus*. Mean Concentrations of Pb, Zn, Ni and Cd in the fish species, sediments and water samples were observed to be higher than the World Health Organisation (WHO) permissible limit.The findings of this research are indicating the likelihood that Dadin kowa dam is polluted with heavy metals.

RECOMMENDATIONS

The government should have a framework strategy to broadly survey the Dadin Kowa dam, whereby specific sources of pollution should be identified in order to curtail it; People should be advised to be cautious in utilizing water and *O. niloticus* and *C. gariepinus* caught from Dadin kowa dam. The public should be educated on the harmful effects of toxicity of heavy metals particularly, the bioaccumulation effects. Furthermore, research should be carried out by relevant governmental and non-governmental agencies to further investigate our findings for proper action to be taken in order to save guard the public health.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

This study analyzed the correlation of fish consumption among households in Lagos State. A multistage random sampling technique was used to select 400 household fish consumers. The first stage was the stratification of the study area into cells of high, medium and low-density area of Lagos state. In the second stage Two Local Government Area was selected from each of the cells (Lagos Island, Eti Osa, Surulere, Shomolu, Kosofe and Oshodi/Isolo Local Government Area. In the third stage a list of all the households in each of the Local Government Area was obtained from the National Population List. A structured questionnaire was used to collect the data needed for the study.The data were analyzed using the descriptive statistics and inferential statistics (multinomial logit model and multiple regression). The result shows the male household are more (52.5%) than the female household (47.5%). The average monthly expenditure on fish by household was ₦5.9. Result of the descriptive statistics further shows that the largest number of consumers (60.7%) had preference for fresh fish.. Smoked fish was the second most preferred fish form consumed by the households (54.7%). While dried fish emerged was consumed by 52.7% of the households making it the third preferred fish form. The least preferred form of fish consumed in the area was frozen fish and 50.7% of the household consumed this fish form. The result of the multinomial result shows that Education, Age, mode of income, Gender and Household income were statistically significant at 5% Level of probability. The multiple regression result shows that only three regresors (Age, Household income, and marital status) out of seven regressors were statistically significant at 5% level of probability. The study recommends the improvement of the market for fish consumption by creating value through packaging processing and storage and better storage facilities. This can be achieved by government provision of steady power supply and agro processing industries which must be linked to production for household consumption.

Keywords: *Analysis, Correlation, Fish Consumption, Pattern, Lagos-State.*

INTRODUCTION

The fishery subsector in Nigeria holds the potential to contribute to food security and reduce rural fishery sub sector hunger by providing employment to many Nigerians, it is also a major contributor to GDP. Its contribution to GDP as at 1990 Constant basic prices stood at ₦9,240.54, ₦ 9,810.63, ₦10,395.40 and ₦1,012.63 in 2008, 2009, 2010 and 2011, respectively (Central Bank of Nigeria, 2011). Apart from providing employment for over five hundred thousand people, it contributes over 40 percent of the animal protein intake of the resource poor people (Sani *et al.*, 2009).

Fish is an important component of a modern healthy diet and also a critical food source for developing countries Fish provides key macro and micro nutrients, protein and are low in saturated fat (Lynch & Macmillan, 2017). fish consumption has been linked to a wide array of health benefits for infants and adult including the developing foetus (Millen *et al.*, 2015) According to Nesheim and Taktine (2007), fish can supply up to 50 percent or more of high quality protein, mineral elements (B6, B12, niacin, thiamine, riboflavin, Vitamin E) and essential fatty acid such as oleic acid and omega3 fatty acid.

The United Nation Food and Agriculture organization noted that world population growth has outweighed fish production due to increased fish consumption. (FAO. 2018c) Fish consumption per capita across the world has increased from 9.0kg in 1961 to 20.5kg in 2017 FAO (2018d). Considering the upsurge in population growth, urbanization and demographic dynamics (Falaye & Jenyo-Oni, 2009). Fish consumption (demand) raises enormous challenges for Nigerian economy. Utilization of fish varies for food and non-food purposes across countries and regions. More importantly, the utilization of fish for direct human consumption increased significantly over the years from 67 percent to 88 percent in 2016 (Verbeke,& Vakier, 2015). Hence, the consumption pattern for fish has peculiar implications for the sub-sector in various economies.

Fish plays a vital role in feeding the world's population and contributing significantly to the dietary protein intake of hundreds of millions of the populace. On a global scale, almost 16 percent of total average intake of animal protein was attributable to fish in 1988 (FAO 1990). In the developing worlds, fish is a highly acceptable food that supplies as much as 40 percent of all animal protein available of the countries. The low income earners in Nigeria consume proportionally more of fish than meat or other sources of animal protein. Over the past 15 years, however, fish has enjoyed an explosive increase in demand and this demand has also increase its price. There is heightened awareness in the developed world of the nutritional and health benefit of fish products low in fat and calories and high in protein, vitamins, mineral and polyunsaturated fatty acids. Increased attention to fish and fish products caused prices to spiral with potentially serious consequences for consumers. While the bulk of fish harvested is still used for domestic consumption. Increased world demand for fish is placing pressure on developing countries to export fish to earn foreign exchange. The objectives of the study are to:examine the socio-economic characteristics of the household, determine the factors influencing consumer's expenditure on fish and identify the constraints for fish consumption in the study area.

METHODOLOGY

This study was carried out in Lagos State Nigeria. Lagos State is located in the south-western part of the Nigeria. On the North and East Lagos is bounded by Ogun State. In the West the state shares boundaries with the Republic of Benin. Lagos state is bounded to the south by Atlantic Ocean. Twenty two percent of state land area (3,577 km^2) are lagoons and creeks. Lagos state lies within the latitude 6^0 and 24^1 and 6^0 31^1 N, longitude $3^0 16^1$ and $3^0 37^1$. There are twenty local Government Areas in Lagos State. The state has a population of 9,013,534. (National population commission, 2006). The highest maximum temperature ever recorded in Lagos was 37.3ºC (99.1ºF) and the minimum 13.9ºC (57.0ºF) (Lagos Meteorological Organization 2012). . A multistage random sampling technique was used to select 400 household fish consumers. The first stage was the stratification of the study area into cells of high, medium and low-density area of Lagos state. In the second stage Two Local Government Area was selected from each of the cells (Lagos Island, Eti Osa, Surulere, Shomolu, Kosofe and Oshodi/Isolo Local Government Area. In the third stage a list of all the households in each of the Local Government Area was obtained from the National Population List. A structured questionnaire was used to collect the data needed for the study.The data were analyzed using the descriptive statistics and inferential statistics (multinomial logit model and multiple regression)

RESULT AND DISCUSSION

Table 1. Socio-economcs Characteristics of Respondents in the study Area.

Variable	Category	Frequency N= 400	Percentage	Mean	Standard Deviation
	Male	210	52.5		
	Female	190	47.5		
	Single	155	38.75

Source: Field Survey Data, 2023.

The socio-economic characteristics analyzed include: gender, age, marital status, family size, household income, occupation and forms of fish consumed.

Gender of the household heads is an important factor that has significant influence on the preference and consumption pattern of fish by households. The distribution of household by gender and forms of fish is presented in Table 1.0 and shows that although the percentage of male headed households (52.5%) was more than female headed household (47.5%), the difference was marginal. This is in line with result of Chianu & Tsujii(2007) where 99.7% of the surveyed household were male headed. The distribution of the household by marital status is presented in Table 1.0. The table shows that 53.75% of the households were married while 38.75% are and 7.5% were singles and widowed respectively. This shows that there is the tendency for more purchase of fish. and increased consumption by households headed by married people than singles due to expansion in family size and greater responsibilities in terms of expenditures on food items. Therefore there is a tendency for more purchases of fish. (Amao & Ayantoye 2014). According to Aminu *et al*. (2016) there is a tendency for the age of the household head to affect the consumption pattern of a household and may determine to an extent the type, quality and nutrition of a given household. The table shows that 25.75% of household heads fell within the age group of 41-50years. Age could be an important determinant in the quality and quantity of protein requirement of an individual and households because food consumption pattern generally follows the body consumption (Amao *et al.*, 2006). Amao & Ayantoye, 2014). Educational status and years of education changes taste over time and usually affects consumption pattern, preference for food items and nutrition of a household. This is because consumers become aware of the nutritional value of food items like beef, eggs and fish and subsequently enhance their consumption. The distribution of household head by level of educational attainment is presented in Table 1.0. The result shows that household heads with secondary education had the highest percentage of 25.75%. This was followed by households head with primary education having 22.0%. Household's heads with tertiary education having 20.0% and households head with informal education was 17.0% of the total respondents. Respondent that went through adult literacy education had the least percentage (15.25%).This is in agreement with Babalola D. A & Isitor S .U, 2014) which state that that increasing educational status have positively impact on food expenditure.

Result in Table 1.0 shows that majority of the respondents (50.5%) belong to an extended family in the study while those with nuclear family is less with a sample household of 49.5%. This result shows that household with extended family are more than household with nuclear family. Family size have a significant effect on the consumption pattern of fish consumed. As the family size increases, there is tendency for the household to consume more food generally, fish inclusive. Table 1.0 shows the distribution of household family size. The result shows that high percentage of the household had between 2-5 members representing 53.25% of sample household. This is followed by household with < 2 members representing 36.25% of sample household and >5 representing 10.5% of sample household. This result towards small family size in the study area which may be attributed to the level of education of the respondents and their corresponding awareness of family planning measures. Information on demographic patterns in Nigeria also shows that urban households are usually smaller than rural households (Statista Research Department, 2021) The frequency distribution of income determines the type of income distribution most prominent in the study area. Table 1.0 shows that, about9.75% of all households sampled earn less than ₦10,000 per month. About 11.25% are in the range of ₦10,000--₦19000 per month, while about 16.5%fall within the income group of₦20,000--₦29,000per month. Households earning between ₦30,000-₦39,000permonthconstitute about17.25 percent of all respondents interviewed, while those earning between ₦40,000-₦49,000 and ₦50,000 and above per month, accounted for19.5%, and 25.75% respectively of all the households sampled in the study area. This reveals that majority of the households in the study fall within the low income group as presented in Table 1.0 while those in the high income class are relatively few. Low income may affect overall fish consumption and further determine the form of fish consumed by households
Table 1.0 shows that 54.5% of total sampled respondents were non salary earners. 45.5% of total sampled respondents were salary earners. A priori expectation is that the probability for salary earners to have a more planned and consistent consumption pattern than the non- salary earners is higher. This may also influence an increase in household purchasing power. However, most of the household in the study area are non-salary earners. Table 1.0 shows that 32.5% of the total sample had their own business (trading) and represent. 17.5% of household heads were in the professional group comprising of banker. 12.5% of the sample household heads were farmers. 13.25% of sampled respondents were artisans and apprentices accounted for about 13.25% of sampled respondents.
Also Table 1.0 shows the average monthly expenditure on fish by household size, it was observed that the average monthly expenditure (₦13,954,500) on fish increases as the household size increases. This was found to be true for the average monthly expenditure on fish by the age of the household head (₦3,640.00).

Table 2 Multiple regression output showing factors influencing household fish Consumption in the study Area.

Variables	Beta Coeff	t-value
(Constant)	5522.640	6.766
Education level of household head (year)	4.8870	1.176
Age of household head (year)	6.125*	3.713
Household Income (naira)	2.1086*	2.723

Household Size	9.957*	3.140
Mode of Income (Dummy: salaried =0; Non salaried =1)	-6.886	-1.846
Gender (Dummy: male =0;. female =1)	4.993	.014
Marital status (Dummy: Married =1; Single =0)	-1.213	-3.228

Adjusted R^2 = 0.49; F-statistics = 5.493*; Reference category = Fresh Fish form; *P<0.05

Source: Field Survey Data, 2023.

The result of the factors influencing households' fish expenditure in the study area is presented in Table 2. The coefficient of determination, R^2 is 0.49 showing that the linear regression explains 49% of the variance in the data. Since F statistics is significant at (P <0.05), this means there is overall significance of the model.

The beta coefficient of the age of the household head is positive and significant (β=6.125, p=005) thus a unit change in the age (increase) of the respondent will lead to 6.125 change (increase) in fish expenditure. It also shows that the higher the age of the household head, the higher the consumption expenditure on fish. The descriptive result of the age composition of the respondents shows that most of the respondents are relatively old thus it is expected that expenditure on fish will be high if supply is improved in the study area *ceteris paribus*. This findings agrees with Ayanwu (2012) in Rivers state, Nigeria which states that increase in age leads to increase in the quantity of fish consumed.

The beta coefficient of household income is positive and statistically significant as 5 per cent level (β=2.1086, p=0.005) showing that income is directly related to expenditure on fish. This suggests that a change (increase) in household income will cause expenditure on fish to increase by 2.1086. That is, the higher the income, the higher the fish consumption expenditure. This agrees with a priori expectation that with higher disposable income, expenditure on food increases. However, most of the households in the study area are low-income households. This findings is consistent with that of Aromolaran A. B & Akintunde O.A 1998 in Delta State, Nigeria, Fabiyi Y.L 1985 in Calabar, Cross Rivers State, Nigeria and Ayanwu, S.O 2012 in Rivers State, Nigeria.

The beta coefficient of household size is positive and statistically significant at 5 percent level (β=9.957, p=005) of probability, thus suggesting that household size is also directly related to expenditure on fish. It also implies that an increment in the size of the household will lead to an increase in the fish consumption expenditure. Similar result was also obtained by Ibrahim M I999 in Kano and Sharu, A.A 2000 in Sokoto metropolis, Nigeria, in the demand for soybean and meat respectively as sources of protein

Based on the multiple regression result, the earlier stated null hypothesis which says that household personal characteristics do not significantly influence consumer expenditure on fish, is rejected in favour of the alternative hypothesis.

Table 3. Distribution of Respondents according to Constraints faced by Households in the study Area.

Constraint	**Frequency**	Percentage
Distance from the Market	101	67.3
Low Traded Volume of Fish	18	12.0
Health Reasons	41	27.3

Source: Field Survey Data, (2023).

The result in Table 3 reveals that majority (69.3%) of the respondents faced rapid fish spoilage as constraint because they consume fresh fish and preserved by refrigerating or sun drying. Rapid spoilage of fish could be as a result of poor power supply to power the refrigerator use for preservation of the product. While 67.3% sampled fish consuming household accounting for distance from the market as their challenge, other constraint include high price of fish (64%). High prices of the product could be as a result of high transportation, high cost of production and high cost of preservation. Low level of consumer income (41.3%), health reasons (27.3), religious belief (25.3%) and low traded volume (12%).

CONCLUSION

Based on the findings Fresh fish is the highest form of fish in the consumer market, whereas smoked fish is the lowest priced. As the income of the consumers increases, they buy only a little more smoked and frozen fish because most smoked fish consumed in the metropolis are perceived to be of low quality. Wealthier consumers tend to buy more of fresh fish and dried fish (such as stock fish) which consumer perceived to be of better quality in terms of nutrition and safety. The dried and fresh forms of fish are substitute mainly because the most common type of fresh fish in the area (the cat fish) is also the dried fish in the market.

RECOMMENDATIONS

1. With increasing awareness of health and nutritional importance of fish, especially among older folks, supply of fish should be encouraged and facilitated locally through improvement of local production so that low income household can affordably consume
2. Facilitation of supply of fresh and frozen fish is recommended because it attracts higher preference especially in the open market.
3. Based on the findings, the study recommends that fish prices should be stabilized, adequate cold storage facilities should be purchased by the fish mongers
4. Fishery sector should expand their ponds and be encouraged to produce more fresh fish at affordable prices for the masses.
5. It has been revealed that a light increment of income distribution in favour of the low income class will improve fish consumption for many of these consumers.
6. There is a need therefore to increase domestic fish supply in the country and ensure fish supplies to consumers at affordable prices in all market in the metropolis.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Seed production is an inevitable requirement for sustainability of aquaculture industry. This process is basically managing fish at different early growth and developmental stages of its life cycle. However, it has been observed that fry stage is the most critical stage threatened with high rate of mortality. And high growth rate of the fry could catalyse the fish to pass through this critical stage speedily which is an indirect technique to curb mortality as well. In order to achieve this, a study on feeding trial was carried out at the Aquatic Bio-Resources unit of the National Biotechnology Development Agency, Katsina whereby the effects of different levels of dietary betaine hydrochloride on the growth response of fry of Clarias gariepinus were evaluated. ***Betaine*** *hydrochloride* ***was incorporated at*** *0.0g/100g, 0.25g/100g, 0.5g/100g, 0.75g/100g and 1.0g/100g* ***in*** *Coppens fish feeds (0.2 – 0.5mm) of 49% crude protein.* ***The experimental diets were fed to*** *the* ***fry*** *(n = 1,500 with Mean initial weight = 0.26±0.0g)* ***for 28 days in*** *15 plastic hatchery tanks (semi flow-through system)****.*** *Fry were fed at a fixed feeding rate of 5% body weight 4 times daily between the hours of 07:00 and 23:00 at regular interval****.*** *Data generated were analysed using One - way ANOVA at P = 0.05.* ***The results indicated that fry*** *fed* ***diet supplemented with betaine hydrochloride at 0.5g/100g level has significantly the highest values of Mean Weight Gain*** *(2.34±1.02g/fish)****, Daily Weight Gain*** *(0.083±0.09 g/day)****, Specific Growth Rate (****3.57±0.11 %/day)* ***but also significantly least (best) value of FCR*** *(0.155±0.04).* ***Survival rate of over 88% were recorded from each of the fry fed all the diets with betaine hydrochloride and the control (****0.0g/100g****) indicating that the water quality parameters were not affected by the diets used in this study. Therefore, the supplementation of fry feed with betaine hydrochloride can promotes fry growth in hatchery production and is recommended at0.5g/100g level.***

INTRODUCTION
Clarias gariepinus (Burchell, 1822) which belongs to the family Clariidae is the most cultured and economically important freshwater fish species that contributes immensely to the annual freshwater fish production in Nigeria (Awodiran *et al.,* 2019). It is readily acceptable among Nigerian fish farmers and consumers; hence, it commands high commercial values, and is an important source of animal protein (Omitoyin, 2007). It also serves as a model organism in research; it is also cultured intensively and extensively in Africa, Europe and Asia (Ali, 2022). The economic benefits of this fish species are due to its hardiness, fast growth, large size attainable and ability to withstand and tolerate harsh environmental conditions (Awodiran *et al.*, 2019).

Aquaculture has been grown rapidly for food production in the last few decades (Ali, 2022). The increase in aquaculture is said to be paralleled with a corresponding increase in the cost of fish feed, since feed is a significant expense in all aquaculture operations, the need to maximize feed consumption and reduce feed wastage is of paramount importance (Murthy *et al.* 2016), that encouraged researchers to develop fish production in different scientific ways to raise quality and quantity production and lower costs, which including special fish diets supplemented with growth promoters as feed additives such as betaine hydrochloride as reported by Leong - Seng *et al.* (2019) which positively affect the body weight gain improvement and decrease food consumption to improve and raise the production level without any negative effect on public health and consumer.

Betaine is amino acid derivatives which is derive from amino acid glycin (is the trimethyl glycin), is a metabolite of plant and animal tissues, betaine is considered as a by - product of sugar beet processing, betaine has nutritional function commonly used as feed additive in animal, poultry and aquatic nutrition, betaine improve growth performance, health status, feed digestibility, palatability, flesh quality and immune status of fish species (Abed Ali and Al - Faragi, 2017). Therefore, this study was carried out to evaluate the effects of different levels of dietary betaine hydrochloride on the growth response of *Clarias gariepinus* fry

MATERIALS AND METHODS

Study Area

The study was carried out at the hatchery room of the Aquatic Bio-Resources unit of the National Biotechnology Development Agency (Bio-resources Development Centre) Katsina, Katsina State. The fry for experiment were bred at the hatchery room of Aquatic Bio-Resources unit of the Bio-Resources Development Centre, Katsina. The fry were 4 days old at the commencement of the feeding trial

Experimental Diets

Coppens fish feeds (0.2 – 0.5mm) were used as the basal diets for this study and were obtained from feed suppliers at Katsina. While the betaine hydrochloride was obtained from Bon Amour Pharmacy Limited Lagos, Nigeria, imported from Piping Rock Health Products, Ronkonkoma, New - York, USA.

Experimental diets were prepared by incorporating betaine hydrochloride at four graded levels namely 0.25g, 0.5g, 0.75g and 1.0g/100g feed into Coppens fish feeds (0.2 – 0.5mm). Diet without betaine additive i.e. 0.0g/100g feed served as the control and coded as T_0 (0.0g), T_1 (0.25g), T_2 (0.5g), T_3 (0.75g) and T_4 (1.0g) respectively). The betaine hydrochloride was included at the measured quantity for each diet and was diluted into 10 ml of warm water to form a solution. The solution was sprayed onto the Coppens fish feeds (0.2 – 0.5mm). The betaine hydrochloride additive Coppens fish feeds (0.2 – 0.5mm) were prepared in 100g each time.

Experimental Design

Each treatment was applied to 100 fry (each weighing 0.26±0.0g) in triplicate making a total of 15 plastic hatchery tanks (semi flow - through system). Water quality parameters monitored includes; pH, dissolved Oxygen (DO), temperature and ammonia. Fry were fed at a fixed feeding rate of 5% body weight 4 times daily between the hours of 07:00 and 23:00 at regular interval for a period of 28 days. The initial body weight of each set of fry was measured using a digital weighing balance before stocking and subsequently bulk weighing of fry in each tank was done after every 7 days, the growth response parameters were computed and analysed according to the following equations as described by Stickey *et al.* (2006).

$Mean\ weight\ gain\ =\ \text{final weight (g)} - \text{initial weight (g)}$

$Daily\ weight\ gain\ =\ \text{final weight (g)} - \text{initial weight (g)/experimental days}$

$SGR = \{(log\ \text{final weight (g)} - log\ \text{initial weight (g)})/\ culture\ period\} \times 100$

$\text{FCR (g/g)} = \text{feed intake (g)/weight gain (g)}$

$Survival\ rate = (final\ no.of\ fish/initial\ no.of\ fish) \times 100$

Statistical Analysis

The data obtained were subjected to one - way analysis of variance (ANOVA) using the GraphPad instant package for windows 2010 of Statistical Analysis System (SAS, 2010). Mean separation was done (at P = 0.05) using Fisher's least significance difference (LSD) to separate the means in cases of significant difference.

RESULTS AND DISCUSSION

The proximate composition of the Coppens fish feeds (0.2 – 0.5mm) fed to the *Clarias gariepinus* fry is presented in Table 1. All the diets contain 49% crude protein, 12% crude lipid, 6.0% crude fibre, 8.0% ash, 1.5% calcium, 8.0% moisture and 1.5% phosphorus.

Table 1: Proximate Composition of Coppens Fry Feeds (0.2 – 0.5 mm) Used for the Study

Nutrients	Percentage (%)
Crude protein	49
Crude lipid	12
Crude fibre	6.0
Ash	8.0
Calcium	1.5
Moisture	8.0
Phosphorus	1.5

Data on the growth response of the *Clarias gariepinus* fry fed different levels of dietary betaine hydrochloride are given in Table 2. There was significant difference amongst the fry fed treatment diets in terms of MWG, DWG, SGR and FCR. The highest growth response in terms of MWG (2.34±1.02g/fish), DWG (0.083±0.09 g/day) and SGR (3.57±0.11 %/day) were recorded from the fry fed betaine incorporated diet at 0.5g/100g feed T_2. Similarly, the least (best) FCR (0.155±0.04) was recorded from the fry fed diet T_2. The highest survival rate (88.9±1.07%) was recorded from the fry fed diet T_2. There was no significant difference in terms of the survival rate of the treatment diets. During the experimental period, the water quality parameters monitored such as the

water temperature, pH, dissolved oxygen and ammonia were within the recommended range for *Clarias gariepinus* culture.
Growth response such as the MWG, DWG and SGR were highest in the fry fed diet T_2 which was in agreement with the findings of Sogbesan *et. al.* (2022) who reported a similar result for *Clarias gariepinus* fingerlings fed dietary betaine additive diets and Ali (2022) for *Clarias gariepinus* juveniles fed different levels of dietary betaine additive diets. The FCR was least (best) in the fry fed diet T_2 containing betaine additive at 0.5g/100g feed which was in consistent with the findings of Ekasari *et al.* (2021) who reported a similar result for *Epinephelus lanceolatus* × *Epinephelus fuscoguttatus* juvenile fed dietary betaine additive at 0.5g/kg feed and Sogbesan *et. al.* (2022) who reported a similar result for *Clarias gariepinus* fingerlings when betaine additive was added to the diet at 0.5g/100g feed.
The highest MWG, DWG, SGR and the least (best) FCR recorded from the fry fed diet T_2 containing betaine additive at 0.5g/100g feed indicated that the betaine additive has a beneficial effect when added to the diet at optimal level but, below or beyond that level may negatively affect the catabolic activity and was in support with the findings Leong - Seng *et al.* (2019) who reported a similar result for *Epinephelus fuscoguttatus* fingerlings fed betaine additive diet.
The high survival rate values recorded from all the treatment diets used in this study indicated that the diets were well tolerated by the fry and also the water quality parameters were not affected by the incorporation of betaine hydrochloride into the diets.

Table 2: Growth Response of *Clarias gariepinus* Fry to Treatment Diets

Parameters	T_0	T_1	T_2	T_3	T_3
Initial mean weight (g/fry)	0.26 ± 0.0^a	0.26 ± 0.0^a	0.26 ± 0.0^a	0.26 ± 0.0^a	0.26 ± 0.0^a
Final mean weight (g/fry)	1.81 ± 0.11^a	1.83 ± 0.16^a	2.60 ± 1.33^b	1.86 ± 0.18^a	1.88 ± 0.19^a
Mean weight gain (g/fry)	1.55 ± 0.02^a	1.57 ± 0.06^a	2.34 ± 1.02^b	1.60 ± 0.82^a	1.62 ± 0.05^a
Daily growth rate (g/day)	0.055 ± 0.03^a	0.083 ± 0.09^b	0.056 ± 0.02^a	0.057 ± 0.01^a	0.058 ± 0.05^a
Specific growth rate (%/day)	3.00 ± 0.18^b	3.02 ± 0.12^b	3.57 ± 0.11^c	3.05 ± 0.03^b	3.06 ± 0.09^b
Feed conversion ratio (g/fry)	0.234 ± 0.02^a	0.231 ± 0.01^a	0.155 ± 0.04^b	0.227 ± 0.03^a	0.224 ± 0.07^a
Survival rate (%)	88.6 ± 1.02^a	88.0 ± 1.01^a	88.9 ± 1.07^a	88.3 ± 1.04^a	88.1 ± 0.06^a

Mean values in each row with similar superscripts are not significantly different ($p>0.05$).
Keys:
T_0 - Betaine (0.0g/100g)
T_1 - Betaine (0.25g/100g)
T_2 - Betaine (0.5g/100g)
T_3 - Betaine (0.75g/100g)
T_4 - Betaine (1.0g/100g)

CONCLUSION AND RECOMMENDATION

Findings from this study indicated that when betaine hydrochloride was used as additive in the diet of fry of *Clarias gariepinus* it promoted desired growth response of the fry. Betaine hydrochloride at inclusion level 0.5g/100g feed tends to be more significant in many parameters, hence, it is recommended.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The present study aimed to determine the fatty acid composition of crab (Portunus trituberculatus) obtained from Lagos coastal water using GC-MS chromatography. A total of 14 Fatty acids were identified, with Vaccenic acid and Palmitic acid being the most abundant. The Total Saturated Fatty acid (SFA) content was found to be (26.83%), while the Total Monounsaturated Fatty Acid (MUFA) and Total Polyunsaturated Fatty Acid (PUFA) contents were (29.03%) and (36.18%) respectively. The Omega-3 (ω-3) Fatty Acid Content was found to be (36.18%), while Docosahexaenoic Acid (DHA) and Eicosapentaenoic Acid (EPA) being the major contributors. The Omega-6 (ω-6) Fatty Acid Content was found to be (5.73%), with Arachidonic acid being the major contributor. The values obtained for the PUFA to SFA was in the ratio of 1:35. The results of this study suggested that Portunus trituberculatus collected from Lagos coastal water is a good source of SFA, MUFA, PUFA, and ω-3 and ω -6 fatty acids, which are essential for maintaining human health.
Keywords: *Portunus trituberculatus, Fatty acids, Vaccenic acids, Palmitic acids, Saturated, Monounsaturated, polyunsaturated Fatty acids.*

INTRODUCTION
Fatty acids are the building blocks of the fat in our bodies and the food we eat. During digestion, the body breaks down fats into fatty acids, which can then be absorbed into the blood. They are classified as carboxylic acids with hydrocarbon chains spanning from 4 to 24 carbon atoms, which makes up the majority of lipids. It can be completely saturated (no double bonds on the hydrocarbon chain) or mono- or poly-unsaturated (one or more double bonds on the hydrocarbon chain). The melting point and solubility of fatty acids and/or the compounds that contain them are largely determined by the length and degree of unsaturation (number of double bonds) of the hydrocarbon chain (Dunbar *et al*., 2014). Many studies have been conducted over the years to examine the impact of various dietary lipid sources on aquatic animal growth, physiology, metabolism, welfare, and product quality (Yuan *et al*., 2020). The quality of farmed aquatic animals has a considerable impact on consumer preferences and purchasing behaviors, ultimately influencing the success or failure of farming organizations (Hardy and Lee, 2010). This is assessed by a combination of nutritional value (e.g., protein, amino acid, fatty acid, vitamin, and mineral content) and sensory quality (e.g., skin or fillet color, texture, flavor, and odor) of the edible component (fish fillet or crab/shrimp flesh) (Yuan *et al*., 2020).
Essential fatty acids are lipids that the human body cannot synthesize and are mostly composed of omega 3 (ω-3) and omega 6 (ω-6) fatty acids, which are polyunsaturated fatty acids (PUFAs). These PUFAs (ω-3 and ω-6) are defined by the number of carbons from the Fatty Acid methyl terminal for the first double bond (Dunbar *et al*., 2014). The ω -3 are primarily Eicosapentaenoic acid (EPA) and Docosahexaenoic acid (DHA), whereas the ω -6 are primarily linoleic acid (LA) and are required in varying proportions in the human diet. In the human diet, fish is the primary source of long-chain ω-3 fatty acids (Watters *et al*., 2012). These PUFAs have several advantages and are also known as biological regulators of human health problems (Deckelbaum and Torrejon, 2012; Dunbar *et al*., 2014; Watters *et al*., 2012).
The swimming crab, *Portunus trituberculatus*, is a popular and widely distributed marine crustacean in China, Japan, and Korea, where it is consumed and employed as a raw material in the processing industry (Han *et al*., 2018; Hao *et al*., 2021). Swimming crabs are widely known for their excellent nutritional value, which includes an abundance of highly unsaturated fatty acids (PUFA) (Jin *et al*., 2013). Therefore, this study seeks to Evaluate

the fatty acid composition of crab (*Portunus trituberculatus*) fished along Lagos coastal water using GC-MS chromatography.

MATERIALS AND METHODS

Sources of Materials/Equipment

The Raw sample used in this study the *Portunus trituberculatus* tissues was obtained from Lagos coastal water Lagos Nigeria. The samples were separately packed in a clean polythene bags and transported in ice boxes prior to analysis while the Analytical grade chloroform/methanol (2:1 v/v), distilled water and rotary evaporator were obtained from the Chemistry Laboratory of the Institute for Oceanography and Marine Research. (NIOMR) Lagos state.

Method of Sample Preparation

The samples (Crab tissues) were washed with distilled water and the edible muscle part was removed using a sharp forceps and homogenized with a mixer grinder. Homogenized samples were packed in sealed polythene bags, labeled properly and stored under a freezer for further analysis. The lipids in the muscle tissue were extracted using the method described by Bligh and Dyer, 1959. Lipid content was determined as a percentage value using the gravimetric method. The extract was used to generate the fatty acid methyl ester (AOCS Method c2.66).

Gas Chromatography equipped with mass spectrometer were employed (GC-MS) with FTD Detector (GC-MS-QP2010SE Shimadzu; Japan) analysis was conducted using 1-µL split injections onto a 105 m (fused silica) DB wax column (Restek, PA). The initial column temperature was held at 100°C for 4 min, before being increased to 240°C at a rate of 3°C min^{-1}. The injector temperature was held constant at 225°C and the detector temperature was 285°C. Helium was used as the carrier gas and column flow was held at 1 mL min^{-1}. The calibration curve was constructed using the FAME (Larodan, Sweden). Heptadecanoic acid was added to each and every sample as an internal standard

RESULTS AND DISCUSSION

The profile and percentage composition of the fatty acid present in *P .trituberculatus* meat were analyzed using GC-MS techniques and 14 different fatty acids were identified as shown in Table 1. The total composition of the SFA, MUFA, and PUFA are presented in Figure 1. From Table 1, Vaccenic acid 18:1(ω- 7) was the most predominant with 10.62% followed by palmitic acid 16:0 (9.81%), heptadecanoic acid 17.0 (9.41%) docosahexaenoic acid (DHA) 22:6 (ω -3) (9.11%), then oleic acid 18:1(ω- 9) (8.60%), while myristic acid and tridecanoic acid were 3.0% and 4.54% respectively. The findings also indicated that PUFA is the predominant compound among the investigated fatty acids SFA, MUFA, and PUFA. These PUFAs are likely to be useful in preventing or reversing some of the side effects of retroviral drugs, its direct intake also alters the cell membrane, which in turn modulates cell/ tissue response to infection, injury, and inflammatory actions (Dias, 2006).A higher ratio is considered the most beneficial for human beings. However, the higher content of the (ω -6) PUFAs may lead to many inflammatory diseases (Simapholous, 2002). Therefore Food and Agricultural Organization and the World Health Organization (WHO) of the United Nations have recommended the dietary(ω -3) to (ω -6) PUFA ratio should at least be 0.1 to 0.2 (Wu *et al*.,2010). *P. trituberculatus* shows the (ω -3) to (ω -6) ratio as 1.35 therefore, the edible muscle part of the crab may be considered a healthy seafood item.

Table 3: Percentage Composition of Free Fatty Acid in the Muscle Tissue of *P. trituberculatus* (Crab).

Fatty acid composition of *P. trituberculatus* muscle.	The number of carbon chains	Percentage (%) composition
Tridecanoic acid	13	4.54
Myristic acid	14	3.0
Pentadecanoic acid	15	5.47
Palmitic acid	16	9.81
Heptadecanoic acid	17	9.41
Stearic acid	18	4.41
Oleic acid	18:1	8.60
Vaccenic acid	18:1	10.62
Linolenic acid	18:3	5.11
Eicosenic acid	20:1	1.87
Arachidonic acid	20:2	5.73
Eicosapentanoic acid	20:5	9.11
Eicosadienoic acid	22:4	5.81
Dicosahexanoic acid	22:6	8.55
SFA		26.83
MUFA		29.03
PUFA		36.18

(ω 3)	30.44
(ω- 6)	5.73
(ω-7)	10.62
(ω-9)	8.60
PUFA/SFA	1.35

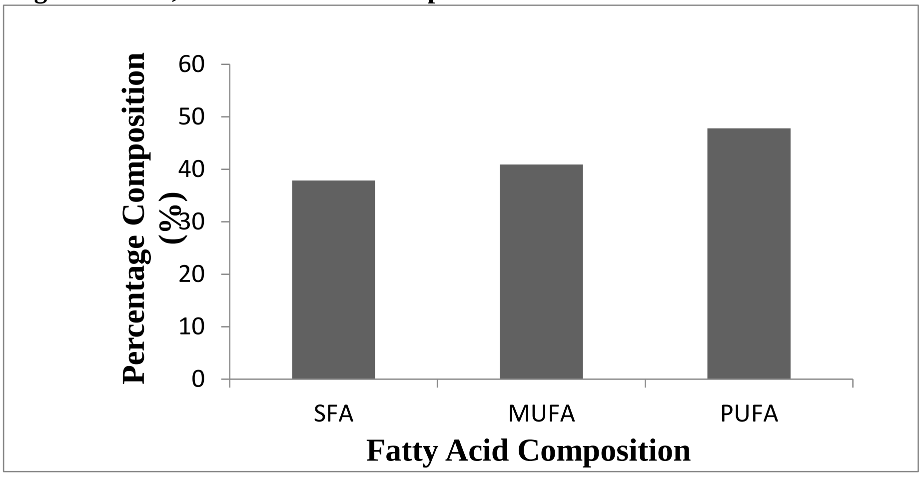

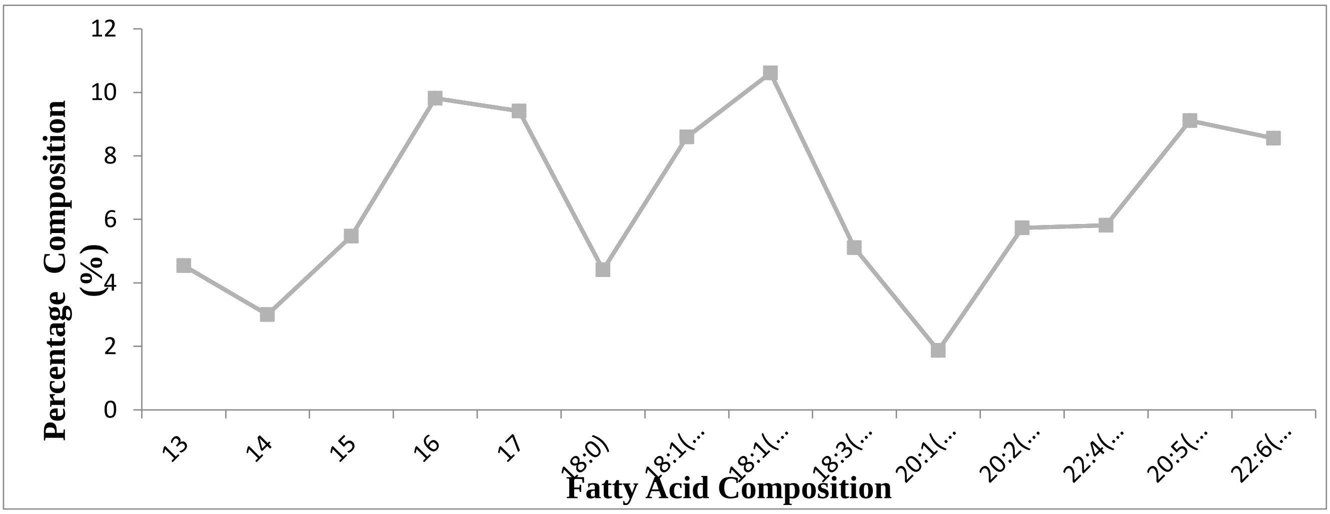

Figure 2: Percentage fatty acid composition of *Portunus trituberculatus*

CONCLUSION

This study was conducted on the fatty acids composition of *Portunus trituberculatus* crab collected from Lagos coastal water using GC-MS chromatography technique which provides valuable insights into the nutritional value of this crab species. The study found that this crab species is a rich source of essential fatty acids such as SFA, MUFA, and PUFA and both ω -3 and ω- 6 fatty acids. The high content of omega-3 fatty acids, specifically (DHA) and (EPA), in this crab species makes it a particularly beneficial enhancer of healthy unsaturated fatty acids as addition to a healthy diet.

Conclusively, the results obtained from this study provided a valuable information /data on the importance of addition and consumption of sea foods such as crab in human diet which are major sources of essential fatty acids that helps to lower risk of heart disease thereby improving our overall health and well-being.

RECOMMENDATION

From the findings in this research work, it can be recommended that,

1. The tissue of Crab (*P. trituberculatus)* is a good source essential fatty acids that are important for lower risk of heart disease because it contains saturated fatty acid, monounsaturated fatty acid and poly unsaturated fatty acid which are essential for maintaining human health condition. The high content of

omega-3 fatty acids in this crab species may be particularly beneficial for maintaining cardiovascular health and reducing inflammation in the body.

2. Further analysis can be evaluated on the fatty acids profile of the samples.

Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT

An experiment was conducted to test the effects of replacing groundnut cake with fermented African locust bean (Parkia biglobosa) seed meal (FALBM) on egg quality traits of Bovan Brown layers. A total of 180 Bovan's Brown layers of 30 weeks of age were allotted into five dietary treatments in a completely randomized design (CRD) comprising 3 replicates per treatment. FALBM was incorporated at 0, 25, 50, 75 and 100% (as diets A, B, C, D and E respectively) replacement levels as an alternative source of protein to groundnut cake. The birds were housed in battery cages measuring 40cm length, 35cm width and 40cm height and fed the experimental diets for a period of 42 days. The data generated from the experiment were subjected to analysis of variance (ANOVA) and significant (P<0.05) differences among treatment means were compared using Duncan's multiple range test. The results of egg quality parameters revealed that diets had no significant (P>0.05)effect on all the parameters measured, except for egg weight (67.6g for birds fed diet A and 65.83g for birds fed diet E) and yolk weight (18.41g for birds fed diet A and 16.71g for birds fed diet C) which were significantly (P<0.05) differently across the treatments means. The values obtained for egg weights ranged from 67.61 to 65.83g/egg, birds on control diet (A) was significantly higher (P<0.05) compared with other treatments means. Similarly, the values obtained for yolk weight showed that birds fed diet A (control) had the highest (P<0.05) value (value of the yolk weight and unit, please) while birds fed diet D presented the least (value of the yolk weight and unit, please). It is therefore recommended that experiment with different processing methods should be done in order to ascertain the effects of processing on the nutritional value of African Locust Bean.

INTRODUCTION

Poultry eggs are one of the most attractive targets for nutrition manipulation, owing to the extraordinary sensitivity of most of its traits to dietary factors. Varied and special nutritional approaches are developed targeting the specific properties of eggs (Wang *et al*., 2017). The quality traits of an egg are parameters that affect its acceptability to the consumer (Duman *et al*., 2016). The first concern of egg quality modulation is to reduce the defects of eggs, either on appearance or on flavor/taste (Wang *et al*., 2017).

Evaluation of egg quality parameters is essential both for table eggs and for the production of hatching eggs (Rotimi *et al*., 2022). The egg size and internal quality of eggs are important for both table and hatching eggs (Alkan *et al*., 2013).There are studies on the relationship between egg weight and egg quality parameters (Olawumi and Ogunlade, 2008; Sarica *et al*., 2012). As for the poultry industry, egg production is now hampered by a heavy shortage of feed ingredients (Wang *et al.*, 2017). Additionally, to meet the severe challenge, the egg industry should inevitably develop in a more sustainable way, aiming to maximize production at the lowest cost and slightest environmental impacts (Godfray *et al.,* 2010). The high cost of animal protein has directed interest towards several leguminous seed proteins as potential sources of vegetable protein for human food and livestock feed. Among the plant species, grain legumes are considered as the major source of dietary proteins. They are consumed worldwide, especially in developing and under developed countries where consumption of animal protein may be limited as a result of economic, social, cultural or religious factors (Esenwah and Ikenebomeh, 2008).

These sources of conventional feed ingredient are more expensive and not readily available to all producers at all locations due to competing demand for the commodity between man and livestock, adverse climatic condition and the use of these ingredient in the biofuel industry (Iji *et al.,* 2011). This stimulated the search for alternative feed ingredient particularly protein sources for poultry.Among these alternatives is African locust bean seed which is rich in protein and is used as a flavorintensifier for soups and stew. According to Omafuvbe *et al.,* (2004), its crude protein content is similar to other beans like cowpea, jack beans, lima beans and pigeon pea. It is a rich source of essential amino acid**s,** minerals and vitamins.

Improved performance traits, nitrogen retention and feed utilization of broilers fed fermented African locust beans as a replacement of groundnut cake have been reported by Kolo (2000); Ayanwale and Ari (2002) and Dawodu (2009). It is therefore on this positive attribute that this study was therefore carried out to assess the egg quality of laying chickens fed fermented African locust beans a substitute for groundnut cake. The aim of this experiment was to evaluate the possibility of composing a diet with a replacement of FALBM up to100% to groundnut cake in the diets feedingredients as major source of protein. The experiment compriseda 30 weeks of age production period with egg quality analysis and evaluate the cost benefit of using FALBM in the formulation of the experimental diet.

MATERIALS AND METHODS

Experimental Site and Location

The study was conducted at Sensor farm. The farm is located at DanladiNasidi housing estate in Kumbotso Local Government Area of Kano state between June 2019 and May 2020. The area is located within latitude of coordinate 11^0 88 'N and 8^0 50, E and longitudes 11^0 53 N and 8^0 30 E. Kano is bordered with Kaduna state on the South west, Bauchi state in south east, Katsina state in the north west and Jigawa state in the north east. (Dakata andYelwa, 2012). The area is characterized with tropical wet and dry seasons (Olofin, 1987) a wet season (May-September) and dry season (October - April). The annual rainfall and temperature ranges between 886mm and 960 and 21^0Cand 46^0C, respectively and humidity ranges between 20-40% (dry Season) and 60-80% (wet season) (KNARDA, 2006).

Source of Experimental Feed Ingredients and Formulation of the Diet

Ingredient for the formulation which include maize, groundnut cake, limestone, wheat offal, fish meal and bone-meal were purchased from feed raw material market at TafawaBalewa road Kano. African locust bean was purchased from makole mark*et al*ong Maiduguri road while lysine, methionine and Vitamin/ mineral premix were purchased from Animal Care Services Consult limited Kano.

The ingredients were milled by local feed millers using hammer mill and mixer. The experimental diets were formulated to contain different levels of fermented African locust as an alternative protein source to groundnut cake as shown in Table 1.

Processing and Fermentation of Locust Bean Seed

Eighty kilograms (80kg) of locust bean seed was cleaned, washed and poured into a container containing 200 liters of boiled water. It was allowed to soak for 24 hours, excess water was later removed and allowed to ferment for 3 days in an air tight polythene bags. Fermented seeds was then removed after 3 days and spread on a polythene bags to be sun dried for 3 days.

Experimental Birds and Their Managements

A total of one hundred and eighty 180 Bovan's Brown layerchickens of 30 weeks of age were used in the experiment for a period of six weeks. The birds were housed in battery cages measuring 40cm length, 35cm width and 40cm height. The house waswell ventilated, in an east-west orientation. The birds were fed commercial layer mash prior to the commencement of the experiment at 30 Weeks of age and were earlier vaccinated against common poultry diseases Newcastle, infectious bursal disease, coccidiosis, fowl pox, infectious bronchitis and egg drop syndrome. A known quantity of feed and water was provided *ad libitum* throughout the experimental period.

Source of Experimental Birds

A total of 180Bovan's Brown layers were purchased from Sovet International Limited at Tarauni, Kano.

Treatments and Experimental Design

The experiment was laid in a completely randomized design (CRD) as outlined by Steel and Torrie (1980). The birds were allotted to 5 groups of different levels of inclusion of fermented African locust beans and each group was replicated three times with 12 birds per replicate. FALBM was incorporated at 0, 25, 50, 75 and 100% as an alternative source of protein to groundnut cake.

Data Collection

Data were collected after seven days adaptation period. Feed intake, egg production, minimum and maximum temperature, humidity and mortality were monitored on daily basis, while egg quality was monitored weekly bases, and cost of feed per egg.

Egg Quality Assessment

After four weeks of the experiment, two fresh eggs were randomly selected from each replicate for external and internal quality assessment for 3 consecutive days. Each egg was weighed and broken into a Petri Dish with a knife and the yolk was separated from the albumen using a yolk separator. Albumen and yolk weights were measured using a sensitive electronic scale to the nearest 0.0lg. Shell thickness was measured with the aid of micro meter screw gauge (Panda *et al*., 2003).

Egg shell weight was determined after emptying the egg contents. The shell interior was cleaned with a tissue paper and allowed to dry, thereafter the weight was taken using a sensitive scale. The color of yolk was scored visually with the aid of the Roche Colour fan (numbered from 1-15, indicating very light to orange colouration), the colour fan was placed near the yolk to determine the colour that matches the yolk and colour number was noted. The length of the egg was measured using vernier calliper between the pointed end and the broad end. Similarly, width of the egg was taken at the widest point.

Chemical analysis

The samples of the experimental diets, raw and fermented African locust bean were properly ground and labeled at the animal science laboratory Bayero University Kano. They were then subjected to proximate analysis to determine the nutrients (CP, CF, EE, Ca and P) compositions according to procedures as outlined by AOAC (1990). The Concentrations of trypsin inhibitor, tannin and phytate were determined using the procedural methods as outlined by Liener (1979), Dawra *et al.* (1988) and Maga (1983), respectively

Feed Cost

Costs of experimental feed ingredients were taken in accordance with the prevailing price during the formulation of the experimental diets. The cost of each experimental diet, the average cost of actual feed consumed (₦ /kg) and the cost of the feed/ egg (₦/egg) were calculated by using the cost of each ingredient (₦) used in the diet formulation.

Statistical Analysis

The data generated from the experiment were subjected to analysis of variance (ANOVA) using SAS (1999) statistical package. Significant differences between the means were determined using Duncan's multiple Range Test (Duncan, 1955).

RESULTS

Proximate Composition of the Experimental Diets Fed Graded Levels of FALBM

Result of the proximate composition of the experimental diets fed to layer chickens is presented in Table 2. The result showed dry matter ranged from 89.86 – 95.30%, Diet A had the highest value while diet E presented the lowest value for dry matter. The trend indicated that dry matter decreased at increasing inclusion levels of FALBM. Values recorded for crude protein ranged from 15.66 – 16.38 %, ether extract ranged from 2.33-3.16%, and crude fiber ranges from 4.43-4.56% while the ash contents ranged from 4.25-5.47%. The trend for the above proximate components decreased with increasing levels of FALBM for dry matter, crude protein, ether extract and nitrogen free extract. Mean while the values increase with increasing increase levels of FALBM for crude fiber and ash contents.

Table 2: Proximate Composition of Experimental Diets

	Diets (FALBM %)				
Parameter	A(0)	B(25)	C(50)	D(75)	E(100)
DM	95.30	94.06	92.93	92.06	89.86
CP	16.38	16.23	16.13	16.05	15.66
CF	4.43	4.53	4.53	4.56	4.56
EE	3.16	2.81	2.56	2.41	2.33

Ash	4.25	4.80	5.18	5.18	5.47

DM: dry matter, CP: crude protein, CF: crude fiber, EE: ether Extract, NFE: nitrogen free extract FALBM: Fermented African locust bean meal.

Effect of feeding graded levels of FALBM on egg quality parameters of layer chickens.

Table 3 contains the effect graded levels of inclusion FALBM on egg quality. The results shows no-significant (P>0.05) differences in all the parameters measured, except for egg weight and yolk weight which were significantly (P>0.05) different across the treatment means. Values for egg weight showed that birds fed diet A had significantly (P<0.05) highest value compared to other treatment means. The values for birds fed diet A were statistically (P>0.05) similar with birds fed diet B. Values obtained for birds fed diet B is statistically similar birds fed diet C and D while birds fed diet E had values that are statistically (P>0.05) similar with birds fed diet C and D. Yolk weight values showed that birds fed diet A had significantly (P<0.05) highest value compared to other treatment means. Birds fed diet A were statistically (P>0.05) similar with birds fed diet B. Values obtained for birds fed diet B ~~is~~ are statistically similar with birds fed diet C, D and E.

Cost of Diets Formulated

The cost of 100 kg of each of the experimental diet revealed a constant decrease from ₦9, 635in diet A to ₦9, and 235 in diet E. The cost of maize is higher in diet A and C (₦4300) followed by ₦4200 for B and E. diet D has the least cost of maize (₦4100). The cost ground cake in 100 kg of the experimental diets was constantly decreasing from N2080 in diet A to ₦520 in diet D. Diet E had zero cost of ground cake. On the other hand, the cost FALBM increased from ₦440 in diet B to ₦1760 in diet E. Diet A had zero cost of FALBM. Other ingredients like fish meal, bone meal, lime stone, salt, premix, lysine and methionine were all constant from diets A to E.

Table 4: Cost analysis of layer chickens fed graded levels of fermented African locust bean meal

	Diets (FALBM %)				
Parameter	**A(0)**	**B(25)**	**C(50)**	**D(75)**	**E(100)**
CED(₦)	9632	9485	9465	9250	9235
CF/kg(₦)	96.32	94.85	94.65	92.50	92.35

CED: Cost of experimental dietCF/kg: cost of feed/kilogram.

DISCUSSION

The proximate composition of experimental diets of layer chickens fed graded levels of FALBM indicated that dry matter content decreased as the levels of FALBM was increased. All the parameters including crude fiber and ash increased as the level of the FALBM were increased while dry matter, crude protein, ether extract and nitrogen free extract decreases as the levels of FALBM increases in the diets. The decrease in dry matter, ether extract and nitrogen free extract and increase in ash and crude fiber content of the diet could be due inclusion levels of FALBM in the treatment diets. The results obtained for dry matter, ether extract and nitrogen free extract in this study is in line with the work the of Akanji*et al*. (2015) who evaluated egg laying performance and blood chemistry of birds fed fermented and unfermented African locust beans diets. The results obtained for crude protein in this study contradict the feedings of Akanji*et al*. (2015) who reported increase in crude protein content of FALBM. The difference in crude protein content could be due to period of boiling and sources of African locust bean meal.

The results of egg quality parameters revealed no-significant (P>0.05) differences in all the parameters measured, except for egg weight and yolk weight which were significantly (P<0.05) different across the treatments means. This is an indication that FALBM has no detrimental effect on egg shell formation. The observation is in agreement with ~~the~~ earlier reports of ~~(~~Babangida and Ubosi~~,~~ (2006)~~;~~ and Bawa~~,~~ (2011) who reported no significant difference (P>0.05) in the egg shape index of Japanese quails fed graded levels of dietary protein.

Effect of graded levels of FALBM in diet of laying chickens on egg quality parameter revealed significant differences in mean egg weight and yolk. The lower egg weight and yolk weight obtained for birds in treatment 5 could be due to the increased level of FALBM in the diet. This could be due to lower levels of crude protein and nitrogen free extract of diet compared with other diets as revealed by the proximate composition of the experimental diets. Novak *et al*., (2008) revealed that Lowering CP in laying hen diets reduced egg weight through the period 18-60 weeks-old. Summers *et al*. (1991) and Lopez and Leeson (1995) also reported that layer egg weight is strongly related to the content of CP in the diet.

The result indicates lower cost in FALBM base diets compared with the control. This is due to the relatively lower cost of FALBM to groundnut cake at the period when the ingredients where purchased. The lowest cost (₦ 92.35) per kg of diet obtained in this study is higher than (₦ 72.86/unit) per kg diet obtained by Tamburawa *et al*. (2017) who evaluated the effect of soaked and fermented African locust bean seeds meal on the performance, organs and carcass characteristics of broiler chickens. This could be due to the seasonal variation in the price of ingredient.

CONCLUSION AND RECOMMENDATIONS

It was concluded that replacing groundnut cake with fermented African locust bean (*Parkia biglibosa*) seed meal (FALBM) appeared to have no positive influence on the egg quality of Bovan's Brown layers. However, the inclusion of FALBM had positive influence on the total cost of the experimental diet, from A (25%) to E (100%) FALBM replacement levels.

Based on this research it is recommended thatfermented African locust bean meal can be incorporated up to 25% in the diet of layer chickens without any deleterious effect. Meanwhile, further research should be conducted in which another method of processing African locust bean should be used in order to better enhance it utilization by layer chicken.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
Serological study was conducted to determine the prevalence of brucellosis in some settled Cattle Farms in Daura Local Government Area, Katsina State, Nigeria. A total of 500 cattle sampled sera from 6 Farms across ages breeds and sexes were collected and examined for antibodies against Brucella species using Rose Bengal plate test (RBPT). Information about the Sex, Age, and Breeds of Cattle were collected using structured questionnaire. Association between prevalence of the disease and Age, Sex and Breeds of cattle were determined using Chi-square Statistics. The result obtained revealed the overall prevalence of 35 (7%). The highest prevalence was observed in cattle aged between 4-6 years old, 18 (3.6%) while the least prevalence of 1 (0.2%) was recorded in cattle aged above 9 years. Based on sex, the infection was higher in Female 22 (4.4%) than male 13 (2.6%). There is a significant association between the prevalence of Brucellosis and the sex of cattle at ($P \leq 0.05$). However, there is no significant association between prevalence of the disease, the age and breeds of Cattle examined. The study confirmed the presence of brucellosis in the study area and cattle in the screened farms were likely to transmit the disease to humans and other susceptible animals. It is recommended that all the infected animals should be immediately restricted, and treated or culled to avoid further spread of the infection. Susceptible animals should be vaccinated and Public should be enlightened about the zoonotic aspect of the disease.
Keywords: *Brucellosis, Cattle, prevalence, RBPT*

INTRODUCTION
Brucellosis is an infectious, contagious disease primarily of Animals caused by a number of host-adapted species of the Gram-negative intracellular bacteria of the genus *Brucella*. The disease is one of the most widespread zoonoses in the world (Munir *et al.*, 2010). It is one of the most devastating trans-boundary animal diseases and also a major trade barrier and economically very important as a major cause of losses in the livestock industry (Gul and Khan, 2007). Brucellosis infection is widespread globally and is endemic in many developing countries including Nigeria and it has been reported in various parts of the country and in various animal species and in humans (Mai *et al.*, 2018; 2012; Saleh *et al*., 2016; Cadmus *et al*., 2006; and Kudi *et al*., 2015). In a large seroprevalence survey of brucellosis in cattle herds under diverse production systems in northern Nigeria, Mai *et al*. (2012) reported a significantly higher seroprevalence of Brucellosis in cattle with the overall level of 37% using RBPT and 26.3% after confirmation with c-ELISA. Many cases have been reported in various literatures (Agada *et al*., 2017; Adamu *et al*., 2016; Saleh *et al*., 2016).
The disease is well known for its effects on decreasing productivity of infected livestock by causing abortions, reducing fertility and decreasing milk yield, resulting in substantial economic losses (Nicoletti, 1980). Other symptoms that characterised the disease include; sterility, in bulls still birth, and retained placenta, in females orchitis, hygroma and epididymitis in males (Adams, 2002). However, the rare symptoms like mastitis, repeat breeding and joint ill were also reported (Chakravarty *et al.*, 2007). There is an occupational risk to veterinarians, abattoir workers and farmers who handle infected animals/carcasses and aborted fetuses or placentas. Brucellosis is also one of the most easily acquired laboratory infections (OIE, 2006).
Yagupsky and Baron (2005) reported that *Brucella* infection is readily transmissible to humans, causing acute febrile illness – undulant fever – which may progress to a more chronic form and can also produce serious complications affecting the musculo–skeletal, cardiovascular, and central nervous systems. If not treated at the acute stage. Infection is often due to occupational exposure and is essentially acquired by the oral, respiratory, or conjunctival routes, but ingestion of dairy products constitutes the main risk to the general public. The incidence

of the disease in human is thus closely tied to the prevalence of infection in sheep, goat and cattle and to practices that allow exposure to humans, to potentially or susceptible infected animals or their products (Carrera *et al.*, 2006).

RESULTS AND DISCUSSION

To have an insight in to the role of cattle in the epidemiology of brucellosis, we conducted a study to determine the prevalence of brucellosis in some settled cattle Farms in Daura Local Government Area, Katsina State, Nigeria. A total of 500 Bovine serum samples were collected from six settled Cattle farms and tested for the presence of *Brucella* antibodies using Rose Bengal Plate Test (RBPT) as described by Alton *et al.* (1975).

The overall prevalence of brucellosis observed in all the six farms combined was 35 (7%). This is in line with the result of the investigation carried out on cattle by Adamu *et al*. (2016) in three senatorial zones of Katsina State which revealed the prevalence of (5.4%) using RBPT. Similarly, Farouk *et al*. (2011) also reported the much lower overall herds' prevalence of (4.04%) using RBPT from Jigawa State.

The prevalence among the age groups showed that cattle aged between 3-6 years had a prevalence of 18 (3.6%) followed by those between the ages of 7-9 years 11 (2.2%), 0-3 years 5 (1%), and those aged above 9 years 1 (0.2%). This supported the result of investigation conducted in Katsina State by Adamu *et al*. (2016), which reported the seroprevalence of 6.3% in cattle aged 4-5 years, followed by 5.5% in cattle aged <4 years then cattle with the age band of 5-7 years shows the prevalence of 4.6%, whereas cattle aged above 7 years shows the least seroprevalence of 4.0%. Our result revealed no statistically significant association at ($p \leq 0.05$) among all the age groups tested. This is also as reported by Adamu *et al*. (2016).

Based on sex, the result revealed the highest prevalence in female than in male with 22 (4.4%) and 13 (2.6%) respectively using RBPT. Statistically, this shows the significant association between the sex of cattle and the prevalence of the disease at (≤ 0.05). This is because female cows remain the locale of infection, which helps to spread the disease from one animal to another, either through lactation or during mating. Pregnancy and lactation were reported to enhance susceptibility to infection. The growth of virulent strains of *Brucella* organism was reported to be stimulated more in females because of the presence of higher volume of D-erythritol normally found in fetal tissue than in testes and seminal vesicle (Bayemi *et al*., 2009). These thoughts provide proofs as to the different rates of prevalence of bovine brucellosis in relation to sex of animals concern. In addition, this finding agreed with earlier reports of Junaidu *et al*. (2011) which stated that the foci of *brucella* infection remain in females, which spread the infection from one animal to another. Also, Adamu *et al*. (2016) reported the similar result of higher prevalence in female (7.6%) than male (5.8%).

In regard to the breeds of cattle examined, the highest rate of infection was indicated in white Fulani (Bunaji) with prevalence of 18 (3.6%) followed by Friesian with 8 (1.6%), Cross breeds 5(1%), Wadara 3(0.6%), Bokolo 1 (0.2%) and Bororo 0 (0%). There was no significant association between the breeds of cattle examined and the prevalence of the brucellosis at ($p \leq 0.05$). This corresponds with the report of Saleh *et al*. (2017) who reported that brucellosis is more prevalent in white Fulani among cattle slaughtered in three municipal abattoirs of Jigawa state. Cadmus *et al*. (2006) also reported the highest prevalence of Brucellosis in White Fulani cattle over Red Bororo, Sokoto gudali and Cross breeds.

CONCLUSION AND RECOMMENDATIONS

This study shows that brucellosis is endemic in the study area. Cattle of all ages and both sexes were carrying the disease and infected cattle in the herds examined were likely to transmit the disease to humans and other susceptible animals. It is recommended that thorough antimortem and post-mortem inspections should be carried out daily and slaughtered and all infected animals should be isolated and treated immediately slaughtered to enable the total eradication of the disease. Food products derived from animals should be properly cooked to protect the consumers from *Brucella* infection and integrating vaccination against brucellosis into the annual vaccination program of livestock is highly recommended.

PROCEEDINGS OF THE
57th Annual Conference of the
Agricultural Society of Nigeria
23rd – 27th Oct., 2023

ABSTRACT
The study determined the effects of storage methods and durations on some quality parameters of Japanese quail eggs. The study was conducted at the laboratory of the Federal Polytechnic Daura, Daura, Katsina state, Nigeria. A total of 100 freshly laid eggs of Japanese quails were used for the experiment, the eggs were obtained from the poultry farm of Federal Polytechnic Daura, Daura, Katsina state. The experiment was laid in a 4 by 4 factorial arrangement in a completely randomized design (C.R.D) consisting of 4 storage methods namely oiling or shell coating, Room temperature, Earthen pot and covering with leaves and 4 durations of storage i.e. 0, 7, 14, and 21 days and 4 replicates respectively. All the proximate values for all the storage methods and durations were all significantly (p<0.05) different, values for moisture under oiling method ranged from 2.00 – 3.00%. Values for crude protein under storage duration ranged from 27.20 - 35.00%. Values for Haugh unit for clay storage varied from 56.00 – 58. 20%, while yolk index for oiling method ranged from 0.20 to 0.40. It was concluded that oiling method best preserved the egg of the four methods used. Oiling storage method was recommended for storing and preserving Japanese quail eggs
Keywords: *Storage, Duration, Quality Parameters, Japanese Quail, Eggs*

INTRODUCTION
The market for Japanese quails *(Coturnix japonica*) has long provided developing countries with a stable vitamin-rich source of alternative animal proteins that are low in fat content, plus eggs that contain 2.47 percent less fat than chicken eggs, all working together to boost the human immune system. High level of phosphorus, iron, and vitamin A, B1, and B2 all mean that quail fit nicely into society's definition of what constitutes a healthy diet and lifestyle. Bruce (2019).
All foods have limited shelf life which vary on the type of food, place of the storage and storage condition. Eggs deteriorates rapidly between the period of storage and consumption. Egg quality can be affected by the environmental condition as well as it nutritional properties and values such as temperature, relative humidity of storage as well as gaseous environment storage time. Storage can modify some characteristics of eggs including loss of water, carbon dioxide, and subsequent increase in pH of the albumen Ducupere, (2001). Quality parameters are factors or limits which affect the way eggs can be stored. Any given food has an influence on the acceptance and rejection of the food by the consumers, this is as a result of either internal or external quality problems. External quality parameters of egg is focused on shell cleanliness, texture, and shape whereas, internal quality parameters refers to egg white (albumen) cleanliness and viscosity, size of the air cell, Yolk shape and yolk strength (Kul and Seker, 2004). The objective of this study therefore was to determine the effects of some storage methods and duration on some quality parameters of Japanese quails' eggs, with a view to advising farmers, Quail egg sellers and consumers appropriately.

MATERIALS AND METHODS
Experimental Location
The study was conducted at the laboratory of the Federal Polytechnic Daura, Daura, Katsina state. Daura is a local government in Katsina state and it lies on Latitude 13^0 1'53.38"N, and Longitude 8.19'21.12"E. Daura has an area of 217.3KM^2 and population of around 224,884 persons. The area has two distinct climate, rainy season approximately from May to October and dry season from November to April with an average annual rainfall of 190mm (7.48) (National Geospatial Intelligence Agency, 2012).

Experimental Eggs

A total of 100 freshly laid eggs of Japanese quails were used for the experiment, the eggs were obtained from the poultry farm of Federal Polytechnic Daura, Daura, Katsina state.

Experimental Design

The experiment was laid in a 4 by 4 factorial arrangement in a completely randomized design consisting of 4 storage methods namely Oiling or Shell coating, Room temperature, Earthen pot and covered with leaves and 4 durations of storage i.e. 0, 7, 14, and 21 days and 4 replicates with 25 eggs per replicate

Experimental Procedure

A total of 100 freshly laid eggs of almost equal size from *Coturnix japonica* breed of layers in poultry farm of Federal Polytechnic Daura were obtained and divided into 4 equal parts comprising 25 eggs were stored in each 4 different storage methods as shown beneath.

Oiling: (shell coating) In this method the eggs was immersed into odourless ground nut oil, allowed to drain for at least 1 minute and stored at room temperature on a flat surface.

Could it be that a plate supposed to be here? If yes insert it

If no, delete this caption Eggs coated with groundnut oil and stored under room temperature Room temperature (Untreated): In this method the eggs was placed in egg tray untreated and store at room temperature.

Plate 1: Eggs coated with groundnut oil and stored under room temperature

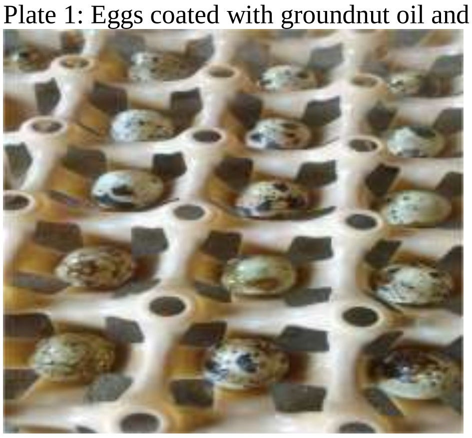

Plate 2: Eggs stored under room temperature (Untreated)

Earthen pot: In this method the eggs was kept in a wide-mouthed earthen pot and stored at room temperature.

Plate 3: Eggs stored in earthen pot under room temperature

Covered with leaves=In this method the eggs were kept at room temperature and covered them with fresh mango leaves. The leaves were changed every 48 hours.

Plate 4: Eggs stored under room temperature and covered with mango leaves
